17.57. **IDENTIFY** and **SET UP:** Call the temperature at the interface between the wood and the styrofoam T. The heat current in each material is given by $H = kA(T_H - T_C)/L$.

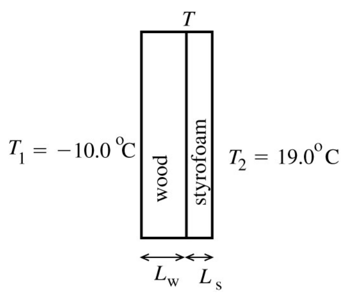

Figure 17.57

See Figure 17.57.
Heat current through the wood: $H_w = k_w A(T - T_1)L_w$
Heat current through the styrofoam: $H_s = k_s A(T_2 - T)/L_s$

In steady-state heat does not accumulate in either material. The same heat has to pass through both materials in succession, so $H_w = H_s$.

EXECUTE: **(a)** This implies $k_w A(T - T_1)/L_w = k_s A(T_2 - T)/L_s$

$k_w L_s (T - T_1) = k_s L_w (T_2 - T)$

$$T = \frac{k_w L_s T_1 + k_s L_w T_2}{k_w L_s + k_s L_w} = \frac{-0.0176\ \text{W}\cdot{}^\circ\text{C/K} + 0.01539\ \text{W}\cdot{}^\circ\text{C/K}}{0.00257\ \text{W/K}} = -0.86^\circ\text{C}.$$

EVALUATE: The temperature at the junction is much closer in value to T_1 than to T_2. The styrofoam has a very small k, so a larger temperature gradient is required for than for wood to establish the same heat current.

(b) IDENTIFY and **SET UP:** Heat flow per square meter is $\dfrac{H}{A} = k\left(\dfrac{T_H - T_C}{L}\right)$. We can calculate this either for the wood or for the styrofoam; the results must be the same.

EXECUTE: <u>Wood</u>: $\dfrac{H_w}{A} = k_w \dfrac{T - T_1}{L_w} = (0.080\ \text{W/m}\cdot\text{K})\dfrac{-0.86^\circ\text{C} - (-10.0^\circ\text{C})}{0.030\ \text{m}} = 24\ \text{W/m}^2.$

<u>Styrofoam</u>: $\dfrac{H_s}{A} = k_s \dfrac{T_2 - T}{L_s} = (0.027\ \text{W/m}\cdot\text{K})\dfrac{19.0^\circ\text{C} - (-0.86^\circ\text{C})}{0.022\ \text{m}} = 24\ \text{W/m}^2.$

EVALUATE: H must be the same for both materials and our numerical results show this. Both materials are good insulators and the heat flow is very small.

17.58. **IDENTIFY:** This problem is about heat flow, so we use $\dfrac{Q}{t} = \dfrac{kA(T_H - T_C)}{L}$.

SET UP: $T_H - T_C = 175^\circ\text{C} - 35^\circ\text{C}$. $1\ \text{K} = 1\ \text{C}^\circ$, so there is no need to convert the temperatures to kelvins.

EXECUTE: **(a)** $\dfrac{Q}{t} = \dfrac{(0.040\ \text{W/m}\cdot\text{K})(1.40\ \text{m}^2)(175^\circ\text{C} - 35^\circ\text{C})}{4.0\times10^{-2}\ \text{m}} = 196\ \text{W}.$

(b) The power input must be 196 W, to replace the heat conducted through the walls.

EVALUATE: The heat current is small because k is small for fiberglass.

17.59. **IDENTIFY:** We compare the thermal conductivity of several materials.

SET UP and EXECUTE: **(a)** Touch metal, glass, and wood. The result is that the metal is the coldest and the wood the warmest.

(b) From Table 17.5: $k_{Cu} = 385\ \text{W/m}\cdot\text{K}$, k_{wood} is between $0.12\ \text{W/m}\cdot\text{K}$ and $0.04\ \text{W/m}\cdot\text{K}$, and $k_{glass} = 0.8\ \text{W/m}\cdot\text{K}$. Our ranking agrees with these thermal conductivities.

EVALUATE: The large variation in the thermal conductivity of wood is due to the density of the wood. The more air that is trapped within its fibers, the poorer it is at conducting heat because $k_{\text{air}} = 0.024$ $\text{W/m}\cdot\text{K}$, making a very poor conductor of heat (but therefore an excellent insulator).

17.60. IDENTIFY: $\dfrac{Q}{t} = \dfrac{kA\Delta T}{L}$. Q/t is the same for both sections of the rod.

SET UP: For copper, $k_{\text{c}} = 385\ \text{W/m}\cdot\text{K}$. For steel, $k_{\text{s}} = 50.2\ \text{W/m}\cdot\text{K}$.

EXECUTE: **(a)** For the copper section, $\dfrac{Q}{t} = \dfrac{(385\ \text{W/m}\cdot\text{K})(4.00\times10^{-4}\ \text{m}^2)(100°\text{C} - 65.0°\text{C})}{1.00\ \text{m}} = 5.39\ \text{J/s}.$

(b) For the steel section, $L = \dfrac{kA\Delta T}{(Q/t)} = \dfrac{(50.2\ \text{W/m}\cdot\text{K})(4.00\times10^{-4}\ \text{m}^2)(65.0°\text{C} - 0°\text{C})}{5.39\ \text{J/s}} = 0.242\ \text{m}.$

EVALUATE: The thermal conductivity for steel is much less than that for copper, so for the same ΔT and A, a smaller L for steel would be needed for the same heat current as in copper.

17.61. IDENTIFY and SET UP: The heat conducted through the bottom of the pot goes into the water at 100°C to convert it to steam at 100°C. We can calculate the amount of heat flow from the mass of material that changes phase. Then use $H = kA(T_{\text{H}} - T_{\text{C}})/L$ to calculate T_{H}, the temperature of the lower surface of the pan.

EXECUTE: $Q = mL_{\text{v}} = (0.390\ \text{kg})(2256\times10^3\ \text{J/kg}) = 8.798\times10^5\ \text{J}$

$H = Q/t = 8.798\times10^5\ \text{J}/180\ \text{s} = 4.888\times10^3\ \text{J/s}$

Then $H = kA(T_{\text{H}} - T_{\text{C}})/L$ says that $T_{\text{H}} - T_{\text{C}} = \dfrac{HL}{kA} = \dfrac{(4.888\times10^3\ \text{J/s})(8.50\times10^{-3}\ \text{m})}{(50.2\ \text{W/m}\cdot\text{K})(0.150\ \text{m}^2)} = 5.52\ \text{C°}$

$T_{\text{H}} = T_{\text{C}} + 5.52\ \text{C°} = 100°\text{C} + 5.52\ \text{C°} = 105.5°\text{C}.$

EVALUATE: The larger $T_{\text{H}} - T_{\text{C}}$ is the larger H is and the faster the water boils.

17.62. IDENTIFY: Apply $H = kA(T_{\text{H}} - T_{\text{C}})/L$ and solve for A.

SET UP: The area of each circular end of a cylinder is related to the diameter D by $A = \pi R^2 = \pi(D/2)^2$. For steel, $k = 50.2\ \text{W/m}\cdot\text{K}$. The boiling water has $T = 100°\text{C}$, so $\Delta T = 300\ \text{K}$.

EXECUTE: $\dfrac{Q}{t} = kA\dfrac{\Delta T}{L}$ and $190\ \text{J/s} = (50.2\ \text{W/m}\cdot\text{K})A\left(\dfrac{300\ \text{K}}{0.500\ \text{m}}\right)$. This gives $A = 6.308\times10^{-3}\ \text{m}^2$, and $D = \sqrt{4A/\pi} = \sqrt{4(6.308\times10^{-3}\ \text{m}^2)/\pi} = 8.96\times10^{-2}\ \text{m} = 8.96\ \text{cm}.$

EVALUATE: H increases when A increases.

17.63. IDENTIFY: Assume the temperatures of the surfaces of the window are the outside and inside temperatures. Use the concept of thermal resistance. For part (b) use the fact that when insulating materials are in layers, the R values are additive.

SET UP: From Table 17.5, $k = 0.8\ \text{W/m}\cdot\text{K}$ for glass. $R = L/k$.

EXECUTE: **(a)** For the glass, $R_{\text{glass}} = \dfrac{5.20\times10^{-3}\ \text{m}}{0.8\ \text{W/m}\cdot\text{K}} = 6.50\times10^{-3}\ \text{m}^2\cdot\text{K/W}.$

$$H = \frac{A(T_{\text{H}} - T_{\text{C}})}{R} = \frac{(1.40\ \text{m})(2.50\ \text{m})(39.5\ \text{K})}{6.50\times10^{-3}\ \text{m}^2\cdot\text{K/W}} = 2.1\times10^4\ \text{W}$$

(b) For the paper, $R_{\text{paper}} = \dfrac{0.750\times10^{-3}\ \text{m}}{0.05\ \text{W/m}\cdot\text{K}} = 0.015\ \text{m}^2\cdot\text{K/W}$. The total R is

$R = R_{\text{glass}} + R_{\text{paper}} = 0.0215\ \text{m}^2\cdot\text{K/W}$. $H = \dfrac{A(T_{\text{H}} - T_{\text{C}})}{R} = \dfrac{(1.40\ \text{m})(2.50\ \text{m})(39.5\ \text{K})}{0.0215\ \text{m}^2\cdot\text{K/W}} = 6.4\times10^3\ \text{W}.$

EVALUATE: The layer of paper decreases the rate of heat loss by a factor of about 3.

17.64. IDENTIFY: The rate of energy radiated per unit area is $\frac{H}{A} = e\sigma T^4$.

SET UP: A perfect blackbody has $e = 1$.

EXECUTE: **(a)** $\frac{H}{A} = (1)(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)(273\ \text{K})^4 = 315\ \text{W/m}^2$

(b) $\frac{H}{A} = (1)(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)(2730\ \text{K})^4 = 3.15\times10^6\ \text{W/m}^2$

EVALUATE: When the Kelvin temperature increases by a factor of 10 the rate of energy radiation increases by a factor of 10^4.

17.65. IDENTIFY: Use $H = Ae\sigma T^4$ to calculate A.

SET UP: $H = Ae\sigma T^4$ so $A = H/e\sigma T^4$

150-W and all electrical energy consumed is radiated says $H = 150$ W.

EXECUTE: $A = \dfrac{150\ \text{W}}{(0.35)(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)(2450\ \text{K})^4} = 2.1\times10^{-4}\ \text{m}^2(1\times10^4\ \text{cm}^2/1\ \text{m}^2) = 2.1\ \text{cm}^2$

EVALUATE: Light-bulb filaments are often in the shape of a tightly wound coil to increase the surface area; larger A means a larger radiated power H.

17.66. IDENTIFY: The net heat current is $H = Ae\sigma(T^4 - T_s^4)$. A power input equal to H is required to maintain constant temperature of the sphere.

SET UP: The surface area of a sphere is $4\pi r^2$.

EXECUTE: $H = 4\pi(0.0150\ \text{m})^2(0.35)(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)[(3000\ \text{K})^4 - (290\ \text{K})^4] = 4.54\times10^3\ \text{W}$.

EVALUATE: Since $3000\ \text{K} > 290\ \text{K}$ and H is proportional to T^4, the rate of emission of heat energy is much greater than the rate of absorption of heat energy from the surroundings.

17.67. IDENTIFY: Apply $H = Ae\sigma T^4$ and calculate A.

SET UP: For a sphere of radius R, $A = 4\pi R^2$. $\sigma = 5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4$. The radius of the earth is $R_E = 6.37\times10^6$ m, the radius of the sun is $R_{sun} = 6.96\times10^8$ m, and the distance between the earth and the sun is $r = 1.50\times10^{11}$ m.

EXECUTE: The radius is found from $R = \sqrt{\dfrac{A}{4\pi}} = \sqrt{\dfrac{H/(\sigma T^4)}{4\pi}} = \sqrt{\dfrac{H}{4\pi\sigma}\dfrac{1}{T^2}}$.

(a) $R_a = \sqrt{\dfrac{(2.7\times10^{32}\ \text{W})}{4\pi(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)}}\dfrac{1}{(11{,}000\ \text{K})^2} = 1.61\times10^{11}\ \text{m}$

(b) $R_b = \sqrt{\dfrac{(2.10\times10^{23}\ \text{W})}{4\pi(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)}}\dfrac{1}{(10{,}000\ \text{K})^2} = 5.43\times10^6\ \text{m}$

EVALUATE: **(c)** The radius of Procyon B is comparable to that of the earth, and the radius of Rigel is comparable to the earth-sun distance.

17.68. IDENTIFY: This problem deals with the thermal expansion for water in the range of 0°C to 10°C.

SET UP: Use Fig. 17.12 in the textbook. From analytic geometry, a parabola with vertex at the point (h,k) and opening upward is $(x-h)^2 = 4p(y-k)$ with $p > 0$. In this case, $h = 4.0$°C and $k = 1.00003$ cm^3. We want to find the equation for $V(T)$ with T in degrees Celsius.

EXECUTE: **(a)** Using the equation for a parabola gives $(T - 4.0°\text{C})^2 = 4p(V - 1.00003\ \text{cm}^3)$. We need to find 4$p$. From the graph, $V = 1.00015$ cm^3 when $T = 0$°C, so $(-4.0°\text{C})^2 = 4p(1.00015 - 1.00003)\text{cm}^3$, which gives $4p = 1.33\times10^5\ (\text{C}°)^2/\text{cm}^3$. Therefore

$(T - 4.0°\text{C})^2 = \left[1.33\times10^5 (\text{C}°)^2 / \text{cm}^3\right](V - 1.00003\,\text{cm}^3)$. Now solve for V which gives

$V = \left[7.5\times10^{-6}\text{cm}^3 / (\text{C}°)^2\right](T - 4.0°\text{C})^2 + 1.00003\ \text{cm}^3$. From this result, we see that A = 1.00003 cm^3 and $B = 7.5\times10^{-6}\text{cm}^3 / (\text{C}°)^2$.

(b) Use $dV = \beta(T_\text{C})Vdt$, where $V = A + B(T - 4.0°\text{C})^2$ and $V \approx 1$ cm^3 (because the graph in the Fig. 17.12 is for 1 gram of water), which gives $dV = d\left[A + B(T - 4.0°\text{C})^2\right] = 2B(T - 4°\text{C})dT$. Therefore $\beta(T) = 2B(T - 4°\text{C})$.

At 1.0°C: $\beta = 2\left[7.5\times10^{-6}\text{cm}^3 / (\text{C}°)^2\right](1.0°\text{C} - 4.0°\text{C}) = -4.5\times10^{-5} / \text{C}°$.

At 4.0°C: $\beta = 0$.

At 7.0°C: $\beta = 4.5\times10^{-5} / \text{C}°$.

At 10.0°C: $\beta = 9.0\times10^{-5} / \text{C}°$.

EVALUATE: With V = 1.0 cm^3, $\beta = dV/dT$ is the slope of the graph in Fig. 17.12. From this graph, we can see that the slope is zero when T = 4.0°C. Also when T = 1.0°C and 7.0°C (3C° within 4.0°C), the slope has the same magnitude but different sign. This also agrees with our result.

17.69. **IDENTIFY:** Use $\Delta L = L_0 \alpha \Delta T$ to find the change in diameter of the sphere and the change in length of the cable. Set the sum of these two increases in length equal to 2.00 mm.

SET UP: $\alpha_\text{brass} = 2.0\times10^{-5}\ \text{K}^{-1}$ and $\alpha_\text{steel} = 1.2\times10^{-5}\ \text{K}^{-1}$.

EXECUTE: $\Delta L = (\alpha_\text{brass} L_{0,\text{brass}} + \alpha_\text{steel} L_{0,\text{steel}})\Delta T$.

$$\Delta T = \frac{2.00\times10^{-3}\ \text{m}}{(2.0\times10^{-5}\ \text{K}^{-1})(0.350\ \text{m}) + (1.2\times10^{-5}\ \text{K}^{-1})(10.5\ \text{m})} = 15.0\ \text{C}°.\quad T_2 = T_1 + \Delta T = 35.0°\text{C}.$$

EVALUATE: The change in diameter of the brass sphere is 0.10 mm. This is small, but should not be neglected.

17.70. **IDENTIFY:** The tension in the wire is related to the speed of waves on the wire, and it also related to the thermal stress in the wire.

SET UP: The thermal stress is $\dfrac{F}{A} = -Y\alpha\Delta T$, $v = f\lambda$, and $v = \sqrt{\dfrac{F}{\mu}}$. In the fundamental mode $\lambda = 2L$.

We know that L = 0.400 m and at 20.0°C, f_1 = 440 Hz.

EXECUTE: **(a)** We want the tension F in the wire when f_1 = 440 Hz at 20.0°C. We know that $\lambda = 2L$ = 0.800 m and $v = \sqrt{\dfrac{F}{\mu}}$, where $\mu = m/L$ = (0.00250 kg)/(0.400 m) = 6.25×10^{-3} kg/m. Solving $v = \sqrt{\dfrac{F}{\mu}}$ for F and using $v = f\lambda$ gives $F = \mu(f\lambda)^2$. For the numbers here we have

$F = (6.25\times10^{-3}\ \text{kg/m})\left[(440\ \text{Hz})(0.800\ \text{m})\right]^2 = 774$ N.

(b) Now f_1 = 460 Hz and we want to find the temperature of the wire. The thermal stress is $\dfrac{F}{A} = -Y\alpha\Delta T$, so we need F and A to find ΔT. The wavelength is the same as in part (a) because the wire has not changed length, but the frequency has changed. As before, we use $v = f\lambda$ and $v = \sqrt{\dfrac{F}{\mu}}$ to get F, giving $F = \mu(f\lambda)^2$. The numbers are the same as before except that f = 460 Hz instead of 440 Hz. The result is F = 846.4 N. (Note that the tension has *increased*.) Now find the cross-sectional area A of the wire. We know its mass, length, and density, so we use $m = \rho V = \rho AL$ which gives $A = \dfrac{m}{\rho L}$

$= \dfrac{0.00250 \text{ kg}}{(7800 \text{ kg/m}^3)(0.400 \text{ m})} = 8.013\times 10^{-7} \text{ m}^2$. We are now ready to use $\dfrac{F}{A} = -Y\alpha\Delta T$ to find ΔT. The F in that equation is not the tension. Rather it is the *difference* in tension when the temperature is changed by ΔT. It is the force needed to maintain the length of the wire. The wire would tend to contract so the tension prevents this. Therefore F = 846.4 N – 774 N = 72 N. Solving $\dfrac{F}{A} = -Y\alpha\Delta T$ for ΔT gives $\Delta T = -\dfrac{F}{AY\alpha}$. For the numbers here we get

$\Delta T = -\dfrac{72 \text{ N}}{(8.013\times 10^{-7} \text{m}^2)(20\times 10^{10} \text{ Pa})(1.2\times 10^{-5} \text{ K})} = -37$ C°. The new temperature is $T = T_0 + \Delta T =$ 20.0°C + (–37 C°) = –17°C.

EVALUATE: Heating the wire would have caused it to expand which would have decreased the tension and hence lowered the fundamental frequency.

17.71. IDENTIFY: We are dealing the thermal expansion of a volume of liquid when heat is added to it.

SET UP: Use $Q = mc\Delta T$, $\Delta V = \beta L_0 \Delta T$, and $m = \rho V$.

EXECUTE: Using the above equations gives $Q = mc\Delta T = \rho Vc\Delta T$. From $\Delta V = \beta L_0 \Delta T$ we have $\Delta T = \dfrac{\Delta V}{\beta\rho}$, so $Q = \rho Vc\dfrac{\Delta V}{\beta V}$. Solving for c gives $c = \dfrac{Q\beta}{\rho\Delta V}$.

EVALUATE: Our result indicates that if c is large, a large amount of heat Q will be needed to change its volume. This is a reasonable result.

17.72. IDENTIFY: In this problem, we are dealing with the effect of thermal expansion on the period of a simple pendulum.

SET UP: At 20.0°C the length L of the copper wire is 3.00 m. We want to find the percent change in the period if the temperature is increased to 220°C. We know that $T = 2\pi\sqrt{\dfrac{L}{g}}$ and $\Delta L = \alpha L_0 \Delta T$, and we want $\dfrac{\Delta T}{T_1}$.

EXECUTE: At 20.0°C: $T_1 = 2\pi\sqrt{\dfrac{L}{g}}$. At 22.0°C: $T_2 = 2\pi\sqrt{\dfrac{L_2}{g}} = 2\pi\sqrt{\dfrac{L+\Delta L}{g}}$. Using $\Delta L = \alpha L_0 \Delta T$ gives $T_2 = 2\pi\sqrt{\dfrac{L+\Delta L}{g}} = 2\pi\sqrt{\dfrac{L+\alpha L\Delta T}{g}} = 2\pi\sqrt{\dfrac{L}{g}}\sqrt{1+\alpha\Delta T}$. We want $\dfrac{\Delta T}{T_1}$ which is $\dfrac{\Delta T}{T_1}$ =

$$\frac{T_2 - T_1}{T_1} = \frac{T_2}{T_1} - 1 = \frac{2\pi\sqrt{\dfrac{L}{g}}\sqrt{1+\alpha\Delta T}}{2\pi\sqrt{\dfrac{L}{g}}} - 1 = \sqrt{1+\alpha\Delta T} - 1.$$ For copper we have

$\alpha\Delta T = (1.7\times 10^{-5} \text{ K}^{-1})(200 \text{ K}) = 3.4\times 10^{-3}$, which is much less than 1. Therefore we can use the approximation $(1 + x)^n \approx 1 + nx$, which in this case is $\sqrt{1+x} = (1 + x)^{1/2} \approx 1 + x/2$, where $x = \alpha\Delta T$.

This gives $\dfrac{\Delta T}{T_1} = \sqrt{1+\alpha\Delta T} - 1 \approx \dfrac{\alpha\Delta T}{2} = \dfrac{3.4\times 10^{-3}}{2} = 0.0017 = 0.17\%$.

EVALUATE: Even for a temperature change as large as 200°C, the percent change is only 0.17%. This illustrates that thermal expansion typically produces very small fractional length changes. Note that the fact that the pendulum bob was fused quartz played no role in the solution; it was extraneous information.

17.73. **IDENTIFY** and **SET UP:** Use the temperature difference in M° and in C° between the melting and boiling points of mercury to relate M° to C°. Also adjust for the different zero points on the two scales to get an equation for T_{M} in terms of T_{C}.

(a) EXECUTE: normal melting point of mercury: $-39°\text{C} = 0.0°\text{M}$

normal boiling point of mercury: $357°\text{C} = 100.0°\text{M}$

$100.0\ \text{M}° = 396\ \text{C}°$ so $1\ \text{M}° = 3.96\ \text{C}°$

Zero on the M scale is -39 on the C scale, so to obtain T_{C} multiply T_{M} by 3.96 and then subtract 39°:

$T_{\text{C}} = 3.96T_M - 39°$

Solving for T_{M} gives $T_{\text{M}} = \frac{1}{3.96}(T_{\text{C}} + 39°)$

The normal boiling point of water is 100°C; $T_{\text{M}} = \frac{1}{3.96}(100° + 39°) = 35.1°\text{M}$.

(b) $10.0\ \text{M}° = 39.6\ \text{C}°$

EVALUATE: A M° is larger than a C° since it takes fewer of them to express the difference between the boiling and melting points for mercury.

17.74. **IDENTIFY:** $v = \sqrt{F/\mu} = \sqrt{FL/m}$. For the fundamental, $\lambda = 2L$ and $f = \dfrac{v}{\lambda} = \dfrac{1}{2}\sqrt{\dfrac{F}{mL}}$. F, v and λ change when T changes because L changes. $\Delta L = L\alpha\Delta T$, where L is the original length.

SET UP: For copper, $\alpha = 1.7\times10^{-5}\ (\text{C}°)^{-1}$.

EXECUTE: **(a)** We can use differentials to find the frequency change because all length changes are small percents. $\Delta f \approx \dfrac{\partial f}{\partial L}\Delta L$ (only L changes due to heating).

$$\Delta f = \tfrac{1}{2}\tfrac{1}{2}(F/mL)^{-1/2}(F/m)(-1/L^2)\Delta L = -\tfrac{1}{2}\left(\tfrac{1}{2}\sqrt{\frac{F}{mL}}\right)\frac{\Delta L}{L} = -\tfrac{1}{2}f\frac{\Delta L}{L}.$$

$\Delta f = -\frac{1}{2}(\alpha\Delta T)f = -\frac{1}{2}(1.7\times10^{-5}\ (\text{C}°)^{-1})(40\ \text{C}°)(440\ \text{Hz}) = -0.15\ \text{Hz}$. The frequency decreases since the length increases.

(b) $\Delta v = \dfrac{\partial v}{\partial L}\Delta L.$

$$\frac{\Delta v}{v} = \frac{\frac{1}{2}(FL/m)^{-1/2}(F/m)\Delta L}{\sqrt{FL/m}} = \frac{\Delta L}{2L} = \frac{\alpha\Delta T}{2} = \frac{1}{2}(1.7\times10^{-5}\ (\text{C}°)^{-1})(40\ \text{C}°) = 3.4\times10^{-4} = 0.034\%.$$

(c) $\lambda = 2L$ so $\Delta\lambda = 2\Delta L \rightarrow \dfrac{\Delta\lambda}{\lambda} = \dfrac{2\Delta L}{2L} = \dfrac{\Delta L}{L} = \alpha\Delta T.$

$\dfrac{\Delta\lambda}{\lambda} = (1.7\times10^{-5}\ (\text{C}°)^{-1})(40\ \text{C}°) = 6.8\times10^{-4} = 0.068\%$. λ increases.

EVALUATE: The wave speed and wavelength increase when the length increases and the frequency decreases. The percentage change in the frequency is -0.034%. The fractional change in all these quantities is very small.

17.75. **IDENTIFY** and **SET UP:** Use $\Delta V = V_0\beta\Delta T$ for the volume expansion of the oil and of the cup. Both the volume of the cup and the volume of the olive oil increase when the temperature increases, but β is larger for the oil so it expands more. When the oil starts to overflow, $\Delta V_{\text{oil}} = \Delta V_{\text{glass}} + (3.00\times10^{-3}\ \text{m})A$, where A is the cross-sectional area of the cup.

EXECUTE: $\Delta V_{\text{oil}} = V_{0,\text{oil}}\beta_{\text{oil}}\Delta T = (9.7\ \text{cm})A\beta_{\text{oil}}\Delta T$. $\Delta V_{\text{glass}} = V_{0,\text{glass}}\beta_{\text{glass}}\Delta T = (10.0\ \text{cm})A\beta_{\text{glass}}\Delta T$.

$(9.7\ \text{cm})A\beta_{\text{oil}}\Delta T = (10.0\ \text{cm})A\beta_{\text{glass}}\Delta T + (0.300\ \text{cm})A$. The A divides out. Solving for ΔT gives $\Delta T = 47.4\ \text{C}°$. $T_2 = T_1 + \Delta T = 69.4°\text{C}$.

EVALUATE: If the expansion of the cup is neglected, the olive oil will have expanded to fill the cup when $(0.300\text{ cm})A = (9.7\text{ cm})A\beta_{\text{oil}}\Delta T$, so $\Delta T = 45.5\text{ C}°$ and $T_2 = 77.5°\text{C}$. Our result is somewhat higher than this. The cup also expands but not as much since $\beta_{\text{glass}} << \beta_{\text{oil}}$.

17.76. **IDENTIFY:** As the tape changes temperature, the distances between the markings will increase, thus making the readings inaccurate.

SET UP: For steel, $\alpha = 1.2\times10^{-5}\,(\text{C}°)^{-1}$. The two points that match the length of the object are 25.970 m apart at $20.0°\text{C}$. Find the distance between them at $5.00°\text{C}$. For linear expansion, $L = L_0(1+\alpha\Delta T)$.

EXECUTE: $L = L_0(1+\alpha\Delta T) = (25.970\text{ m})[1+(1.2\times10^{-5}\,(\text{C}°)^{-1})(5.00°\text{C} - 20.0°\text{C})] = 25.965\text{ m}$. The true distance between the points is 25.965 m.

EVALUATE: The error in measurement is 25.970 m – 25.965 m = 0.005 m = 5 mm. This is not likely to be a very serious error in a measurement of nearly 30 m. If greater precision is needed, some sort of laser measuring device would probably be used.

17.77. **IDENTIFY** and **SET UP:** Call the metals *A* and *B*. Use the data given to calculate α for each metal.

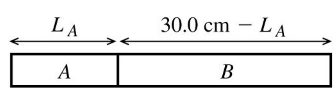
EXECUTE: $\Delta L = L_0\alpha\Delta T$ so $\alpha = \Delta L/(L_0\Delta T)$

metal *A*: $\alpha_A = \dfrac{\Delta L}{L_0\Delta T} = \dfrac{0.0650\text{ cm}}{(30.0\text{ cm})(100\text{ C}°)} = 2.167\times10^{-5}\ (\text{C}°)^{-1}$

metal *B*: $\alpha_B = \dfrac{\Delta L}{L_0\Delta T} = \dfrac{0.0350\text{ cm}}{(30.0\text{ cm})(100\text{ C}°)} = 1.167\times10^{-5}\ (\text{C}°)^{-1}$

EVALUATE: L_0 and ΔT are the same, so the rod that expands the most has the larger α.

IDENTIFY and **SET UP:** Now consider the composite rod (Figure 17.77). Apply $\Delta L = L_0\alpha\Delta T$. The target variables are L_A and L_B, the lengths of the metals *A* and *B* in the composite rod.



$\Delta T = 100\text{ C}°$
$\Delta L = 0.058\text{ cm}$

Figure 17.77

EXECUTE: $\Delta L = \Delta L_A + \Delta L_B = (\alpha_A L_A + \alpha_B L_B)\Delta T$

$\Delta L/\Delta T = \alpha_A L_A + \alpha_B(0.300\text{ m} - L_A)$

$$L_A = \frac{\Delta L/\Delta T - (0.300\text{ m})\alpha_B}{\alpha_A - \alpha_B} = \frac{(0.058\times10^{-2}\text{ m})/(100\text{ C}°) - (0.300\text{ m})(1.167\times10^{-5}(\text{C}°)^{-1})}{1.00\times10^{-5}\ (\text{C}°)^{-1}} = 23.0\text{ cm}$$

$L_B = 30.0\text{ cm} - L_A = 30.0\text{ cm} - 23.0\text{ cm} = 7.0\text{ cm}$

EVALUATE: The expansion of the composite rod is similar to that of rod *A*, so the composite rod is mostly metal *A*.

17.78. **IDENTIFY:** The copper sphere is radiating energy and is therefore cooling down. So we are dealing with heat capacity and thermal radiation.

SET UP: The rate at which heat is radiated is $H = Ae\sigma T^4$ and $Q = mc\Delta T$. For this sphere e = 1.00 and $c = 390\text{ J/kg}\cdot\text{K}$, and $m = \rho V$. The radiated energy in time *t* is *Ht*.

EXECUTE: **(a)** We want the time *t* that it takes the sphere to cool by 1.00 K due to the radiation, assuming that *H* remains constant. The heat for the copper sphere to cool down by 1 K is $Q = mc\Delta T$ = $\rho Vc\Delta T$, so *Ht* = *Q*. This gives $A\sigma T^4 t = \rho Vc\Delta T$. Using $A = 4\pi R^2$ and $V = \frac{4}{3}\pi R^3$, the previous equation becomes $\sigma T^4 t = \dfrac{\rho Rc\Delta T}{3}$. Solving for *t* using *T* = 300 K, $c = 390\text{ J/kg}\cdot\text{K}$, $\Delta T = 1\text{ K}$, ρ = 8900 kg/m^3, and *R* = 0.0500 m, we get *t* = 126 s = 2.10 min.

(b) $\dfrac{\Delta H}{H} = \dfrac{H_2 - H_1}{H_1} = \dfrac{H_2}{H_1} - 1 = \dfrac{A\sigma T_2^4}{A\sigma T_1^4} - 1 = \left(\dfrac{299\text{ K}}{300\text{ K}}\right)^4 - 1 = -0.0133.$

EVALUATE: The fractional change in H is so small that neglecting it was a reasonable option. The fractional change is negative because the sphere is decreasing in temperature so the rate of radiation is decreasing.

17.79. **IDENTIFY:** The change in length due to heating is $\Delta L_T = L_0\alpha\Delta T$ and this need not equal ΔL. The change in length due to the tension is $\Delta L_F = \dfrac{FL_0}{AY}$. Set $\Delta L = \Delta L_F + \Delta L_T$.

SET UP: $\alpha_{\text{brass}} = 2.0\times10^{-5}\ (\text{C}°)^{-1}$. $\alpha_{\text{steel}} = 1.5\times10^{-5}\ (\text{C}°)^{-1}$. $Y_{\text{steel}} = 20\times10^{10}$ Pa.

EXECUTE: **(a)** The change in length is due to the tension and heating. $\dfrac{\Delta L}{L_0} = \dfrac{F}{AY} + \alpha\Delta T$. Solving for F/A, $\dfrac{F}{A} = Y\left(\dfrac{\Delta L}{L_0} - \alpha\Delta T\right)$.

(b) The brass bar is given as "heavy" and the wires are given as "fine," so it may be assumed that the stress in the bar due to the fine wires does not affect the amount by which the bar expands due to the temperature increase. This means that ΔL is not zero, but is the amount $\alpha_{\text{brass}}L_0\Delta T$ that the brass expands, and so

$\dfrac{F}{A} = Y_{\text{steel}}(\alpha_{\text{brass}} - \alpha_{\text{steel}})\Delta T = (20\times10^{10}\text{ Pa})(2.0\times10^{-5}\ (\text{C}°)^{-1} - 1.2\times10^{-5}\ (\text{C}°)^{-1})(120\text{ C}°) = 1.92\times10^{8}\text{ Pa}.$

EVALUATE: The length of the brass bar increases more than the length of the steel wires. The wires remain taut and are under tension when the temperature of the system is raised above 20°C.

17.80. **IDENTIFY** and **SET UP:** $v = \sqrt{F/\mu}$. The coefficient of linear expansion α is defined by $\Delta L = L_0\alpha\Delta T$. This can be combined with $Y = \dfrac{F/A}{\Delta L/L_0}$ to give $\Delta F = -Y\alpha A\Delta T$ for the change in tension when the temperature changes by ΔT. Combine the two equations and solve for α.

EXECUTE: $v_1 = \sqrt{F/\mu}$, $v_1^2 = F/\mu$ and $F = \mu v_1^2$

The length and hence μ stay the same but the tension decreases by $\Delta F = -Y\alpha A\Delta T$.

$v_2 = \sqrt{(F + \Delta F)/\mu} = \sqrt{(F - Y\alpha A\Delta T)/\mu}$

$v_2^2 = F/\mu - Y\alpha A\,\Delta T/\mu = v_1^2 - Y\alpha A\,\Delta T/\mu$

And $\mu = m/L$ so $A/\mu = AL/m = V/m = 1/\rho$. ($A$ is the cross-sectional area of the wire, V is the volume of a length L.) Thus $v_1^2 - v_2^2 = \alpha(Y\Delta T/\rho)$ and $\alpha = \dfrac{v_1^2 - v_2^2}{(Y/\rho)\,\Delta T}$.

EVALUATE: When T increases the tension decreases and v decreases.

17.81. **(a) IDENTIFY** and **SET UP:** The diameter of the ring undergoes linear expansion (increases with T) just like a solid steel disk of the same diameter as the hole in the ring. Heat the ring to make its diameter equal to 2.5020 in.

EXECUTE: $\Delta L = \alpha L_0\Delta T$ so $\Delta T = \dfrac{\Delta L}{L_0\alpha} = \dfrac{0.0020\text{ in.}}{(2.5000\text{ in.})(1.2\times10^{-5}(\text{C}°)^{-1})} = 66.7\text{ C}°$

$T = T_0 + \Delta T = 20.0°\text{C} + 66.7\text{ C}° = 87°\text{C}$

(b) IDENTIFY and **SET UP:** Apply the linear expansion equation to the diameter of the brass shaft and to the diameter of the hole in the steel ring.

EXECUTE: $L = L_0(1 + \alpha\Delta T)$

Want L_s (steel) $= L_b$ (brass) for the same ΔT for both materials: $L_{0s}(1+\alpha_s\Delta T) = L_{0b}(1+\alpha_b\Delta T)$ so

$L_{0s} + L_{0s}\alpha_s\Delta T = L_{0b} + L_{0b}\alpha_b\Delta T$

$$\Delta T = \frac{L_{0b} - L_{0s}}{L_{0s}\alpha_s - L_{0b}\alpha_b} = \frac{2.5020 \text{ in.} - 2.5000 \text{ in.}}{(2.5000 \text{ in.})(1.2\times10^{-5}(\text{C}°)^{-1}) - (2.5020 \text{ in.})(2.0\times10^{-5}(\text{C}°)^{-1})}$$

$$\Delta T = \frac{0.0020}{3.00\times10^{-5} - 5.00\times10^{-5}} \text{ C}° = -100 \text{ C}°$$

$T = T_0 + \Delta T = 20.0°\text{C} - 100 \text{ C}° = -80°\text{C}$

Evaluate: Both diameters decrease when the temperature is lowered but the diameter of the brass shaft decreases more since $\alpha_b > \alpha_s$; $|\Delta L_b| - |\Delta L_s| = 0.0020$ in.

17.82. **Identify:** Calculate the total food energy value for one doughnut. $K = \frac{1}{2}mv^2$.

Set Up: 1 cal = 4.186 J

Execute: **(a)** The energy is $(2.0 \text{ g})(4.0 \text{ kcal/g}) + (17.0 \text{ g})(4.0 \text{ kcal/g}) + (7.0 \text{ g})(9.0 \text{ kcal/g}) = 139$ kcal. The time required is $(139 \text{ kcal})/(510 \text{ kcal/h}) = 0.273 \text{ h} = 16.4$ min.

(b) $v = \sqrt{2K/m} = \sqrt{2(139\times10^3 \text{ cal})(4.186 \text{ J/cal})/(60 \text{ kg})} = 139 \text{ m/s} = 501 \text{ km/h}$.

Evaluate: When we set $K = Q$, we must express Q in J, so we can solve for v in m/s.

17.83. **Identify:** We mix an unknown liquid at 90.0°C with water at 0.0°C and measure the final equilibrium temperature T. The heat lost by the unknown liquid is equal to the heat gained by the water, so $Q_{\text{net}} = 0$.

Set Up: $Q_{\text{net}} = Q_{\text{water}} + Q_{\text{unknown}}$. We need to relate the mass of the water m_w to T in order to interpret the graph of m_w versus T^{-1}. Let x refer to the unknown liquid. We want to find c_x. For temperature changes, we use $Q = mc\Delta T$.

Execute: Using $Q_{\text{net}} = Q_{\text{water}} + Q_{\text{unknown}} = 0$ gives $m_w c_w \Delta T_w + m_x c_x \Delta T_x = 0$. Solve for m_w as a function of T^{-1}. $m_w c_w (T - 0.0°\text{C}) = m_x c_x (90.0°\text{C} - T)$, so $m_w = \left(\frac{m_x c_x}{c_w}\right)\left(\frac{90.0°\text{C}}{T} - 1\right)$. The graph of m_w versus T^{-1} should be a straight line having slope equal to $\frac{m_x c_x 90.0°\text{C}}{c_w}$. Solving for c_x gives

$$c_x = \frac{c_w(\text{slope})}{m_x(90.0°\text{C})} = \frac{(4190 \text{ J/kg}\cdot\text{K})(2.15 \text{ kg}\cdot\text{C}°)}{(0.050 \text{ kg})(90.0°\text{C})} = 2000 \text{ J/kg}\cdot\text{K}.$$

Evaluate: From Table 17.3 we see that c_x is about half that of water, but close to that of ice, ethanol, and ethylene glycol, so we get a reasonable result.

17.84. **Identify:** $Q_{\text{system}} = 0$. Assume that the normal melting point of iron is above 745°C so the iron initially is solid.

Set Up: For water, $c = 4190$ J/kg·K and $L_v = 2256\times10^3$ J/kg. For solid iron, $c = 470$ J/kg·K.

Execute: The heat released when the iron slug cools to 100°C is $Q = mc\Delta T =$ $(0.1000 \text{ kg})(470 \text{ J/kg}\cdot\text{K})(645 \text{ K}) = 3.03\times10^4$ J. The heat absorbed when the temperature of the water is raised to 100°C is $Q = mc\Delta T = (0.0850 \text{ kg})(4190 \text{ J/kg}\cdot\text{K})(80.0 \text{ K}) = 2.85\times10^4$ J. This is less than the heat released from the iron and $3.03\times10^4 \text{ J} - 2.85\times10^4 \text{ J} = 1.81\times10^3$ J of heat is available for converting some of the liquid water at 100°C to vapor. The mass m of water that boils is

$$m = \frac{1.81\times10^3 \text{ J}}{2256\times10^3 \text{ J/kg}} = 8.01\times10^{-4} \text{ kg} = 0.801 \text{ g}.$$

(a) The final temperature is 100°C.

(b) There is $85.0 \text{ g} - 0.801 \text{ g} = 84.2 \text{ g}$ of liquid water remaining, so the final mass of the iron and remaining water is 184.2 g.

EVALUATE: If we ignore the phase change of the water and write $m_{\text{iron}}c_{\text{iron}}(T - 745°\text{C}) + m_{\text{water}}c_{\text{water}}(T - 20.0°\text{C}) = 0$, when we solve for T we will get a value slightly larger than 100°C. That result is unphysical and tells us that some of the water changes phase.

17.85. IDENTIFY and SET UP: To calculate Q, use $Q = mc\,\Delta T$ in the form $dQ = nC\,dT$ and integrate, using $C(T)$ given in the problem. C_{av} is obtained from $C = \frac{1}{n}\frac{dQ}{dT}$ using the finite temperature range instead of an infinitesimal dT.

EXECUTE: (a) $dQ = nCdT$

$$Q = n\int_{T_1}^{T_2} C\,dT = n\int_{T_1}^{T_2} k(T^3/\theta^3)dT = (nk/\theta^3)\int_{T_1}^{T_2} T^3\,dt = (nk/\theta^3)\left(\tfrac{1}{4}T^4\Big|_{T_1}^{T_2}\right)$$

$$Q = \frac{nk}{4\theta^3}\left(T_2^4 - T_1^4\right) = \frac{(1.50\text{ mol})(1940\text{ J/mol}\cdot\text{K})}{4(281\text{ K})^3}\left[(40.0\text{ K})^4 - (10.0\text{ K})^4\right] = 83.6\text{ J}.$$

(b) $C_{\text{av}} = \dfrac{1}{n}\dfrac{\Delta Q}{\Delta T} = \dfrac{1}{1.50\text{ mol}}\left(\dfrac{83.6\text{ J}}{40.0\text{ K} - 10.0\text{ K}}\right) = 1.86\text{ J/mol}\cdot\text{K}$

(c) $C = k(T/\theta)^3 = (1940\text{ J/mol}\cdot\text{K})(40.0\text{ K}/281\text{ K})^3 = 5.60\text{ J/mol}\cdot\text{K}$

EVALUATE: C is increasing with T, so C at the upper end of the temperature integral is larger than its average value over the interval.

17.86. IDENTIFY: We are looking at the thermal radiation from the logs in a campfire.

SET UP and EXECUTE: The net radiation rate is $H_{\text{net}} = Ae\sigma\left(T^4 - T_s^4\right)$.

(a) Estimate: Log diameter is 25 cm = 0.25 m and length is 0.50 m.

(b) The total area is that of the two faces plus the side: $A = 2A_{\text{face}} + A_{\text{side}} = 2\pi R^2 + 2\pi RL$. For our log, we have $A = 2\pi(0.125\text{ m})^2 + 2\pi(0.125\text{ m})(0.50\text{ m}) = 0.49\text{ m}^2$.

(c) We want the net radiated power for $T = 700°\text{C} = 973\text{ K}$, $T_s = 20.0°\text{C} = 293\text{ K}$, and $e = 1$. Therefore $H_{\text{net}} = Ae\sigma\left(T^4 - T_s^4\right)$ = $(0.49\text{ m}^2)(5.67\times10\text{ W/m}^2\cdot\text{K}^4)\left[(973\text{ K})^4 - (293\text{ K})^4\right]$ so we get H_{net} = 2.5×10^4 W.

EVALUATE: On a chilly night when the temperature is 0°C (273 K) the rate of radiation would be even greater. As any camper knows, campfires can get very hot and radiate a lot of energy, as we have discovered.

17.87. IDENTIFY: Apply $Q = mc\Delta T$ to the air in the room.

SET UP: The mass of air in the room is $m = \rho V = (1.20\text{ kg/m}^3)(3200\text{ m}^3) = 3840\text{ kg}$. $1\text{ W} = 1\text{ J/s}$.

EXECUTE: (a) $Q = (3000\text{ s})(140\text{ students})(100\text{ J/s}\cdot\text{student}) = 4.20\times10^7\text{ J}$.

(b) $Q = mc\Delta T$. $\Delta T = \dfrac{Q}{mc} = \dfrac{4.20\times10^7\text{ J}}{(3840\text{ kg})(1020\text{ J/kg}\cdot\text{K})} = 10.7\text{ C°}$.

(c) $\Delta T = (10.7\text{ C°})\left(\dfrac{280\text{ W}}{100\text{ W}}\right) = 30.0\text{ C°}$.

EVALUATE: In the absence of a cooling mechanism for the air, the air temperature would rise significantly.

17.88. IDENTIFY: $dQ = nCdT$ so for the temperature change $T_1 \to T_2$, $Q = n\int_{T_1}^{T_2} C(T)dT$.

SET UP: $\int dT = T$ and $\int TdT = \frac{1}{2}T^2$. Express T_1 and T_2 in kelvins: $T_1 = 300\text{ K}$, $T_2 = 500\text{ K}$.

EXECUTE: Denoting C by $C = a + bT$, a and b independent of temperature, integration gives

$$Q = n\left[a(T_2 - T_1) + \frac{b}{2}(T_2^2 - T_1^2)\right].$$

$Q = (3.00 \text{ mol})[(29.5 \text{ J/mol}\cdot\text{K})(500 \text{ K} - 300 \text{ K}) + (4.10\times10^{-3} \text{ J/mol}\cdot\text{K}^2)((500 \text{ K})^2 - (300 \text{ K})^2)].$

$Q = 1.97\times10^4$ J.

EVALUATE: If C is assumed to have the constant value 29.5 J/mol·K, then $Q = 1.77\times10^4$ J for this temperature change. At $T_1 = 300$ K, $C = 32.0$ J/mol·K and at $T_2 = 500$ K, $C = 33.6$ J/mol·K. The average value of C is 32.8 J/mol·K. If C is assumed to be constant and to have this average value, then $Q = 1.97\times10^4$ J, which is equal to the correct value.

17.89. **IDENTIFY:** The energy generated in the body is used to evaporate water, which prevents the body from overheating.

SET UP: Energy is (power)(time); calculate the heat energy Q produced in one hour. The mass m of water that vaporizes is related to Q by $Q = mL_v$. 1.0 kg of water has a volume of 1.0 L.

EXECUTE: **(a)** $Q = (0.80)(500 \text{ W})(3600 \text{ s}) = 1.44\times10^6$ J. The mass of water that evaporates each hour is $m = \dfrac{Q}{L_v} = \dfrac{1.44\times10^6 \text{ J}}{2.42\times10^6 \text{ J/kg}} = 0.60$ kg.

(b) (0.60 kg/h)(1.0 L/kg) = 0.60 L/h. The number of bottles of water is

$\dfrac{0.60 \text{ L/h}}{0.750 \text{ L/bottle}} = 0.80$ bottles/h.

EVALUATE: It is not unreasonable to drink 8/10 of a bottle of water per hour during vigorous exercise.

17.90. **IDENTIFY:** If it cannot be gotten rid of in some way, the metabolic energy transformed to heat will increase the temperature of the body.

SET UP: From Problem 17.89, $Q = 1.44\times10^6$ J and $m = 70$ kg. $Q = mc\Delta T$. Convert the temperature change in C° to F° using that 9 F° = 5 C°.

EXECUTE: **(a)** $Q = mc\Delta T$ so $\Delta T = \dfrac{Q}{mc} = \dfrac{1.44\times10^6 \text{ J}}{(70 \text{ kg})(3480 \text{ J/kg}\cdot\text{C}°)} = 5.9$ C°.

(b) $\Delta T = (5.9°\text{C})\left(\dfrac{9 \text{ F}°}{5 \text{ C}°}\right) = 10.6°\text{F}$. $T = 98.6°\text{F} + 10.6 \text{ F}° = 109°\text{F}$.

EVALUATE: A temperature this high can cause heat stroke and be lethal.

17.91. **IDENTIFY** and **SET UP:** The heat produced from the reaction is $Q_{\text{reaction}} = mL_{\text{reaction}}$, where L_{reaction} is the heat of reaction of the chemicals.

$Q_{\text{reaction}} = W + \Delta U_{\text{spray}}$

EXECUTE: For a mass m of spray, $W = \frac{1}{2}mv^2 = \frac{1}{2}m(19 \text{ m/s})^2 = (180.5 \text{ J/kg})m$ and

$\Delta U_{\text{spray}} = Q_{\text{spray}} = mc\Delta T = m(4190 \text{ J/kg}\cdot\text{K})(100°\text{C} - 20°\text{C}) = (335{,}200 \text{ J/kg})m.$

Then $Q_{\text{reaction}} = (180 \text{ J/kg} + 335{,}200 \text{ J/kg})m = (335{,}380 \text{ J/kg})m$ and $Q_{\text{reaction}} = mL_{\text{reaction}}$ implies $mL_{\text{reaction}} = (335{,}380 \text{ J/kg})m.$

The mass m divides out and $L_{\text{reaction}} = 3.4\times10^5$ J/kg.

EVALUATE: The amount of energy converted to work is negligible for the two significant figures to which the answer should be expressed. Almost all of the energy produced in the reaction goes into heating the compound.

17.92. **IDENTIFY:** The bike peddler generates energy, 70% of which goes into melting the ice. We are dealing with a change of phase of the ice and the power generated by turning the bicycle wheel.

SET UP: The bike peddler generates 25.0 N·m of torque while peddling to turn the bike wheel at 30.0 rev/min = 3.142 rad/s. The power due to this torque is $P = \tau\omega$, the energy E it produces in time t is $E = Pt$, the heat Q to melt ice is $Q = mL_f$, and the heat to raise the water temperature is $Q = mc\Delta T$.

EXECUTE: **(a)** The target variable is the time to melt 3.00 kg of ice at 0.0°C. All the ice is at 0.0°C so all the energy from peddling is used only to melt the ice. This heat is $Q = mL_f =$ $(3.00\text{ kg})(334\times10^3\text{ J/kg}) = 1.00\times10^6\text{ J}$. The peddling power is $P = \tau\omega = (25.0\text{ N}\cdot\text{m})(3.142\text{ rad/s}) =$ 78.55 W. Only 70% of this power is used to melt ice, so the available power is (0.70)(78.55 W) = 55.0 W. The heat from this power in time t is $Q = Pt$, and this must be $1.00\times10^6\text{ J}$ to melt the ice. Therefore $1.00\times10^6\text{ J} = (55.0\text{ W})t$, so $t = 1.8\times10^4\text{ s} = 5.1\text{ h}$.

(b) The additional heat is required to raise the water temperature from 0.0°C to 10.5°C. We use $Q = mc\Delta T$ where m is the mass of 6.0 L of water plus 3.00 kg of melted ice. One liter is 6000 cm^3, and each cm^3 has a mass of 1.00 g, so 6.0 L of water has a mass of 6000 g = 6.0 kg. The total water mass is 9.0 kg. The heat is $Q = mc\Delta T = (9.00\text{ kg})(4190\text{ J/kg}\cdot\text{K})(10.5\text{ C}°) = 3.96\times10^5\text{ J}$. The cyclist is providing 55.0 W of power, so $(55.0\text{ W})t = 3.96\times10^5\text{ J}$, which gives $t = 7200\text{ s} = 2.0\text{ h}$.

EVALUATE: It takes about 2½ times as long to melt the ice than to heat all the water by 10.5°C. This difference in time occurs because L_f is large for water.

17.93. **IDENTIFY:** The heat lost by the water is equal to the amount of heat gained by the ice. First calculate the amount of heat the water could give up if it is cooled to 0.0°C. Then see how much heat it would take to melt all of the ice. If the heat to melt the ice is less than the heat the water would give up, the ice all melts and then the resulting water is heated to some final temperature.

SET UP: $Q = mc\,\Delta T$ and $Q = mL_f$.

EXECUTE: **(a)** Heat from water if cooled to 0.0°C: $Q = mc\,\Delta T$

$Q = mc\,\Delta T = (1.50\text{ kg})(4190\text{ J/kg}\cdot\text{K})(28.0\text{ K}) = 1.760\times10^5\text{ J}$

Heat to melt all of the ice: $Q = mc\,\Delta T + mL_f = m(c\Delta T + L_f)$

$Q = (0.600\text{ kg})[(2100\text{ J/kg}\cdot\text{K})(22.0\text{ K}) + 3.34\times10^5\text{ J/kg}] = 2.276\times10^5\text{ J}$

Since the heat required to melt all the ice is greater than the heat available by cooling the water to 0.0°C, not all the ice will melt.

(b) Since not all the ice melts, the final temperature of the water (and ice) will be 0.0°C. So the heat from the water will melt only part of the ice. Call m the mass of the melted ice. Therefore $Q_{\text{from water}} = 1.760\times10^5\text{ J} = (0.600\text{ kg})(2100\text{ J/kg}\cdot\text{K})(22.0\text{ K}) + m(3.34\times10^5\text{ J/kg})$, which gives $m =$ 0.444 kg, which is the amount of ice that melts. The mass of ice remaining is 0.600 kg – 0.444 kg = 0.156 kg. The final temperature will be 0.0°C since some ice remains in the water.

EVALUATE: An alternative approach would be to assume that all the ice melts and find the final temperature of the water in the container. This actually comes out to be negative, which is not possible if all the ice melts. Therefore not all the ice could have melted. Once you know this, proceed as in part (b).

17.94. **IDENTIFY:** The amount of heat lost by the soft drink and mug is equal to the heat gained by the ice. The ice must first be heated to 0.0°C, then melted, and finally the resulting water heated to the final temperature of the system.

SET UP: Assume that all the ice melts. If we calculate $T_f < 0$, we will know this assumption is incorrect. For aluminum, $c_a = 910\text{ J/kg}\cdot\text{K}$. For water, $L_f = 3.35\times10^5\text{ J/kg}$ and $c_w = 4.19\times10^3\text{ J/kg}\cdot\text{K}$. For ice, $c_i = 2100\text{ J/kg}\cdot\text{K}$. The density of water is $1.00\times10^3\text{ kg/m}^3$, so 1.00 L of water has mass 1.00 kg.

EXECUTE: For the soft drink:

$Q_w = m_w c_w\,\Delta T_w = (2.00\text{ kg})(4.19\times10^3\text{ J/kg}\cdot\text{K})(T - 20.0°\text{C}) = (8380\text{ J/K})T - 1.676\times10^5\text{ J}.$

For the mug: $Q_a = m_a c_a\,\Delta T_a = (0.257\text{ kg})(910\text{ J/kg}\cdot\text{K})(T - 20.0°\text{C}) = (234\text{ J/K})T - 4.68\times10^3\text{ J}.$

For the ice: $Q_i = m_i c_i\,\Delta T_i + m_i L_f + m_i c_w\,\Delta T_w$.

$Q_i = (0.120\text{ kg})[(2100\text{ J/kg}\cdot\text{K})(15.0\text{ C°}) + 3.34\times10^5\text{ J/kg} + (4.19\times10^3\text{ J/kg}\cdot\text{K})(T - 0\text{ C°})].$

$Q_i = 4.386\times10^4\text{ J} + (503\text{ J/K})T.$

$\sum Q = 0$ gives

$(8380\text{ J/K})T - 1.676\times10^5\text{ J} + (234\text{ J/K})T - 4.68\times10^3\text{ J} + 4.386\times10^4\text{ J} + (503\text{ J/K})T = 0.$

$$T = \frac{1.284\times10^5\text{ J}}{9117\text{ J/K}} = 14.1°\text{C}.$$

EVALUATE: $T > 0°\text{C}$, so our assumption that all the ice melts is correct. Note that the ice and the water from the melted ice have different specific heat capacities.

17.95. **IDENTIFY** and **SET UP:** Assume that all the ice melts and that all the steam condenses. If we calculate a final temperature T that is outside the range 0°C to 100°C then we know that this assumption is incorrect. Calculate Q for each piece of the system and then set the total $Q_{\text{system}} = 0$.

EXECUTE: **(a)** Copper can (changes temperature from 0.0° to T; no phase change):

$Q_{\text{can}} = mc\Delta T = (0.446\text{ kg})(390\text{ J/kg}\cdot\text{K})(T - 0.0°\text{C}) = (173.9\text{ J/K})T$

Ice (melting phase change and then the water produced warms to T):

$Q_{\text{ice}} = +mL_f + mc\Delta T = (0.0950\text{ kg})(334\times10^3\text{ J/kg}) + (0.0950\text{ kg})(4190\text{ J/kg}\cdot\text{K})(T - 0.0°\text{C})$

$Q_{\text{ice}} = 3.173\times10^4\text{ J} + (398.0\text{ J/K})T.$

Steam (condenses to liquid and then water produced cools to T):

$Q_{\text{steam}} = -mL_v + mc\Delta T = -(0.0350\text{ kg})(2256\times10^3\text{ J/kg}) + (0.0350\text{ kg})(4190\text{ J/kg}\cdot\text{K})(T - 100.0°\text{C})$

$Q_{\text{steam}} = -7.896\times10^4\text{ J} + (146.6\text{ J/K})T - 1.466\times10^4\text{ J} = -9.362\times10^4\text{ J} + (146.6\text{ J/K})T$

$Q_{\text{system}} = 0$ implies $Q_{\text{can}} + Q_{\text{ice}} + Q_{\text{steam}} = 0.$

$(173.9\text{ J/K})T + 3.173\times10^4\text{ J} + (398.0\text{ J/K})T - 9.362\times10^4\text{ J} + (146.6\text{ J/K})T = 0$

$(718.5\text{ J/K})T = 6.189\times10^4\text{ J}$

$$T = \frac{6.189\times10^4\text{ J}}{718.5\text{ J/K}} = 86.1°\text{C}.$$

(b) No ice, no steam, and $0.0950\text{ kg} + 0.0350\text{ kg} = 0.130\text{ kg}$ of liquid water.

EVALUATE: This temperature is between 0°C and 100°C so our assumptions about the phase changes being complete were correct.

17.96. **IDENTIFY:** The final amount of ice is less than the initial mass of water, so water remains and the final temperature is 0°C. The ice added warms to 0°C and heat comes out of water to convert that water to ice. Conservation of energy says $Q_i + Q_w = 0,$ where Q_i and Q_w are the heat flows for the ice that is added and for the water that freezes.

SET UP: Let m_i be the mass of ice that is added and m_w is the mass of water that freezes. The mass of ice increases by 0.434 kg, so $m_i + m_w = 0.434\text{ kg}.$ For water, $L_f = 334\times10^3\text{ J/kg}$ and for ice $c_i = 2100\text{ J/kg}\cdot\text{K}.$ Heat comes out of the water when it freezes, so $Q_w = -mL_f.$

EXECUTE: $Q_i + Q_w = 0$ gives $m_i c_i(15.0\text{ C°}) + (-m_w L_f) = 0,$ $m_w = 0.434\text{ kg} - m_i,$ so $m_i c_i(15.0\text{ C°}) + (-0.434\text{ kg} + m_i)L_f = 0.$

$$m_i = \frac{(0.434\text{ kg})L_f}{c_i(15.0\text{ C°}) + L_f} = \frac{(0.434\text{ kg})(334\times10^3\text{ J/kg})}{(2100\text{ J/kg}\cdot\text{K})(15.0\text{ K}) + 334\times10^3\text{ J/kg}} = 0.397\text{ kg}.$$ 0.397 kg of ice was added.

EVALUATE: The mass of water that froze when the ice at -15.0C° was added was $0.884\text{ kg} - 0.450\text{ kg} - 0.397\text{ kg} = 0.037\text{ kg}.$

17.97. **IDENTIFY** and **SET UP:** Heat comes out of the steam when it changes phase and heat goes into the water and causes its temperature to rise. $Q_{\text{system}} = 0$. First determine what phases are present after the system has come to a uniform final temperature.

EXECUTE: (a) Heat that must be removed from steam if all of it condenses is

$Q = -mL_{\text{v}} = -(0.0400\text{ kg})(2256\times10^3\text{ J/kg}) = -9.02\times10^4\text{ J}$

Heat absorbed by the water if it heats all the way to the boiling point of 100°C:

$Q = mc\Delta T = (0.200\text{ kg})(4190\text{ J/kg}\cdot\text{K})(50.0\text{ C°}) = 4.19\times10^4\text{ J}$

(b) Mass of steam that condenses is $m = Q/L_{\text{v}} = 4.19\times10^4\text{ J}/2256\times10^3\text{ J/kg} = 0.0186\text{ kg}$.

Thus there is $0.0400\text{ kg} - 0.0186\text{ kg} = 0.0214\text{ kg}$ of steam left. The amount of liquid water is $0.0186\text{ kg} + 0.200\text{ kg} = 0.219\text{ kg}$.

EVALUATE: The water can't absorb enough heat for all the steam to condense. Steam is left and the final temperature then must be 100°C.

17.98. **IDENTIFY:** Heat is conducted out of the body. At steady state, the rate of heat flow is the same in both layers (fat and fur).

SET UP: Since the model is only a crude approximation to a bear, we will make the simplifying assumption that the surface area of each layer is constant and given by the surface area of a sphere of radius 1.5 m. Let the temperature of the fat-air boundary be T. A section of the two layers is sketched in Figure 17.98. A Kelvin degree is the same size as a Celsius degree, so $\text{W/m}\cdot\text{K}$ and $\text{W/m}\cdot\text{C°}$ are equivalent units. At steady state the heat current through each layer is equal to 50 W. The area of each layer is $A = 4\pi r^2$, with $r = 0.75$ m. Use $H = kA\dfrac{T_{\text{H}} - T_{\text{C}}}{L}$.

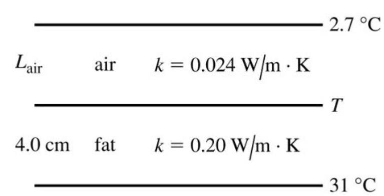


Figure 17.98

EXECUTE: **(a)** Apply $H = kA\dfrac{T_{\text{H}} - T_{\text{C}}}{L}$ to the fat layer and solve for $T_{\text{C}} = T$. For the fat layer

$$T_{\text{H}} = 31°\text{C}.\quad T = T_{\text{H}} - \frac{HL}{kA} = 31°\text{C} - \frac{(50\text{ W})(4.0\times10^{-2}\text{ m})}{(0.20\text{ W/m}\cdot\text{K})(4\pi)(0.75\text{ m})^2} = 31°\text{C} - 1.4°\text{C} = 29.6°\text{C}.$$

(b) Apply $H = kA\dfrac{T_{\text{H}} - T_{\text{C}}}{L}$ to the air layer and solve for $L = L_{\text{air}}$. For the air layer $T_{\text{H}} = T = 29.6°\text{C}$ and

$$T_{\text{C}} = 2.7°\text{C}.\quad L = \frac{kA(T_{\text{H}} - T_{\text{C}})}{H} = \frac{(0.024\text{ W/m}\cdot\text{K})(4\pi)(0.75\text{ m})^2(29.6°\text{C} - 2.7°\text{C})}{50\text{ W}} = 9.1\text{ cm}.$$

EVALUATE: The thermal conductivity of air is much lass than the thermal conductivity of fat, so the temperature gradient for the air must be much larger to achieve the same heat current. So, most of the temperature difference is across the air layer.

17.99. **IDENTIFY:** Apply $H = kA\dfrac{T_{\text{H}} - T_{\text{C}}}{L}$.

SET UP: For the glass use $L = 12.45$ cm, to account for the thermal resistance of the air films on either side of the glass.

EXECUTE: **(a)** $H = (0.120 \text{ W/m}\cdot\text{K})\ (2.00\times 0.95 \text{ m}^2)\left(\dfrac{28.0 \text{ C}°}{5.0\times 10^{-2} \text{ m} + 1.8\times 10^{-2} \text{ m}}\right) = 93.9 \text{ W}.$

(b) The heat flow through the wood part of the door is reduced by a factor of $1 - \dfrac{(0.50)^2}{(2.00\times 0.95)} = 0.868,$

so it becomes 81.5 W. The heat flow through the glass is

$H_{\text{glass}} = (0.80 \text{ W/m}\cdot\text{K})(0.50 \text{ m})^2\left(\dfrac{28.0 \text{ C}°}{12.45\times 10^{-2} \text{ m}}\right) = 45.0 \text{ W},$ and so the ratio is $\dfrac{81.5 + 45.0}{93.9} = 1.35.$

EVALUATE: The single-pane window produces a significant increase in heat loss through the door. (See Problem 17.101).

17.100. **IDENTIFY:** This problem deals with thermal stress.

SET UP: The metal bar tends to expand as its temperature rises from 0°C to T, but it cannot do this because it is confined by the concrete slab which does not expand appreciably. The force F on the bar due to this thermal stress is the normal force for the static friction force that supports the bar and the container it is lifting. Our target variable is the mass m of the heaviest container this system can support, and the thermal stress is $F / A = -Y\alpha\Delta T$.

EXECUTE: $f_S = w_{\text{bar}} + w_{\text{container}}$. The force magnitude is $F = AY\alpha\Delta T = AY\alpha T$. For the heaviest container, static friction is a maximum, so $f_S = \mu_S n$, where $n = F$. The area A is the area of contact between the slab and the cylindrical bar, so $A = 2\pi rd$. Using M for the mass of the bar and m for the mass of the container, we have $\mu_S(2\pi rd)Y\alpha T = Mg + mg$. Solving for m gives

$m = M + 2\pi\mu_S rdY\alpha T / g$.

EVALUATE: The slab would need to be very strong to support a reasonably heavy container (including its contents).

17.101. **IDENTIFY** and **SET UP:** Use H written in terms of the thermal resistance R: $H = A\Delta T/R$, where $R = L/k$ and $R = R_1 + R_2 + \ldots$ (additive).

EXECUTE: <u>single pane:</u> $R_s = R_{\text{glass}} + R_{\text{film}}$, where $R_{\text{film}} = 0.15 \text{ m}^2\cdot\text{K/W}$ is the combined thermal resistance of the air films on the room and outdoor surfaces of the window.

$R_{\text{glass}} = L/k = (4.2\times 10^{-3} \text{ m})/(0.80 \text{ W/m}\cdot\text{K}) = 0.00525 \text{ m}^2\cdot\text{K/W}$

Thus $R_s = 0.00525 \text{ m}^2\cdot\text{K/W} + 0.15 \text{ m}^2\cdot\text{K/W} = 0.1553 \text{ m}^2\cdot\text{K/W}.$

<u>double pane:</u> $R_d = 2R_{\text{glass}} + R_{\text{air}} + R_{\text{film}}$, where R_{air} is the thermal resistance of the air space between the panes. $R_{\text{air}} = L/k = (7.0\times 10^{-3} \text{ m})/(0.024 \text{ W/m}\cdot\text{K}) = 0.2917 \text{ m}^2\cdot\text{K/W}$

Thus $R_d = 2(0.00525 \text{ m}^2\cdot\text{K/W}) + 0.2917 \text{ m}^2\cdot\text{K/W} + 0.15 \text{ m}^2\cdot\text{K/W} = 0.4522 \text{ m}^2\cdot\text{K/W}$

$H_s = A\Delta T/R_s,\ H_d = A\Delta T/R_d$, so $H_s/H_d = R_d/R_s$ (since A and ΔT are same for both)

$H_s/H_d = (0.4522 \text{ m}^2\cdot\text{K/W})/(0.1553 \text{ m}^2\cdot\text{K/W}) = 2.9$

EVALUATE: The heat loss is about a factor of 3 less for the double-pane window. The increase in R for a double pane is due mostly to the thermal resistance of the air space between the panes.

17.102. **IDENTIFY:** Apply $H = \dfrac{kA\Delta T}{L}$ to each rod. Conservation of energy requires that the heat current through the copper equals the sum of the heat currents through the brass and the steel.

SET UP: Denote the quantities for copper, brass and steel by 1, 2, and 3, respectively, and denote the temperature at the junction by T_0.

EXECUTE: (a) $H_1 = H_2 + H_3$. Using $H = kA(T_H - T_C)/L$ and dividing by the common area gives

$\frac{k_1}{L_1}(100°\text{C} - T_0) = \frac{k_2}{L_2}T_0 + \frac{k_3}{L_3}T_0$. Solving for T_0 gives $T_0 = \frac{(k_1/L_1)}{(k_1/L_1)+(k_2/L_2)+(k_3/L_3)}(100°\text{C})$.
Substitution of numerical values gives $T_0 = 78.4°\text{C}$.

(b) Using $H = \frac{kA}{L}\Delta T$ for each rod, with $\Delta T_1 = 21.6\ \text{C}°$, $\Delta T_2 = \Delta T_3 = 78.4\ \text{C}°$ gives

$H_1 = 12.8\ \text{W}$, $H_2 = 9.50\ \text{W}$ and $H_3 = 3.30\ \text{W}$.

EVALUATE: In part (b), H_1 is seen to be the sum of H_2 and H_3.

17.103. **IDENTIFY:** The jogger radiates heat but the air radiates heat back into the jogger.
SET UP: The emissivity of a human body is taken to be 1.0. In the equation for the radiation heat current, $H_{\text{net}} = Ae\sigma(T^4 - T_s^4)$, the temperatures must be in kelvins.

EXECUTE: **(a)** $P_{\text{jog}} = (0.80)(1300\ \text{W}) = 1.04 \times 10^3\ \text{J/s}$.

(b) $H_{\text{net}} = Ae\sigma(T^4 - T_s^4)$, which gives

$H_{\text{net}} = (1.85\ \text{m}^2)(1.00)(5.67 \times 10^{-8}\ \text{W/m}^2 \cdot \text{K}^4)([306\ \text{K}]^4 - [313\ \text{K}]^4) = -87.1\ \text{W}$. The person gains 87.1 J of heat each second by radiation.
(c) The total excess heat per second is $1040\ \text{J/s} + 87\ \text{J/s} = 1130\ \text{J/s}$.

(d) In $1\ \text{min} = 60\ \text{s}$, the runner must dispose of $(60\ \text{s})(1130\ \text{J/s}) = 6.78 \times 10^4\ \text{J}$. If this much heat goes to evaporate water, the mass *m* of water that evaporates in one minute is given by $Q = mL_v$, so

$$m = \frac{Q}{L_v} = \frac{6.78 \times 10^4\ \text{J}}{2.42 \times 10^6\ \text{J/kg}} = 0.028\ \text{kg} = 28\ \text{g}.$$

(e) In a half-hour, or 30 minutes, the runner loses $(30\ \text{min})(0.028\ \text{kg/min}) = 0.84\ \text{kg}$. The runner must drink 0.84 L, which is $\frac{0.84\ \text{L}}{0.750\ \text{L/bottle}} = 1.1$ bottles.

EVALUATE: The person *gains* heat by radiation since the air temperature is greater than his skin temperature.

17.104. **IDENTIFY:** The nonmechanical part of the basal metabolic rate (i.e., the heat) leaves the body by radiation from the surface.
SET UP: In the radiation equation, $H_{\text{net}} = Ae\sigma(T^4 - T_s^4)$, the temperatures must be in kelvins; $e = 1.0$, $T = 30°\text{C} = 303\ \text{K}$, and $T_s = 18°\text{C} = 291\ \text{K}$. Call the basal metabolic rate BMR.

EXECUTE: **(a)** $H_{\text{net}} = Ae\sigma(T^4 - T_s^4)$.

$H_{\text{net}} = (2.0\ \text{m}^2)(1.0)(5.67 \times 10^{-8}\ \text{W/m}^2 \cdot \text{K}^4)([303\ \text{K}]^4 - [291\ \text{K}]^4) = 140\ \text{W}$.
(b) $(0.80)\text{BMR} = 140\ \text{W}$, so $\text{BMR} = 180\ \text{W}$.

EVALUATE: If the emissivity of the skin were less than 1.0, the body would radiate less so the BMR would have to be lower than we found in (b).

17.105. **(a) IDENTIFY** and **EXECUTE:** Heat must be conducted from the water to cool it to 0°C and to cause the phase transition. The entire volume of water is not at the phase transition temperature, just the upper surface that is in contact with the ice sheet.
(b) IDENTIFY: The heat that must leave the water in order for it to freeze must be conducted through the layer of ice that has already been formed.
SET UP: Consider a section of ice that has area *A*. At time *t* let the thickness be *h*. Consider a short time interval *t* to $t + dt$. Let the thickness that freezes in this time be *dh*. The mass of the section that freezes in the time interval *dt* is $dm = \rho\, dV = \rho A\, dh$. The heat that must be conducted away from this mass of water to freeze it is $dQ = dmL_f = (\rho A L_f)dh$. $H = dQ/dt = kA(\Delta T/h)$, so the heat *dQ* conducted in time

dt throughout the thickness h that is already there is $dQ = kA\left(\frac{T_H - T_C}{h}\right)dt$. Solve for dh in terms of dt and integrate to get an expression relating h and t.

EXECUTE: Equate these expressions for dQ.

$$\rho A L_f dh = kA\left(\frac{T_H - T_C}{h}\right)dt$$

$$h\,dh = \left(\frac{k(T_H - T_C)}{\rho L_f}\right)dt$$

Integrate from $t = 0$ to time t. At $t = 0$ the thickness h is zero.

$$\int_0^h h\,dh = [k(T_H - T_C)/\rho L_f]\int_0^t dt$$

$$\tfrac{1}{2}h^2 = \frac{k(T_H - T_C)}{\rho L_f}t \text{ and } h = \sqrt{\frac{2k(T_H - T_C)}{\rho L_f}}\sqrt{t}$$

The thickness after time t is proportional to $\sqrt{t}$.

(c) The expression in part (b) gives

$$t = \frac{h^2 \rho L_f}{2k(T_H - T_C)} = \frac{(0.25\text{ m})^2(920\text{ kg/m}^3)(334\times10^3\text{ J/kg})}{2(1.6\text{ W/m}\cdot\text{K})(0°\text{C} - (-10°\text{C}))} = 6.0\times10^5\text{ s}$$

$t = 170$ h.

(d) Find t for $h = 40$ m. t is proportional to h^2, so $t = (40\text{ m}/0.25\text{ m})^2(6.00\times10^5\text{ s}) = 1.5\times10^{10}$ s. This is about 500 years. With our current climate this will not happen.

EVALUATE: As the ice sheet gets thicker, the rate of heat conduction through it decreases. Part (d) shows that it takes a very long time for a moderately deep lake to totally freeze.

17.106. **IDENTIFY:** $I_1 r_1^2 = I_2 r_2^2$. Apply $H = Ae\sigma T^4$ to the sun.

SET UP: $I_1 = 1.50\times10^3\text{ W/m}^2$ when $r = 1.50\times10^{11}$ m.

EXECUTE: **(a)** The energy flux at the surface of the sun is

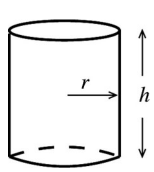
$$I_2 = (1.50\times10^3\text{ W/m}^2)\left(\frac{1.50\times10^{11}\text{ m}}{6.96\times10^8\text{ m}}\right)^2 = 6.97\times10^7\text{ W/m}^2.$$

(b) Solving $H = Ae\sigma T^4$ with $e = 1$, $T = \left[\frac{H}{A}\frac{1}{\sigma}\right]^{\frac{1}{4}} = \left[\frac{6.97\times10^7\text{ W/m}^2}{5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4}\right]^{\frac{1}{4}} = 5920$ K.

EVALUATE: The total power output of the sun is $P = 4\pi r_2^2 I_2 = 4\times10^{26}$ W.

17.107. **IDENTIFY** and **SET UP:** Use $H_{net} = e\sigma A(T^4 - T_s^4)$ to find the net heat current into the can due to radiation. Use $Q = Ht$ to find the heat that goes into the liquid helium, set this equal to mL and solve for the mass m of helium that changes phase.

EXECUTE: Calculate the net rate of radiation of heat from the can. $H_{net} = Ae\sigma(T^4 - T_s^4)$.



The surface area of the cylindrical can is $A = 2\pi rh + 2\pi r^2$. (See Figure 17.107.)

Figure 17.107

$A = 2\pi r(h + r) = 2\pi(0.045\text{ m})(0.250\text{ m} + 0.045\text{ m}) = 0.08341\text{ m}^2.$

$H_{\text{net}} = (0.08341\text{ m}^2)(0.200)(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)((4.22\text{ K})^4 - (77.3\text{ K})^4)$

$H_{\text{net}} = -0.0338\text{ W}$ (the minus sign says that the net heat current is into the can). The heat that is put into the can by radiation in one hour is $Q = -(H_{\text{net}})t = (0.0338\text{ W})(3600\text{ s}) = 121.7\text{ J}$. This heat boils a mass m of helium according to the equation $Q = mL_{\text{f}}$, so $m = \dfrac{Q}{L_{\text{f}}} = \dfrac{121.7\text{ J}}{2.09\times10^4\text{ J/kg}} = 5.82\times10^{-3}\text{ kg} = 5.82\text{ g}.$

EVALUATE: In the expression for the net heat current into the can the temperature of the surroundings is raised to the fourth power. The rate at which the helium boils away increases by about a factor of $(293/77)^4 = 210$ if the walls surrounding the can are at room temperature rather than at the temperature of the liquid nitrogen.

17.108. **IDENTIFY:** We have blackbody radiation. The sphere at 41.0°C (314 K) radiates into the box, but the box at 30.0°C (303 K) radiates back into the sphere. All temperatures must be in kelvins.

SET UP: The rate at which heat is radiated by a blackbody in surroundings is $H_{\text{net}} = e\sigma A(T^4 - T_{\text{s}}^4)$. The target variable is the emissivity e for part (a). We know that $H_{\text{net}} = 0.660$ J/s for the sphere, and $A = 4\pi r^2$ for a sphere.

EXECUTE: **(a)** Using $H_{\text{net}} = e\sigma A(T^4 - T_{\text{s}}^4)$, we put in the numbers and solve for the emissivity e. Using $H_{\text{net}} = 0.660$ J/s, $A = 4\pi r^2 = 4\pi(0.0320\text{ m})^2 = 0.012868\text{ m}^2$, $T = 314$ K, $T_{\text{S}} = 303$ K, and $\sigma = 5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4$, we get $e = 0.700$. Note that this number has no units.

(b) Using $H_{\text{net}} = e\sigma A(T^4 - T_{\text{s}}^4)$, we get

$H = (0.700)(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)(0.012868\text{ m}^2)[(355\text{ K})^4 - (303\text{ K})^4] = 3.81\text{ J/s} = 3.81\text{ W}.$

EVALUATE: The ratio of powers is (3.81 W)/(0.660 W) = 5.77. This is much less than 2^4, which is 16. The temperature must be in kelvins, so a temperature of 82°C (355 K) is not double 41°C (314 K). The temperature ratio is only 355/314 = 1.13.

17.109. **IDENTIFY:** The latent heat of fusion L_{f} is defined by $Q = mL_{\text{f}}$ for the solid $\rightarrow$ liquid phase transition. For a temperature change, $Q = mc\Delta T$.

SET UP: At $t = 1$ min the sample is at its melting point and at $t = 2.5$ min all the sample has melted.

EXECUTE: **(a)** It takes 1.5 min for all the sample to melt once its melting point is reached and the heat input during this time interval is $(1.5\text{ min})(10.0\times10^3\text{ J/min}) = 1.50\times10^4\text{ J}$. $Q = mL_{\text{f}}$.

$$L_{\text{f}} = \frac{Q}{m} = \frac{1.50\times10^4\text{ J}}{0.500\text{ kg}} = 3.00\times10^4\text{ J/kg}.$$

(b) The liquid's temperature rises 30 C° in 1.5 min. $Q = mc\Delta T$.

$$c_{\text{liquid}} = \frac{Q}{m\Delta T} = \frac{1.50\times10^4\text{ J}}{(0.500\text{ kg})(30\text{ C°})} = 1.00\times10^3\text{ J/kg}\cdot\text{K}.$$

The solid's temperature rises 15 C° in 1.0 min. $c_{\text{solid}} = \dfrac{Q}{m\Delta T} = \dfrac{1.00\times10^4\text{ J}}{(0.500\text{ kg})(15\text{ C°})} = 1.33\times10^3\text{ J/kg}\cdot\text{K}.$

EVALUATE: The specific heat capacities for the liquid and solid states are different. The values of c and L_{f} that we calculated are within the range of values in Tables 17.3 and 17.4.

17.110. **IDENTIFY:** The heat lost by the water is equal to the heat gained by the liquid and the cup. The specific heat capacities do not change over the temperature ranges involved. No phase changes are involved.

SET UP: $Q = mc\,\Delta T$, and $Q_{\text{L}} + Q_{\text{m}} + Q_{\text{w}} = 0$, where L is for the liquid, m is for the metal, and w is for water.

EXECUTE: For the first experiment, 0.500 kg of the liquid are used. $Q_{\text{L}} + Q_{\text{m}} + Q_{\text{w}} = 0$ gives

$0 = (0.500\text{ kg})c_{\text{L}}(58.1\text{°C} - 20.0\text{°C}) + (0.200\text{ kg})c_{\text{m}}(58.1\text{°C} - 20.0\text{°C})$

$+ (0.500 \text{ kg})(4190 \text{ J/kg}\cdot\text{K})(58.1°\text{C} - 80.0°\text{C})$

For the second experiment, 1.00 kg of the liquid is used. $Q_L + Q_m + Q_w = 0$ gives
$0 = (1.00 \text{ kg})c_L(49.3°\text{C} - 20.0°\text{C}) + (0.200 \text{ kg})c_m(49.3°\text{C} - 20.0°\text{C})$
$+ (0.500 \text{ kg})(4190 \text{ J/kg}\cdot\text{K})(49.3°\text{C} - 80.0°\text{C})$

The two equations from the two experiments simplify to
$19.050c_L + 7.620c_m = 45{,}880.5$
$29.3c_L + 5.86c_m = 64{,}316.5$
Solving these two equations simultaneously gives $c_m = 1067 \text{ J/kg}\cdot\text{K}$, which rounds to $1070 \text{ J/kg}\cdot\text{K}$, and $c_L = 1981.6 \text{ J/kg}\cdot\text{K}$, which rounds to $1980 \text{ J/kg}\cdot\text{K}$.

EVALUATE: The liquid has about half the specific heat capacity of water. The metal has a specific heat capacity of $1070 \text{ J/kg}\cdot\text{K}$, which is a bit more than that of aluminum. So both answers are physically reasonable.

17.111. **IDENTIFY:** At steady state, the heat current in both bars is the same when they are connected end-to-end. The heat to melt the ice is the heat conducted through the bars.

SET UP: $Q = mL$ and $H = kA\dfrac{T_H - T_C}{L}$.

EXECUTE: With bar A alone: 0.109 kg of ice melts in 45.0 min = (45.0)(60) s. Therefore the heat current is $H = mL_f/t = (0.109 \text{ kg})(334 \times 10^5 \text{ J/kg})/[(45.0)(60) \text{ s}] = 13.48 \text{ J/s} = 13.48 \text{ W}$. Applying this result to the heat flow in bar A gives $H = kA\dfrac{T_H - T_C}{L}$. Solving for k_A gives $k_A = HL/A(T_H - T_C)$. Numerically we get $k_A = (13.48 \text{ W})(0.400 \text{ m})/[(2.50 \times 10^{-4} \text{ m}^2)(100 \text{ C}°)] = 215.7 \text{ W/m}\cdot\text{K}$, which rounds to $216 \text{ W/m}\cdot\text{K}$.
With the two bars end-to-end: The heat current is the same in both bars, so $H_A = H_B$. Using $H = kA\dfrac{T_H - T_C}{L}$ for each bar, we get $\dfrac{k_A A(100°\text{C} - 62.4°\text{C})}{L} = \dfrac{k_B A(62.4°\text{C} - 0°\text{C})}{L}$. Using our result for k_A and canceling A and L, we get $k_B = 130 \text{ W/m}\cdot\text{K}$.
EVALUATE: $k_A = 216 \text{ W/m}\cdot\text{K}$, which is slightly larger than that of aluminum, and $k_B = 130 \text{ W/m}\cdot\text{K}$, which is between that of aluminum and brass. Therefore these results are physically reasonable.

17.112. **IDENTIFY:** The heat of combustion of propane is used to melt ice, so a change of state is involved.
SET UP: The heat to melt ice is $Q = mL_f$. This heat comes from the combustion of propane, which releases 25.6 MJ/L. Only 30% of this heat is used to melt the ice. As the ice melts it is drawn off at 500 mL/min, so that is the rate at which the ice is melting. The propane tank holds 18 L of propane. One liter of water has a mass of 1.00 kg. We want to find out how long the propane tank can keep burning fuel before it runs out.
EXECUTE: The water melts at 500 L/min, which is 0.500 kg/min or 0.008333 kg/s. Therefore the rate at which the propane is providing heat to the ice is $Q/t = mL_f$. This gives
$Q/t = (0.008333 \text{ kg/s})(334\times10^3 \text{ J/kg}) = 2.783\times10^3 \text{ J/s}$. This heat comes from the combustion of propane. The total heat available from an 18-L tank is $(18 \text{ L})(25.6\times10^6 \text{ J/L})$, but only 30% of this heat is available to melt ice. So the available heat is $(0.30)(18 \text{ L})(25.6\times10^6 \text{ J/L}) = 1.3824\times10^8 \text{ J}$. To use up all the propane in the tank, $(Q/t)t = E_{\text{available}}$. Putting in the values we just found gives $(2.783\times10^3 \text{ J/s})t = 1.3824\times10^8 \text{ J}$, so $t = 5.0\times10^4 \text{s} = 830 \text{ min} = 14 \text{ h}$.
EVALUATE: The tank would melt even more ice if more than 30% of its heat went to melting ice.

17.113. **IDENTIFY:** Heat flows through the frustrum of a cone shown in the figure in the textbook. We want to derive an expression for the heat current H through this cone.

SET UP and EXECUTE: Start with $H = kA\dfrac{T_H - T_C}{L}$ and follow the suggestions in the problem.

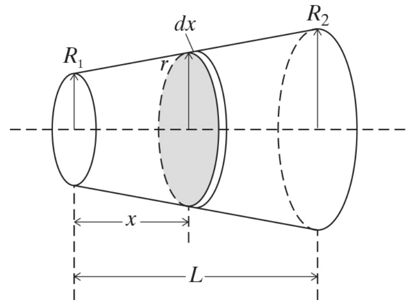


Figure 17.113

Figure 17.113 shown here shows the cone oriented along the x-axis. We break it up into tiny slabs of radius r and thickness dx, as shown. We write the heat current formula for differential differences in temperature and thickness. We also realize that at steady state H is the same at all the slabs, so it is constant. The equation for H becomes $H = kA\dfrac{dT}{dx}$ for the heat current through a slab of thickness dx. The cross-sectional area is $A = \pi r^2$, but r changes with x. So we need to relate r to x. To do so, realize that the side of the cone is a straight line and its equation will give r as a function of x. Using the slope-intercept form of a straight-line equation, $r = Bx + C$. When $x = 0$, $r = R_1$ and when $x = L$, $r = R_2$. The first of these conditions tells us that $C = R_1$, and the second says that $B = \dfrac{R_2 - R_1}{L}$. We can now write the heat flow equation as $H = k\pi(Bx + C)^2\dfrac{dT}{dx}$. Separating variables gives $\dfrac{Hdx}{(Bx+C)^2} = k\pi dT$. Integrating gives $H\displaystyle\int_0^L \frac{dx}{(Bx+C)^2} = \int_{T_H}^{T_C} k\pi dT$. The temperature integral just gives $k\pi\Delta T$ but we need to complete the left-hand-side integral. To do so, let $Bx + C = u$, so $du = Bdx$. The integral becomes $\displaystyle\int\frac{(1/B)du}{u^2} = -\frac{1}{B}u^{-1} = -\frac{1}{Bu}$. Returning to the original variables, we have $H\displaystyle\int_0^L \frac{dx}{(Bx+C)^2} = H\left(-\frac{1}{B(Bx+C)}\right)\Bigg|_0^L = -\frac{H}{B}\left[\frac{1}{BL+C} - \frac{1}{C}\right]$. Carrying out the algebra and putting in the values for B and C gives $HL\left(\dfrac{1}{R_1R_2}\right) = k\pi\Delta T$. Solving for H gives $H = \dfrac{k\pi R_1R_2}{L}(T_H - T_C)$.

EVALUATE: If the cone were reduced to a solid cylinder of radius R_1, H would be $H_1 = k\pi R_1^2\dfrac{\Delta T}{L}$, and if it were a solid cylinder of radius R_2, H would be $H_2 = k\pi R_2^2\dfrac{\Delta T}{L}$. The value we found $H = \dfrac{k\pi R_1R_2}{L}(T_H - T_C)$ is between these two extremes, so it is plausible.

17.114. IDENTIFY: The rate in (iv) is given by $H_{net} = e\sigma A(T^4 - T_s^4)$, with $T = 309$ K and $T_s = 320$ K. The heat absorbed in the evaporation of water is $Q = mL$.

SET UP: $m = \rho V$, so $\dfrac{m}{V} = \rho$.

EXECUTE: **(a)** The rates are: (i) 280 W,

(ii) $(54\ \text{J/h}\cdot\text{C}°\cdot\text{m}^2)(1.5\ \text{m}^2)(11\ \text{C}°)/(3600\ \text{s/h}) = 0.248$ W,

(iii) $(1400\ \text{W/m}^2)(1.5\ \text{m}^2) = 2.10\times10^3$ W,

(iv) $(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)(1.5\ \text{m}^2)((320\ \text{K})^4-(309\ \text{K})^4)=116\ \text{W}.$

The total is 2.50 kW, with the largest portion due to radiation from the sun.

(b) $\dfrac{P}{\rho L_\text{v}}=\dfrac{2.50\times10^3\ \text{W}}{(1000\ \text{kg/m}^3)(2.42\times10^6\ \text{J/kg}\cdot\text{K})}=1.03\times10^{-6}\ \text{m}^3/\text{s}.$ This is equal to 3.72 L/h.

(c) Redoing the above calculations with $e=0$ and the decreased area gives a power of 945 W and a corresponding evaporation rate of 1.4 L/h. Wearing reflective clothing helps a good deal. Large areas of loose-weave clothing also facilitate evaporation.

EVALUATE: The radiant energy from the sun absorbed by the area covered by clothing is assumed to be zero, since $e\approx0$ for the clothing and the clothing reflects almost all the radiant energy incident on it. For the same reason, the exposed skin area is the area used in applying $H_\text{net}=e\sigma A(T^4-T_\text{s}^4)$.

17.115. IDENTIFY: Apply the equation $H=kA(T_\text{H}-T_\text{C})/L$. For a cylindrical surface, the area A in this equation is a function of the distance r from the central axis, and the material must be considered as a series of shells with thickness dr and a temperature difference dT between the inside and outside of the shell. The heat current will be a constant, and must be found by integrating a differential equation.

SET UP: The surface area of the curved side of a cylinder is $2\pi rL$. When $x \ll 1$, $\ln(1+x)\approx x$.

EXECUTE: **(a)** For a cylindrical shell, $H=kA(T_\text{H}-T_\text{C})/L$ becomes $H=k(2\pi rL)\dfrac{dT}{dr}$ or $\dfrac{Hdr}{2\pi r}=kLdT$.

Between the limits $r=a$ and $r=b$, this integrates to $\dfrac{H}{2\pi}\ln(b/a)=kL(T_2-T_1)$, or $H=\dfrac{2\pi kL(T_2-T_1)}{\ln(b/a)}$.

(b) Using $H=k(2\pi rL)\dfrac{dT}{dr}$ from part (a), we integrate: $\int_a^r\dfrac{Hdr}{k2\pi rL}=-\int_{T_2}^T dT$, which gives

$\dfrac{H}{2\pi kL}\ln(r/a)=-(T-T_2)=T_2-T$. Solving for T and using H from part (a) gives

$T=T_2-\dfrac{H}{2\pi kL}\ln(r/a)=\dfrac{(T_2-T_1)2\pi kL\ln(r/a)}{2\pi kL\ln(b/a)}=T_2-\dfrac{(T_2-T_1)\ln(r/a)}{\ln(b/a)}$, which can also be written as

$T(r)=T_2+(T_1-T_2)\dfrac{\ln(r/a)}{\ln(b/a)}$.

(c) For a thin-walled cylinder, $a\approx b$, so $\dfrac{b-a}{a}<<1$. We can write $\dfrac{b}{a}=1+\dfrac{b-a}{a}$, and the log term

becomes $\ln\left(\dfrac{b}{a}\right)=\ln\left(1+\dfrac{b-a}{a}\right)\approx\dfrac{b-a}{a}$ using $\ln(1+x)\approx x$ for $x<<1$. Therefore the rate of heat flow

becomes $H=\dfrac{(T_2-T_1)2\pi kL}{\dfrac{b-a}{a}}=k(2\pi aL)\dfrac{T_2-T_1}{b-a}$. This is equivalent to Eq. (17.21) in which $A=2\pi aL$, which is the surface area of the thin cylindrical shell of radius a and length L.

(d) For steady-state heat flow, the rate of flow through the cork is the same as through the Styrofoam. Using our result from part (a), we have $H_\text{C}=H_\text{S}$, which gives

$(140°\text{C}-T)2\pi k_\text{C}L/(\ln 4/2)=(T-15°\text{C})2\pi k_\text{S}L/(\ln 6/4)$

Cancelling $2\pi L$ and using the given values for k_C and k_S, we get $T=73°\text{C}$.

(e) Use the result of part (a) for H.

$$H=\frac{(140°\text{C}-73°\text{C})2\pi(0.0400\ \text{W/m}\cdot\text{K})(2.00\ \text{m})}{\ln(4/2)}=49\ \text{W}.$$

EVALUATE: As a check, calculate H in the Styrofoam. $\Delta T=73°\text{C}-15°\text{C}=58\ \text{C}°$.

$H_\text{S}=\dfrac{2\pi(2.00\ \text{m})(0.027\ \text{W/m}\cdot\text{K})}{\ln(6.00/4.00)}(58\ \text{C}°)=49\ \text{W}.$ This is the same as we just found, which it should be for steady-state flow.

17.116. **IDENTIFY:** The cryoprotectant must cool from 22°C to –20°C, then it must freeze, and finally it must cool from –20°C to 77 K (–196°C).

SET UP: We use $Q = mc\,\Delta T$ and $Q = mL_f$. $Q_{tot} = Q_1 + Q_2 + Q_3$.

EXECUTE: $Q_1 = mc\,\Delta T = (35 \times 10^{-3}\text{ kg})(4500\text{ J/kg}\cdot\text{K})(42\text{ C°}) = 6.6\text{ kJ}$

$Q_2 = mL_f = (35 \times 10^{-3}\text{ kg})(2.80 \times 10^5\text{ J/kg}) = 9.8\text{ kJ}$

$Q_3 = mc\,\Delta T = (35 \times 10^{-3}\text{ kg})(2000\text{ J/kg}\cdot\text{K})[-196°\text{C} - (-20°\text{C})] = 12.3\text{ kJ}$

$Q_{tot} = 6.6\text{ kJ} + 9.8\text{ kJ} + 12.3\text{ kJ} = 28.7\text{ kJ} \approx 29\text{ kJ} = 2.9 \times 10^4\text{ J}$, which is choice (b).

EVALUATE: This is a large amount of heat for such a small sample, but it must change its temperature from 22°C to –196°C and also freeze.

17.117. **IDENTIFY** and **SET UP:** The graph shows that the specific heat of the solid decreases with temperature, so its average value is less than the $2.0 \times 10^3\text{ J/kg}\cdot\text{K}$ shown in the table.

EXECUTE: Since the average specific heat is less than the value in the table, less heat will need to come out of it to bring it into equilibrium with the cold plate. Therefore a shorter time will be needed for it to come to equilibrium with the cold plate, which is choice (a).

EVALUATE: The average value of the specific heat is about $1500\text{ J/kg}\cdot\text{K}$ between –20°C and –200°C, so the difference in time could be important enough to be concerned about. As we saw in the previous problem, the heat to cool the cryoprotectant from –20°C down to –196°C was the largest contribution to the total heat.

17.118. **IDENTIFY:** The rate of heat conduction should be the same in both cases, but the area in the area in the second case is 4 times the area in the first case since the linear dimensions are both doubled.

SET UP: $H = kA\dfrac{T_H - T_C}{L}$, $H_1 = H_2$, $A_2 = 4A_1$, k and $T_H - T_C$ are the same in both cases.

EXECUTE: Calculate H_1 and H_2 and equate them: $kA_1\dfrac{\Delta T}{L_1} = kA_2\dfrac{\Delta T}{L_2} = k(4A_1)\dfrac{\Delta T}{L_2}$. Cancelling common factors gives $L_2 = 4L_1$, so the layer should be 4 times as thick as it was for the smaller plates, which is choice (d).

EVALUATE: If we doubled only one dimension, then L_2 would have to be only twice as thick as for the smaller plates.

17.119. **IDENTIFY** and **SET UP:** Heat from the cryoprotectant *and* the environment enters the cold plate. You measure the amount of heat that enters the cold plate, and assume that it all came from the cryoprotectant.

EXECUTE: You think that more heat entered the plate from the cryoprotectant than actually did so. This will make you think that the specific heat of the cryoprotectant is greater than it actually is, which is choice (a).

EVALUATE: Heat from the environment could also be entering the cryoprotectant, but since the cold plate is on average colder than the cryoprotectant, more heat will enter the cold plate than will enter the cryoprotectant, so the two effects will not cancel each other out. You will still measure a specific heat that is greater than the actual value.

18

THERMAL PROPERTIES OF MATTER

VP18.4.1. **IDENTIFY:** An ideal gas inside a tire undergoes a temperature change at constant volume, so the ideal gas law applies.

SET UP: Use $pV = nRT$, with $T_1 = 30.0°\text{C} = 303\text{ K}$ and $T_2 = 10.0°\text{C} = 283\text{ K}$.

EXECUTE: **(a)** We want the new pressure p_2. At fixed volume, p/T is constant, so $\frac{p_1}{T_1} = \frac{p_2}{T_2}$ which gives

$$p_2 = p_1\frac{T_2}{T_1} = (5.00\times10^5\text{ Pa})\left(\frac{283\text{ K}}{303\text{ K}}\right) = 4.67\times10^5\text{ Pa}.$$

(b) We want the number n of moles in the tire. Solve $pV = nRT$ for n, giving $n = pV/RT$. Using $p = 5.00\times10^5\text{ Pa}$, $T = 303\text{ K}$, and $V = 1.40\times10^{-3}\text{ m}^3$ gives $n = 0.278$ mol.

EVALUATE: The temperature T must *always* be in Kelvins when using the ideal gas law.

VP18.4.2. **IDENTIFY:** As the balloon rises, the temperature and pressure decrease and the volume increases. The ideal gas law applies.

SET UP: Use $pV = nRT$. Since n remains constant, pV/T is constant.

<u>At sea level</u>: $T_1 = 15.0°\text{C} = 288\text{ K}$, $p_1 = 1.01\times10^5\text{ Pa}$, $V_1 = 13.0\text{ m}^3$.

<u>At 32.0 km</u>: $T_2 = -44.5°\text{C} = 228.5\text{ K}$, $p_2 = 868\text{ Pa}$, $V_2 = ?$

EXECUTE: **(a)** We want the volume at 32.0 km altitude. Since pV/T is constant, we have $\frac{p_1V_1}{T_1} = \frac{p_2V_2}{T_2}$,

so $V_2 = V_1\frac{T_2}{T_1}\frac{p_1}{p_2}$. Putting in the numbers shown above, we get $V_2 = 1.20\times10^3\text{ m}^3$.

(b) We want the ratio of the radii R_2/R_1 of the balloons. Using the volume of a sphere gives us

$$\frac{V_2}{V_1} = \frac{\frac{4}{3}\pi R_2^3}{\frac{4}{3}\pi R_1^3} = \left(\frac{R_2}{R_1}\right)^3, \text{ so } \frac{R_2}{R_1} = \left(\frac{V_2}{V_1}\right)^{1/3} = \left(\frac{1.20\times10^3\text{ m}^3}{13.0\text{ m}^3}\right)^{1/3} = 4.52,$$ so the radius is 4.52 times greater at 32.0 km than it is at sea level.

EVALUATE: The volume at 32.0 km is 1200/13 = 92 times as great as at sea level.

VP18.4.3. **IDENTIFY:** The pressure and temperature of Pluto's atmosphere are much lower than they are in Earth's atmosphere. The ideal gas law applies.

SET UP: Use $pV = nRT$, where $T = 42$ K and $p = 1.0$ Pa on Pluto. The molar mass of N_2 is 0.0028 kg/mol.

EXECUTE: **(a)** We want the molar density of Pluto's atmosphere in mol/m^3. Using $pV = nRT$ gives $n/V = p/RT$. Using $p = 1.0$ Pa and $T = 42$ K, we get $n/V = 2.9\times10^{-3}\text{ mol/m}^3$.

(b) We want the mass density of Pluto's atmosphere in kg/m³. Convert the molar density to mass density using the fact that the molar density of N_2 is 0.028 kg/mol. This gives $(2.9\times10^{-3}\ \text{mol/m})(0.028\ \text{kg/mol}) = 8.0\times10^{-5}\ \text{kg/m}^3$.

EVALUATE: Compare our results on Pluto to those on Earth. $\dfrac{n/V)_\text{P}}{n/V)_\text{E}} = \dfrac{2.9\times10^{-3}\ \text{mol/m}^3}{42\ \text{mol/m}^3} = 6.8\times10^{-5}$.

$\dfrac{m/V)_\text{P}}{m/V)_\text{E}} = \dfrac{8.0\times10^{-5}\ \text{kg/m}^3}{1.2\ \text{kg/m}^3} = 6.7\times10^{-5}$. The ratios are nearly the same, and both are very small due to Pluto's extremely low pressure.

VP18.4.4. **IDENTIFY:** We are investigating the effects of changes in an ideal gas using the ideal gas law.

SET UP: $pV = nRT$, and for constant n we have pV/T is constant. $\rho = m/V$ so $V = m/\rho$. We are given that $\rho_2 = \rho_1(p_2/p_1)^{3/5}$.

EXECUTE: **(a)** We want T_2. $\dfrac{p_1V_1}{T_1} = \dfrac{p_2V_2}{T_2}$, so $T_2 = T_1\dfrac{V_2}{V_1}\dfrac{p_2}{p_1} = T_1\dfrac{p_2}{p_1}\dfrac{m/\rho_1}{m/\rho_2} = T_1\dfrac{p_2}{p_1}\dfrac{\rho_1}{\rho_2}$. Using

$\rho_2 = \rho_1(p_2/p_1)^{3/5}$ gives $T_2 = T_1\dfrac{p_2}{p_1}\dfrac{\rho_1}{\rho_1\left(\dfrac{p_2}{p_1}\right)^{3/5}} = T_1\left(\dfrac{p_2}{p_1}\right)\left(\dfrac{p_1}{p_2}\right)^{3/5} = T_1\left(\dfrac{p_2}{p_1}\right)^{2/5}$.

(b) We want ρ_2/ρ_1 and T_2/T_1 when $p_2 = 0.500p_1$. Using $\rho_2 = \rho_1(p_2/p_1)^{3/5}$ we get

$$\frac{\rho_2}{\rho_1} = \left(\frac{p_2}{p_1}\right)^{3/5} = \left(\frac{0.500p_1}{p_1}\right)^{3/5} = 0.660.$$

Using our result from part (a) gives $\dfrac{T_2}{T_1} = \left(\dfrac{p_2}{p_1}\right)^{2/5} = \left(\dfrac{0.500p_1}{p_1}\right)^{2/5} = 0.758$.

(c) We want ρ_2/ρ_1 and T_2/T_1 when $p_2 = 2.00p_1$. Using $\rho_2 = \rho_1(p_2/p_1)^{3/5}$ we get

$$\frac{\rho_2}{\rho_1} = \left(\frac{p_2}{p_1}\right)^{3/5} = \left(\frac{2.00p_1}{p_1}\right)^{3/5} = 1.52.$$

Using our result from part (a) gives $\dfrac{T_2}{T_1} = \left(\dfrac{p_2}{p_1}\right)^{2/5} = \left(\dfrac{2.00p_1}{p_1}\right)^{2/5} = 1.32$.

EVALUATE: In part (b) our result says that decreasing p decreases ρ, and in part (c) it says that increasing p increases ρ. These are reasonable results.

VP18.7.1. **IDENTIFY:** We are comparing molecular speeds of different molecules.

SET UP and EXECUTE: Use $v_\text{rms} = \sqrt{\dfrac{3RT}{M}}$.

N_2 molecule at 20.0°C: $v_\text{rms} = \sqrt{\dfrac{3RT}{M}} = \sqrt{\dfrac{3R(293\ \text{K})}{28.0\ \text{g/mol}}}$.

He atom with the same v_rms: $v_\text{rms} = \sqrt{\dfrac{3RT}{4.00\ \text{g/mol}}}$

Equate the speeds and solve for T: $\sqrt{\dfrac{3RT}{4.00\ \text{g/mol}}} = \sqrt{\dfrac{3R(293\ \text{K})}{28.0\ \text{g/mol}}}$, $T = 41.86\text{K} = -231°\text{C}$.

EVALUATE: It was not necessary to use R or convert g to kg since they divided out. It is best to save numerical calculations until the end to minimize tedious work.

VP18.7.2. **IDENTIFY:** We are looking at atomic kinetic energy and speed.

SET UP: $v_{\text{rms}} = \sqrt{\dfrac{3kT}{m}}$, $K_{\text{tr}} = \dfrac{3}{2}kT$. We want the average kinetic energy of an atom and the rms speed.

EXECUTE: **(a)** $K_{\text{av}} = \dfrac{3}{2}kT = \dfrac{3}{2}(1.381\times10^{-23}\text{ J/K})(3000\text{ K}) = 6.2\times10^{-20}\text{ J}$.

(b) Use $v_{\text{rms}} = \sqrt{\dfrac{3kT}{m}}$ with T = 3000 K and $m = 1.67\times10^{-27}$ kg, giving v_{rms} = 8600 m/s.

EVALUATE: The speed in part (b) is about 19,000 mph!

VP18.7.3. **IDENTIFY:** We want to find out how many molecules are in a typical room and how much kinetic energy they have.

SET UP: Use $pV = nRT$, $K_{\text{tr}} = \dfrac{3}{2}kT$, $K_{\text{tot}} = NK_{\text{tr}}$, and $N = nN_A$. The target variables are N and K_{tr}.

EXECUTE: **(a)** Solve $pV = nRT$ to get $n = pV/RT$. Using V = (5.0 m)(5.0 m)(2.4 m) = 612 m^3, p = 1.01×10^5 Pa , and T = 293 K gives n = 2488 mol. The number of molecules in 2488 mol is $N = nN_A$ = (2488 mol)(6.022×10^{23} molecules/mol) = 1.5×10^{27} molecules.

(b) $K_{\text{tot}} = NK_{\text{tr}} = N\dfrac{3}{2}kT$. Using T = 293 K and $N = 1.5\times10^{27}$ molecules gives $K_{\text{tot}} = 9.1\times10^6$ J.

(c) We want the speed of the car so its kinetic energy would be 9.1×10^6 J. $K_{\text{car}} = K_{\text{tot}}$ gives

$$\frac{1}{2}mv^2 = K_{\text{tot}},\ \text{so}\ v = \sqrt{\frac{2K_{\text{tot}}}{m}} = \sqrt{\frac{2(9.1\times10^6\text{ J})}{1500\text{ kg}}} = 110\text{ m/s}.$$

EVALUATE: The speed in part (c) is about 250 mph or 400 km/h.

VP18.7.4. **IDENTIFY:** We want to compare the average, average of squares, and rms for the first 10 integers.

SET UP and EXECUTE: **(a)** The average is $n_{\text{av}} = \dfrac{1+2+3+\cdots+10}{10} = \dfrac{55}{10} = 5.5.$

(b) The average of the squares is $\left(n^2\right)_{\text{av}} = \dfrac{1^2+2^2+3^2+\cdots+10^2}{10} = \dfrac{385}{10} = 38.5.$

(c) The rms value is $n_{\text{rms}} = \sqrt{(n^2)_{\text{av}}} = \sqrt{38.5} = 6.20.$

EVALUATE: Note that the rms value is *not* the same as the average value.

VP18.8.1. **IDENTIFY:** We are comparing the mean free path for molecules on Mars with those on Earth.

SET UP: We use $\lambda = \dfrac{kT}{4\pi\sqrt{2}r^2 p}$, with T_M = –63°C = 210 K and T_E = 15°C = 288 K, $p_M = 6.0\times10^2$ Pa .The molecular radius is 2.0×10^{10} m.

EXECUTE: **(a)** We want the mean free path on Mars. Using $\lambda = \dfrac{kT}{4\pi\sqrt{2}r^2 p}$ with values given above we get $\lambda_M = 6.8\times10^{-6}$ m.

(b) We want to compare the mean free path on Mars to that on Earth by finding λ_M / λ_E. Taking the ratio gives $\dfrac{\lambda_M}{\lambda_E} = \dfrac{T_M / p_M}{T_E / p_E} = \left(\dfrac{T_M}{T_E}\right)\left(\dfrac{p_E}{p_M}\right) = \left(\dfrac{210\text{ K}}{288\text{ K}}\right)\left(\dfrac{1.01\times10^5\text{ Pa}}{600\text{ Pa}}\right) = 120.$ The mean free path on Mars is 120 times greater than it is on Earth.

EVALUATE: The low pressure on Mars means that molecules are far apart compared to those on Earth, so they can travel much farther on Mars before running into each other.

VP18.8.2. **IDENTIFY:** We are investigating the mean free path of molecules.

SET UP: Use $\lambda = \dfrac{kT}{4\pi\sqrt{2}r^2 p}$ and $pV = nRT$.

EXECUTE: **(a)** We want to find the pressure so that the mean free path is 1.00 m. Solve $\lambda = \dfrac{kT}{4\pi\sqrt{2}r^2 p}$ for p, giving $p = \dfrac{kT}{4\pi\sqrt{2}r^2 \lambda}$. Using T = 293 K, $r = 2.0\times10^{-10}$ m, and λ = 1.00 m, we get p = 5.7×10^{-3} Pa.

(b) Our target variable is the number of moles n inside the box. Solving $pV = nRT$ for n gives $n = pV/RT$. Using the pressure from part (a) and the same values for the other variables gives $n = 2.3\times10^{-6}$ mol.

EVALUATE: Even at this low pressure, the number of air molecules in the box is $N = nN_A$ = $(2.3\times10^{-6}\text{ mol})(6.022\times10^{23}\text{ molecules/mol}) = 1.4\times10^{18}$ molecules.

VP18.8.3. **IDENTIFY:** We want to find the mean free path and mean free time for helium in a cylindrical tank.

SET UP: We use $\lambda = \dfrac{kT}{4\pi\sqrt{2}r^2 p}$, $v_{\text{rms}} = \sqrt{\dfrac{3RT}{M}}$, and $pV = nRT$. $v_{\text{rms}}t_{\text{mean}} = \lambda$. We know that T = 27.0°C = 300.0 K, $V = 5.00\times10^{-2}\text{ m}^3$, n = 400 mol, and $r = 3.1\times10^{-11}$ m, so $\lambda = 1.2\times10^{-8}$ m.

EXECUTE: **(a)** We want the mean free path. First use $pV = nRT$ to find p, so $p = nRT/V$. Using this result gives $\lambda = \dfrac{kT}{4\pi\sqrt{2}r^2 p} = \dfrac{kT}{4\pi\sqrt{2}r^2\left(\dfrac{nRT}{V}\right)} = \dfrac{kV}{4\pi\sqrt{2}r^2 nR}$. Using the given values for V, n, and r gives $\lambda = 1.2\times10^{-8}$ m.

(b) We want the mean free time. $v_{\text{rms}} = \sqrt{\dfrac{3RT}{M}}$ and $t_{\text{mean}} = \lambda / v_{\text{rms}}$. Combining these equations gives $t_{\text{mean}} = \dfrac{\lambda}{v_{\text{rms}}} = \dfrac{\lambda}{\sqrt{\dfrac{3RT}{M}}} = \lambda\sqrt{\dfrac{M}{3RT}}$. Using $M = 4.00\times10^{-3}$ kg/mol, $\lambda = 1.2\times10^{-8}$ m, and T = 300 K, we get $t_{\text{mean}} = 8.9\times10^{-12}$ s.

EVALUATE: The number of collisions per second would be $1/t_{\text{mean}} = 1.1\times10^{-11}$ collision/s.

VP18.8.4. **IDENTIFY:** We want to find the mean free time for gas molecules.

SET UP: We use $\lambda = \dfrac{kT}{4\pi\sqrt{2}r^2 p}$, $v_{\text{rms}} = \sqrt{\dfrac{3kT}{m}}$, $v_{\text{rms}}t_{\text{mean}} = \lambda$.

EXECUTE: **(a)** Combining the above equations gives $t_{\text{mean}} = \dfrac{\lambda}{v_{\text{rms}}} = \dfrac{\dfrac{kT}{4\pi\sqrt{2}r^2 p}}{\sqrt{\dfrac{3kT}{m}}}$, which simplifies to $t_{\text{mean}} = \dfrac{1}{4\pi r^2 p}\sqrt{\dfrac{mkT}{6}}$.

(b) From part (a), we see that $t_{\text{mean}} \propto \dfrac{\sqrt{T}}{r^2 p}$. From this result we can see the following.

Doubling p would cut t_{mean} in half.

Doubling T would increase t_{mean} by a factor of $\sqrt{2}$.

Doubling r would decrease t_{mean} by a factor of $\dfrac{1}{2^2} = \dfrac{1}{4}$.

Therefore doubling r would have the greatest effect on the mean free time.

EVALUATE: If we doubled all of these quantities at once, the effect would reduce t_{mean} by a factor of $\frac{\sqrt{2}}{8} \approx 0.177$.

18.1. **IDENTIFY:** **(a)** We are asked about a single state of the system.

SET UP: Use $m_{\text{total}} = nM$ to calculate the number of moles and then apply the ideal-gas equation.

EXECUTE: $n = \dfrac{m_{\text{tot}}}{M} = \dfrac{4.86\times10^{-4}\ \text{kg}}{4.00\times10^{-3}\ \text{kg/mol}} = 0.122\ \text{mol}.$

(b) $pV = nRT$ implies $p = nRT/V$. T must be in kelvins, so $T = (18+273)\ \text{K} = 291\ \text{K}$.

$$p = \frac{(0.122\ \text{mol})(8.3145\ \text{J/mol}\cdot\text{K})(291\ \text{K})}{20.0\times10^{-3}\ \text{m}^3} = 1.47\times10^4\ \text{Pa}.$$

$$p = (1.47\times10^4\ \text{Pa})(1.00\ \text{atm}/1.013\times10^5\ \text{Pa}) = 0.145\ \text{atm}.$$

EVALUATE: The tank contains about 1/10 mole of He at around standard temperature, so a pressure around 1/10 atmosphere is reasonable.

18.2. **IDENTIFY:** $pV = nRT$.

SET UP: $T_1 = 41.0°\text{C} = 314\ \text{K}$. $R = 0.08206\ \text{L}\cdot\text{atm/mol}\cdot\text{K}$.

EXECUTE: n and R are constant so $\dfrac{pV}{T} = nR$ is constant. $\dfrac{p_1V_1}{T_1} = \dfrac{p_2V_2}{T_2}$.

$$T_2 = T_1\left(\frac{p_2}{p_1}\right)\left(\frac{V_2}{V_1}\right) = (314\ \text{K})(2)(2) = 1.256\times10^3\ \text{K} = 983°\text{C}.$$

(b) $n = \dfrac{pV}{RT} = \dfrac{(0.180\ \text{atm})(3.20\ \text{L})}{(0.08206\ \text{L}\cdot\text{atm/mol}\cdot\text{K})(314\ \text{K})} = 0.02235\ \text{mol}.$

$$m_{\text{tot}} = nM = (0.02235\ \text{mol})(4.00\ \text{g/mol}) = 0.0894\ \text{g}.$$

EVALUATE: T is directly proportional to p and to V, so when p and V are each doubled the Kelvin temperature increases by a factor of 4.

18.3. **IDENTIFY:** $pV = nRT$.

SET UP: T is constant.

EXECUTE: nRT is constant so $p_1V_1 = p_2V_2$.

$$p_2 = p_1\left(\frac{V_1}{V_2}\right) = (0.355\ \text{atm})\left(\frac{0.110\ \text{m}^3}{0.390\ \text{m}^3}\right) = 0.100\ \text{atm}.$$

EVALUATE: For T constant, p decreases as V increases.

18.4. **IDENTIFY:** $pV = nRT$.

SET UP: $T_1 = 20.0°\text{C} = 293\ \text{K}$.

EXECUTE: **(a)** n, R and V are constant. $\dfrac{p}{T} = \dfrac{nR}{V} = \text{constant}$. $\dfrac{p_1}{T_1} = \dfrac{p_2}{T_2}$.

$$T_2 = T_1\left(\frac{p_2}{p_1}\right) = (293\ \text{K})\left(\frac{1.00\ \text{atm}}{3.00\ \text{atm}}\right) = 97.7\ \text{K} = -175°\text{C}.$$

(b) $p_2 = 1.00\ \text{atm}$, $V_2 = 3.00\ \text{L}$. $p_3 = 3.00\ \text{atm}$. n, R and T are constant so $pV = nRT = \text{constant}$.

$p_2V_2 = p_3V_3$.

$$V_3 = V_2\left(\frac{p_2}{p_3}\right) = (3.00\ \text{L})\left(\frac{1.00\ \text{atm}}{3.00\ \text{atm}}\right) = 1.00\ \text{L}.$$

EVALUATE: The final volume is one-third the initial volume. The initial and final pressures are the same, but the final kelvin temperature is one-third the initial kelvin temperature.

18.5. **IDENTIFY:** This problem compares the ideal gas law to the van der Waals equation for carbon dioxide gas.

SET UP and EXECUTE: The ideal gas law is $pV = nRT$ and the van der Waals equation is $\left(p+\dfrac{an^2}{V^2}\right)(V-nb)=nRT$. We have n = 1 mol, $V = 4.48\times10^{-4}\ \text{m}^3$, and T = 273.0 K.

(a) Using these numbers, $p = nRT/V = 5.7\times10^6$ Pa.

(b) Using the van der Waals equation and solving for p gives $p=\dfrac{nRT}{V-nb}-\dfrac{an^2}{V^2}$. Using the same values as for part (a), and in addition for CO_2 $a=0.364\ \text{J}\cdot\text{m}^3/\text{mol}^2$ and $b=4.27\times10^{-5}\ \text{m}^3/\text{mol}$, we get p = 3.79×10^6 Pa.

EVALUATE: The percent difference is $\dfrac{\Delta p}{p}=\dfrac{3.79-5.07}{5.07}=-0.252=-25.2\%$, which is not very good agreement.

18.6. **IDENTIFY:** $pV=nRT$ and the mass of the gas is $m_{\text{tot}}=nM$.

SET UP: The temperature is $T=22.0°\text{C}=295.15$ K. The average molar mass of air is $M=28.8\times10^{-3}$ kg/mol. For helium $M=4.00\times10^{-3}$ kg / mol.

EXECUTE: **(a)** $m_{\text{tot}}=nM=\dfrac{pV}{RT}M=\dfrac{(1.00\ \text{atm})(0.900\ \text{L})(28.8\times10^{-3}\ \text{kg/mol})}{(0.08206\ \text{L}\cdot\text{atm/mol}\cdot\text{K})(295.15\ \text{K})}=1.07\times10^{-3}$ kg.

(b) $m_{\text{tot}}=nM=\dfrac{pV}{RT}M=\dfrac{(1.00\ \text{atm})(0.900\ \text{L})(4.00\times10^{-3}\ \text{kg/mol})}{(0.08206\ \text{L}\cdot\text{atm/mol}\cdot\text{K})(295.15\ \text{K})}=1.49\times10^{-4}$ kg.

EVALUATE: $n=\dfrac{N}{N_\text{A}}=\dfrac{pV}{RT}$ says that in each case the balloon contains the same number of molecules. The mass is greater for air since the mass of one molecule is greater than for helium.

18.7. **IDENTIFY:** We are asked to compare two states. Use the ideal gas law to obtain T_2 in terms of T_1 and ratios of pressures and volumes of the gas in the two states.

SET UP: $pV=nRT$ and n, R constant implies $pV/T=nR=$ constant and $p_1V_1/T_1=p_2V_2/T_2$.

EXECUTE: $T_1=(27+273)\text{K}=300$ K

$p_1=1.01\times10^5$ Pa

$p_2=2.72\times10^6\ \text{Pa}+1.01\times10^5\ \text{Pa}=2.82\times10^6$ Pa (in the ideal gas equation the pressures must be absolute, not gauge, pressures)

$$T_2=T_1\left(\frac{p_2}{p_1}\right)\left(\frac{V_2}{V_1}\right)=300\ \text{K}\left(\frac{2.82\times10^6\ \text{Pa}}{1.01\times10^5\ \text{Pa}}\right)\left(\frac{46.2\ \text{cm}^3}{499\ \text{cm}^3}\right)=776\ \text{K}$$

$T_2=(776-273)°\text{C}=503°\text{C}$.

EVALUATE: The units cancel in the V_2/V_1 volume ratio, so it was not necessary to convert the volumes in cm^3 to m^3. It was essential, however, to use T in kelvins.

18.8. **IDENTIFY:** $pV=nRT$ and $m=nM$.

SET UP: We must use absolute pressure in $pV=nRT$. $p_1=4.01\times10^5$ Pa, $p_2=2.81\times10^5$ Pa. $T_1=310$ K, $T_2=295$ K.

EXECUTE: **(a)** $n_1=\dfrac{p_1V_1}{RT_1}=\dfrac{(4.01\times10^5\ \text{Pa})(0.075\ \text{m}^3)}{(8.315\ \text{J/mol}\cdot\text{K})(310\ \text{K})}=11.7$ mol.

$m=nM=(11.7\ \text{mol})(32.0\ \text{g/mol})=374$ g.

(b) $n_2 = \dfrac{p_2V_2}{RT_2} = \dfrac{(2.81\times10^5\ \text{Pa})(0.075\ \text{m}^3)}{(8.315\ \text{J/mol}\cdot\text{K})(295\ \text{K})} = 8.59\ \text{mol}.\quad m = 275\ \text{g}.$

The mass that has leaked out is $374\ \text{g} - 275\ \text{g} = 99\ \text{g}$.

EVALUATE: In the ideal gas law we must use absolute pressure, expressed in Pa, and T must be in kelvins.

18.9. **IDENTIFY:** $pV = nRT$.

SET UP: $T_1 = 300\ \text{K},\ T_2 = 430\ \text{K}$.

EXECUTE: **(a)** n, R are constant so $\dfrac{pV}{T} = nR = \text{constant}.\ \dfrac{p_1V_1}{T_1} = \dfrac{p_2V_2}{T_2}$.

$$p_2 = p_1\left(\frac{V_1}{V_2}\right)\left(\frac{T_2}{T_1}\right) = (7.50\times10^3\ \text{Pa})\left(\frac{0.750\ \text{m}^3}{0.410\ \text{m}^3}\right)\left(\frac{430\ \text{K}}{300\ \text{K}}\right) = 1.97\times10^4\ \text{Pa}.$$

EVALUATE: Since the temperature increased while the volume decreased, the pressure must have increased. In $pV = nRT$, T must be in kelvins, even if we use a ratio of temperatures.

18.10. **IDENTIFY:** Use the ideal-gas equation to calculate the number of moles, n. The mass m_{total} of the gas is $m_{\text{total}} = nM$.

SET UP: The volume of the cylinder is $V = \pi r^2 l$, where $r = 0.450$ m and $l = 1.50$ m.

$T = 22.0°\text{C} = 293.15\ \text{K}.\ 1\ \text{atm} = 1.013\times10^5\ \text{Pa}.\ M = 32.0\times10^{-3}\ \text{kg/mol}.\ R = 8.314\ \text{J/mol}\cdot\text{K}.$

EXECUTE: **(a)** $pV = nRT$ gives

$$n = \frac{pV}{RT} = \frac{(21.0\ \text{atm})(1.013\times10^5\ \text{Pa/atm})\pi(0.450\ \text{m})^2(1.50\ \text{m})}{(8.314\ \text{J/mol}\cdot\text{K})(295.15\ \text{K})} = 827\ \text{mol}.$$

(b) $m_{\text{total}} = (827\ \text{mol})(32.0\times10^{-3}\ \text{kg/mol}) = 26.5\ \text{kg}$

EVALUATE: In the ideal-gas law, T must be in kelvins. Since we used R in units of $\text{J/mol}\cdot\text{K}$ we had to express p in units of Pa and V in units of m^3.

18.11. **IDENTIFY:** We are asked to compare two states. Use the ideal-gas law to obtain V_1 in terms of V_2 and the ratio of the temperatures in the two states.

SET UP: $pV = nRT$ and n, R, p are constant so $V/T = nR/p = \text{constant}$ and $V_1/T_1 = V_2/T_2$.

EXECUTE: $T_1 = (19 + 273)\ \text{K} = 292\ \text{K}$ (T must be in kelvins)

$V_2 = V_1(T_2/T_1) = (0.600\ \text{L})(77.3\ \text{K}/292\ \text{K}) = 0.159\ \text{L}.$

EVALUATE: p is constant so the ideal-gas equation says that a decrease in T means a decrease in V.

18.12. **IDENTIFY:** The ideal gas law applies. We should be able to identify the gas from its molecular weight.

SET UP: $pV = nRT$, $\rho = m/V = (m/\text{mole})n/V$. $R = 8.314\ \text{J/mol}\cdot\text{K}$.

EXECUTE: $\rho = m/V = (m/\text{mole})n/V$, so $m/\text{mole} = \dfrac{\rho V}{n} = \rho\dfrac{RT}{p}$, using $pV = nRT$.

$\rho = 1.33\times10^{-3}\ \text{kg/m}^3$, $p = 101.3$ Pa, $T = 293.15$ K.

Therefore $m/\text{mole} = (1.33\times10^{-3}\ \text{kg/m}^3)(8.314\ \text{J/mol}\cdot\text{K})(293.15\ \text{K})/(101.3\ \text{Pa}) = 0.0320\ \text{kg/mol} = 32.0$ g/mol. The gas is probably diatomic oxygen, O_2.

EVALUATE: There are few gases having small molecular weights, so we are quite certain that O_2 is the correct gas.

18.13. **IDENTIFY:** We know the volume of the gas at STP on the earth and want to find the volume it would occupy on Venus where the pressure and temperature are much greater.

SET UP: STP is $T = 273$ K and $p = 1$ atm. Set up a ratio using $pV = nRT$ with nR constant.

$T_{\text{V}} = 1003 + 273 = 1276\ \text{K}.$

EXECUTE: $pV = nRT$ gives $\frac{pV}{T} = nR = \text{constant}$, so $\frac{p_E V_E}{T_E} = \frac{p_V V_V}{T_V}$.

$$V_V = V_E\left(\frac{p_E}{p_V}\right)\left(\frac{T_V}{T_E}\right) = V\left(\frac{1\text{ atm}}{92\text{ atm}}\right)\left(\frac{1276\text{ K}}{273\text{ K}}\right) = 0.0508V.$$

EVALUATE: Even though the temperature on Venus is higher than it is on earth, the pressure there is much greater than on earth, so the volume of the gas on Venus is only about 5% what it is on earth.

18.14. IDENTIFY: $pV = nRT$.

SET UP: $T_1 = 277$ K. $T_2 = 296$ K. Assume the number of moles of gas in the bubble remains constant.

EXECUTE: **(a)** n, R are constant so $\frac{pV}{T} = nR = \text{constant}$. $\frac{p_1 V_1}{T_1} = \frac{p_2 V_2}{T_2}$ and

$$\frac{V_2}{V_1} = \left(\frac{p_1}{p_2}\right)\left(\frac{T_2}{T_1}\right) = \left(\frac{3.50\text{ atm}}{1.00\text{ atm}}\right)\left(\frac{296\text{ K}}{277\text{ K}}\right) = 3.74.$$

(b) This increase in volume of air in the lungs would be dangerous.

EVALUATE: The large decrease in pressure results in a large increase in volume.

18.15. IDENTIFY: We are looking at the gauge pressure in a gas, so we apply the ideal gas law.

SET UP: $pV = nRT$, $p_{\text{tot}} = p_{\text{atm}} + p_{\text{gauge}}$. The pressure we need to use is the *total* pressure since that is the pressure the gas exerts in the container, so $p_{\text{tot}} = 0.876$ atm + 1.000 atm = 1.876 atm.

EXECUTE: Using the numbers given in the problem, $n = pV/RT$. Putting in the numbers gives

$$n = \frac{(1.876\text{ atm})(5.43\text{ L})}{(0.08206\text{ L}\cdot\text{atm/mol}\cdot\text{K})(295.2\text{ K})} = 0.421\text{ mol}.$$

EVALUATE: We use the gauge pressure because that is the actual pressure in the tank. A pressure gauge reads the gauge pressure, but that is not the tank pressure since it is only the pressure above one atmosphere.

18.16. IDENTIFY: $F = pA$ and $pV = nRT$.

SET UP: For a cube, $V / A = L$.

EXECUTE: **(a)** The force of any side of the cube is $F = pA = (nRT / V)A = (nRT) / L,$ since the ratio of area to volume is $A/V = 1/L$. For $T = 20.0°\text{C} = 293.15$ K, so

$$F = \frac{nRT}{L} = \frac{(3\text{ mol})(8.314\text{ J/mol}\cdot\text{K})(293.15\ K)}{0.300\text{ m}} = 2.44\times 10^4\text{ N}.$$

(b) For $T = 100.00°\text{C} = 373.15$ K, so

$$F = \frac{nRT}{L} = \frac{(3\text{ mol})(8.314\text{ J/mol}\cdot\text{K})(373.15\text{ K})}{0.300\text{ m}} = 3.10\times 10^4\text{ N}.$$

EVALUATE: When the temperature increases while the volume is kept constant, the pressure increases and therefore the force increases. The force increases by the ratop T_2/T_1 of Kelvin temperatures.

18.17. IDENTIFY: We know the volume, pressure, and temperature of the gas and want to find its mass and density.

SET UP: $V = 3.00\times 10^{-3}\text{ m}^3$. $T = 295$ K. $p = 2.03\times 10^{-8}$ Pa. The ideal gas law, $pV = nRT$, applies.

EXECUTE: **(a)** $pV = nRT$ gives

$$n = \frac{pV}{RT} = \frac{(2.03\times 10^{-8}\text{ Pa})(3.00\times 10^{-3}\text{ m}^3)}{(8.315\text{ J/mol}\cdot\text{K})(295\text{ K})} = 2.48\times 10^{-14}\text{ mol}.$$ The mass of this amount of gas is

$$m = nM = (2.48\times 10^{-14}\text{ mol})(28.0\times 10^{-3}\text{ kg/mol}) = 6.95\times 10^{-16}\text{ kg}.$$

(b) $\rho = \frac{m}{V} = \frac{6.95\times 10^{-16}\text{ kg}}{3.00\times 10^{-3}\text{ m}^3} = 2.32\times 10^{-13}\text{ kg/m}^3.$

EVALUATE: The density at this level of vacuum is 13 orders of magnitude less than the density of air at STP, which is 1.20 kg/m^3.

18.18. IDENTIFY: Use $\rho = pM / RT$ and solve for p.

SET UP: $\rho = pM / RT$ and $p = RT\rho / M$

$T = (-56.5 + 273.15)\ \text{K} = 216.6\ \text{K}$

For air $M = 28.8 \times 10^{-3}$ kg/mol (Example 18.3).

EXECUTE: $p = \dfrac{(8.3145\ \text{J/mol}\cdot\text{K})(216.6\ \text{K})(0.364\ \text{kg/m}^3)}{28.8 \times 10^{-3}\ \text{kg/mol}} = 2.28 \times 10^4\ \text{Pa}.$

EVALUATE: The pressure is about one-fifth the pressure at sea-level.

18.19. IDENTIFY: $n = \dfrac{m}{M} = \dfrac{N}{N_A}.$

SET UP: $N_A = 6.022 \times 10^{23}$ molecules/mol. For water, $M = 18 \times 10^{-3}$ kg/mol.

EXECUTE: $n = \dfrac{m}{M} = \dfrac{1.00\ \text{kg}}{18 \times 10^{-3}\ \text{kg/mol}} = 55.6\ \text{mol}.$

$N = nN_A = (55.6\ \text{mol})(6.022 \times 10^{23}\ \text{molecules/mol}) = 3.35 \times 10^{25}\ \text{molecules}.$

EVALUATE: Note that we converted M to kg/mol.

18.20. IDENTIFY: The molar mass is $M = N_A m$, where m is the mass of one molecule.

SET UP: $N_A = 6.02 \times 10^{23}$ molecules/mol.

EXECUTE: $M = N_A m = (6.02 \times 10^{23}\ \text{molecules/mol})(1.41 \times 10^{-21}\ \text{kg/molecule}) = 849\ \text{kg/mol}.$

EVALUATE: For a carbon atom, $M = 12 \times 10^{-3}$ kg/mol. If this molecule is mostly carbon, so the average mass of its atoms is the mass of carbon, the molecule would contain $\dfrac{849\ \text{kg/mol}}{12 \times 10^{-3}\ \text{kg/mol}} = 71{,}000$ atoms.

18.21. IDENTIFY: Use $pV = nRT$ to calculate the number of moles and then the number of molecules would be $N = nN_A$.

SET UP: $1\ \text{atm} = 1.013 \times 10^5\ \text{Pa}$. $1.00\ \text{cm}^3 = 1.00 \times 10^{-6}\ \text{m}^3$. $N_A = 6.022 \times 10^{23}$ molecules/mol.

EXECUTE: (a) $n = \dfrac{pV}{RT} = \dfrac{(9.00 \times 10^{-14}\ \text{atm})(1.013 \times 10^5\ \text{Pa/atm})(1.00 \times 10^{-6}\ \text{m}^3)}{(8.314\ \text{J/mol}\cdot\text{K})(300.0\ \text{K})} = 3.655 \times 10^{-18}\ \text{mol}.$

$N = nN_A = (3.655 \times 10^{-18}\ \text{mol})(6.022 \times 10^{23}\ \text{molecules/mol}) = 2.20 \times 10^6\ \text{molecules}.$

(b) $N = \dfrac{pVN_A}{RT}$ so $\dfrac{N}{p} = \dfrac{VN_A}{RT} = \text{constant}$ and $\dfrac{N_1}{p_1} = \dfrac{N_2}{p_2}.$

$N_2 = N_1\left(\dfrac{p_2}{p_1}\right) = (2.20 \times 10^6\ \text{molecules})\left(\dfrac{1.00\ \text{atm}}{9.00 \times 10^{-14}\ \text{atm}}\right) = 2.44 \times 10^{19}\ \text{molecules}.$

EVALUATE: The number of molecules in a given volume is directly proportional to the pressure. Even at the very low pressure in part (a) the number of molecules in $1.00\ \text{cm}^3$ is very large.

18.22. IDENTIFY: We are asked about a single state of the system.

SET UP: Use the ideal-gas law. Write n in terms of the number of molecules N.

(a) EXECUTE: $pV = nRT$, $n = N / N_A$ so $pV = (N / N_A)RT$

$$p = \left(\frac{N}{V}\right)\left(\frac{R}{N_A}\right)T$$

$$p = \left(\frac{80 \text{ molecules}}{1\times10^{-6}\ \text{m}^3}\right)\left(\frac{8.3145\ \text{J/mol}\cdot\text{K}}{6.022\times10^{23}\ \text{molecules/mol}}\right)(7500\ \text{K}) = 8.28\times10^{-12}\ \text{Pa}$$

$p = 8.2\times10^{-17}$ atm. This is much lower than the laboratory pressure of 9×10^{-14} atm in Exercise 18.21.

(b) EVALUATE: The Lagoon Nebula is a very rarefied low pressure gas. The gas would exert *very* little force on an object passing through it.

18.23. IDENTIFY: Use $pV = nRT$ and $n = \dfrac{N}{N_A}$ with $N = 1$ to calculate the volume V occupied by 1 molecule. The length l of the side of the cube with volume V is given by $V = l^3$.

SET UP: $T = 27°\text{C} = 300$ K. $p = 1.00\ \text{atm} = 1.013\times10^5$ Pa. $R = 8.314$ J/mol·K.

$N_A = 6.022\times10^{23}$ molecules/mol.

The diameter of a typical molecule is about 10^{-10} m. $0.3\ \text{nm} = 0.3\times10^{-9}$ m.

EXECUTE: **(a)** $pV = nRT$ and $n = \dfrac{N}{N_A}$ gives

$$V = \frac{NRT}{N_A p} = \frac{(1.00)(8.314\ \text{J/mol}\cdot\text{K})(300\ \text{K})}{(6.022\times10^{23}\ \text{molecules/mol})(1.013\times10^5\ \text{Pa})} = 4.09\times10^{-26}\ \text{m}^3.\quad l = V^{1/3} = 3.45\times10^{-9}\ \text{m}.$$

(b) The distance in part (a) is about 10 times the diameter of a typical molecule.

(c) The spacing is about 10 times the spacing of atoms in solids.

EVALUATE: There is space between molecules in a gas whereas in a solid the atoms are closely packed together.

18.24. IDENTIFY: We are dealing with an ideal monatomic gas. We are removing gas from a tank and doubling the pressure and rms speed at the same time.

SET UP and EXECUTE: We want to know how many moles we need to remove from the tank. The volume stays the same (rigid walls), but n, p, and T can change. We want $p_2 = 2p_1$ and $v_{\text{rms},2} = 2v_{\text{rms},1}$.

We know that $v_{\text{rms}} = \sqrt{\dfrac{2kT}{m}}$ and $pV = nRT$. We want to know about the number of moles, so for the original and final states, the ideal gas law gives $n = \dfrac{p_1V}{RT_1}$ and $n_2 = \dfrac{p_2V}{RT_2}$. Squaring $v_{\text{rms}} = \sqrt{\dfrac{2kT}{m}}$ gives $v_{\text{rms}}^2 = \dfrac{2kT}{m}$. This tells us that if we square v_{rms}, the temperature increases by a factor of 4, which means that $T_2 = 4T_1$. Putting this and $p_2 = 2p_1$ into the ideal gas law gives $n_2 = \dfrac{p_2V}{RT_2} = \dfrac{2p_1V}{R(4T_1)} = \dfrac{1}{2}\dfrac{p_1V}{RT_1} = \dfrac{1}{2}n.$

Therefore we take out $\dfrac{1}{2}n$ moles.

EVALUATE: Just taking out half the moles would cut the pressure in half, and only doubling the rms speed of the molecules would increase the temperature a factor of 4. Doing both together increases the pressure by a factor of 2.

18.25. IDENTIFY: The ideal gas law applies. The translational kinetic energy of a gas depends on its absolute temperature.

SET UP: $pV = nRT$, $K_{\text{tr}} = 3/2\ nRT$, $K = \frac{1}{2}mv^2$.

EXECUTE: **(a)** From $pV = nRT$, we have $n = pV/RT$. Putting this into $K_{\text{tr}} = 3/2\ nRT$, we have

$K_{\text{tr}} = 3/2\ (pV/RT)(RT) = 3/2\ pV = (3/2)(1.013\times10^5\ \text{Pa})(8.00\ \text{m})(12.00\ \text{m})(4.00\ \text{m}) = 5.83\times10^7$ J.

(b) $K = \frac{1}{2}mv^2$: $\frac{1}{2}(2000\ \text{kg})v^2 = 5.83\times10^7$ J, gives $v = 242$ m/s.

EVALUATE: No automobile can travel this fast! Obviously the molecules in the room have a great deal of kinetic energy because there are so many of them.

18.26. **IDENTIFY:** $K_{av} = \frac{3}{2}kT$. $v_{rms} = \sqrt{\dfrac{3RT}{M}}$.

SET UP: $M_{Ne} = 20.180$ g/mol, $M_{Kr} = 83.80$ g/mol, and $M_{Rn} = 222$ g/mol.

EXECUTE: **(a)** $K_{av} = \frac{3}{2}kT$ depends only on the temperature so it is the same for each species of atom in the mixture.

(b) $\dfrac{v_{rms,Ne}}{v_{rms,Kr}} = \sqrt{\dfrac{M_{Kr}}{M_{Ne}}} = \sqrt{\dfrac{83.80 \text{ g/mol}}{20.18 \text{ g/mol}}} = 2.04$. $\dfrac{v_{rms,Ne}}{v_{rms,Rn}} = \sqrt{\dfrac{M_{Rn}}{M_{Ne}}} = \sqrt{\dfrac{222 \text{ g/mol}}{20.18 \text{ g/mol}}} = 3.32$.

$\dfrac{v_{rms,Kr}}{v_{rms,Rn}} = \sqrt{\dfrac{M_{Rn}}{M_{Kr}}} = \sqrt{\dfrac{222 \text{ g/mol}}{83.80 \text{ g/mol}}} = 1.63$.

EVALUATE: The average kinetic energies are the same. The gas atoms with smaller mass have larger v_{rms}.

18.27. **IDENTIFY:** We make several measurements of the pressure and temperature of a gas. Using a graph of the pressure versus the temperature, we want to determine the number N of gas molecules in the container.

SET UP: We use the ideal gas law to find a relationship between p and T_C so we can interpret the graph. The gas volume is $V = 80.0 \text{ cm}^3 = 0.0800$ L. We use $pV = nRT$ and $N = nN_A$. The target variable is N.

EXECUTE: $pV = nRT = nR(T_C + 273)$, so $p = \dfrac{nR(T_C + 273)}{V} = \dfrac{nR}{V}T_C + \dfrac{273nR}{V}$. Therefore a graph of p versus T_C should be a straight line having slope equal to nR/V. Putting this in terms of N gives slope = $\dfrac{nR}{V} = \dfrac{(N/N_A)R}{V}$, so $N = \dfrac{N_A V(\text{slope})}{R}$. Putting in the appropriate numbers gives

$$N = \frac{(6.022\times10^{23} \text{ molec/mol})(0.0800 \text{ L})(1.10 \text{ atm/C°})}{0.08206 \text{ L}\cdot\text{atm/mol}\cdot\text{K}} = 6.46\times10^{23} \text{ molecules.}$$

EVALUATE: The number of moles is $\dfrac{6.46\times10^{23}}{6.022\times10^{23}} = 1.07$ mol.

18.28. **IDENTIFY:** We can relate the temperature to the rms speed and the temperature to the pressure using the ideal gas law. The target variable is the pressure.

SET UP: $v_{rms} = \sqrt{\dfrac{3RT}{M}}$ and $pV = nRT$, where $n = m/M$.

EXECUTE: Use v_{rms} to calculate T: $v_{rms} = \sqrt{\dfrac{3RT}{M}}$ so

$T = \dfrac{Mv_{rms}^2}{3R} = \dfrac{(28.014\times10^{-3} \text{ kg/mol})(182 \text{ m/s})^2}{3(8.314 \text{ J/mol}\cdot\text{K})} = 37.20$ K. The ideal gas law gives $p = \dfrac{nRT}{V}$.

$n = \dfrac{m}{M} = \dfrac{0.226\times10^{-3} \text{ kg}}{28.014\times10^{-3} \text{ kg/mol}} = 8.067\times10^{-3}$ mol. Solving for p gives

$$p = \frac{(8.067\times10^{-3} \text{ mol})(8.314 \text{ J/mol}\cdot\text{K})(37.20 \text{ K})}{1.64\times10^{-3} \text{ m}^3} = 1.52\times10^3 \text{ Pa.}$$

EVALUATE: This pressure is around 1.5% of atmospheric pressure, which is not unreasonable since we have only around 1% of a mole of gas.

18.29. **IDENTIFY:** $v_{\text{rms}} = \sqrt{\dfrac{3kT}{m}}$

SET UP: The mass of a deuteron is $m = m_{\text{p}} + m_{\text{n}} = 1.673\times10^{-27}\ \text{kg} + 1.675\times10^{-27}\ \text{kg} = 3.35\times10^{-27}\ \text{kg}$. $c = 3.00\times10^{8}\ \text{m/s}$. $k = 1.381\times10^{-23}\ \text{J/molecule}\cdot\text{K}$.

EXECUTE: **(a)** $v_{\text{rms}} = \sqrt{\dfrac{3(1.381\times10^{-23}\ \text{J/molecule}\cdot\text{K})(300\times10^{6}\ \text{K})}{3.35\times10^{-27}\ \text{kg}}} = 1.93\times10^{6}\ \text{m/s}$. $\dfrac{v_{\text{rms}}}{c} = 6.43\times10^{-3}$.

(b) $T = \left(\dfrac{m}{3k}\right)(v_{\text{rms}})^2 = \left(\dfrac{3.35\times10^{-27}\ \text{kg}}{3(1.381\times10^{-23}\ \text{J/molecule}\cdot\text{K})}\right)(3.0\times10^{7}\ \text{m/s})^2 = 7.3\times10^{10}\ \text{K}$.

EVALUATE: Even at very high temperatures and for this light nucleus, v_{rms} is a small fraction of the speed of light.

18.30. **IDENTIFY:** $v_{\text{rms}} = \sqrt{\dfrac{3RT}{M}}$, where T is in kelvins. $pV = nRT$ gives $\dfrac{n}{V} = \dfrac{p}{RT}$.

SET UP: $R = 8.314\ \text{J/mol}\cdot\text{K}$. $M = 44.0\times10^{-3}\ \text{kg/mol}$.

EXECUTE: **(a)** For $T = 0.0°\text{C} = 273.15\ \text{K}$, $v_{\text{rms}} = \sqrt{\dfrac{3(8.314\ \text{J/mol}\cdot\text{K})(273.15\ \text{K})}{44.0\times10^{-3}\ \text{kg/mol}}} = 393\ \text{m/s}$. For $T = -100.0°\text{C} = 173\ \text{K}$, $v_{\text{rms}} = 313\ \text{m/s}$. The range of speeds is 393 m/s to 313 m/s.

(b) For $T = 273.15\ \text{K}$, $\dfrac{n}{V} = \dfrac{650\ \text{Pa}}{(8.314\ \text{J/mol}\cdot\text{K})(273.15\ \text{K})} = 0.286\ \text{mol/m}^3$. For $T = 173.15\ \text{K}$,

$\dfrac{n}{V} = 0.452\ \text{mol/m}^3$. The range of densities is $0.286\ \text{mol/m}^3$ to $0.452\ \text{mol/m}^3$.

EVALUATE: When the temperature decreases the rms speed decreases and the density increases.

18.31. **IDENTIFY** and **SET UP:** Apply the analysis of Section 18.3.

EXECUTE: **(a)** $\tfrac{1}{2}m(v^2)_{\text{av}} = \tfrac{3}{2}kT = \tfrac{3}{2}(1.38\times10^{-23}\ \text{J/molecule}\cdot\text{K})(300\ \text{K}) = 6.21\times10^{-21}\ \text{J}$.

(b) We need the mass m of one molecule:

$$m = \frac{M}{N_{\text{A}}} = \frac{32.0\times10^{-3}\ \text{kg/mol}}{6.022\times10^{23}\ \text{molecules/mol}} = 5.314\times10^{-26}\ \text{kg/molecule}.$$

Then $\tfrac{1}{2}m(v^2)_{\text{av}} = 6.21\times10^{-21}\ \text{J}$ (from part (a)) gives

$$(v^2)_{\text{av}} = \frac{2(6.21\times10^{-21}\ \text{J})}{m} = \frac{2(6.21\times10^{-21}\ \text{J})}{5.314\times10^{-26}\ \text{kg}} = 2.34\times10^{5}\ \text{m}^2/\text{s}^2.$$

(c) $v_{\text{rms}} = \sqrt{(v^2)_{\text{rms}}} = \sqrt{2.34\times10^{4}\ \text{m}^2/\text{s}^2} = 484\ \text{m/s}$.

(d) $p = mv_{\text{rms}} = (5.314\times10^{-26}\ \text{kg})(484\ \text{m/s}) = 2.57\times10^{-23}\ \text{kg}\cdot\text{m/s}$.

(e) Time between collisions with one wall is $t = \dfrac{0.20\ \text{m}}{v_{\text{rms}}} = \dfrac{0.20\ \text{m}}{484\ \text{m/s}} = 4.13\times10^{-4}\ \text{s}$.

In a collision $\vec{v}$ changes direction, so $\Delta p = 2mv_{\text{rms}} = 2(2.57\times10^{-23}\ \text{kg}\cdot\text{m/s}) = 5.14\times10^{-23}\ \text{kg}\cdot\text{m/s}$

$F = \dfrac{dp}{dt}$ so $F_{\text{av}} = \dfrac{\Delta p}{\Delta t} = \dfrac{5.14\times10^{-23}\ \text{kg}\cdot\text{m/s}}{4.13\times10^{-4}\ \text{s}} = 1.24\times10^{-19}\ \text{N}$.

(f) pressure $= F/A = 1.24\times10^{-19}\ \text{N}/(0.10\ \text{m})^2 = 1.24\times10^{-17}\ \text{Pa}$ (due to one molecule).

(g) pressure $= 1\ \text{atm} = 1.013\times10^{5}\ \text{Pa}$.

Number of molecules needed is $1.013\times10^{5}\ \text{Pa}/(1.24\times10^{-17}\ \text{Pa/molecule}) = 8.17\times10^{21}$ molecules.

(h) $pV = NkT$ (Eq. 18.18), so $N = \dfrac{pV}{kT} = \dfrac{(1.013\times10^5\ \text{Pa})(0.10\ \text{m})^3}{(1.381\times10^{-23}\ \text{J/molecule}\cdot\text{K})(300\ \text{K})} = 2.45\times10^{22}$ molecules.

(i) From the factor of $\frac{1}{3}$ in $(v_x^2)_{\text{av}} = \frac{1}{3}(v^2)_{\text{av}}$.

EVALUATE: This exercise shows that the pressure exerted by a gas arises from collisions of the molecules of the gas with the walls.

18.32. IDENTIFY: Apply $\lambda = \dfrac{kT}{4\pi\sqrt{2}r^2 p}$ and calculate λ.

SET UP: $1\ \text{atm} = 1.013\times10^5$ Pa, so $p = 3.55\times10^{-8}$ Pa. $r = 2.0\times10^{-10}$ m and $k = 1.38\times10^{-23}$ J/K.

EXECUTE: $\lambda = \dfrac{kT}{4\pi\sqrt{2}r^2 p} = \dfrac{(1.38\times10^{-23}\ \text{J/K})(300\ \text{K})}{4\pi\sqrt{2}(2.0\times10^{-10}\ \text{m})^2(3.55\times10^{-8}\ \text{Pa})} = 1.6\times10^5$ m

EVALUATE: At this very low pressure the mean free path is very large. If $v = 484$ m/s, as in Example 18.8, then $t_{\text{mean}} = \dfrac{\lambda}{v} = 330$ s. Collisions are infrequent.

18.33. IDENTIFY and SET UP: Use equal v_{rms} to relate T and M for the two gases. $v_{\text{rms}} = \sqrt{3RT/M}$, so $v_{\text{rms}}^2/3R = T/M$, where T must be in kelvins. Same v_{rms} so same T/M for the two gases and $T_{N_2}/M_{N_2} = T_{H_2}/M_{H_2}$.

EXECUTE: $T_{N_2} = T_{H_2}\left(\dfrac{M_{N_2}}{M_{H_2}}\right) = [(20+273)\text{K}]\left(\dfrac{28.014\ \text{g/mol}}{2.016\ \text{g/mol}}\right) = 4.071\times10^3$ K

$T_{N_2} = (4071 - 273)°\text{C} = 3800°\text{C}.$

EVALUATE: A N_2 molecule has more mass so N_2 gas must be at a higher temperature to have the same v_{rms}.

18.34. IDENTIFY: $v_{\text{rms}} = \sqrt{\dfrac{3kT}{m}}.$

SET UP: $k = 1.381\times10^{-23}$ J/molecule·K.

EXECUTE: **(a)** $v_{\text{rms}} = \sqrt{\dfrac{3(1.381\times10^{-23}\ \text{J/molecule}\cdot\text{K})(300\ \text{K})}{3.00\times10^{-16}\ \text{kg}}} = 6.44\times10^{-3}\ \text{m/s} = 6.44\ \text{mm/s}$

EVALUATE: **(b)** No. The rms speed depends on the average kinetic energy of the particles. At this T, H_2 molecules would have larger v_{rms} than the typical air molecules but would have the same average kinetic energy and the average kinetic energy of the smoke particles would be the same.

18.35. IDENTIFY: We add heat energy to a gas in a sealed rigid container and want to find the new rms speed of the molecules due to this added energy.

SET UP: We know that at constant volume $Q = nC_V\Delta T$ where $C_V = \dfrac{3}{2}R$ for a monatomic gas, and that $v_{\text{rms}} = \sqrt{\dfrac{3RT}{M}}$. First use $v_{\text{rms}} = \sqrt{\dfrac{3RT}{M}}$ to get the original temperature. Then use $Q = nC_V\Delta T$ to get ΔT, and finally use $v_{\text{rms}} = \sqrt{\dfrac{3RT}{M}}$ again to get the new v_{rms}.

EXECUTE: Get the original temperature T_1. Square $v_{\text{rms}} = \sqrt{\dfrac{3RT}{M}}$ to get $T_1 = \dfrac{Mv_{\text{rms}}^2}{3R}$. Using the numbers gives $T_1 = \dfrac{(0.00400\ \text{kg/mol})(900\ \text{m/s})^2}{3(8.314\ \text{J/mol}\cdot\text{K})} = 129.9$ K. Now get the new temperature T_2. Using

$Q = nC_V\Delta T = n\left(\frac{3}{2}R\right)\Delta T$ gives $2400\text{ J} = (3.00\text{ mol})(3/2)(8.314\text{ J/mol}\cdot\text{K})\Delta T$, so we have ΔT = 64.15 K. Thus $T_2 = T_1 + \Delta T$ = 129.9 K + 64.15 K = 194.05 K. Finally use $v_{\text{rms}} = \sqrt{\frac{3RT}{M}}$ to calculate the new rms speed using T_2 = 194.05 K and M = 0.00400 kg/mol. The result is v_{rms} = 1100 m/s.

EVALUATE: Since $v_{\text{rms}} \propto \sqrt{T}$, when our fractional increase in T is $\frac{194.05}{129.9} = 1.494$, the fractional increase in v_{rms} is $\sqrt{1.494} = 1222$. Thus we would expect that $v_2 = 1.222v_1 = (1.222)(900\text{ m/s}) = 1100$ m/s, which is exactly what we found.

18.36. **IDENTIFY:** We add 6000 J of heat energy to a monatomic gas in a rigid container and want to find the new pressure.

SET UP: We know that $Q = nC_V\Delta T$ where $C_V = \frac{3}{2}R$ for a monatomic gas, and $pV = nRT$. Our target variable is the final pressure, and we know that the volume remains constant.

EXECUTE: Use $Q = nC_V\Delta T$ = 6000 J to find ΔT and from this get the new temperature.

$$\Delta T = \frac{Q}{nC_V} = \frac{Q}{n\left(\frac{3}{2}R\right)} = \frac{6000\text{ J}}{(4.00\text{ mol})(3/2)(8.314\text{ J/mol}\cdot\text{K})} = 120.3\text{ K},\ \text{so } T_2 = 300\text{ K} + 120\text{ K} = 420\text{ K}.$$

Since V and n are constant, $pV = nRT$ gives T/p = constant, so

$$p_2 = p_1\frac{T_2}{T_1} = (6.00\times10^4\text{ Pa})\frac{420\text{ K}}{300\text{ K}} = 8.41\times10^4\text{ Pa}.$$

EVALUATE: The temperature ratio is $\frac{420}{300} = 1.40$ and the pressure ratio is $\frac{8.41}{6.00} = 1.40$, so they agree.

18.37. **IDENTIFY:** Use $dQ = nC_VdT$ applied to a finite temperature change.

SET UP: $C_V = 5R/2$ for a diatomic ideal gas and $C_V = 3R/2$ for a monatomic ideal gas.

EXECUTE: **(a)** $Q = nC_V\Delta T = n\left(\frac{5}{2}R\right)\Delta T$. $Q = (1.80\text{ mol})\left(\frac{5}{2}\right)(8.314\text{ J/mol}\cdot\text{K})(50.0\text{ K}) = 1870\text{ J}$.

(b) $Q = nC_V\Delta T = n\left(\frac{3}{2}R\right)\Delta T$. $Q = (1.80\text{ mol})\left(\frac{3}{2}\right)(8.314\text{ J/mol}\cdot\text{K})(50.0\text{ K}) = 1120\text{ J}$.

EVALUATE: More heat is required for the diatomic gas; not all the heat that goes into the gas appears as translational kinetic energy, some goes into energy of the internal motion of the molecules (rotations).

18.38. **IDENTIFY:** The heat Q added is related to the temperature increase ΔT by $Q = nC_V\Delta T$.

SET UP: For ideal H_2 (a diatomic gas), $C_{V,H_2} = 5/2\,R$, and for ideal Ne (a monatomic gas), $C_{V,\text{Ne}} = 3/2\,R$.

EXECUTE: $C_V\Delta T = \frac{Q}{n}$ = constant, so $C_{V,H_2}\Delta T_{H_2} = C_{V,\text{Ne}}\Delta T_{\text{Ne}}$.

$$\Delta T_{\text{Ne}} = \left(\frac{C_{V,H_2}}{C_{V,\text{Ne}}}\right)\Delta T_{H_2} = \left(\frac{5/2\,R}{3/2\,R}\right)(2.50\text{ C}^\circ) = 4.17\text{ C}^\circ = 4.17\text{ K}.$$

EVALUATE: The same amount of heat causes a smaller temperature increase for H_2 since some of the energy input goes into the internal degrees of freedom.

18.39. **IDENTIFY:** $C = Mc$, where C is the molar heat capacity and c is the specific heat capacity.

$$pV = nRT = \frac{m}{M}RT.$$

SET UP: $M_{N_2} = 2(14.007\text{ g/mol}) = 28.014\times10^{-3}$ kg/mol. For water, $c_w = 4190$ J/kg·K. For N_2, $C_V = 20.76$ J/mol·K.

EXECUTE: **(a)** $c_{N_2} = \dfrac{C}{M} = \dfrac{20.76 \text{ J/mol} \cdot \text{K}}{28.014 \times 10^{-3} \text{ kg/mol}} = 741 \text{ J/kg} \cdot \text{K}$. $\dfrac{c_w}{c_{N_2}} = 5.65$; c_w is over five time larger.

(b) To warm the water, $Q = mc_w \Delta T = (1.00 \text{ kg})(4190 \text{ J/mol} \cdot \text{K})(10.0 \text{ K}) = 4.19 \times 10^4 \text{ J}$. For air,

$$m = \frac{Q}{c_{N_2} \Delta T} = \frac{4.19 \times 10^4 \text{ J}}{(741 \text{ J/kg} \cdot \text{K})(10.0 \text{ K})} = 5.65 \text{ kg}.$$

$$V = \frac{mRT}{Mp} = \frac{(5.65 \text{ kg})(8.314 \text{ J/mol} \cdot \text{K})(293 \text{ K})}{(28.014 \times 10^{-3} \text{ kg/mol})(1.013 \times 10^5 \text{ Pa})} = 4.85 \text{ m}^3 = 4850 \text{ L}.$$

EVALUATE: c is smaller for N_2, so less heat is needed for 1.0 kg of N_2 than for 1.0 kg of water.

18.40. **(a) IDENTIFY** and **SET UP:** $\frac{1}{2}R$ contribution to C_V for each degree of freedom. The molar heat capacity C is related to the specific heat capacity c by $C = Mc$.

EXECUTE: $C_V = 6\left(\frac{1}{2}R\right) = 3R = 3(8.3145 \text{ J/mol} \cdot \text{K}) = 24.9 \text{ J/mol} \cdot \text{K}$. The specific heat capacity is $c_V = C_V / M = (24.9 \text{ J/mol} \cdot \text{K})/(18.0 \times 10^{-3} \text{ kg/mol}) = 1380 \text{ J/kg} \cdot \text{K}$.

(b) For water vapor the specific heat capacity is $c = 2000 \text{ J/kg} \cdot \text{K}$. The molar heat capacity is $C = Mc = (18.0 \times 10^{-3} \text{ kg/mol})(2000 \text{ J/kg} \cdot \text{K}) = 36.0 \text{ J/mol} \cdot \text{K}$.

EVALUATE: The difference is $36.0 \text{ J/mol} \cdot \text{K} - 24.9 \text{ J/mol} \cdot \text{K} = 11.1 \text{ J/mol} \cdot \text{K}$, which is about $2.7\left(\frac{1}{2}R\right)$; the vibrational degrees of freedom make a significant contribution.

18.41. **IDENTIFY:** Apply $v_{mp} = \sqrt{2kT/m}$, $v_{av} = \sqrt{8kT/\pi m}$, and $v_{rms} = \sqrt{3kT/m}$.

SET UP: Note that $\dfrac{k}{m} = \dfrac{R/N_A}{M/N_A} = \dfrac{R}{M}$. $M = 44.0 \times 10^{-3}$ kg/mol.

EXECUTE: **(a)** $v_{mp} = \sqrt{2(8.3145 \text{ J/mol} \cdot \text{K})(300 \text{ K})/(44.0 \times 10^{-3} \text{ kg/mol})} = 3.37 \times 10^2$ m/s.

(b) $v_{av} = \sqrt{8(8.3145 \text{ J/mol} \cdot \text{K})(300 \text{ K})/(\pi(44.0 \times 10^{-3} \text{ kg/mol}))} = 3.80 \times 10^2$ m/s.

(c) $v_{rms} = \sqrt{3(8.3145 \text{ J/mol} \cdot \text{K})(300 \text{ K})/(44.0 \times 10^{-3} \text{ kg/mol})} = 4.12 \times 10^2$ m/s.

EVALUATE: The average speed is greater than the most probable speed and the rms speed is greater than the average speed.

18.42. **IDENTIFY:** Table 18.2 gives the value of v / v_{rms} for which 94.7% of the molecules have a smaller value of v / v_{rms}. $v_{rms} = \sqrt{\dfrac{3RT}{M}}$.

SET UP: For N_2, $M = 28.0 \times 10^{-3}$ kg/mol. $v / v_{rms} = 1.60$.

EXECUTE: $v_{rms} = \dfrac{v}{1.60} = \sqrt{\dfrac{3RT}{M}}$, so the temperature is

$$T = \frac{Mv^2}{3(1.60)^2 R} = \frac{(28.0 \times 10^{-3} \text{ kg/mol})}{3(1.60)^2 (8.3145 \text{ J/mol} \cdot \text{K})} v^2 = (4.385 \times 10^{-4} \text{ K} \cdot \text{s}^2/\text{m}^2) v^2.$$

(a) $T = (4.385 \times 10^{-4} \text{ K} \cdot \text{s}^2/\text{m}^2)(1500 \text{ m/s})^2 = 987$ K.

(b) $T = (4.385 \times 10^{-4} \text{ K} \cdot \text{s}^2/\text{m}^2)(1000 \text{ m/s})^2 = 438$ K.

(c) $T = (4.385 \times 10^{-4} \text{ K} \cdot \text{s}^2/\text{m}^2)(500 \text{ m/s})^2 = 110$ K.

EVALUATE: As T decreases the distribution of molecular speeds shifts to lower values.

18.43. **IDENTIFY:** We want to compare the speed of sound in a gas to the rms speed and average speed of its molecules.

SET UP: $v=\sqrt{\dfrac{\gamma RT}{M}}$ (for sound), $v_{\text{rms}}=\sqrt{\dfrac{3RT}{M}}$, and $v_{\text{av}}=\sqrt{\dfrac{8kT}{\pi m}}$. Using $k/m = R/M$ gives $v_{\text{av}}=\sqrt{\dfrac{8RT}{\pi M}}$.

EXECUTE: **(a)** Compare v_{rms} to v: $\dfrac{v_{\text{rms}}}{v}=\dfrac{\sqrt{3RT/M}}{\sqrt{\gamma RT/M}}=\sqrt{3/\gamma}=\sqrt{3/1.67}=1.34.$

(b) Compare v_{av} to v: $\dfrac{v_{\text{av}}}{v}=\dfrac{\sqrt{8RT/\pi M}}{\sqrt{\gamma RT/M}}=\sqrt{\dfrac{8}{\pi\gamma}}=\sqrt{\dfrac{8}{\pi(1.67)}}=1.23.$

EVALUATE: The average speed is closer to the speed of sound, but both are greater than it.

18.44. **IDENTIFY:** This problem concerns the distribution of molecular speeds.

SET UP and EXECUTE: We want to find the number of atoms within 20% of the rms speed. This means that the limits on v are $v = v_{\text{rms}} \pm 0.20v_{\text{rms}} = \begin{cases} v_{\text{rms}}+0.20v_{\text{rms}}=1.20v_{\text{rms}} \\ v_{\text{rms}}-0.20v_{\text{rms}}=0.80v_{\text{rms}} \end{cases}$. Table 18.2 tells us that if we have N atoms (or molecules), $0.771N$ have speeds less than $1.20v_{\text{rms}}$ and $0.411N$ have speeds less than $0.80v_{\text{rms}}$. Therefore the number with speeds between $0.80v_{\text{rms}}$ and $1.20v_{\text{rms}}$ is $0.771N-0.411N=0.360N$. In 0.0345 mol of gas, the number of molecules is (0.0345 mol)N_A = (0.0345 mol)(6.022×10^{23} molecules/mol) = 2.0776×10^{22} molecules. In this gas the number of molecules with speeds between $0.80v_{\text{rms}}$ and $1.20v_{\text{rms}}$ is (0.360)(2.0776×10^{22}) = 7.48×10^{21}.

EVALUATE: Careful! We do not want the number of molecules that have a speed of 20% the rms speed. We want the number *within* 20% of the rms speed.

18.45. **IDENTIFY:** Refer to the phase diagram in Figure 18.24 in the textbook.

SET UP: For water the triple-point pressure is 610 Pa and the critical-point pressure is 2.212×10^7 Pa.

EXECUTE: **(a)** To observe a solid to liquid (melting) phase transition the pressure must be greater than the triple-point pressure, so $p_1=610$ Pa. For $p<p_1$ the solid to vapor (sublimation) phase transition is observed.

(b) No liquid to vapor (boiling) phase transition is observed if the pressure is greater than the critical-point pressure. $p_2=2.212\times10^7$ Pa. For $p_1<p<p_2$ the sequence of phase transitions is solid to liquid and then liquid to vapor.

EVALUATE: Normal atmospheric pressure is approximately 1.0×10^5 Pa, so the solid to liquid to vapor sequence of phase transitions is normally observed when the material is water.

18.46. **IDENTIFY:** Apply the definition of relative humidity given in the problem. $pV=nRT=\dfrac{m_{\text{tot}}}{M}RT$.

SET UP: $M=18.0\times10^{-3}$ kg/mol.

EXECUTE: **(a)** The pressure due to water vapor is $(0.60)(2.34\times10^3\text{ Pa})=1.40\times10^3$ Pa.

(b) $m_{\text{tot}}=\dfrac{MpV}{RT}=\dfrac{(18.0\times10^{-3}\text{ kg/mol})(1.40\times10^3\text{ Pa})(1.00\text{ m}^3)}{(8.3145\text{ J/mol}\cdot\text{K})(293.15\text{ K})}=10\text{ g}.$

EVALUATE: The vapor pressure of water vapor at this temperature is much less than the total atmospheric pressure of 1.0×10^5 Pa.

18.47. **IDENTIFY:** We are investigating characteristics of the gas in a party balloon.
SET UP: Estimate: The sound intensity level is 95 dB. The sound lasts 100 ms = 0.10 s. We use $I = P/A = P/4\pi r^2$ and $\beta = (10 \text{ dB})\log\dfrac{I}{I_0}$.

EXECUTE: **(a)** $95 \text{ dB} = (10 \text{ dB})\log\dfrac{I}{I_0}$, so $I = 10^{9.5} I_0 = 10^{9.5}\ 10^{-12} \text{ W/m}^2 = 3.2\times10^{-3} \text{ W/m}^2$. The intensity is $I = P/A$, so $P_{av} = IA = (3.2\times10^{-3} \text{ W/m}^2)(4\pi)(2.0 \text{ m})^2 = 0.16$ W. The energy E in this sound is $E = P_{av}t = (0.16 \text{ W})(0.10 \text{ s}) = 0.016$ J.
(b) $T = E/A = E/(4\pi r^2) = (0.016 \text{ J})/[4\pi(0.075 \text{ m})^2] = 0.23 \text{ J/m}^2$.
(c) $p_{gauge} = T/R = (0.23 \text{ J/m}^2)/(0.075 \text{ m}) = 3.0$ Pa.
EVALUATE: These results are only a rough approximation for the gauge pressure.

18.48. **IDENTIFY:** The ideal gas law will tell us the number of moles of gas in the room, which we can use to find the number of molecules.
SET UP: $pV = nRT$, $N = nN_A$, and $m = nM$.
EXECUTE: **(a)** $T = 27.0°\text{C} + 273 = 300$ K. $p = 1.013\times10^5$ Pa.

$$n = \frac{pV}{RT} = \frac{(1.013\times10^5 \text{ Pa})(216 \text{ m}^3)}{(8.314 \text{ J/mol}\cdot\text{K})(300 \text{ K})} = 8773 \text{ mol}.$$

$N = nN_A = (8773 \text{ mol})(6.022\times10^{23} \text{ molecules/mol}) = 5.28\times10^{27}$ molecules.

(b) $V = (216 \text{ m}^3)(1 \text{ cm}^3/10^{-6} \text{ m}^3) = 2.16\times10^8 \text{ cm}^3$. The particle density is

$$\frac{5.28\times10^{27} \text{ molecules}}{2.16\times10^8 \text{ cm}^3} = 2.45\times10^{19} \text{ molecules/cm}^3.$$

(c) $m = nM = (8773 \text{ mol})(28.014\times10^{-3} \text{ kg/mol}) = 246$ kg.

EVALUATE: A cubic centimeter of air (about the size of a sugar cube) contains around 10^{19} molecules, and the air in the room weighs about 500 lb!

18.49. **IDENTIFY:** We can model the atmosphere as a fluid of constant density, so the pressure depends on the depth in the fluid, as we saw in Section 12.2.
SET UP: The pressure difference between two points in a fluid is $\Delta p = \rho gh$, where h is the difference in height of two points.
EXECUTE: **(a)** $\Delta p = \rho gh = (1.2 \text{ kg/m}^3)(9.80 \text{ m/s}^2)(1000 \text{ m}) = 1.18\times10^4$ Pa.
(b) At the bottom of the mountain, $p = 1.013\times10^5$ Pa. At the top, $p = 8.95\times10^4$ Pa.

$$pV = nRT = \text{constant so } p_bV_b = p_tV_t \text{ and } V_t = V_b\left(\frac{p_b}{p_t}\right) = (0.50 \text{ L})\left(\frac{1.013\times10^5 \text{ Pa}}{8.95\times10^4 \text{ Pa}}\right) = 0.566 \text{ L}.$$

EVALUATE: The pressure variation with altitude is affected by changes in air density and temperature and we have neglected those effects. The pressure decreases with altitude and the volume increases. You may have noticed this effect: bags of potato chips "puff up" when taken to the top of a mountain.

18.50. **IDENTIFY:** As the pressure on the bubble changes, its volume will change. As we saw in Section 12.2, the pressure in a fluid depends on the depth.
SET UP: The pressure at depth h in a fluid is $p = p_0 + \rho gh$, where p_0 is the pressure at the surface. $p_0 = p_{air} = 1.013\times10^5$ Pa. The density of water is $\rho = 1000 \text{ kg/m}^3$.

EXECUTE: $p_1 = p_0 + \rho gh = 1.013\times10^5$ Pa + (1000 kg/m^3)(9.80 m/s^2)(25 m) $= 3.463\times10^5$ Pa.

$p_2 = p_{\text{air}} = 1.013\times10^5$ Pa. $V_1 = 1.0\text{ mm}^3$. n, R and T are constant so $pV = nRT =$ constant. $p_1V_1 = p_2V_2$ and $V_2 = V_1\left(\dfrac{p_1}{p_2}\right) = (1.0\text{ mm}^3)\left(\dfrac{3.463\times10^5\text{ Pa}}{1.013\times10^5\text{ Pa}}\right) = 3.4\text{ mm}^3$.

EVALUATE: This is a large change and would have serious effects.

18.51. IDENTIFY: The buoyant force on the balloon must be equal to the weight of the load plus the weight of the gas.

SET UP: The buoyant force is $F_{\text{B}} = \rho_{\text{air}}Vg$. A lift of 290 kg means $\dfrac{F_{\text{B}}}{g} - m_{\text{hot}} = 290\text{ kg}$, where m_{hot} is the mass of hot air in the balloon. $m = \rho V$.

EXECUTE: $m_{\text{hot}} = \rho_{\text{hot}}V$. $\dfrac{F_{\text{B}}}{g} - m_{\text{hot}} = 290\text{ kg}$ gives $(\rho_{\text{air}} - \rho_{\text{hot}})V = 290\text{ kg}$.

Solving for ρ_{hot} gives $\rho_{\text{hot}} = \rho_{\text{air}} - \dfrac{290\text{ kg}}{V} = 1.23\text{ kg/m}^3 - \dfrac{290\text{ kg}}{500.0\text{ m}^3} = 0.65\text{ kg/m}^3$. $\rho_{\text{hot}} = \dfrac{pM}{RT_{\text{hot}}}$.

$\rho_{\text{air}} = \dfrac{pM}{RT_{\text{air}}}$. $\rho_{\text{hot}}T_{\text{hot}} = \rho_{\text{air}}T_{\text{air}}$ so

$$T_{\text{hot}} = T_{\text{air}}\left(\frac{\rho_{\text{air}}}{\rho_{\text{hot}}}\right) = (288\text{ K})\left(\frac{1.23\text{ kg/m}^3}{0.65\text{ kg/m}^3}\right) = 545\text{ K} = 272°\text{C}.$$

EVALUATE: This temperature is well above normal air temperatures, so the air in the balloon would need considerable heating.

18.52. IDENTIFY: The ideal gas law applies. The gas pressure supports the disk and whatever is on it.
SET UP: For constant temperature, $pV = nRT$ gives $p_1V_1 = p_2V_2$. Call A the area of the disk, m the mass of the disk, M the mass of the lead brick, and h_2 the final height of the disk. $p = F_\perp/A$.

EXECUTE: $p_1 = mg/A$, $p_2 = (m + M)g/A$. For constant temperature, $p_1V_1 = p_2V_2$, which gives $p_2 = p_1(V_1/V_2) = (mg/A)(Ah/Ah_2) = (m + M)g/A$. Solving for h_2 gives $h_2 = mh/(m + M)$, which gives $h_2 = (3.00\text{ kg})(4.00\text{ m})/(12.0\text{ kg}) = 1.00\text{ m}$.
EVALUATE: Since $p \to 4p$, $V \to \frac{1}{4}V$, so it is reasonable that $h \to \frac{1}{4}h$, as we found.

18.53. IDENTIFY: We are asked to compare two states. Use the ideal-gas law to obtain m_2 in terms of m_1 and the ratio of pressures in the two states. Apply $pV = \dfrac{m_{\text{total}}}{M}RT$ to the initial state to calculate m_1.

SET UP: $pV = nRT$ can be written $pV = (m/M)RT$

T, V, M, R are all constant, so $p/m = RT/MV =$ constant.

So $p_1/m_1 = p_2/m_2$, where m is the mass of the gas in the tank.

EXECUTE: $p_1 = 1.30\times10^6\text{ Pa} + 1.01\times10^5\text{ Pa} = 1.40\times10^6\text{ Pa}$

$p_2 = 3.40\times10^5\text{ Pa} + 1.01\times10^5\text{ Pa} = 4.41\times10^5\text{ Pa}$

$m_1 = p_1VM/RT$; $V = hA = h\pi r^2 = (1.00\text{ m})\pi(0.060\text{ m})^2 = 0.01131\text{ m}^3$

$$m_1 = \frac{(1.40\times10^6\text{ Pa})(0.01131\text{ m}^3)(44.1\times10^{-3}\text{ kg/mol})}{(8.3145\text{ J/mol}\cdot\text{K})((22.0 + 273.15)\text{K})} = 0.2845\text{ kg}$$

Then $m_2 = m_1\left(\dfrac{p_2}{p_1}\right) = (0.2845\text{ kg})\left(\dfrac{4.41\times10^5\text{ Pa}}{1.40\times10^6\text{ Pa}}\right) = 0.0896\text{ kg}$.

m_2 is the mass that remains in the tank. The mass that has been used is

$m_1 - m_2 = 0.2845\text{ kg} - 0.0896\text{ kg} = 0.195\text{ kg}$.

EVALUATE: Note that we have to use absolute pressures. The absolute pressure decreases by a factor of approximately 3 and the mass of gas in the tank decreases by a factor of approximately 3.

18.54. IDENTIFY: Apply $pV = nRT$ to the air inside the diving bell. The pressure p at depth y below the surface of the water is $p = p_{\text{atm}} + \rho gy$.

SET UP: $p = 1.013\times10^5$ Pa. $T = 300.15$ K at the surface and $T' = 280.15$ K at the depth of 13.0 m.

EXECUTE: **(a)** The height h' of the air column in the diving bell at this depth will be proportional to the volume, and hence inversely proportional to the pressure and proportional to the Kelvin temperature:

$$h' = h\frac{p}{p'}\frac{T'}{T} = h\frac{p_{\text{atm}}}{p_{\text{atm}} + \rho gy}\frac{T'}{T}.$$

$$h' = (2.30\text{ m})\frac{(1.013\times10^5\text{ Pa})}{(1.013\times10^5\text{ Pa}) + (1030\text{ kg/m}^3)(9.80\text{ m/s}^2)(73.0\text{ m})}\left(\frac{280.15\text{ K}}{300.15\text{ K}}\right) = 0.26\text{ m}.$$

The height of the water inside the diving bell is $h - h' = 2.04$ m.

(b) The necessary gauge pressure is the term ρgy from the above calculation, $p_{\text{gauge}} = 7.37\times10^5$ Pa.

EVALUATE: The gauge pressure required in part (b) is about 7 atm.

18.55. IDENTIFY: We are investigating the movement of air above a campfire. The air is heated by the fire and expands so the number of molecules in a given volume decreases.

SET UP and EXECUTE: The mass of a volume of air is $m = nM_{\text{air}}$, where M is the molar mass and n is the number of moles. If m_{out} is the the mass of gas out of the heated region and m_{in} is the mass within that region, the upward force F_{up} on a parcel of air above the fire can be roughly approximated by $F_{\text{up}} = (m_{\text{out}} - m_{\text{in}})g$. We can use $pV = nRT$ and $\sum F_y = ma_y$.

(a) We want the acceleration a of the air parcel as a function of $T_{\text{out}}/T_{\text{in}}$. Using $m = nM_{\text{air}}$ we have $F_{\text{up}} = (m_{\text{out}} - m_{\text{in}})g = (n_{\text{out}}M_{\text{air}} - n_{\text{in}}M_{\text{air}})g = M_{\text{air}}(n_{\text{out}} - n_{\text{in}})g$. Now solve for n in $pV = nRT$ to get $n = pV/RT$ and use this in the equation for F_{up}, which gives $F_{\text{up}} = \frac{M_{\text{air}}g}{R}\left(\frac{p_{\text{out}}V_{\text{out}}}{T_{\text{out}}} - \frac{p_{\text{in}}V_{\text{in}}}{T_{\text{in}}}\right)$. As stated in the problem, the pressure above the fire is the same as the ambient pressure, so $p_0 = p_1 = p_{\text{amb}}$. This gives $F_{\text{up}} = \frac{M_{\text{air}}gp_{\text{amb}}}{R}\left(\frac{V_{\text{out}}}{T_{\text{out}}} - \frac{V_{\text{in}}}{T_{\text{in}}}\right)$. Now apply $\sum F_y = ma_y$ where m is the mass of air in the air parcel over the fire. This mass is $m = n_{\text{in}}M_{\text{air}}$, so $F_{\text{up}} = \frac{M_{\text{air}}gp_{\text{amb}}}{R}\left(\frac{V_{\text{out}}}{T_{\text{out}}} - \frac{V_{\text{in}}}{T_{\text{in}}}\right) = n_{\text{in}}M_{\text{air}}a$. Substituting for n_{in} gives $\frac{M_{\text{air}}gp_{\text{amb}}}{R}\left(\frac{V_{\text{out}}}{T_{\text{out}}} - \frac{V_{\text{in}}}{T_{\text{in}}}\right) = \left(\frac{p_{\text{in}}V_{\text{in}}}{RT_{\text{in}}}\right)M_{\text{air}}a$. We are told that $p_{\text{in}} = p_{\text{amb}}$ and the masses are for similar volumes of air, so $V_{\text{in}} = V_{\text{out}}$, this equation simplifies to $F_{\text{up}} = g\left(\frac{1}{T_0} - \frac{1}{T_1}\right) = \left(\frac{1}{T_{\text{in}}}\right)a$. Solving for a we get $a = \left(\frac{T_{\text{in}}}{T_{\text{out}}} - 1\right)g$.

(b) Solving for T_{in} as a function of a gives $T_{\text{in}} = T_{\text{out}}\left(\frac{a}{g} + 1\right)$.

(c) Estimate: $a \approx 1.5g$.

(d) $T_{\text{out}} = 15°\text{C} = 288$ K, so $T_{\text{in}} = (288\text{ K})\left(\frac{1.5g}{g} + 1\right) = 720\text{ K}$ � 450°C.

EVALUATE: This would be a roaring fire at 840°F!

18.56. **IDENTIFY:** For constant temperature, the variation of pressure with altitude is calculated in Example 18.4 to be $p = p_0 e^{-Mgy/RT}$. $v_{\text{rms}} = \sqrt{\dfrac{3RT}{M}}$.

SET UP: $g_{\text{earth}} = 9.80\text{ m/s}^2$. $T = 460°\text{C} = 733\text{ K}$. $M = 44.0\text{ g/mol} = 44.0\times10^{-3}\text{ kg/mol}$.

EXECUTE: **(a)** $\dfrac{Mgy}{RT} = \dfrac{(44.0\times10^{-3}\text{ kg/mol})(0.894)(9.80\text{ m/s}^2)(1.00\times10^3\text{ m})}{(8.314\text{ J/mol}\cdot\text{K})(733\text{ K})} = 0.06326.$

$p = p_0 e^{-Mgy/RT} = (92\text{ atm})e^{-0.06326} = 86\text{ atm}$. The pressure is 86 earth-atmospheres, or 0.94 Venus-atmospheres.

(b) $v_{\text{rms}} = \sqrt{\dfrac{3RT}{M}} = \sqrt{\dfrac{3(8.314\text{ J/mol}\cdot\text{K})(733\text{ K})}{44.0\times10^{-3}\text{ kg/mol}}} = 645\text{ m/s}$. v_{rms} has this value both at the surface and at an altitude of 1.00 km.

EVALUATE: v_{rms} depends only on T and the molar mass of the gas. For Venus compared to earth, the surface temperature, in kelvins, is nearly a factor of three larger and the molecular mass of the gas in the atmosphere is only about 50% larger, so v_{rms} for the Venus atmosphere is larger than it is for the earth's atmosphere.

18.57. **IDENTIFY:** Air and water can be pumped in and out of a diving bell.

SET UP and EXECUTE: The average density can be changed by pumping water in and out of the bell. We use $\rho = m/V$, $p = p_0 + \rho gh$, and $pV = nRT$.

(a) We want to know what volume of seawater to add to the bell so it is neutrally buoyant. The average density of the bell and all its contents must be equal to the density of seawater. Call m_b the mass of the bell, m_d the mass of the diver, and m_w the mass of the added water. Using $\rho_{\text{bell}} = \rho_{\text{seawater}}$ gives

$\dfrac{m_b + m_d + m_w}{V_{\text{bell}}} = \rho_{\text{seawater}}$. Using $V_{\text{bell}} = \pi r^2 L$ and solving for m_w gives $m_w = \pi r^2 L\rho_{\text{seawater}} - m_b - m_d$.

Using $\rho_{\text{seawater}} = 1025\text{ kg/m}^3$, $r = 0.750$ m, $L = 2.50$ m, $m_b = 4350$ kg, and $m_d = 80.0$ kg, we get $m_w =$ 98.31 kg. The volume of this water is $V = m/\rho$ so $V = \dfrac{98.31\text{ kg}}{1025\text{ kg/m}^3} = 0.0959\text{ m}^3 = 95.9\text{ L}$.

(b) We want to know the rate at which we should release air from the tank to maintain a constant pressure as the bell descends at a steady 1.0 m/s, so we want dn/dt. Combining $p = p_0 + \rho gh$ and $pV = nRT$ gives $p_0 + \rho gh = (RT/V)n$. Taking the time derivative of both sides of this equation gives

$\rho g\dfrac{dy}{dt} = \left(\dfrac{RT}{V}\right)\dfrac{dn}{dt}$. Solving for dn/dt gives $\dfrac{dn}{dt} = \dfrac{\rho gV}{RT}\dfrac{dy}{dt} = \dfrac{\rho gVv}{RT}$. V is the volume of air in the bell which is $V = V_b - V_w = \pi r^2 L - V_w = \pi(0.750\text{ m})^2(2.50\text{ m}) - 0.0959\text{ m}^3 = 4.322\text{ m}^3$. Using this value for V plus $\rho = 1025\text{ kg/m}^3$, $T = 293$ K, $v = 1.00$ m/s, $R = 8.314\text{ J/mol}\cdot\text{K}$, and $L = 2.50$ m, we get $dn/dt =$ 17.8 mol/s.

(c) The tank contains 600 ft^3 of gas, which is 1.6992×10^4 L. It was loaded at standard conditions of 1.0 atm at 0°C = 273 K, so $n = pV/RT$. Putting in the numbers gives $n = 758.5$ mol. The tank releases gas at a rate of 17.8 mol/s, so (17.8 mol/s)t = 758.5 mol, which gives $t = 42.6$ s. During this time the bell is descending at a steady 1.00 m/s, so the distance it travels is (1.00 m/s)(42.6 s) = 42.6 m.

EVALUATE: At 42.6 m the water pressure would be $p = p_0 + \rho gh = p_0 + (1025\text{ kg/m}^3)(g)(42.6\text{ m}) =$ 5.3 atm, so the diving bell should not have any leaks!

18.58. **IDENTIFY:** In part (a), apply $pV = nRT$ to the ethane in the flask. The volume is constant once the stopcock is in place. In part (b) apply $pV = \dfrac{m_{\text{tot}}}{M}RT$ to the ethane at its final temperature and pressure.

SET UP: $1.50\text{ L} = 1.50\times10^{-3}\text{ m}^3$. $M = 30.1\times10^{-3}\text{ kg/mol}$. Neglect the thermal expansion of the flask.

EXECUTE: (a) $p_2 = p_1(T_2/T_1) = (1.013\times10^5\ \text{Pa})(300\ \text{K}/550\ \text{K}) = 5.525\times10^4\ \text{Pa},$ which rounds to 5.53×10^4 Pa.

(b) $m_{\text{tot}} = \left(\dfrac{p_2V}{RT_2}\right)M = \left(\dfrac{(5.525\times10^4\ \text{Pa})(1.50\times10^{-3}\ \text{m}^3)}{(8.3145\ \text{J/mol}\cdot\text{K})(300\ \text{K})}\right)(30.1\times10^{-3}\ \text{kg/mol}) = 1.00\ \text{g}.$

EVALUATE: We could also calculate m_{tot} with $p = 1.013\times10^5$ Pa and $T = 550$ K, and we would obtain the same result. Originally, before the system was warmed, the mass of ethane in the flask was $m = (1.00\ \text{g})\left(\dfrac{1.013\times10^5\ \text{Pa}}{5.525\times10^4\ \text{Pa}}\right) = 1.83\ \text{g}.$

18.59. (a) IDENTIFY: Consider the gas in one cylinder. Calculate the volume to which this volume of gas expands when the pressure is decreased from $(1.20\times10^6\ \text{Pa} + 1.01\times10^5\ \text{Pa}) = 1.30\times10^6\ \text{Pa}$ to 1.01×10^5 Pa. Apply the ideal-gas law to the two states of the system to obtain an expression for V_2 in terms of V_1 and the ratio of the pressures in the two states.

SET UP: $pV = nRT$

n, R, T constant implies $pV = nRT = \text{constant}$, so $p_1V_1 = p_2V_2$.

EXECUTE: $V_2 = V_1(p_1/p_2) = (1.90\ \text{m}^3)\left(\dfrac{1.30\times10^6\ \text{Pa}}{1.01\times10^5\ \text{Pa}}\right) = 24.46\ \text{m}^3$

The number of cylinders required to fill a $750\ \text{m}^3$ balloon is $750\ \text{m}^3 / 24.46\ \text{m}^3 = 30.7$ cylinders.

EVALUATE: The ratio of the volume of the balloon to the volume of a cylinder is about 400. Fewer cylinders than this are required because of the large factor by which the gas is compressed in the cylinders.

(b) IDENTIFY: The upward force on the balloon is given by Archimedes's principle: $B =$ weight of air displaced by balloon $= \rho_{\text{air}}Vg$. Apply Newton's second law to the balloon and solve for the weight of the load that can be supported. Use the ideal-gas equation to find the mass of the gas in the balloon.

SET UP: The free-body diagram for the balloon is given in Figure 18.59.

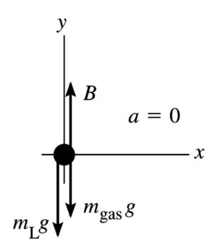

Figure 18.59

m_{gas} is the mass of the gas that is inside the balloon; m_{L} is the mass of the load that is supported by the balloon.

EXECUTE: $\sum F_y = ma_y$

$B - m_{\text{L}}g - m_{\text{gas}}g = 0$

$\rho_{\text{air}}Vg - m_{\text{L}}g - m_{\text{gas}}g = 0$

$m_{\text{L}} = \rho_{\text{air}}V - m_{\text{gas}}$

Calculate m_{gas}, the mass of hydrogen that occupies $750\ \text{m}^3$ at 15°C and $p = 1.01\times10^5$ Pa.

$pV = nRT = (m_{\text{gas}}/M)RT$

gives $m_{\text{gas}} = pVM/RT = \dfrac{(1.01\times10^5\ \text{Pa})(750\ \text{m}^3)(2.02\times10^{-3}\ \text{kg/mol})}{(8.3145\ \text{J/mol}\cdot\text{K})(288\ \text{K})} = 63.9\ \text{kg}.$

Then $m_{\text{L}} = (1.23\ \text{kg/m}^3)(750\ \text{m}^3) - 63.9\ \text{kg} = 859\ \text{kg},$ and the weight that can be supported is $w_{\text{L}} = m_{\text{L}}g = (859\ \text{kg})(9.80\ \text{m/s}^2) = 8420\ \text{N}.$

(c) $m_L = \rho_{air}V - m_{gas}$

$m_{gas} = pVM / RT = (63.9 \text{ kg})((4.00 \text{ g/mol}) / (2.02 \text{ g/mol})) = 126.5 \text{ kg}$ (using the results of part (b)).

Then $m_L = (1.23 \text{ kg/m}^3)(750 \text{ m}^3) - 126.5 \text{ kg} = 796 \text{ kg}.$

$w_L = m_L g = (796 \text{ kg})(9.80 \text{ m/s}^2) = 7800 \text{ N}.$

EVALUATE: A greater weight can be supported when hydrogen is used because its density is less.

18.60. IDENTIFY: The upward force exerted by the gas on the piston must equal the piston's weight. Use $pV = nRT$ to calculate the volume of the gas, and from this the height of the column of gas in the cylinder.

SET UP: $F = pA = p\pi r^2$, with $r = 0.100 \text{ m}$ and $p = 0.300 \text{ atm} = 3.039\times10^4 \text{ Pa}$. For the cylinder, $V = \pi r^2 h.$

EXECUTE: **(a)** $p\pi r^2 = mg$ and $m = \dfrac{p\pi r^2}{g} = \dfrac{(3.039\times10^4 \text{ Pa})\pi(0.100 \text{ m})^2}{9.80 \text{ m/s}^2} = 97.4 \text{ kg}.$

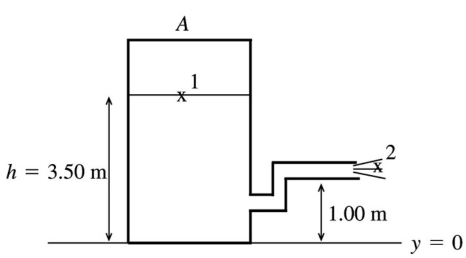
(b) $V = \pi r^2 h$ and $V = nRT/p$. Combining these equations gives $h = nRT/\pi r^2 p$, which gives

$$h = \frac{(1.80 \text{ mol})(8.314 \text{ J/mol}\cdot\text{K})(293.15 \text{ K})}{\pi(0.100 \text{ m})^2(3.039\times10^4 \text{ Pa})} = 4.60 \text{ m}.$$

EVALUATE: The calculation assumes a vacuum $(p = 0)$ in the tank above the piston.

18.61. IDENTIFY: Apply Bernoulli's equation to relate the efflux speed of water out the hose to the height of water in the tank and the pressure of the air above the water in the tank. Use the ideal-gas equation to relate the volume of the air in the tank to the pressure of the air.

SET UP: Points 1 and 2 are shown in Figure 18.61.



$p_1 = 4.20\times10^5 \text{ Pa}$

$p_2 = p_{air} = 1.00\times10^5 \text{ Pa}$

large tank implies $v_1 \approx 0$

Figure 18.61

EXECUTE: **(a)** $p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$

$\frac{1}{2}\rho v_2^2 = p_1 - p_2 + \rho g(y_1 - y_2)$

$v_2 = \sqrt{(2/\rho)(p_1 - p_2) + 2g(y_1 - y_2)}$

$v_2 = 26.2 \text{ m/s}.$

(b) $\underline{h = 3.00 \text{ m}}$

The volume of the air in the tank increases so its pressure decreases. $pV = nRT = \text{constant}$, so

$pV = p_0V_0$ (p_0 is the pressure for $h_0 = 3.50 \text{ m}$ and p is the pressure for $h = 3.00 \text{ m}$)

$p(4.00 \text{ m} - h)A = p_0(4.00 \text{ m} - h_0)A$

$$p = p_0\left(\frac{4.00 \text{ m} - h_0}{4.00 \text{ m} - h}\right) = (4.20\times10^5 \text{ Pa})\left(\frac{4.00 \text{ m} - 3.50 \text{ m}}{4.00 \text{ m} - 3.00 \text{ m}}\right) = 2.10\times10^5 \text{ Pa}.$$

Repeat the calculation of part (a), but now $p_1 = 2.10\times10^5 \text{ Pa}$ and $y_1 = 3.00 \text{ m}.$

$v_2 = \sqrt{(2/\rho)(p_1 - p_2) + 2g(y_1 - y_2)}$

$v_2 = 16.1$ m/s

$\underline{h = 2.00 \text{ m}}$

$$p = p_0\left(\frac{4.00 \text{ m} - h_0}{4.00 \text{ m} - h}\right) = (4.20\times10^5 \text{ Pa})\left(\frac{4.00 \text{ m} - 3.50 \text{ m}}{4.00 \text{ m} - 2.00 \text{ m}}\right) = 1.05\times10^5 \text{ Pa}$$

$v_2 = \sqrt{(2/\rho)(p_1 - p_2) + 2g(y_1 - y_2)}$

$v_2 = 5.44$ m/s.

(c) $v_2 = 0$ means $(2/\rho)(p_1 - p_2) + 2g(y_1 - y_2) = 0$

$p_1 - p_2 = -\rho g(y_1 - y_2)$

$y_1 - y_2 = h - 1.00$ m

$p = p_0\left(\frac{0.50 \text{ m}}{4.00 \text{ m} - h}\right) = (4.20\times10^5 \text{ Pa})\left(\frac{0.50 \text{ m}}{4.00 \text{ m} - h}\right)$. This is p_1, so

$$(4.20\times10^5 \text{ Pa})\left(\frac{0.50 \text{ m}}{4.00 \text{ m} - h}\right) - 1.00\times10^5 \text{ Pa} = (9.80 \text{ m/s}^2)(1000 \text{ kg/m}^3)(1.00 \text{ m} - h)$$

$(210/(4.00 - h)) - 100 = 9.80 - 9.80h,$ with h in meters.

$210 = (4.00 - h)(109.8 - 9.80h)$

$9.80h^2 - 149h + 229.2 = 0$ and $h^2 - 15.20h + 23.39 = 0$

quadratic formula: $h = \frac{1}{2}\left(15.20 \pm \sqrt{(15.20)^2 - 4(23.39)}\right) = (7.60 \pm 5.86)$ m

h must be less than 4.00 m, so the only acceptable value is $h = 7.60 \text{ m} - 5.86 \text{ m} = 1.74$ m.

EVALUATE: The flow stops when $p + \rho g(y_1 - y_2)$ equals air pressure. For $h = 1.74$ m, $p = 9.3\times10^4$ Pa and $\rho g(y_1 - y_2) = 0.7\times10^4$ Pa, so $p + \rho g(y_1 - y_2) = 1.0\times10^5$ Pa, which is air pressure.

18.62. IDENTIFY: The vertical forces on the plastic sphere must balance. Archimedes's principle and the ideal gas law both apply.

SET UP: $pV = nRT$, $\rho = m/V$. Call V the volume of the sphere, m its mass, and ρ its volume. Let ρ_a be the density of the air and F the tension in the thread. The buoyant force B is equal to the weight of the air displaced by the sphere, so $B = \rho_a Vg$.

EXECUTE: **(a)** Balancing vertical forces gives $F + B = mg$. $B = \rho_a Vg$ and $V = m/\rho$.

For the air: ρ_a = (mass of n moles)/(volume of n moles) = Mn/V, where M is the molar mass of air, which is 28.8 g/mol = 0.0288 kg/mol. From $pV = nRT$ we have $n/V = p/RT$, so the density of air is $\rho_a = M(n/V) = Mp/RT$.

$\rho_a = (0.0288 \text{ kg/mol})(1.013\times10^5 \text{ Pa})/[(8.314 \text{ J/mol}\cdot\text{K})(298.15 \text{ K})] = 1.177 \text{ kg/m}^3$.

Therefore $B = \rho_a Vg = \rho_a (m/\rho)g$

$B = (1.177 \text{ kg/m}^3)(0.00900 \text{ kg})(9.80 \text{ m/s}^2)/(4.00 \text{ kg/m}^3) = 0.02595$ N.

$F = mg - B = (0.00900 \text{ kg})(9.80 \text{ m/s}^2) - 0.02595 \text{ N} = 0.0622$ N.

(b) If the buoyant force increases, the tension decreases, so $\Delta F = -\Delta B = -\frac{mg}{\rho}\Delta\rho_a$. This gives us

$\Delta F = -\frac{mg}{\rho}(\rho_{a,2} - \rho_{a,1})$. Using $\rho_a = pM/RT$, this equation becomes

$\Delta F = -\frac{mgpM}{\rho R}\left(\frac{1}{T_2} - \frac{1}{T_1}\right) = \frac{mgpM}{\rho R}\left(\frac{1}{T_1} - \frac{1}{T_2}\right)$. Putting in the numbers gives

$$\Delta F = \frac{(0.00900 \text{ kg})(9.80 \text{ m/s}^2)(1.013\times10^5 \text{ Pa})(0.0288 \text{ kg/mol})}{(4.00 \text{ kg/m}^3)(8.314 \text{ J/mol}\cdot\text{K})}\left(\frac{1}{278.15 \text{ K}} - \frac{1}{308.15 \text{ K}}\right)$$

$\Delta F = 2.71\times10^{-3}$ N = 2.71 mN. The positive sign tells us that the tension increases.

EVALUATE: As the air temperature increased, its density decreased, so the buoyant force it exerted decreased. So it is reasonable that the tension should increase.

18.63. **IDENTIFY** and **SET UP:** Apply $m_{\text{total}} = nM$ to find *n* and then use Avogadro's number to find the number of molecules.

EXECUTE: Calculate the number of water molecules *N*.

Number of moles: $n = \dfrac{m_{\text{tot}}}{M} = \dfrac{50 \text{ kg}}{18.0\times10^{-3} \text{ kg/mol}} = 2.778\times10^{3} \text{ mol}$

$N = nN_{\text{A}} = (2.778\times10^{3} \text{ mol})(6.022\times10^{23} \text{ molecules/mol}) = 1.7\times10^{27} \text{ molecules}$

Each water molecule has three atoms, so the number of atoms is $3(1.7\times10^{27}) = 5.1\times10^{27}$ atoms.

EVALUATE: We could also use the masses in Example 18.5 to find the mass *m* of one H_2O molecule: $m = 2.99\times10^{-26}$ kg. Then $N = m_{\text{tot}}/m = 1.7\times10^{27}$ molecules, which checks.

18.64. **IDENTIFY:** Use the ideal gas law to find the number of moles of air taken in with each breath and from this calculate the number of oxygen molecules taken in. Then find the pressure at an elevation of 2000 m and repeat the calculation.

SET UP: The number of molecules in a mole is $N_{\text{A}} = 6.022\times10^{23}$ molecules/mol. $R = 0.08206 \text{ L}\cdot\text{atm/mol}\cdot\text{K}$. Example 18.4 shows that the pressure variation with altitude *y*, when constant temperature is assumed, is $p = p_0 e^{-Mgy/RT}$. For air, $M = 28.8\times10^{-3}$ kg/mol.

EXECUTE: **(a)** $pV = nRT$ gives $n = \dfrac{pV}{RT} = \dfrac{(1.00 \text{ atm})(0.50 \text{ L})}{(0.08206 \text{ L}\cdot\text{atm/mol}\cdot\text{K})(293.15 \text{ K})} = 0.0208 \text{ mol.}$

$N = (0.210)nN_{\text{A}} = (0.210)(0.0208 \text{ mol})(6.022\times10^{23} \text{ molecules/mol}) = 2.63\times10^{21} \text{ molecules.}$

(b) $\dfrac{Mgy}{RT} = \dfrac{(28.8\times10^{-3} \text{ kg/mol})(9.80 \text{ m/s}^2)(2000 \text{ m})}{(8.314 \text{ J/mol}\cdot\text{K})(293.15 \text{ K})} = 0.2316.$

$p = p_0 e^{-Mgy/RT} = (1.00 \text{ atm})e^{-0.2316} = 0.793 \text{ atm.}$

N is proportional to *n*, which is in turn proportional to *p*, so

$N = \left(\dfrac{0.793 \text{ atm}}{1.00 \text{ atm}}\right)(2.63\times10^{21} \text{ molecules}) = 2.09\times10^{21} \text{ molecules.}$

(c) Less O_2 is taken in with each breath at the higher altitude, so the person must take more breaths per minute.

EVALUATE: A given volume of gas contains fewer molecules when the pressure is lowered and the temperature is kept constant.

18.65. **IDENTIFY:** The mass of one molecule is the molar mass, *M*, divided by the number of molecules in a mole, N_{A}. The average translational kinetic energy of a single molecule is $\frac{1}{2}m(v^2)_{\text{av}} = \frac{3}{2}kT$. Use $pV = NkT$ to calculate *N*, the number of molecules.

SET UP: $k = 1.381\times10^{-23} \text{ J/molecule}\cdot\text{K}$. $M = 28.0\times10^{-3}$ kg/mol. $T = 295.15$ K. The volume of the balloon is $V = \frac{4}{3}\pi(0.250 \text{ m})^3 = 0.0654 \text{ m}^3$. $p = 1.25 \text{ atm} = 1.27\times10^{5}$ Pa.

EXECUTE: **(a)** $m = \dfrac{M}{N_{\text{A}}} = \dfrac{28.0\times10^{-3} \text{ kg/mol}}{6.022\times10^{23} \text{ molecules/mol}} = 4.65\times10^{-26} \text{ kg.}$

(b) $\frac{1}{2}m(v^2)_{\text{av}} = \frac{3}{2}kT = \frac{3}{2}(1.381\times10^{-23} \text{ J/molecule}\cdot\text{K})(295.15 \text{ K}) = 6.11\times10^{-21} \text{ J.}$

(c) $N = \dfrac{pV}{kT} = \dfrac{(1.27\times10^{5} \text{ Pa})(0.0654 \text{ m}^3)}{(1.381\times10^{-23} \text{ J/molecule}\cdot\text{K})(295.15 \text{ K})} = 2.04\times10^{24} \text{ molecules.}$

(d) The total average translational kinetic energy is
$N\left(\frac{1}{2}m(v^2)_{\text{av}}\right) = (2.04\times10^{24}\text{ molecules})(6.11\times10^{-21}\text{ J/molecule}) = 1.25\times10^4\text{ J}.$

EVALUATE: The number of moles is $n = \dfrac{N}{N_\text{A}} = \dfrac{2.04\times10^{24}\text{ molecules}}{6.022\times10^{23}\text{ molecules/mol}} = 3.39\text{ mol}.$

$K_\text{tr} = \frac{3}{2}nRT = \frac{3}{2}(3.39\text{ mol})(8.314\text{ J/mol}\cdot\text{K})(295.15\text{ K}) = 1.25\times10^4\text{ J},$ which agrees with our results in part (d).

18.66. **IDENTIFY:** $pV = nRT = \dfrac{N}{N_\text{A}}RT.$ Deviations will be noticeable when the volume V of a molecule is on the order of 1% of the volume of gas that contains one molecule.

SET UP: The volume of a sphere of radius r is $V = \dfrac{4}{3}\pi r^3.$

EXECUTE: The volume of gas per molecule is $\dfrac{RT}{N_\text{A}p},$ and the volume of a molecule is about

$V_0 = \dfrac{4}{3}\pi(2.0\times10^{-10}\text{ m})^3 = 3.4\times10^{-29}\text{ m}^3.$ Denoting the ratio of these volumes as

$f,\ p = f\dfrac{RT}{N_\text{A}V_0} = f\dfrac{(8.3145\text{ J / mol}\cdot\text{K})(300\text{ K})}{(6.022\times10^{23}\text{ molecules / mol})(3.4\times10^{-29}\text{ m}^3)} = (1.2\times10^8\text{ Pa})f.$

"Noticeable deviations" is a subjective term, but f on the order of 1.0% gives a pressure of 10^6 Pa.

EVALUATE: The forces between molecules also cause deviations from ideal-gas behavior.

18.67. **IDENTIFY** and **SET UP:** At equilibrium $F(r) = 0.$ The work done to increase the separation from r_2 to ∞ is $U(\infty) - U(r_2).$

(a) EXECUTE: $U(r) = U_0[(R_0 / r)^{12} - 2(R_0 / r)^6]$

From Chapter 14: $F(r) = 12(U_0/R_0)[(R_0/r)^{13} - (R_0/r)^7].$ The graphs are given in Figure 18.67.

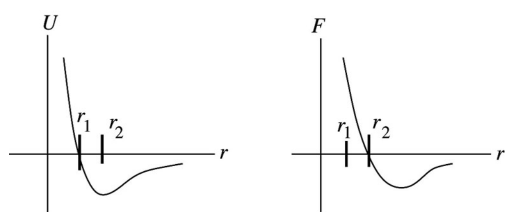


Figure 18.67

(b) Equilibrium requires $F = 0;$ occurs at point $r_2.$ r_2 is where U is a minimum (stable equilibrium).

(c) $U = 0$ implies $(R_0/r)^{12}2(R_0/r)^6 = 0$

$(r_1/R_0)^6 = 1/2$ and $r_1 = R_0/(2)^{1/6}.$

$F = 0$ implies $(R_0/r)^{13} - (R_0/r)^7 = 0$

$(r_2/R_0)^6 = 1$ and $r_2 = R_0.$

Then $r_1/r_2 = (R_0/2^{1/6})/R_0 = 2^{-1/6}.$

(d) $W_\text{other} = \Delta U.$

At $r \to \infty,$ $U = 0,$ so $W = -U(R_0) = -U_0[(R_0/R_0)^{12} - 2(R_0/R_0)^6] = +U_0.$

EVALUATE: The answer to part (d), $U_0,$ is the depth of the potential well shown in the graph of $U(r).$

18.68. **IDENTIFY:** Use $pV = nRT$ to calculate the number of moles, *n*. Then $K_{\text{tr}} = \frac{3}{2}nRT$. The mass of the gas, m_{tot}, is given by $m_{\text{tot}} = nM$.

SET UP: $5.00\ \text{L} = 5.00\times10^{-3}\ \text{m}^3$.

EXECUTE: **(a)** $n = \dfrac{pV}{RT} = \dfrac{(1.01\times10^5\ \text{Pa})(5.00\times10^{-3}\ \text{m}^3)}{(8.314\ \text{J/mol}\cdot\text{K})(300\ \text{K})} = 0.2025\ \text{moles}$

$K_{\text{tr}} = \frac{3}{2}(0.2025\ \text{mol})(8.314\ \text{J/mol}\cdot\text{K})(300\ \text{K}) = 758\ \text{J}$.

(b) $m_{\text{tot}} = nM = (0.2025\ \text{mol})(2.016\times10^{-3}\ \text{kg/mol}) = 4.08\times10^{-4}\ \text{kg}$. The kinetic energy due to the speed of the jet is $K = \frac{1}{2}mv^2 = \frac{1}{2}(4.08\times10^{-4}\ \text{kg})(300.0\ \text{m/s})^2 = 18.4\ \text{J}$. The total kinetic energy is $K_{\text{tot}} = K + K_{\text{tr}} = 18.4\ \text{J} + 758\ \text{J} = 776\ \text{J}$. The percentage increase is

$\dfrac{K}{K_{\text{tot}}}\times100\% = \dfrac{18.4\ \text{J}}{776\ \text{J}}\times100\% = 2.37\%$.

(c) No. The temperature is associated with the random translational motion, and that hasn't changed.

EVALUATE: The equation $pV = \dfrac{2}{3}K_{\text{tr}}$ gives $K_{\text{tr}} = \frac{3}{2}pV = \frac{3}{2}(1.01\times10^5\ \text{Pa})(5.00\times10^{-3}\ \text{m}^3) = 758\ \text{J}$, which agrees with our result in part (a). $v_{\text{rms}} = \sqrt{\dfrac{3RT}{M}} = 1.93\times10^3\ \text{m/s}$. v_{rms} is a lot larger than the speed of the jet, so the percentage increase in the total kinetic energy, calculated in part (b), is small.

18.69. **IDENTIFY:** The equipartition principle says that each atom has an average kinetic energy of $\frac{1}{2}kT$ for each degree of freedom. There is an equal average potential energy.

SET UP: The atoms in a three-dimensional solid have three degrees of freedom and the atoms in a two-dimensional solid have two degrees of freedom.

EXECUTE: **(a)** In the same manner that $C_V = 3R$ was obtained, the heat capacity of the two-dimensional solid would be $2R = 16.6\ \text{J/mol}\cdot\text{K}$.

(b) The heat capacity would behave qualitatively like those in Figure 18.21 in the textbook, and the heat capacity would decrease with decreasing temperature.

EVALUATE: At very low temperatures the equipartition theorem doesn't apply. Most of the atoms remain in their lowest energy states because the next higher energy level is not accessible.

18.70. **IDENTIFY:** $v_{\text{rms}} = \sqrt{\dfrac{3kT}{m}}$.

SET UP: $M = 1.99\times10^{30}\ \text{kg}$, $R = 6.96\times10^8\ \text{m}$ and $G = 6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2$.

EXECUTE: **(a)** $v_{\text{rms}} = \sqrt{\dfrac{3kT}{m}} = \sqrt{\dfrac{3(1.38\times10^{-23}\ \text{J/K})(5800\ \text{K})}{(1.67\times10^{-27}\ \text{kg})}} = 1.20\times10^4\ \text{m/s}$.

(b) $v_{\text{escape}} = \sqrt{\dfrac{2GM}{R}} = \sqrt{\dfrac{2(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(1.99\times10^{30}\ \text{kg})}{(6.96\times10^8\ \text{m})}} = 6.18\times10^5\ \text{m/s}$.

EVALUATE: **(c)** The escape speed is about 50 times the rms speed, and either Figure 18.23 in the textbook, the Maxwell-Boltzmann distribution, or Table 18.2 will indicate that there is a negligibly small fraction of molecules with the escape speed.

18.71. **(a) IDENTIFY** and **SET UP:** Apply conservation of energy $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$, where $U = -Gmm_{\text{p}}/r$. Let point 1 be at the surface of the planet, where the projectile is launched, and let point 2 be far from the earth. Just barely escapes says $v_2 = 0$.

EXECUTE: Only gravity does work says $W_{\text{other}} = 0$.

$U_1 = -Gmm_{\text{p}}/R_{\text{p}}$; $r_2 \to \infty$ so $U_2 = 0$; $v_2 = 0$ so $K_2 = 0$.

The conservation of energy equation becomes $K_1 - Gmm_\text{p}/R_\text{p} = 0$ and $K_1 = Gmm_\text{p}/R_\text{p}$.

But $g = Gm_\text{p}/R_\text{p}^2$ so $Gm_\text{p}/R_\text{p} = R_\text{p}g$ and $K_1 = mgR_\text{p}$, as was to be shown.

EVALUATE: The greater gR_p is, the more initial kinetic energy is required for escape.

(b) IDENTIFY and SET UP: Set K_1 from part (a) equal to the average kinetic energy of a molecule as given by the equation $\frac{1}{2}m(v^2)_\text{av} = \frac{3}{2}kT$. $\frac{1}{2}m(v^2)_\text{av} = mgR_\text{p}$ (from part (a)). But also, $\frac{1}{2}m(v^2)_\text{av} = \frac{3}{2}kT$, so $mgR_\text{p} = \frac{3}{2}kT$.

EXECUTE: $T = \dfrac{2mgR_\text{p}}{3k}$

Nitrogen:

$m_{\text{N}_2} = (28.0\times10^{-3}\text{ kg/mol})/(6.022\times10^{23}\text{ molecules/mol}) = 4.65\times10^{-26}\text{ kg/molecule}$

$$T = \frac{2mgR_\text{p}}{3k} = \frac{2(4.65\times10^{-26}\text{ kg/molecule})(9.80\text{ m/s}^2)(6.37\times10^6\text{ m})}{3(1.381\times10^{-23}\text{ J/molecule}\cdot\text{K})} = 1.40\times10^5\text{ K}$$

Hydrogen:

$m_{\text{H}_2} = (2.02\times10^{-3}\text{ kg/mol})/(6.022\times10^{23}\text{ molecules/mol}) = 3.354\times10^{-27}\text{ kg/molecule}$

$$T = \frac{2mgR_\text{p}}{3k} = \frac{2(3.354\times10^{-27}\text{ kg/molecule})(9.80\text{ m/s}^2)(6.37\times10^6\text{ m})}{3(1.381\times10^{-23}\text{ J/molecule}\cdot\text{K})} = 1.01\times10^4\text{ K}$$

(c) $T = \dfrac{2mgR_\text{p}}{3k}$

Nitrogen:

$$T = \frac{2(4.65\times10^{-26}\text{ kg/molecule})(1.63\text{ m/s}^2)(1.74\times10^6\text{ m})}{3(1.381\times10^{-23}\text{ J/molecule}\cdot\text{K})} = 6370\text{ K}$$

Hydrogen:

$$T = \frac{2(3.354\times10^{-27}\text{ kg/molecule})(1.63\text{ m/s}^2)(1.74\times10^6\text{ m})}{3(1.381\times10^{-23}\text{ J/molecule}\cdot\text{K})} = 459\text{ K}$$

(d) EVALUATE: The "escape temperatures" are much less for the moon than for the earth. For the moon a larger fraction of the molecules at a given temperature will have speeds in the Maxwell-Boltzmann distribution larger than the escape speed. After a long time most of the molecules will have escaped from the moon.

18.72. IDENTIFY: The ideal gas law applies. The rms speed depends on the Kelvin temperature of the gas.

SET UP: $pV = nRT$, $v_\text{rms} = \sqrt{3kT/m}$. For constant volume, the ideal gas law gives $p_2/T_2 = p_1/T_1$. All temperatures must be in kelvins.

EXECUTE: Solving for p_2 gives $p_2 = p_1(T_2/T_1)$. Solving $v_\text{rms} = \sqrt{3kT/m}$ for T gives $T = \dfrac{m}{3k}v_\text{rms}^2$. Applying this result to the pressure equation gives

$$p_2 = p_1\frac{(m/3k)v_{\text{rms},2}^2}{(m/3k)v_{\text{rms},1}^2} = (2.00\text{ atm})\left(\frac{276\text{ m/s}}{176\text{ m/s}}\right)^2 = 4.92\text{ atm}.$$ The change in pressure is

4.92 atm – 2.00 atm = 2.92 atm.

EVALUATE: An increase in speed of (100 m/s)/(176 m/s) = 57% produced an increase in pressure of (2.92 atm)/(2.00 atm) = 146%. The large increase in pressure for a much smaller increase in molecular speed is due to the fact that the temperature, and hence the pressure, depends on the *square* of the molecular speed.

18.73. **IDENTIFY** and **SET UP:** Evaluate the integral as specified in the problem.

EXECUTE: $\int_0^\infty v^2 f(v)\,dv = 4\pi(m/2\pi kT)^{3/2}\int_0^\infty v^4 e^{-mv^2/2kT}\,dv.$

The integral formula with $n=2$ gives $\int_0^\infty v^4 e^{-av^2}\,dv = (3/8a^2)\sqrt{\pi/a}.$

Apply with $a = m/2kT,$

$\int_0^\infty v^2 f(v)\,dv = 4\pi(m/2\pi kT)^{3/2}(3/8)(2kT/m)^2\sqrt{2\pi kT/m} = (3/2)(2kT/m) = 3kT/m.$

EVALUATE: $\frac{1}{2}m(v^2)_{\text{av}} = \frac{3}{2}kT$ says $\frac{1}{2}m(v^2)_{\text{av}} = 3kT/2,$ so $(v^2)_{\text{av}} = 3kT/m,$ in agreement with our calculation.

18.74. **IDENTIFY:** The equipartition principle says that each molecule has average kinetic energy of $\frac{1}{2}kT$ for each degree of freedom. $I = 2m(L/2)^2,$ where L is the distance between the two atoms in the molecule. $K_{\text{rot}} = \frac{1}{2}I\omega^2.$ $\omega_{\text{rms}} = \sqrt{(\omega^2)_{\text{av}}}.$

SET UP: The mass of one atom is $m = M/N_{\text{A}} = (16.0\times10^{-3}\ \text{kg/mol})/(6.022\times10^{23}\ \text{molecules/mol}) =$ 2.66×10^{-26} kg.

EXECUTE: **(a)** The two degrees of freedom associated with the rotation for a diatomic molecule account for two-fifths of the total kinetic energy, so $K_{\text{rot}} = nRT = (1.00\ \text{mol})(8.3145\ \text{J/mol}\cdot\text{K})(300\ \text{K}) = 2.49\times10^3$ J.

(b) $I = 2m(L/2)^2 = 2\left(\dfrac{16.0\times10^{-3}\ \text{kg/mol}}{6.022\times10^{23}\,\text{molecules/mol}}\right)(6.05\times10^{-11}\ \text{m})^2 = 1.94\times10^{-46}\ \text{kg}\cdot\text{m}^2.$

(c) Since the result in part (b) is for one mole, the rotational kinetic energy for one atom is $K_{\text{rot}}/N_{\text{A}}$ and $\omega_{\text{rms}} = \sqrt{\dfrac{2K_{\text{rot}}/N_{\text{A}}}{I}} = \sqrt{\dfrac{2(2.49\times10^3\ \text{J})}{(1.94\times10^{-46}\ \text{kg}\cdot\text{m}^2)(6.022\times10^{23}\ \text{molecules/mol})}} = 6.52\times10^{12}\ \text{rad/s}.$ This is much larger than the typical value for a piece of rotating machinery.

EVALUATE: The average rotational period, $T = \dfrac{2\pi\ \text{rad}}{\omega_{\text{rms}}},$ for molecules is very short.

18.75. **IDENTIFY:** $f(v)dv$ is the probability that a particle has a speed between v and $v+dv.$ The equation for the Maxwell-Boltzmann distribution gives $f(v).$ v_{mp} is given by $v_{\text{mp}} = \sqrt{2kT/m}.$

SET UP: For O_2, the mass of one molecule is $m = M/N_{\text{A}} = 5.32\times10^{-26}$ kg.

EXECUTE: **(a)** $f(v)dv$ is the fraction of the particles that have speed in the range from v to $v+dv.$ The number of particles with speeds between v and $v+dv$ is therefore $dN = Nf(v)dv$ and

$\Delta N = N\int_v^{v+\Delta v} f(v)dv.$

(b) Setting $v = v_{\text{mp}} = \sqrt{\dfrac{2kT}{m}}$ in $f(v)$ gives $f(v_{\text{mp}}) = 4\pi\left(\dfrac{m}{2\pi kT}\right)^{3/2}\left(\dfrac{2kT}{m}\right)e^{-1} = \dfrac{4}{e\sqrt{\pi}v_{\text{mp}}}.$ For oxygen gas at 300 K, $v_{\text{mp}} = 3.95\times10^2$ m/s and $f(v)\Delta v = 0.0421.$

(c) Increasing v by a factor of 7 changes f by a factor of 7^2e^{-48}, and $f(v)\Delta v = 2.94\times10^{-21}.$

(d) Multiplying the temperature by a factor of 2 increases the most probable speed by a factor of $\sqrt{2},$ and the answers are decreased by $\sqrt{2}$: 0.0297 and $2.08\times10^{-21}.$

(e) Similarly, when the temperature is one-half what it was in parts (b) and (c), the fractions increase by $\sqrt{2}$ to 0.0595 and $4.15\times10^{-21}.$

EVALUATE: **(f)** At lower temperatures, the distribution is more sharply peaked about the maximum (the most probable speed), as is shown in Figure 18.23a in the textbook.

18.76. **IDENTIFY:** Follow the procedure specified in the problem.

SET UP: If $v^2 = x$, then $dx = 2v dv$.

EXECUTE: $\int_0^\infty v f(v) dv = 4\pi \left(\frac{m}{2\pi kT}\right)^{3/2} \int_0^\infty v^3 e^{-mv^2/2kT} dv$. Making the suggested change of variable,

$v^2 = x$. $2v dv = dx$, $v^3 dv = (1/2) x\, dx$, and the integral

becomes $\int_0^\infty v f(v) dv = 2\pi \left(\frac{m}{2\pi kT}\right)^{3/2} \int_0^\infty x e^{-mx/2kT}\, dx = 2\pi \left(\frac{m}{2\pi kT}\right)^{3/2} \left(\frac{2kT}{m}\right)^2 = \frac{2}{\sqrt{\pi}} \sqrt{\frac{2kT}{m}} = \sqrt{\frac{8kT}{\pi m}}$

which is the equation $v_{av} = \sqrt{8kT/\pi m}$.

EVALUATE: The integral $\int_0^\infty v f(v) dv$ is the definition of v_{av}.

18.77. **IDENTIFY:** At equilibrium the net upward force of the gas on the piston equals the weight of the piston. When the piston moves upward the gas expands, the pressure of the gas drops and there is a net downward force on the piston. For simple harmonic motion the net force has the form $F_y = -ky$, for a displacement y from equilibrium, and $f = \frac{1}{2\pi}\sqrt{\frac{k}{m}}$.

SET UP: $pV = nRT$. T is constant.

EXECUTE: **(a)** The difference between the pressure, inside and outside the cylinder, multiplied by the area of the piston, must be the weight of the piston. The pressure in the trapped gas is $p_0 + \frac{mg}{A} = p_0 + \frac{mg}{\pi r^2}$.

(b) When the piston is a distance $h + y$ above the cylinder, the pressure in the trapped gas is $\left(p_0 + \frac{mg}{\pi r^2}\right)\left(\frac{h}{h+y}\right)$ and for values of y small compared to h, $\frac{h}{h+y} = \left(1 + \frac{y}{h}\right)^{-1} \sim 1 - \frac{y}{h}$. The net force, taking the positive direction to be upward, is then

$$F_y = \left[\left(p_0 + \frac{mg}{\pi r^2}\right)\left(1 - \frac{y}{h}\right) - p_0\right](\pi r^2) - mg = -\left(\frac{y}{h}\right)(p_0 \pi r^2 + mg).$$

This form shows that for positive h, the net force is down; the trapped gas is at a lower pressure than the equilibrium pressure, and so the net force tends to restore the piston to equilibrium.

(c) The angular frequency of small oscillations would be given by

$$\omega^2 = \frac{(p_0 \pi r^2 + mg)/h}{m} = \frac{g}{h}\left(1 + \frac{p_0 \pi r^2}{mg}\right).\quad f = \frac{\omega}{2\pi} = \frac{1}{2\pi}\sqrt{\frac{g}{h}}\left(1 + \frac{p_0 \pi r^2}{mg}\right)^{1/2}.$$

If the displacements are not small, the motion is not simple harmonic. This can be seen be considering what happens if $y \sim -h$; the gas is compressed to a very small volume, and the force due to the pressure of the gas would become unboundedly large for a finite displacement, which is not characteristic of simple harmonic motion. If $y >> h$ (but not so large that the piston leaves the cylinder), the force due to the pressure of the gas becomes small, and the restoring force due to the atmosphere and the weight would tend toward a constant, and this is not characteristic of simple harmonic motion.

EVALUATE: The assumption of small oscillations was made when $\frac{h}{h+y}$ was replaced by $1 - y/h$; this is accurate only when y/h is small.

18.78. **IDENTIFY** and **SET UP:** For an ideal gas, its pressure approaches zero as its temperature approaches absolute zero. For volume expansion, $\Delta V = V_0 \beta \Delta T$.

EXECUTE: **(a)** Graph the pressure p versus the temperature T. This graph is shown in Figure 18.78.

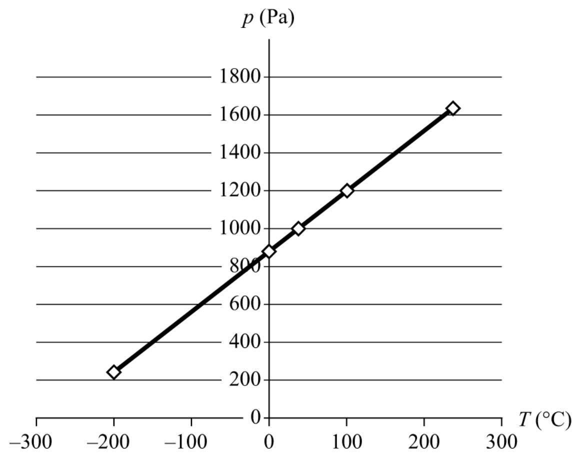

Figure 18.78

The best-fit equation for the graph is $p = (3.2289\ \text{Pa/C°})T + 888.81\ \text{Pa}$. The temperature when $p = 0$ is given by $T = -\dfrac{888.81\ \text{Pa}}{3.2289\ \text{Pa/C°}} = -275°\text{C}$, so this temperature is our determined value for absolute zero.

(b) Solve $\Delta V = V_0 \beta \Delta T$ for the fractional change in volume:

$$\frac{\Delta V}{V} = \beta \Delta T = (3.6\times10^{-5}\ \text{K}^{-1})(232°\text{C} + 195.8°\text{C}) = 1.5\times10^{-2} = 1.5\%.$$

EVALUATE: If the temperature range in an experiment is much less than the extremes in the table, it may be acceptable to ignore the change in volume of the cylinder. But for the range shown in the table, ignoring the volume change of the cylinder would cause a small but significant error.

18.79. IDENTIFY: The measurement gives the dew point. Relative humidity is defined in Problem 18.46, and the vapor pressure table is given with the problem in the text.

SET UP: relative humidity $= \dfrac{\text{partial pressure of water vapor at temperature } T}{\text{vapor pressure of water at temperature } T}$. At $28.0°\text{C}$ the vapor pressure of water is 3.78×10^3 Pa.

EXECUTE: **(a)** The experiment shows that the dew point is $16.0°\text{C}$, so the partial pressure of water vapor at $30.0°\text{C}$ is equal to the vapor pressure at $16.0°\text{C}$, which is 1.81×10^3 Pa.

Thus the relative humidity $= \dfrac{1.81\times10^3\ \text{Pa}}{4.25\times10^3\ \text{Pa}} = 0.426 = 42.6\%$.

(b) For a relative humidity of 35%, the partial pressure of water vapor is $(0.35)(3.78\times10^3\ \text{Pa}) = 1.323\times10^3\ \text{Pa}$. This is close to the vapor pressure at $12°\text{C}$, which would be at an altitude $(30°\text{C} - 12°\text{C})/(0.6\ \text{C°}/100\ \text{m}) = 3\ \text{km}$ above the ground.

(c) For a relative humidity of 80%, the vapor pressure will be the same as the water pressure at around $24°\text{C}$, corresponding to an altitude of about 1 km.

EVALUATE: The lower the dew point is compared to the air temperature, the smaller the relative humidity. Clouds form at a lower height when the relative humidity at the surface is larger.

18.80. IDENTIFY and **SET UP:** With the multiplicity of each score denoted by n_i, the average score is $\left(\dfrac{1}{150}\right)\sum n_i x_i$ and the rms score is $\left[\left(\dfrac{1}{150}\right)\sum n_i x_i^2\right]^{1/2}$. Read the numbers from the bar graph in the problem.

EXECUTE: **(a)** For example, $n_1x_1 = (11)(10)$, $n_2x_2 = (12)(20)$, $n_3x_3 = (24)(30)$, etc. The result is 54.6.

(b) Using the same data, the result is 61.1.

EVALUATE: (c) The rms score is higher than the average score since the rms calculation gives more weight to the higher scores.

18.81. IDENTIFY: We are looking at collisions between nitrogen molecules N_2. Each molecule contains two nitrogen atoms, each of mass $m = 2.3\times10^{-26}$ kg and length $2r$ = 188 pm = 188×10^{-12} m.

SET UP: For a point mass, $I = mr^2$. We also know that $K_{tot} = \frac{1}{2}mv_{cm}^2 + \frac{1}{2}I\omega^2$, $L = I\omega$, and for a point mass $L = mvr$. Angular momentum is conserved during the collision. Since it is an elastic collision, kinetic energy is also conserved.

EXECUTE: **(a)** We want the moment of inertia of a N_2 molecule. Calling m the mass of a single nitrogen atom, we have $I = 2(mr^2) = 2(2.3\times10^{-26}\text{ kg})(94.0\times10^{-12}\text{ m})^2 = 4.1\times10^{-46}\text{ kg}\cdot\text{m}^2$.

(b) and (c) We want to look at conservation of energy and angular momentum during the collision. The mass of each molecule is $2m$.

<u>Energy conservation</u>: $\frac{1}{2}(2m)v_1^2 + \frac{1}{2}(2m)v_1^2 = \frac{1}{2}(2m)v_2^2 + \frac{1}{2}(2m)v_2^2 + \frac{1}{2}I\omega^2 + \frac{1}{2}I\omega^2$. Using $I = 2mr^2$, this equation becomes $v_1^2 = v_2^2 + r^2\omega^2$, giving $v_f = \sqrt{v_i^2 - r^2\omega^2}$.

<u>Angular momentum conservation</u>: Using $L = mvr$ for a translating point mass gives $mv_1(2r) + mv_1(2r) = 2I\omega$. Using $I = 2mr^2$ and simplifying gives $4mv_1r = 4mr^2\omega$, so $\omega = v_i / r$. Combining this result with $v_f = \sqrt{v_i^2 - r^2\omega^2}$ gives $v_f = \sqrt{v_i^2 - v_i^2} = 0$. The final results are: $\omega = v_i / r$ and $v_f = 0$.

(d) The target variable is ω when $v_i = v_{rms}$. Use $v_{rms} = \sqrt{\frac{3kT}{m}}$ with T = 293 K and m = $2(2.3)\times10^{-26}\text{ kg} = 4.6\times10^{-26}\text{ kg}$. This gives v_{rms} = 514 m/s. From part (c) we have $\omega = v_i / r$ so

$$\omega = \frac{514\text{ m/s}}{94\times10^{-12}\text{ m}} = 5.5\times10^{12}\text{ rad/s}.$$

EVALUATE: The molecules stop translational motion but continue to rotate, so all the initial translational kinetic energy is transformed into rotational kinetic energy. We also should note that linear momentum must be conserved during the collision. The initial momentum is zero since the molecules have equal but opposite velocities. The final momentum is zero because they both stop, so momentum is conserved.

18.82. IDENTIFY: The gas pressure in a pneumatic lift is used to support heavy loads.

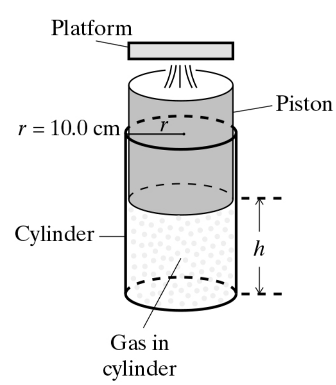

Figure 18.82

SET UP: Fig. 18.82 shows this pneumatic life. The mass of the piston and platform together is 50.0 kg, the gas temperature is a constant 20.0°C = 293 K, and the outside pressure is 1.00 atm. We use $pV = nRT$ and $p = F/A$.

EXECUTE: **(a)** Our target variable is h in the figure. There is 1.00 mol of gas in the cylinder and no load on the platform. The cylinder is airtight, so the only pressure inside is due to the gas that is there. The force due to the pressure on the bottom of the piston supports the weight of the piston and the platform and it also balances the force on the top of the piston due to atmospheric pressure (remember the cylinder is airtight). Using $F = pA$, we have $F = pA = mg + p_{\text{atm}}A$, which becomes $p = \dfrac{mg}{A} + p_{\text{atm}}$.

Using $pV = nRT$, where $V = Ah$ is the volume of gas in the cylinder, we get $\left(\dfrac{mg}{A} + p_{\text{atm}}\right)Ah = nRT$.

Solving for h gives $h = \dfrac{nRT}{mg + p_{\text{atm}}A}$. Using $A = \pi R^2$ with $R = 0.100$ m, $p_{\text{atm}} = 1.01\times10^5$ Pa, $n = 1.00$ mol, $m = 50.0$ kg, and $T = 293$ K, we get $h = 0.665$ m.

(b) The *change* in pressure supports the *added* weight, and this change is due to the change in volume. Since $p = \dfrac{F}{A}$, it follows that $\Delta p = \dfrac{\Delta F}{A}$, where ΔF is the added weight of $(200\text{ kg})(9.80\text{ m/s}^2) = 1960$ N. Using $pV = nRT$ we have

$\Delta p = p_2 - p_1 = nRT\left(\dfrac{1}{V_2} - \dfrac{1}{V_1}\right) = nRT\left(\dfrac{1}{Ah_2} - \dfrac{1}{Ah_1}\right)$. Solving for $1/h_2$ gives

$\dfrac{1}{h_2} = \dfrac{A\Delta p}{nRT} + \dfrac{1}{h_1} = \dfrac{A\left(\dfrac{\Delta F}{A}\right)}{nRT} + \dfrac{1}{h_1} = \dfrac{\Delta F}{nRT} + \dfrac{1}{h_1}$. Putting in $h_1 = 0.665$ m, $\Delta F = 1960$ N, $T = 293$ K, and $n = 1.00$ mol, we have $h_2 = 0.4332$ m. The distance platform drops is $h_1 - h_2 = 0.665\text{ m} - 0.433\text{ m} = 0.232$ m.

(c) The piston and load rise back to the original position, so they rise by a distance $\Delta h = 0.232$ m from part (b). We want to find the amount of gas Δn that enters the cylinder. The pressure must remain the same to support the load, so $p = \dfrac{(m_{\text{piston}} + m_{\text{load}})g}{A} + p_{\text{atm}}$. Using $pV = nRT$ with constant p and T, we have $p\Delta V = RT\Delta n$. Combining this result with $\Delta V = A\Delta h$ and our equation for p, we get

$\left[\dfrac{(m_{\text{piston}} + m_{\text{load}})g}{A} + p_{\text{atm}}\right]A\Delta h = RT\Delta n$. Solving for Δn using $m_{\text{piston}} + m_{\text{load}} = 250$ kg, $\Delta h = 0.232$ m, $T = 293$ K, and $A = \pi R^2$ with $R = 0.100$ m, we get $\Delta n = 0.536$ mol.

(d) We want to find Δn to raise the platform an additional 2.00 m. Everything is the same as in part (c) except that $\Delta h = 2.00$ m instead of 0.232 m. To save a lot of arithmetic, take the ratio of Δn for the two cases and divide out all the common factors. This leaves $\dfrac{\Delta n_2}{\Delta n_1} = \dfrac{\Delta h_2}{\Delta h_1}$, so

$$\Delta n_2 = \Delta n_1 \frac{\Delta h_2}{\Delta h_1} = (0.536\text{ mol})\left(\frac{2.00\text{ m}}{0.232\text{ m}}\right) = 4.62\text{ mol}.$$

(e) We want the rate $\Delta n/\Delta t$ at which air should be introduced so that the platform rises at a steady 10.0 cm/s = 0.100 m/s. From part (c), we have $\left[\dfrac{(m_{\text{piston}} + m_{\text{load}})g}{A} + p_{\text{atm}}\right]A\Delta h = RT\Delta n$. Solving for Δn gives $\Delta n = \left[\dfrac{(m_{\text{piston}} + m_{\text{load}})g}{A} + p_{\text{atm}}\right]\dfrac{A\Delta h}{RT}$. Divide by Δt and realize that $\Delta h/\Delta t = v = 0.100$ m/s, giving $\Delta n = \left[\frac{(m_{\text{piston}} + m_{\text{load}})g}{A} + p_{\text{atm}}\right]\frac{Av}{RT}$. Putting in $v = 0.100$ m/s along with the same numbers as before, we get $\Delta n / \Delta t = 0.231$ mol/s = 231 millimol/s.

EVALUATE: In most cases we've dealt with, the amount of gas has remained constant. But in this case the pressure was increased in parts (c), (d) and (e) by adding gas to the cylinder. This is how you inflate your car tires.

18.83. **IDENTIFY:** The equation $\lambda = \frac{V}{4\pi\sqrt{2}r^2N}$ gives the mean free path λ. In the equation $t_{\text{mean}} = \frac{V}{4\pi\sqrt{2}r^2vN}$, use $v_{\text{rms}} = \sqrt{\frac{3RT}{M}}$ in place of v. $pV = nRT = NkT$. The escape speed is $v_{\text{escape}} = \sqrt{\frac{2GM}{R}}$.

SET UP: For atomic hydrogen, $M = 1.008\times10^{-3}$ kg/mol.

EXECUTE: **(a)** From $\lambda = \frac{V}{4\pi\sqrt{2}r^2N}$, we have

$\lambda = [4\pi\sqrt{2}r^2(N/V)]^{-1} = [4\pi\sqrt{2}(5.0\times10^{-11}\text{ m})^2(50\times10^6\text{ m}^{-3})]^{-1} = 4.5\times10^{11}\text{ m}.$

(b) $v_{\text{rms}} = \sqrt{3RT/M} = \sqrt{3(8.3145\text{ J/mol}\cdot\text{K})(20\text{ K})/(1.008\times10^{-3}\text{ kg/mol})} = 703\text{ m/s}$, and the time between collisions is then $(4.5\times10^{11}\text{ m})/(703\text{ m/s}) = 6.4\times10^8\text{ s}$, about 20 yr. Collisions are not very important.

(c) $p = (N/V)kT = (50/1.0\times10^{-6}\text{ m}^3)(1.381\times10^{-23}\text{ J/K})(20\text{ K}) = 1.4\times10^{-14}\text{ Pa}.$

(d) $v_{\text{escape}} = \sqrt{\frac{2GM}{R}} = \sqrt{\frac{2G(Nm/V)(4\pi R^3/3)}{R}} = \sqrt{(8\pi/3)G(N/V)mR^2}$

$v_{\text{escape}} = \sqrt{(8\pi/3)(6.673\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(50\times10^6\text{ m}^{-3})(1.67\times10^{-27}\text{ kg})(10\times9.46\times10^{15}\text{ m})^2}$

$v_{\text{escape}} = 650\text{ m/s}$. This is lower than v_{rms} and the cloud would tend to evaporate.

(e) In equilibrium (clearly not *thermal* equilibrium), the pressures will be the same; from $pV = NkT$, $kT_{\text{ISM}}(N/V)_{\text{ISM}} = kT_{\text{nebula}}(N/V)_{\text{nebula}}$ and the result follows.

(f) With the result of part (e),

$$T_{\text{ISM}} = T_{\text{nebula}}\left(\frac{(N/V)_{\text{nebula}}}{(N/V)_{\text{ISM}}}\right) = (20\text{ K})\left(\frac{50\times10^6\text{ m}^3}{(200\times10^{-6}\text{ m}^3)^{-1}}\right) = 2\times10^5\text{ K},$$

more than three times the temperature of the sun. This indicates a high average kinetic energy, but the thinness of the ISM means that a ship would not burn up.

EVALUATE: The temperature of a gas is determined by the average kinetic energy per atom of the gas. The energy density for the gas also depends on the number of atoms per unit volume, and this is very small for the ISM.

18.84. **IDENTIFY:** Follow the procedure of Example 18.4, but use $T = T_0 - \alpha y$.

SET UP: $\ln(1+x) \approx x$ when x is very small.

EXECUTE: **(a)** $\frac{dp}{dy} = -\frac{pM}{RT}$, which in this case becomes $\frac{dp}{p} = -\frac{Mg}{R}\frac{dy}{T_0 - \alpha y}$. This integrates to

$$\ln\left(\frac{p}{p_0}\right) = \frac{Mg}{R\alpha}\ln\left(1 - \frac{\alpha y}{T_0}\right),\ \text{or}\ p = p_0\left(1 - \frac{\alpha y}{T_0}\right)^{Mg/R\alpha}.$$

(b) For sufficiently small α, $\ln\left(1 - \frac{\alpha y}{T_0}\right) \approx -\frac{\alpha y}{T_0}$, and this gives the expression derived in Example 18.4.

(c) $\left(1-\dfrac{(0.6\times10^{-2}\ \text{C}°/\text{m})(8863\ \text{m})}{(288\ \text{K})}\right)=0.8154,\ \dfrac{Mg}{R\alpha}=\dfrac{(28.8\times10^{-3})(9.80\ \text{m/s}^2)}{(8.3145\ \text{J/mol}\cdot\text{K})(0.6\times10^{-2}\ \text{C}°/\text{m})}=5.6576$ and

$p_0(0.8154)^{5.6576}=0.315\ \text{atm}$, which is 0.95 of the result found in Example 18.4.

EVALUATE: The pressure is calculated to decrease more rapidly with altitude when we assume that T also decreases with altitude.

18.85. **IDENTIFY** and **SET UP:** Noble gases are monatomic, but nitrogen and oxygen are diatomic, and k is proportional to C_V.

EXECUTE: For a monatomic gas, $C_V = 3/2\ R$, but for a diatomic gas $C_V = 5/2\ R$. A small C_V will give a small k, which means that that a monatomic gas has a smaller thermal conductivity than a diatomic gas. This is true because rotational modes are not present for a monatomic gas, but they are present for a diatomic gas. This makes choice (a) the correct one.

EVALUATE: An added advantage of noble gases is that they are less reactive than other gases and therefore would not react with the window materials.

18.86. **IDENTIFY** and **SET UP:** $k \propto \dfrac{C_V}{r^2\sqrt{M}}$.

EXECUTE: Take the ratio of the thermal conductivities for xenon and helium.

$\dfrac{k_{\text{Xe}}}{k_{\text{He}}}=\sqrt{\dfrac{M_{\text{He}}}{M_{\text{Xe}}}}\left(\dfrac{r_{\text{He}}}{r_{\text{Xe}}}\right)^2=\sqrt{\dfrac{4.0\ \text{g/mol}}{131\ \text{g/mol}}}\left(\dfrac{0.13\ \text{nm}}{0.22\ \text{nm}}\right)^2=0.061$, which is choice (b).

EVALUATE: Since both He and Xe are monatomic, they have the same C_V so this cancels out in the ratio.

18.87. **IDENTIFY** and **SET UP:** The rate of effusion is proportional to v_{rms} and $v_{\text{rms}}=\sqrt{3kT/m}$, so the rate $R = Cv_{\text{rms}} = C\sqrt{3kT/m}$, where C is a constant.

EXECUTE: Take the ratio of the rates for helium and xenon:

$\dfrac{R_{\text{He}}}{R_{\text{Xe}}}=\dfrac{C\sqrt{3kT/M_{\text{He}}}}{C\sqrt{3kT/M_{\text{Xe}}}}=\sqrt{\dfrac{M_{\text{Xe}}}{M_{\text{He}}}}=\sqrt{\dfrac{131}{4.0}}=5.7\approx 6$, which makes choice (c) correct.

EVALUATE: At a given temperature, helium atoms will be moving faster than xenon atoms, so they will more easily move through any small openings (leaks) in the window seal.

19

THE FIRST LAW OF THERMODYNAMICS

VP19.5.1. **IDENTIFY:** We investigate several thermodynamic processes and apply the first law of thermodynamics.

SET UP: The first law of thermodynamics is $\Delta U = Q - W$.

EXECUTE: **(a)** $\Delta U = Q - W$: 2.50×10^3 J $= Q -$ 3.25×10^3 J . $Q =$ 5.75×10^3 J .

(b) $\Delta U = Q - W$: $\Delta U = -7.00\times10^3$ J $- 2.50\times10^4$ J $= -3.20\times10^4$ J.

(c) $\Delta U = Q - W$: 4.25×10^3 J $= 2.40\times10^3$ J $- W$. $W = -1.85\times10^3$ J.

EVALUATE: Careful! Q is the heat put *into* the gas and W is the work done *by* the gas. If heat comes *out* of the gas, Q will be negative. If work is done *on* the gas, W will be negative.

VP19.5.2. **IDENTIFY:** We want to calculate the work that a gas does in various thermodynamic processes.

SET UP: $W = p\Delta V$ if pressure is constant. In general $W = \int p dV$. The work done by a gas is equal to the area under the curve on a pV-diagram.

EXECUTE: **(a)** The pressure is constant, so we use $W = p\Delta V = p(V_2 - V_1) =$

$(6.20\times10^4\ \text{Pa})(4.50\times10^{-3}\ \text{m}^3 - 2.00\times10^{-3}\ \text{m}^3) = 155$ J.

(b) $\Delta V = 0$ so $W = 0$.

(c) Pressure is constant so $W = p\Delta V$ $= (1.25\times10^5\ \text{Pa})(-3.00\times10^{-3}\ \text{m}^3) = -375$ J.

(d) First sketch a pV-diagram of the process, as shown in Fig. VP19.5.2. The work done by the gas is the area under the curve. This area is made up of a triangle above a rectangle. The work is $W = A_{\text{triangle}} + A_{\text{rectangle}}$ which gives

$$W = \frac{1}{2}(2.50\times10^{-3}\ \text{m}^3)(4.00\times10^5\ \text{Pa}) + (2.50\times10^{-3}\ \text{m}^3)(1.50\times10^5\ \text{Pa}) = 875\ \text{J}.$$

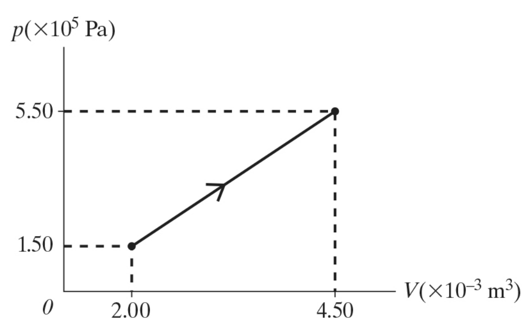

Figure VP19.5.2

EVALUATE: For more complicated curves, the area under the curve can be replaced by the definite integral $W = \int pdV$.

VP19.5.3. IDENTIFY: A gas undergoes various thermodynamic changes. We want to determine the work it does and the heat energy put into it. The ideal gas law and the first law of thermodynamics apply.

SET UP: We apply $\Delta U = Q - W$, $W = p\Delta V$ for constant pressure, and $pV = nRT$. We know that $p_1 = 2.00\times10^5$ Pa and $V_1 = 3.60\times10^{-3}$ m^3.

EXECUTE: **(a)** We want the work the gas does and its internal energy change. First find the work W done by the gas during the two processes 1 and 2. $W = W_1 + W_2$. This gives

$W = p_1\Delta V_1 + p\Delta V_2 = p_1\Delta V_1 + 0 = (2.00\times10^5 \text{ Pa})(-1.20\times10^{-3} \text{ m}^3) = -2.40\times10^2$ J.

Now use $\Delta U = Q - W$ = 1560 J – (–240 J) = 1.80×10^3 J.

(b) We want to find the work the gas does and how much heat flows into the gas. As before,

$W = W_1 + W_2 = p_1\Delta V_1 + p_2\Delta V_2 = 0 + p_2\Delta V_2 = (6.00\times10^5 \text{ Pa})(-1.20\times10^{-3} \text{ m}^3) = -7.20\times10^2$ J.

Now apply $\Delta U = Q - W$ but we first need to find ΔU.

For the process in (a): $p_1V_1 = (2.00\times10^5 \text{ Pa})(3.60\times10^{-3} \text{ m}^3)$ = 720 J

$p_2V_2 = (6.00\times10^5 \text{ Pa})(2.40\times10^{-3} \text{ m}^3)$ = 1440 J

For the process in (b): $p_1V_1 = (2.00\times10^5 \text{ Pa})(3.60\times10^{-3} \text{ m}^3)$ = 720 J

$p_2V_2 = (6.00\times10^5 \text{ Pa})(2.40\times10^{-3} \text{ m}^3)$ = 1440 J

In both cases, the *change* in pV is $\Delta(pV)$ = 720 J. From $pV = nRT$ we see that $nR\Delta T = \Delta(pV)$. Therefore for these two processes, ΔT is the same because $\Delta(pV)$ is the same, and if ΔT is the same, ΔU must also be the same. So $\Delta U = 1.80\times10^3$ J as we found in part (a). Now we use $\Delta U = Q - W$: 1.80×10^3 J $= Q - (-7.20\times10^2$ J), which gives $Q = 1.08\times10^3$ J.

EVALUATE: Note that ΔU depends only on ΔT, so if ΔT is the same ΔU must be the same, no matter what the process. ΔU is independent of path.

VP19.5.4. IDENTIFY: Heat flows into the solid CO_2 causing the gas to do work and change its internal energy. The first law of thermodynamics applies.

SET UP: $\Delta U = Q - W$, for sublimation $Q = mL_{sub}$, where $L_{sub} = 5.71\times10^5$ J/kg. At constant pressure $W = p\Delta V$.

EXECUTE: **(a)** $Q = mL_{sub} = (6.0 \text{ kg})(5.71\times10^5 \text{ J/kg}) = 3.4\times10^6$ J.

(b) We want the work. The pressure is constant so the work done is

$W = p\Delta V = (1.01\times10^5 \text{ Pa})(3.4 \text{ m}^3 - 0.0040 \text{ m}^3) = 3.4\times10^5$ J.

(c) We want the change in internal energy. $\Delta U = Q - W = 3.4\times10^6 \text{ J} - 3.4\times10^5 \text{ J} = 3.1\times10^6$ J.

EVALUATE: The internal energy change is due to an increase in the electrical potential energy of CO_2 molecules.

VP19.6.1. IDENTIFY: This problem involves molar heat capacity and internal energy for the monatomic gas neon.

SET UP: $Q = nC_V\Delta T$, $C_V = \frac{3}{2}R$ for a monatomic gas, $\Delta U = Q - W$. The target variable is the change in internal energy ΔU.

EXECUTE: **(a)** At constant volume, $W = 0$, so $\Delta U = Q = nC_V\Delta T = n\frac{3}{2}R\Delta T$. Using n = 4.00 mol and ΔT = 20.0 K gives ΔU = 998 J.

(b) Since ΔU is independent of path, it is the same for constant volume and constant pressure processes (or any other process) if ΔT is the same. Therefore $\Delta U = Q_V = nC_V\Delta T = n\frac{3}{2}R\Delta T$. Using n = 4.00 mol and ΔT = 15.0 K gives ΔU = 748 J.

(c) Use the same reasoning as in part (b) since ΔU is independent of path. We have $\Delta U = n\frac{3}{2}R\Delta T$, and using n = 4.00 mol and ΔT = 12.0 K gives ΔU = 599 J.

EVALUATE: For *any* ideal gas processes, if ΔT is the same, ΔU is the same.

VP19.6.2. **IDENTIFY:** We are investigating the behavior of ideal N_2 gas. The ideal gas law and the first law of thermodynamics both apply.

SET UP: Use $pV = nRT$, $\Delta U = Q - W$, $Q = nC_V\Delta T$, and $C_V = \frac{3}{2}R$.

EXECUTE: **(a)** We want the initial volume of the gas. Solving $pV = nRT$ for V gives $V = nRT/p$. Using n = 2.10 mol, T = 300 K, and $p = 1.00\times10^5$ Pa gives $V = 5.24\times10^{-2}\ \text{m}^3$.

(b) (i) We want T_2 and ΔU when the pressure doubles at constant volume. For constant volume, $pV = nRT$ tells us that if p doubles, T also doubles, so T_2 = 600 K = 327°C.

For constant volume, W = 0, so $\Delta U = Q = nC_V\Delta T = n\frac{5}{2}R\Delta T$. Using n = 2.10 mol and ΔT = 300 K gives $\Delta U = 1.31\times10^4$ J.

(ii) We want T_2 and ΔU when the volume doubles at constant pressure. For constant pressure, $pV = nRT$ tells us that if V doubles, T also doubles, so T_2 = 600 K = 327°C. By the4 same reasoning as in part (ii), $\Delta U = 1.31\times10^4$ J.

(iii) We want T_2 and ΔU when both pressure and volume double. From $pV = nRT$ we see that if *both* p and V double, the product pV increases by a factor of 4. Therefore T also increases by a factor of 4, so $T_2 = 4T_1$ = 4(300 K) = 1200 K = 927°C.

Now ΔT = 1200 K – 300 K = 900 K, which is 3 times the change in parts (i) and (ii), so ΔU is 3 times as large as before. Therefore $\Delta U = 3(1.31\times10^4\ \text{J}) = 3.93\times10^4$ J.

EVALUATE: Note that if we quadruple the Kelvin temperature we do *not* quadruple the Celsius temperature.

VP19.6.3. **IDENTIFY:** Ideal monatomic argon gas goes through changes in its temperature and pressure. We want to find the resulting change in its internal energy. The ideal gas law and first law of thermodynamics both apply.

SET UP: We use $pV = nRT$, $\Delta U = Q - W$, $\Delta U = nC_V\Delta T$ for *any* process, and $C_V = \frac{3}{2}R$ for a monatomic gas. $pV = nRT$ tells us that $\Delta(pV) = nR\Delta T$, so $\Delta T = \frac{\Delta(pV)}{nR}$. This gives $\Delta U = nC_V\Delta T = n\left(\frac{3}{2}R\right)\frac{\Delta(pV)}{nR} = \frac{3}{2}\Delta(pV) = \frac{3}{2}(p_2V_2 - p_1V_1)$. We want to find ΔU for each process. We know that $p_1 = 1.20\times10^5$ Pa and $V_1 = 0.250\ \text{m}^3$ for each process.

EXECUTE: **(a)** $V_1 = V_2 = 0.250\ \text{m}^3$ and $p_2 = 2.4\times10^5$ Pa. Use $\Delta U = \frac{3}{2}(p_2V_2 - p_1V_1)$ which becomes

$$\Delta U = \frac{3}{2}V_1(p_2 - p_1) = \frac{3}{2}(0.250\ \text{m}^3)(1.20\times10^5\ \text{Pa}) = 4.50\times10^4\ \text{J}.$$

(b) $p_1 = p_2 = 1.20\times10^5$ Pa and $V_2 = 0.125$ m^3. Use $\Delta U = \frac{3}{2}(p_2V_2 - p_1V_1)$ which becomes ΔU = $\frac{3}{2}p_1(V_2 - V_1) = \frac{3}{2}(1.20\times10^5 \text{ Pa})(0.125 \text{ m}^3 - 0.250 \text{ m}^3) = -2.25\times10^4$ J.

(c) $p_2 = 1.80\times10^5$ Pa and $V_2 = 0.600$ m^3. Use $\Delta U = \frac{3}{2}(p_2V_2 - p_1V_1)$ which gives $\Delta U = 1.17\times10^5$ J.

EVALUATE: Even though only one of the processes was at constant volume, we could use $\Delta U = nC_V\Delta T$ to calculate ΔU because ΔU is the same *as if* the process were at constant volume. Remember that ΔU is independent of path.

VP19.6.4. **IDENTIFY:** We increase the temperature of a gas from T to $2T$ by isochoric, isobaric, and adiabatic processes. In each case we want to find the change in the internal energy of the gas, the heat flow into it, and work done by the gas. The first law of thermodynamics applies.

SET UP: $\Delta U = Q - W$, $\Delta U = nC_V\Delta T$, at constant pressure $Q = nC_p\Delta T$, and for a diatomic gas $C_V = \frac{5}{2}R$ and $C_p = \frac{7}{2}R$. The target variable is ΔU for each process.

EXECUTE: **(a)** The *volume* is constant for an isochoric process, so $W = 0$. Therefore $\Delta U = Q - W$ gives $\Delta U = Q = nC_V\Delta T$. Since the temperature increases from T to $2T$, $\Delta T = 2T - T = T$. Thus ΔU = $Q = nC_V\Delta T = n\left(\frac{5}{2}R\right)T = \frac{5}{2}nRT.$

(b) The *pressure* is constant for an isobaric process. $Q = nC_p\Delta T = n\left(\frac{7}{2}R\right)T = \frac{7}{2}nRT$. $\Delta U = nC_V\Delta T$ = $\frac{5}{2}nRT$, the same as in part (a). From $\Delta U = Q - W$ we have $W = Q - \Delta U = \frac{7}{2}nRT - \frac{5}{2}nRT = nRT$.

(c) For an adiabatic process, no heat enters or leaves the gas, so $Q = 0$. From part (a) we know that $\Delta U = nC_V\Delta T = \frac{5}{2}nRT$. $\Delta U = Q - W$ gives $W = Q - \Delta U = 0 - \Delta U = -\frac{5}{2}nRT$.

EVALUATE: As we have seen here, doubling the gas temperature can have different results depending on how the process is carried out.

VP19.7.1. **IDENTIFY:** We are investigating monatomic argon gas during an adiabatic expansion.

SET UP: pV^γ is constant during an adiabatic process, $\gamma = C_p / C_V$, $W = \frac{C_V}{R}(p_1V_1 - p_2V_2)$.

EXECUTE: **(a)** $\gamma = \frac{C_p}{C_V} = \frac{5/2R}{3/2R} = 5/3.$

(b) We want the final pressure p_2. Since pV^γ is constant, we have $p_1V_1^\gamma = p_2V_2^\gamma$ which gives $p_2 = p_1\left(\frac{V_1}{V_2}\right)^\gamma$. Using $p_1 = 4.00\times10^5$ Pa, $V_1 = 2.00\times10^{-3}$ m^3, $V_2 = 6.00\times10^{-3}$ m^3, and $\gamma = 5/3$, we have $p_2 = 6.41\times10^4$ Pa.

(c) We want the work W. $W = \frac{C_V}{R}(p_1V_1 - p_2V_2) = \frac{3/2R}{R}(p_1V_1 - p_2V_2) = \frac{3}{2}(p_1V_1 - p_2V_2)$. Using the pressures and volumes above, we get $W = 623$ J.

EVALUATE: Careful! An adiabatic process is *not* the same as an isothermal process. The temperature can change during an adiabatic process but not during an isothermal process.

VP19.7.2. **IDENTIFY:** We are investigating diatomic oxygen O_2 gas during an adiabatic compression.

SET UP: $TV^{\gamma-1}$ and pV^{γ} are constant during an adiabatic process, $\gamma = C_p / C_V$,

$W = \dfrac{1}{\gamma-1}(p_1V_1 - p_2V_2)$.

EXECUTE: **(a)** $\gamma = \dfrac{C_p}{C_V} = \dfrac{7/2R}{5/2R} = 7/5$.

(b) We want the final volume V_2. Since $TV^{\gamma-1}$ is constant, we have $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$ which gives $V_2^{\gamma-1} = V_1^{\gamma-1}\dfrac{T_1}{T_2}$. Taking the $\gamma-1$ root gives $V_2 = V_1\left(\dfrac{T_1}{T_2}\right)^{1/(\gamma-1)} = V_1\left(\dfrac{T_1}{T_2}\right)^{5/2}$. Using $p_1 = 1.00\times10^5$ Pa, $V_1 = 6.50\times10^{-3}\ \text{m}^3$, $T_1 = 325$ K, and $T_2 = 855$ K, we have $V_2 = 5.79\times10^{-4}\ \text{m}^3$.

(c) We want the final pressure p_2. pV^{γ} is constant so $p_1V_1^{\gamma} = p_2V_2^{\gamma}$. Solving for p_2 gives $p_2 = p_1\left(\dfrac{V_1}{V_2}\right)^{\gamma}$. Using $p_1 = 1.00\times10^5$ Pa, $V_1 = 6.50\times10^{-3}\ \text{m}^3$, and $V_2 = 5.79\times10^{-4}\ \text{m}^3$, we get $p_2 = 2.95\times10^6$ Pa.

(d) We want the work done by the gas during this compression. Use $W = \dfrac{1}{\gamma-1}(p_1V_1 - p_2V_2)$ and put in the numbers from above, we get $W = -2650$ J. The minus sign tells us that work is done *on* the gas to compress it.

EVALUATE: Regardless of the process, the gas must still obey the ideal gas law, so pV/T should be the same for states 1 and 2. Using the values for the pressure, volume, and temperature of each state, we get $p_1V_1/T_1 = 2.00$ J/K and $p_2V_2/T_2 = 2.00$ J/K, so our results are consistent with the ideal gas law.

VP19.7.3. **IDENTIFY:** Monatomic neon gas expands adiabatically.

SET UP: $TV^{\gamma-1}$ and pV^{γ} are constant during an adiabatic process and $\gamma = C_p / C_V = 5/3$. We also have $\Delta U = Q - W$, $\Delta U = nC_V\Delta T$, $pV = nRT$. We know $T_1 = 305$ K, $V_1 = 0.0400\ \text{m}^3$, and $V_2 = 0.0900\ \text{m}^3$, and $n = 5.00$ mol. $Q = 0$ for an adiabatic process.

EXECUTE: **(a)** We want the initial pressure p_1. Solving $pV = nRT$ gives $p_1 = nRT_1/V_1$. Using the numbers above gives $p_1 = 3.17\times10^5$ Pa.

(b) We want the final pressure p_2. Since pV^{γ} is constant, $p_1V_1^{\gamma} = p_2V_2^{\gamma}$. Solving for p_2 gives $p_2 = p_1\left(\dfrac{V_1}{V_2}\right)^{\gamma}$. Using $\gamma = 5/3$ and the values for the volumes and pressure, we get $p_2 = 8.20\times10^4$ Pa.

(c) We want the final temperature T_2. Since $TV^{\gamma-1}$ is constant, $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$. Solving for T_2 gives $T_2 = T_1\left(\dfrac{V_1}{V_2}\right)^{\gamma-1}$. Using $T_1 = 305$ K and the values for the volumes, we have $T_2 = 178$ K.

(d) We want the work done by the gas. For an adiabatic process, $Q = 0$, so $\Delta U = Q - W$ gives $W = -\Delta U = -nC_V\Delta T = -n\left(\dfrac{3}{2}R\right)\Delta T$. Using $\Delta T = 178\ \text{K} - 305\ \text{K}$ and $n = 5.00$ mol, we get $W = 7940$ J.

EVALUATE: We can check the answer in part (d) by using $W = \dfrac{1}{\gamma-1}(p_1V_1 - p_2V_2)$. Putting in the numbers from above gives $W = 7950$ J. The slight difference in the last digit is from rounding.

VP19.7.4. **IDENTIFY:** Diatomic hydrogen gas H_2 expands adiabatically.

SET UP: $TV^{\gamma-1}$ and pV^{γ} are constant during an adiabatic process and $\gamma = C_p / C_V = 7/5$. We also have $\Delta U = Q - W$, $\Delta U = nC_V\Delta T$, $pV = nRT$. We know that $T_1 = 325$ K, $T_2 = 195$ K, and $n = 1.25$ mol. $Q = 0$ for an adiabatic process.

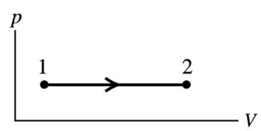
EXECUTE: **(a)** We want the work done by the gas. Using $\Delta U = Q - W$ with $Q = 0$ gives $W = -\Delta U = -nC_V\Delta T = -n\left(\frac{5}{2}R\right)\Delta T = -(1.25\text{ mol})(5/2)(8.314\text{ J/mol}\cdot\text{K})(130\text{ K})$, so $W = -3.38\times10^3$ J.

(b) We want V_2/V_1. Since $TV^{\gamma-1}$ is constant, $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$, which gives Using the numbers gives $\frac{V_2}{V_1} = \left(\frac{325\text{ K}}{195\text{ K}}\right)^{5/2} = 3.59.$

(c) We want p_2/p_1. Solving $p_1V_1^{\gamma} = p_2V_2^{\gamma}$ for p_2/p_1 gives $\frac{p_2}{p_1} = \left(\frac{V_1}{V_2}\right)^{\gamma} = \left(\frac{1}{3.59}\right)^{7/5} = 0.167.$

EVALUATE: The gas must also obey the ideal gas law, so we check the ratio p_2/p_1 ratio. Using $pV = nRT$ this ratio is $\frac{p_2}{p_1} = \frac{nRT_2/V_2}{nRT_1/V_1} = \left(\frac{T_2}{T_1}\right)\left(\frac{V_1}{V_2}\right) = \left(\frac{195\text{ K}}{325\text{ K}}\right)\left(\frac{1}{3.59}\right) = 0.167,$ which agrees with our result in part (c).

19.1. **(a) IDENTIFY** and **SET UP:** The pressure is constant and the volume increases.



The pV-diagram is sketched in Figure 19.1.

Figure 19.1

(b) $W = \int_{V_1}^{V_2} p\,dV$. Since p is constant, $W = p\int_{V_1}^{V_2} dV = p(V_2 - V_1)$. The problem gives T rather than p and V, so use the ideal gas law to rewrite the expression for W.

EXECUTE: $pV = nRT$ so $p_1V_1 = nRT_1$, $p_2V_2 = nRT_2$; subtracting the two equations gives $p(V_2 - V_1) = nR(T_2 - T_1)$. Thus the work is $W = nR(T_2 - T_1)$ during a constant pressure process for an ideal gas. Then $W = nR(T_2 - T_1) = (2.00\text{ mol})(8.3145\text{ J/mol}\cdot\text{K})(107°\text{C} - 27°\text{C}) = +1330$ J.

EVALUATE: The gas expands when heated and does positive work.

19.2. **IDENTIFY:** At constant pressure, $W = p\Delta V = nR\Delta T$. Since the gas is doing work, it must be expanding, so ΔV is positive, which means that ΔT must also be positive.

SET UP: $R = 8.3145$ J/mol·K. ΔT has the same numerical value in kelvins and in C°.

EXECUTE: $\Delta T = \frac{W}{nR} = \frac{2.40\times10^3\text{ J}}{(6\text{ mol})(8.3145\text{ J/mol}\cdot\text{K})} = 48.1\text{ K}$. $\Delta T_K = \Delta T_C$ and $T_2 = 27.0°\text{C} + 48.1\text{ C}° = 75.1°\text{C}$.

EVALUATE: When $W > 0$ the gas expands. When p is constant and V increases, T increases.

19.3. **IDENTIFY:** For an isothermal process $W = nRT\ln(p_1/p_2)$. $pV = nRT$ says V decreases when p increases and T is constant.

SET UP: $T = 65.0 + 273.15 = 338.15$ K. $p_2 = 3p_1$.

EXECUTE: **(a)** The pV-diagram is sketched in Figure 19.3.

(b) $W = (2.00\text{ mol})(8.314\text{ J/mol}\cdot\text{K})(338.15\text{ K})\ln\left(\dfrac{p_1}{3p_1}\right) = -6180\text{ J}.$

EVALUATE: Since V decreases, W is negative.

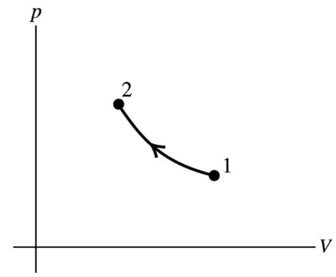


Figure 19.3

19.4. **IDENTIFY:** The work done in a cycle is the area enclosed by the cycle in a pV diagram.
SET UP: **(a)** 1 mm of Hg $= 133.3$ Pa. $p_{\text{gauge}} = p - p_{\text{air}}$. In calculating the enclosed area only changes in pressure enter and you can use gauge pressure. $1\text{ L} = 10^{-3}\text{ m}^3$.
(b) Since $pV = nRT$ and T is constant, the maximum number of moles of air in the lungs is when pV is a maximum. In the ideal gas law the absolute pressure $p = p_{\text{gauge}} + p_{\text{air}}$ must be used.
$p_{\text{air}} = 760$ mm of Hg. 1 mm of Hg = 1 torr.
EXECUTE: **(a)** By counting squares and noting that the area of 1 square is (1 mm of Hg)(0.1 L), we estimate that the area enclosed by the cycle is about $7.5\text{ (mm of Hg)}\cdot\text{L} = 1.00\text{ N}\cdot\text{m}$. The net work done is positive.
(b) The maximum pV is when $p = 11\text{ torr} + 760\text{ torr} = 771\text{ torr} = 1.028\times10^5\text{ Pa}$ and $V = 1.4\text{ L} = 1.4\times10^{-3}\text{ m}^3$. The maximum pV is $(pV)_{\text{max}} = 144\text{ N}\cdot\text{m}$. $pV = nRT$ so

$$n_{\text{max}} = \frac{(pV)_{\text{max}}}{RT} = \frac{144\text{ N}\cdot\text{m}}{(8.315\text{ J/mol}\cdot\text{K})(293\text{ K})} = 0.059\text{ mol}.$$

EVALUATE: While inhaling the gas does positive work on the lungs, but while exhaling the lungs do work on the gas, so the net work is positive.

19.5. **IDENTIFY:** For an isothermal process $W = nRT\ln(p_1/p_2)$. Solve for p_1.
SET UP: For a compression (V decreases) W is negative, so $W = -392$ J. $T = 295.15$ K.
EXECUTE: **(a)** $\dfrac{W}{nRT} = \ln\left(\dfrac{p_1}{p_2}\right)$. $\dfrac{p_1}{p_2} = e^{W/nRT}$.

$$\frac{W}{nRT} = \frac{-392\text{ J}}{(0.305\text{ mol})(8.314\text{ J/mol}\cdot\text{K})(295.15\text{ K})} = -0.5238.$$

$p_1 = p_2 e^{W/nRT} = (1.76\text{ atm})e^{-0.5238} = 1.04\text{ atm}.$
(b) In the process the pressure increases and the volume decreases. The pV-diagram is sketched in Figure 19.5.
EVALUATE: W is the work done by the gas, so when the surroundings do work on the gas, W is negative. The gas was compressed at constant temperature, so its pressure must have increased, which means that $p_1 < p_2$, which is what we found.

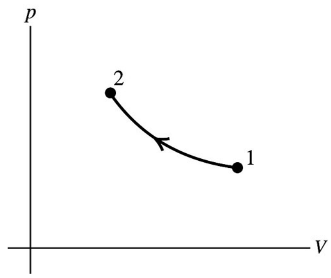

Figure 19.5

19.6. **(a) IDENTIFY** and **SET UP:** The pV-diagram is sketched in Figure 19.6.

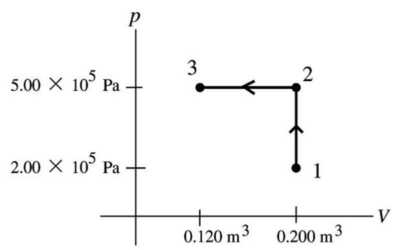

Figure 19.6

(b) Calculate W for each process, using the expression for W that applies to the specific type of process.
EXECUTE: $1 \to 2: \ \Delta V = 0,$ so $W = 0$

$2 \to 3:$ Since p is constant, $W = p\,\Delta V = (5.00\times10^5 \text{ Pa})(0.120 \text{ m}^3 - 0.200 \text{ m}^3) = -4.00\times10^4 \text{ J}$ (W is negative since the volume decreases in the process.)

$W_{\text{tot}} = W_{1\to2} + W_{2\to3} = -4.00\times10^4 \text{ J}.$

EVALUATE: The volume decreases so the total work done is negative.

19.7. **IDENTIFY:** Calculate W for each step using the appropriate expression for each type of process.
SET UP: When p is constant, $W = p\Delta V$. When $\Delta V = 0,\ W = 0.$

EXECUTE: **(a)** $W_{13} = p_1(V_2 - V_1), W_{32} = 0, W_{24} = p_2(V_1 - V_2)$ and $W_{41} = 0.$ The total work done by the system is $W_{13} + W_{32} + W_{24} + W_{41} = (p_1 - p_2)(V_2 - V_1),$ which is the area in the pV plane enclosed by the loop.

(b) For the process in reverse, the pressures are the same, but the volume changes are all the negatives of those found in part (a), so the total work is negative of the work found in part (a).
EVALUATE: When $\Delta V > 0,\ W > 0$ and when $\Delta V < 0,\ W < 0.$

19.8. **IDENTIFY:** An ideal gas undergoes a process during which its pressure is directly proportional to its volume.
SET UP: We want the work done by the gas. We know that $p = \alpha V$ where $\alpha > 0$. The work done by (or on) the gas is the area under the curve in a pV-diagram. Start by making such a diagram in Fig. 19.8.

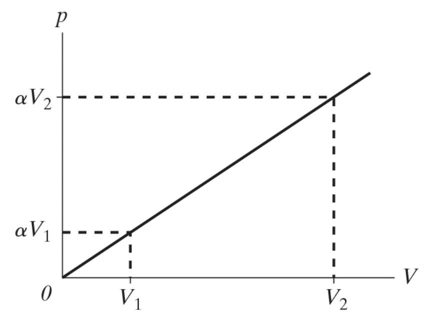

Figure 19.8

EXECUTE: The region from V_1 to V_2 is composed of a triangle plus a rectangle, so the total area is $W = A = A_{\text{tri}} + A_{\text{rect}} = \frac{1}{2}(V_2 - V_1)(\alpha V_2 - \alpha V_1) + (V_2 - V_1)(\alpha V_1) = \frac{\alpha}{2}\left(V_2^2 - V_1^2\right).$

EVALUATE: Since $V_2 > V_1$, the work is positive so the gas does work.

19.9. **IDENTIFY:** $\Delta U = Q - W$. For a constant pressure process, $W = p\Delta V$.

SET UP: $Q = +1.15\times10^5$ J, since heat enters the gas.

EXECUTE: **(a)** $W = p\Delta V = (1.65\times10^5 \text{ Pa})(0.320 \text{ m}^3 - 0.110 \text{ m}^3) = 3.47\times10^4$ J.

(b) $\Delta U = Q - W = 1.15\times10^5 \text{ J} - 3.47\times10^4 \text{ J} = 8.04\times10^4$ J.

EVALUATE: **(c)** $W = p\Delta V$ for a constant pressure process and $\Delta U = Q - W$ both apply to any material. The ideal gas law wasn't used and it doesn't matter if the gas is ideal or not.

19.10. **IDENTIFY:** The type of process is not specified. We can use $\Delta U = Q - W$ because this applies to all processes. Calculate ΔU and then from it calculate ΔT.

SET UP: Q is positive since heat goes into the gas; $Q = +1500$ J.

W is positive since gas expands; $W = +2100$ J.

EXECUTE: $\Delta U = 1500 \text{ J} - 2100 \text{ J} = -600$ J.

We can also use $\Delta U = n(\frac{3}{2}R)\,\Delta T$ since this is true for any process for an ideal gas.

$$\Delta T = \frac{2\,\Delta U}{3nR} = \frac{2(-600 \text{ J})}{3(5.00 \text{ mol})(8.3145 \text{ J/mol}\cdot\text{K})} = -9.62 \text{ C}^\circ$$

$T_2 = T_1 + \Delta T = 127^\circ\text{C} + (-9.62 \text{ C}^\circ) = 117^\circ\text{C}.$

EVALUATE: More energy leaves the gas in the expansion work than enters as heat. The internal energy therefore decreases, and for an ideal gas this means the temperature decreases. We didn't have to convert ΔT to kelvins since ΔT is the same on the Kelvin and Celsius scales.

19.11. **IDENTIFY:** Part *ab* is isochoric, but *bc* is not any of the familiar processes.

SET UP: $pV = nRT$ determines the Kelvin temperature of the gas. The work done in the process is the area under the curve in the *pV* diagram. Q is positive since heat goes into the gas.

$1 \text{ atm} = 1.013\times10^5$ Pa. $1 \text{ L} = 1\times10^{-3} \text{ m}^3$. $\Delta U = Q - W$.

EXECUTE: **(a)** The lowest T occurs when pV has its smallest value. This is at point a, and

$$T_a = \frac{p_a V_a}{nR} = \frac{(0.20 \text{ atm})(1.013\times10^5 \text{ Pa/atm})(2.0 \text{ L})(1.0\times10^{-3} \text{ m}^3/\text{L})}{(0.0175 \text{ mol})(8.315 \text{ J/mol}\cdot\text{K})} = 278 \text{ K}.$$

(b) *a to b*: $\Delta V = 0$ so $W = 0$.

b to c: The work done by the gas is positive since the volume increases. The magnitude of the work is the area under the curve so $W = \frac{1}{2}(0.50 \text{ atm} + 0.30 \text{ atm})(6.0 \text{ L} - 2.0 \text{ L})$ and

$W = (1.6 \text{ L}\cdot\text{atm})(1\times10^{-3} \text{ m}^3/\text{L})(1.013\times10^5 \text{ Pa/atm}) = 162$ J.

(c) For *abc*, $W = 162$ J. $\Delta U = Q - W = 215 \text{ J} - 162 \text{ J} = 53$ J.

EVALUATE: 215 J of heat energy went into the gas. 53 J of energy stayed in the gas as increased internal energy and 162 J left the gas as work done by the gas on its surroundings.

19.12. IDENTIFY and SET UP: Calculate W using the equation for a constant pressure process. Then use $\Delta U = Q - W$ to calculate Q.

EXECUTE: **(a)** $W = \int_{V_1}^{V_2} p\, dV = p(V_2 - V_1)$ for this constant pressure process.

$W = (1.80\times10^5 \text{ Pa})(1.20 \text{ m}^3 - 1.70 \text{ m}^3) = -9.00\times10^4 \text{ J}$. (The volume decreases in the process, so W is negative.)

(b) $\Delta U = Q - W$. $Q = \Delta U + W = -1.40\times10^5 \text{ J} + (-9.00\times10^4 \text{ J}) = -2.30\times10^5 \text{ J}$. Negative Q means heat flows out of the gas.

(c) EVALUATE: $W = \int_{V_1}^{V_2} p\, dV = p(V_2 - V_1)$ (constant pressure) and $\Delta U = Q - W$ apply to *any* system, not just to an ideal gas. We did not use the ideal gas equation, either directly or indirectly, in any of the calculations, so the results are the same whether the gas is ideal or not.

19.13. IDENTIFY: We read values from the pV-diagram and use the ideal gas law, as well as the first law of thermodynamics.

SET UP: Use $pV = nRT$ to calculate T at each point. The work done in a process is the area under the curve in the pV diagram. $\Delta U = Q - W$ for all processes.

EXECUTE: **(a)** $pV = nRT$ so $T = \dfrac{pV}{nR}$.

Point a: $T_a = \dfrac{(2.0\times10^5 \text{ Pa})(0.010 \text{ m}^3)}{(0.450 \text{ mol})(8.315 \text{ J/mol}\cdot\text{K})} = 535 \text{ K}$.

Point b: $T_b = \dfrac{(5.0\times10^5 \text{ Pa})(0.070 \text{ m}^3)}{(0.450 \text{ mol})(8.315 \text{ J/mol}\cdot\text{K})} = 9350 \text{ K}$.

Point c: $T_c = \dfrac{(8.0\times10^5 \text{ Pa})(0.070 \text{ m}^3)}{(0.450 \text{ mol})(8.315 \text{ J/mol}\cdot\text{K})} = 15{,}000 \text{ K}$.

(b) The work done by the gas is positive since the volume increases. The magnitude of the work is the area under the curve: $W = \frac{1}{2}(2.0\times10^5 \text{ Pa} + 5.0\times10^5 \text{ Pa})(0.070 \text{ m}^3 - 0.010 \text{ m}^3) = 2.1\times10^4 \text{ J}$.

(c) $\Delta U = Q - W$ so $Q = \Delta U + W = 15{,}000 \text{ J} + 2.1\times10^4 \text{ J} = 3.6\times10^4 \text{ J}$.

EVALUATE: Q is positive so heat energy goes into the gas.

19.14. IDENTIFY: $\Delta U = Q - W$. For a constant pressure process, $W = p\Delta V$.

SET UP: $Q = +2.20\times10^6 \text{ J}$; $Q > 0$ since this amount of heat goes into the water.

$p = 2.00 \text{ atm} = 2.03\times10^5 \text{ Pa}$.

EXECUTE: **(a)** $W = p\Delta V = (2.03\times10^5 \text{ Pa})(0.824 \text{ m}^3 - 1.00\times10^{23} \text{ m}^3) = 1.67\times10^5 \text{ J}$

(b) $\Delta U = Q - W = 2.20\times10^6 \text{ J} - 1.67\times10^5 \text{ J} = 2.03\times10^6 \text{ J}$.

EVALUATE: $2.20\times10^6 \text{ J}$ of energy enters the water. $1.67\times10^5 \text{ J}$ of energy leaves the materials through expansion work and the remainder stays in the material as an increase in internal energy.

19.15. IDENTIFY: For a certain thermondynamics process, $|Q|$ = 100 J and $|W|$ = 300 J. The first law of thermodynamics applies.

SET UP and EXECUTE: We use $\Delta U = Q - W$ and want to find Q and W for each value of ΔU.

(a) ΔU = +400 J: 400 J = $Q - W$, so Q = +100 J and W = –300 J.
(b) ΔU = +200 J: 200 J = $Q - W$, so Q = –100 J and W = –300 J.
(c) ΔU = –200 J: –200 J = $Q - W$, so Q = +100 J and W = +300 J.

(d) $\Delta U = -400$ J: -400 J $= Q - W$, so $Q = -100$ J and $W = +300$ J.

EVALUATE: All the quantities in $\Delta U = Q - W$ can be positive and negative.

19.16. **IDENTIFY:** $\Delta U = Q - W$.

SET UP: $Q < 0$ when heat leaves the gas.

EXECUTE: For an isothermal process, $\Delta U = 0$, so $W = Q = -410$ J.

EVALUATE: In a compression the volume decreases and $W < 0$.

19.17. **IDENTIFY:** For a constant pressure process, $W = p\Delta V$, $Q = nC_p\Delta T$, and $\Delta U = nC_V\Delta T$. $\Delta U = Q - W$ and $C_p = C_V + R$. For an ideal gas, $p\Delta V = nR\Delta T$.

SET UP: From Table 19.1, $C_V = 28.46$ J/mol·K.

EXECUTE: **(a)** The pV diagram is shown in Figure 19.17 (next page).

(b) $W = pV_2 - pV_1 = nR(T_2 - T_1) = (0.250 \text{ mol})(8.3145 \text{ J/mol}\cdot\text{K})(100.0 \text{ K}) = 208$ J.

(c) The work is done on the piston.

(d) Since $\Delta U = nC_V\Delta T$ holds for any process, we have

$\Delta U = nC_V\Delta T = (0.250 \text{ mol})(28.46 \text{ J/mol}\cdot\text{K})(100.0 \text{ K}) = 712$ J.

(e) Either $Q = nC_p\Delta T$ or $Q = \Delta U + W$ gives $Q = 920$ J to three significant figures.

(f) The lower pressure would mean a correspondingly larger volume, and the net result would be that the work done would be the same as that found in part (b).

EVALUATE: $W = nR\Delta T$, so W, Q and ΔU all depend only on ΔT. When T increases at constant pressure, V increases and $W > 0$. ΔU and Q are also positive when T increases.

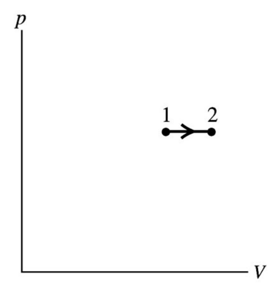

Figure 19.17

19.18. **IDENTIFY:** For constant volume $Q = nC_V\Delta T$. For constant pressure, $Q = nC_p\Delta T$. For any process of an ideal gas, $\Delta U = nC_V\Delta T$.

SET UP: $R = 8.315$ J/mol·K. For helium, $C_V = 12.47$ J/mol·K and $C_p = 20.78$ J/mol·K.

EXECUTE: **(a)** $Q = nC_V\Delta T = (0.0100 \text{ mol})(12.47 \text{ J/mol}\cdot\text{K})(40.0 \text{ C}°) = 4.99$ J. The pV-diagram is sketched in Figure 19.18a.

(b) $Q = nC_p\Delta T = (0.0100 \text{ mol})(20.78 \text{ J/mol}\cdot\text{K})(40.0 \text{ C}°) = 8.31$ J. The pV-diagram is sketched in Figure 19.18b.

(c) More heat is required for the constant pressure process. ΔU is the same in both cases. For constant volume $W = 0$ and for constant pressure $W > 0$. The additional heat energy required for constant pressure goes into expansion work.

(d) $\Delta U = nC_V\Delta T = 4.99$ J for both processes. ΔU is path independent and for an ideal gas depends only on ΔT.

EVALUATE: $C_p = C_V + R$, so $C_p > C_V$.

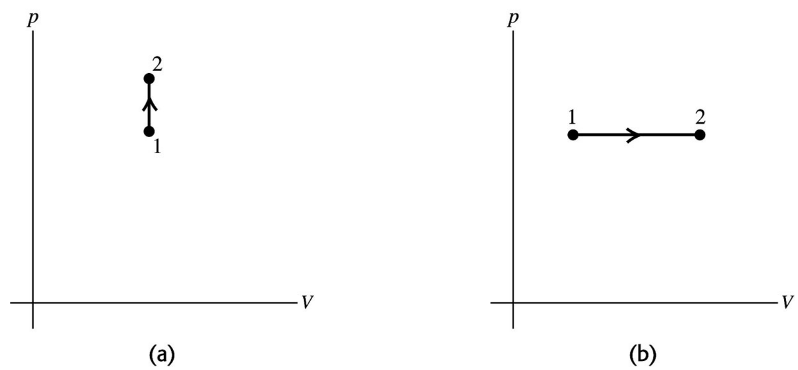

Figure 19.18

19.19. **IDENTIFY:** For constant volume, $Q = nC_V\Delta T$. For constant pressure, $Q = nC_p\Delta T$.

SET UP: From Table 19.1 in the text, $C_V = 20.76 \text{ J/mol}\cdot\text{K}$ and $C_p = 29.07 \text{ J/mol}\cdot\text{K}$.

EXECUTE: **(a)** Using $Q = nC_V\Delta$, $\Delta T = \dfrac{Q}{nC_V} = \dfrac{645 \text{ J}}{(0.185 \text{ mol})(20.76 \text{ J/mol}\cdot\text{K})} = 167.9 \text{ K}$ and $T = 948 \text{ K}$.

The pV-diagram is sketched in Figure 19.19a.

(b) Using $Q = nC_p\Delta T$, $\Delta T = \dfrac{Q}{nC_p} = \dfrac{645 \text{ J}}{(0.185 \text{ mol})(29.07 \text{ J/mol}\cdot\text{K})} = 119.9 \text{ K}$ and $T = 900 \text{ K}$.

The pV-diagram is sketched in Figure 19.19b.

EVALUATE: At constant pressure some of the heat energy added to the gas leaves the gas as expansion work and the internal energy change is less than if the same amount of heat energy is added at constant volume. ΔT is proportional to ΔU.

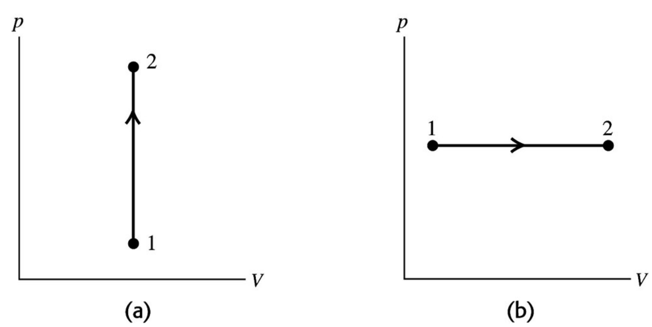

Figure 19.19

19.20. IDENTIFY: A monatomic ideal gas goes between points a and b by two different paths.

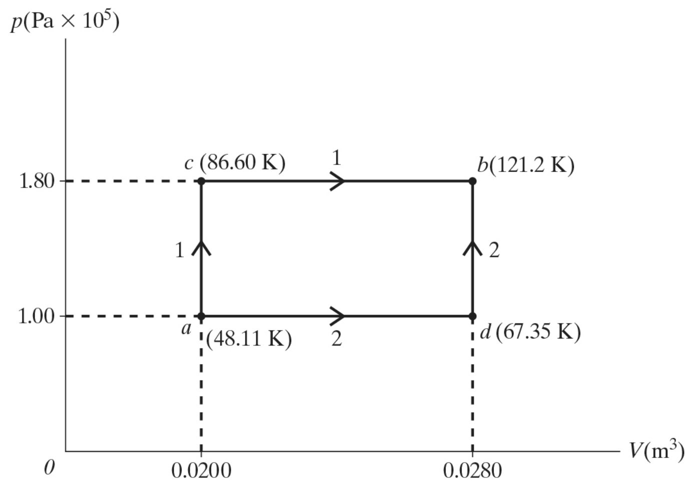

Figure 19.20

SET UP: We want to calculate $Q - W$ for each of the two paths shown in the figure. For a monatomic ideal gas $C_V = \frac{3}{2}R$ and $C_p = \frac{5}{2}R$. We also have $Q_V = nC_V\Delta T$, $Q_p = nC_p\Delta T$, $\Delta U = Q - W$, and $pV = nRT$. All of the processes in these paths are either at constant volume or constant pressure, so we first find the temperature at each of the four points and add them to the pV-diagram.

EXECUTE: From $pV = nRT$ we get $T = pV/nR$. Using the values on the pV-diagram for point a, we have $p_a = 1.00\times10^5$ Pa, $V_a = 0.0200\ \text{m}^3$ and $n = 5.00$ mol. This gives $T_a = 48.11$ K. We could do the same thing for the other three points. Or we could use the fact that, for example, during segment ac the volume is constant, so T/p is constant. This gives us $\frac{T_c}{T_a} = \frac{p_c}{p_a} = \frac{1.80\times10^5\ \text{Pa}}{1.00\times10^5\ \text{Pa}} = 1.8$, so $T_c = 1.8T_a = (1.8)(48.11\ \text{K}) = 86.60$ K. We could apply this type of procedure to the other path segments. The final result is $T_b = 121.2$ K and $T_d = 67.35$ K.

(a) Segment ac: Volume is constant, so $Q_{ac} = nC_V\Delta T_{ac} = n\left(\frac{3}{2}R\right)\Delta T_{ac}$. Using $n = 5.00$ mol and $\Delta T = T_c - T_a = 86.60\ \text{K} - 48.11\ \text{K} = 38.49\ \text{K}$ gives $Q_{ac} = 2400$ J.

$W_{ac} = 0$ because volume is constant.

Segment cb: Pressure is constant, so $Q_{cb} = nC_p\Delta T_{cb} = n\left(\frac{5}{2}R\right)\Delta T_{cb}$. Using the same value for n and $\Delta T = 121.2\ \text{K} - 86.60\ \text{K} = 34.6\ \text{K}$ gives $Q_{cb} = 3595.8$ J.

W_{cb} is the area under the curve in the pV-diagram, which gives us

$W_{cb} = (0.0280\ \text{m}^3 - 0.0200\ \text{m}^3)(1.80\times10^5\ \text{Pa}) = 1440$ J.

Path 1: $Q_1 = Q_{ac} + Q_{cb} = 2400\ \text{J} + 3595.8\ \text{J} = 6000$ J.

(b) Follow the same procedure as for path 1. The results are

Segment ad: Pressure is constant. $Q_{ad} = 2000$ J. W_{ad} = area under the curve = 800 J.

Segment db: Volume is constant. $Q_{db} = 3358$ J. $W_{db} = 0$ because the volume is constant.

Path 2: $Q_2 = 2000\ \text{J} + 3358\ \text{J} = 5360$ J. $W_2 = 800$ J.

(c) Path 1: $Q_1 - W_1 = 6000\ \text{J} - 1440\ \text{J} = 4560$ J.

Path 2: $Q_2 - W_1 = 5360\ \text{J} - 800\ \text{J} = 4560$ J.

The quantity $Q - W$ is the same for both paths.

EVALUATE: Recognize from the first law of thermodynamics that $Q - W$ is equal to ΔU. Since ΔU for an ideal gas depends only on ΔT, and ΔT is the same for paths 1 and 2 since it is $T_b - T_a$ for both of them, it follows that ΔU is the same for both paths. Therefore $Q - W$ must be the same.

19.21. IDENTIFY: $\Delta U = Q - W$. For an ideal gas, $\Delta U = C_V\,\Delta T,$ and at constant pressure, $W = p\Delta V = nR\Delta T$.

SET UP: $C_V = \frac{3}{2}R$ for a monatomic gas.

EXECUTE: $\Delta U = n\left(\frac{3}{2}R\right)\Delta T = \frac{3}{2}p\Delta V = \frac{3}{2}W$. Then $Q = \Delta U + W = \frac{5}{2}W$, so $W/Q = \frac{2}{5}$.

EVALUATE: For diatomic or polyatomic gases, C_V is a different multiple of R and the fraction of Q that is used for expansion work is different.

19.22. IDENTIFY: Apply $pV = nRT$ to calculate T. For this constant pressure process, $W = p\Delta V$. $Q = nC_p\Delta T$. Use $\Delta U = Q - W$ to relate Q, W, and ΔU.

SET UP: $2.50\text{ atm} = 2.53\times10^5\text{ Pa}$. For a monatomic ideal gas, $C_V = 12.47\text{ J/mol}\cdot\text{K}$ and $C_p = 20.78\text{ J/mol}\cdot\text{K}$.

EXECUTE: **(a)** $T_1 = \dfrac{pV_1}{nR} = \dfrac{(2.53\times10^5\text{ Pa})(3.20\times10^{-2}\text{ m}^3)}{(3.00\text{ mol})(8.314\text{ J/mol}\cdot\text{K})} = 325\text{ K}.$

$$T_2 = \frac{pV_2}{nR} = \frac{(2.53\times10^5\text{ Pa})(4.50\times10^{-2}\text{ m}^3)}{(3.00\text{ mol})(8.314\text{ J/mol}\cdot\text{K})} = 456\text{ K}.$$

(b) $W = p\Delta V = (2.53\times10^5\text{ Pa})(4.50\times10^{-2}\text{ m}^3 - 3.20\times10^{-2}\text{ m}^3) = 3.29\times10^3\text{ J}.$

(c) $Q = nC_p\Delta T = (3.00\text{ mol})(20.78\text{ J/mol}\cdot\text{K})(456\text{ K} - 325\text{ K}) = 8.17\times10^3\text{ J}.$

(d) $\Delta U = Q - W = 4.88\times10^3\text{ J}.$

EVALUATE: We could also calculate ΔU as $\Delta U = nC_V\Delta T = (3.00\text{ mol})(12.47\text{ J/mol}\cdot\text{K})(456\text{ K} - 325\text{ K}) = 4.90\times10^3\text{ J}$, which agrees with the value we calculated in part (d).

19.23. IDENTIFY: $\Delta U = Q - W$. Apply $Q = nC_p\Delta T$ to calculate C_p. Apply $\Delta U = nC_V\Delta T$ to calculate C_V. $\gamma = C_p/C_V$.

SET UP: $\Delta T = 15.0\text{ C}° = 15.0\text{ K}$. Since heat is added, $Q = +970\text{ J}$.

EXECUTE: **(a)** $\Delta U = Q - W = 1970\text{ J} - 223\text{ J} = 747\text{ J}.$

(b) $C_p = \dfrac{Q}{n\Delta T} = \dfrac{970\text{ J}}{(1.75\text{ mol})(15.0\text{ K})} = 37.0\text{ J/mol}\cdot\text{K}.$ $C_V = \dfrac{\Delta U}{n\Delta T} = \dfrac{747\text{ J}}{(1.75\text{ mol})(15.0\text{ K})} = 28.5\text{ J/mol}\cdot\text{K}.$

$$\gamma = \frac{C_p}{C_V} = \frac{37.0\text{ J/mol}\cdot\text{K}}{28.5\text{ J/mol}\cdot\text{K}} = 1.30.$$

EVALUATE: The value of γ we calculated is similar to the values given in Tables 19.1 for polyatomic gases.

19.24. IDENTIFY: A monatomic gas is compressed at constant pressure, so this is an isobaric compression.

SET UP: We want to find the work W, heat flow Q, and internal energy change ΔU. We know that $pV = nRT$, $\Delta U = Q - W$, $W = p\Delta V$ when pressure is constant, $Q_p = nC_p\Delta T$, and $\Delta U = nC_V\Delta T$. For an ideal monatomic gas $C_V = \dfrac{3}{2}R$ and $C_p = \dfrac{5}{2}R$.

EXECUTE: **(a)** We want the work done by (or on) the gas. $W = p\Delta V = p(V_2 - V_1)$, which gives $W = (1.80\times10^4\text{ Pa})(0.0500\text{ m}^3 - 0.0800\text{ m}^3) = -540\text{ J}$. The minus sign tells us that work is done *on* the gas.

(b) At constant pressure we have $Q_p = nC_p\Delta T = n\left(\frac{5}{2}R\right)\Delta T$. At constant pressure, $pV = nRT$ tells us that $p\Delta V = nR\Delta T$, so $\Delta T = \frac{p\Delta V}{nR} = \frac{W}{nR}$. Therefore $Q_p = n\left(\frac{5}{2}R\right)\left(\frac{W}{nR}\right) = \frac{5}{2}W = \frac{5}{2}(-540\text{ J}) = -1350\text{ J}$.
The minus sign tells us that heat *leaves* the gas.
(c) $\Delta U = Q - W = -1350\text{ J} - (-540\text{ J}) = -810\text{ J}$. The internal energy *decreases*.

EVALUATE: As a check in part (c), use $\Delta U = nC_V\Delta T = Q_p = n\left(\frac{3}{2}R\right)\left(\frac{W}{nR}\right) = \frac{3}{2}W$, so $Q_p = \frac{3}{2}(-540\text{ J}) = -810\text{ J}$, which agrees with our result.

19.25. IDENTIFY: Calculate W and ΔU and then use the first law to calculate Q.
(a) SET UP: $W = \int_{V_1}^{V_2} p\,dV$

$pV = nRT$ so $p = nRT/V$

$W = \int_{V_1}^{V_2} (nRT/V)\,dV = nRT\int_{V_1}^{V_2} dV/V = nRT\ln(V_2/V_1)$ (work done during an isothermal process).

EXECUTE: $W = (0.150\text{ mol})(8.3145\text{ J/mol}\cdot\text{K})(350\text{ K})\ln(0.25V_1/V_1) = (436.5\text{ J})\ln(0.25) = -605\text{ J}$.
EVALUATE: W for the gas is negative, since the volume decreases.
(b) SET UP: $\Delta U = nC_V\Delta T$ for any ideal gas process.
EXECUTE: $\Delta T = 0$ (isothermal) so $\Delta U = 0$.
EVALUATE: $\Delta U = 0$ for any ideal gas process in which T doesn't change.
(c) SET UP: $\Delta U = Q - W$
EXECUTE: $\Delta U = 0$ so $Q = W = -605\text{ J}$. (Q is negative; the gas liberates 605 J of heat to the surroundings.)
EVALUATE: $Q = nC_V\Delta T$ is only for a constant volume process, so it doesn't apply here.
$Q = nC_p\Delta T$ is only for a constant pressure process, so it doesn't apply here.

19.26. IDENTIFY: We want to investigate how much heat input goes into work for the expansion of liquid ethanol.
SET UP: We are looking at the work W by expanding ethanol due to heat input Q. We use $W = p\Delta V$ when pressure is constant, $\rho = m/V$, $Q = mc\Delta T$ and $\Delta V = \beta V_0\Delta T$.
EXECUTE: **(a)** m = (46.1 g/mol)(5.00 mol) = 0.231 kg.
(b) We want the heat Q that enters the ethanol. $Q = mc\Delta T$ = (0.231 kg)(2428 J/kg·K)(50 K) = 2.80×10^4 J.
(c) We want the work done by the ethanol $W = p\Delta V$ and $\Delta V = \beta V_0\Delta T$. Combining these gives $\Delta V = p\beta V_0\Delta T$. We know the mass and density of the ethanol, so use $\rho = m/V$, which gives $V_0 = m/\rho$. Therefore $W = p\beta(m/\rho)\Delta T$. Using $p = 1.01\times10^5$ Pa, $\beta = 75\times10^{-5}\text{ K}^{-1}$, $\Delta T = 50$ K, ρ = 810 kg/m^3, and m = 0.231 kg gives W = 1.08 J which rounds to W = 1.1 J.
(d) $\frac{W}{Q} = \frac{1.08\text{ J}}{2.80\times10^4\text{ J}} = 3.8\times10^{-5}$.
EVALUATE: The work is a very small fraction of the heat input. Most of that heat goes into increasing the internal energy and therefore the temperature of the ethanol.

19.27. **IDENTIFY:** For an adiabatic process of an ideal gas, $p_1V_1^\gamma = p_2V_2^\gamma$, $W = \dfrac{1}{\gamma-1}(p_1V_1 - p_2V_2)$, and $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$.

SET UP: For a monatomic ideal gas $\gamma = 5/3$.

EXECUTE: **(a)** $p_2 = p_1\left(\dfrac{V_1}{V_2}\right)^\gamma = (1.50\times10^5\ \text{Pa})\left(\dfrac{0.0800\ \text{m}^3}{0.0400\ \text{m}^3}\right)^{5/3} = 4.76\times10^5\ \text{Pa}.$

(b) This result may be substituted into $W = \dfrac{1}{\gamma-1}p_1V_1(1-(V_1/V_2)^{\gamma-1})$, or, substituting the above form for p_2, $W = \dfrac{1}{\gamma-1}p_1V_1(1-(V_1/V_2)^{\gamma-1}) = \dfrac{3}{2}(1.50\times10^5\ \text{Pa})(0.0800\ \text{m}^3)\left(1-\left(\dfrac{0.0800}{0.0400}\right)^{2/3}\right) = -1.06\times10^4\ \text{J}.$

(c) From $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$, $(T_2/T_1) = (V_2/V_1)^{\gamma-1} = (0.0800/0.0400)^{2/3} = 1.59$, and since the final temperature is higher than the initial temperature, the gas is heated.

EVALUATE: In an adiabatic compression $W < 0$ since $\Delta V < 0$. $Q = 0$ so $\Delta U = -W$. $\Delta U > 0$ and the temperature increases.

19.28. **IDENTIFY:** For an adiabatic process of an ideal gas, $p_1V_1^\gamma = p_2V_2^\gamma$, no heat enters or leaves the gas. The ideal gas law still applies.

SET UP: $p_1V_1^\gamma = p_2V_2^\gamma$, $pV = nRT$, $W = \int_{V_1}^{V_2} p\,dV$. For an ideal monatomic gas, $\gamma = 5/3$.

EXECUTE: Solving $p_1V_1^\gamma = p_2V_2^\gamma$ for p_2 and rearranging gives $p_2 = p_1\left(\dfrac{V_1}{V_2}\right)^\gamma$, so we need to find V_2.

Applying $W = \int_{V_1}^{V_2} p\,dV$ to an adiabatic process, we use the fact that pV^γ = constant. In this case, the constant is $p_1V_1^\gamma$ (since we know p_1 and V_1), and we'll call it K for the time being. This tells us that $p = K/V^\gamma$. Using this in the integral, we get $W = \int_{V_1}^{V_2} p\,dV = \int_{V_1}^{V_2} K/V^\gamma\,dV = \dfrac{K}{1-\gamma}\left(V_2^{1-\gamma} - V_1^{1-\gamma}\right)$.

$K = p_1V_1^\gamma = (2500\ \text{Pa})(2.10\ \text{m}^3)^{5/3} = 8609\ \text{N}\cdot\text{m}^3$, $W = 1480$ J, and $\gamma = 5/3$. Putting in these numbers and solving for V_2 gives $V_2 = 2.8697\ \text{m}^3$. Putting this value into $p_2 = p_1\left(\dfrac{V_1}{V_2}\right)^\gamma$ gives

$$p_2 = (2500\ \text{Pa})\left(\frac{2.10\ \text{m}^3}{2.8697\ \text{m}^3}\right)^{5/3} = 1490\ \text{Pa} = 1.49\ \text{kPa}.$$

EVALUATE: The pressure dropped because the gas expanded adiabatically and did work, so our result is reasonable. An alternative approach is the following: We know that $Q = 0$ and $\Delta U = n\left(\dfrac{3}{2}R\right)\Delta T$. We have $W = -\Delta U$, so $\Delta U = -1480$ J. Therefore $-1480\ \text{J} = n\left(\dfrac{3}{2}R\right)\Delta T$, which gives $\Delta T = -23.73$ K.

The ideal gas law gives $T_1 = p_1V_1/nR = (2500\ \text{Pa})(2.10\ \text{m}^3)/[(5.00\ \text{mol})(8.314\ \text{J/mol}\cdot\text{K})] = 126.3$ K.
Therefore $T_2 = T_1 + \Delta T = +102.6$ K. Using $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$ gives

$V_2^{2/3} = V_1^{2/3}\left(\dfrac{T_1}{T_2}\right) = (2.10\ \text{m}^3)\left(\dfrac{126.3\ \text{K}}{102.6\ \text{K}}\right) = 2.019\ \text{m}^2$, so $V_2 = (2.019\ \text{m}^2)^{3/2} = 2.869\ \text{m}^3$. Therefore

$p_2 = nRT_2/V_2 = (5.00\ \text{mol})(8.314\ \text{J/mol}\cdot\text{K})(102.6\ \text{K})/(2.869\ \text{m}^3) = 1490\ \text{Pa} = 1.49\ \text{kPa}.$

19.29. **(a) IDENTIFY and SET UP:** In the expansion the pressure decreases and the volume increases. The pV-diagram is sketched in Figure 19.29.

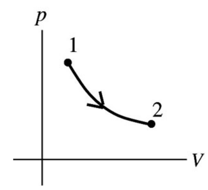

Figure 19.29

(b) Adiabatic means $Q = 0$.

Then $\Delta U = Q - W$ gives $W = -\Delta U = -nC_V\,\Delta T = nC_V(T_1 - T_2)$.

$C_V = 12.47\ \text{J/mol}\cdot\text{K}$ (Table 19.1).

EXECUTE: $W = (0.450\ \text{mol})(12.47\ \text{J/mol}\cdot\text{K})(66.0°\text{C} - 10.0°\text{C}) = +314\ \text{J}$.

W positive for $\Delta V > 0$ (expansion)

(c) $\Delta U = -W = -314\ \text{J}$.

EVALUATE: There is no heat energy input. The energy for doing the expansion work comes from the internal energy of the gas, which therefore decreases. For an ideal gas, when T decreases, U decreases.

19.30. **IDENTIFY:** Assume the expansion is adiabatic. $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$ relates V and T. Assume the air behaves as an ideal gas, so $\Delta U = nC_V\Delta T$. Use $pV = nRT$ to calculate n.

SET UP: For air, $C_V = 29.76\ \text{J/mol}\cdot\text{K}$ and $\gamma = 1.40$. $V_2 = 0.800V_1$. $T_1 = 293.15\ \text{K}$.

$p_1 = 2.026\times10^5\ \text{Pa}$. For a sphere, $V = \frac{4}{3}\pi r^3$.

EXECUTE: **(a)** $T_2 = T_1\left(\dfrac{V_1}{V_2}\right)^{\gamma-1} = (293.15\ \text{K})\left(\dfrac{V_1}{0.800V_1}\right)^{0.40} = 320.5\ \text{K} = 47.4°\text{C}$.

(b) $V_1 = \frac{4}{3}\pi r^3 = \dfrac{4\pi}{3}(0.1195\ \text{m})^3 = 7.15\times10^{-3}\ \text{m}^3$.

$$n = \frac{p_1V_1}{RT_1} = \frac{(2.026\times10^5\ \text{Pa})(7.15\times10^{-3}\ \text{m}^3)}{(8.314\ \text{J/mol}\cdot\text{K})(293.15\ \text{K})} = 0.594\ \text{mol}.$$

$\Delta U = nC_V\Delta T = (0.594\ \text{mol})(20.76\ \text{J/mol}\cdot\text{K})(321\ \text{K} - 293\ \text{K}) = 345\ \text{J}$.

EVALUATE: We could also use $\Delta U = -W = -\dfrac{1}{\gamma-1}(p_1V_1 - p_2V_2)$ to calculate ΔU, if we first found p_2 from $pV = nRT$.

19.31. **IDENTIFY:** Combine $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$ with $pV = nRT$ to obtain an expression relating T and p for an adiabatic process of an ideal gas.

SET UP: $T_1 = 299.15\ \text{K}$.

EXECUTE: $V = \dfrac{nRT}{p}$ so $T_1\left(\dfrac{nRT_1}{p_1}\right)^{\gamma-1} = T_2\left(\dfrac{nRT_2}{p_2}\right)^{\gamma-1}$ and $\dfrac{T_1^\gamma}{p_1^{\gamma-1}} = \dfrac{T_2^\gamma}{p_2^{\gamma-1}}$.

$$T_2 = T_1\left(\frac{p_2}{p_1}\right)^{(\gamma-1)/\gamma} = (299.15\ \text{K})\left(\frac{0.850\times10^5\ \text{Pa}}{1.01\times10^5\ \text{Pa}}\right)^{0.4/1.4} = 284.8\ \text{K} = 11.6°\text{C}.$$

EVALUATE: For an adiabatic process of an ideal gas, when the pressure decreases the temperature decreases.

19.32. IDENTIFY: $pV = nRT$ For an adiabatic process, $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$.

SET UP: For an ideal monatomic gas, $\gamma = 5/3$.

EXECUTE: **(a)** $T = \dfrac{pV}{nR} = \dfrac{(1.00\times10^5 \text{ Pa})(2.50\times10^{-3} \text{ m}^3)}{(0.1 \text{ mol})(8.3145 \text{ J/mol}\cdot\text{K})} = 301 \text{ K}.$

(b) (i) Isothermal: If the expansion is *isothermal*, the process occurs at constant temperature and the final temperature is the same as the initial temperature, namely 301 K.

$p_2 = p_1(V_1/V_2) = \frac{1}{2}p_1 = 5.00\times10^4$ Pa.

(ii) Isobaric: $\Delta p = 0$ so $p_2 = 1.00\times10^5$ Pa. $T_2 = T_1(V_2/V_1) = 2T_1 = 602$ K.

(iii) Adiabatic: Using $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$, $T_2 = \dfrac{T_1V_1^{\gamma-1}}{V_2^{\gamma-1}} = \dfrac{(301 \text{ K})(V_1)^{0.67}}{(2V_1)^{0.67}} = (301 \text{ K})(\tfrac{1}{2})^{0.67} = 189 \text{ K}.$ Then

$pV = nRT$ gives $p_2 = 3.14\times10^4$ Pa.

EVALUATE: In an isobaric expansion, T increases. In an adiabatic expansion, T decreases.

19.33. IDENTIFY: As helium undergoes an adiabatic process it's Kelvin temperature doubles.

SET UP: Treat helium as an ideal monatomic gas, so $\gamma = 5/3$. We also have $pV = nRT$ and $p_1V_1^\gamma = p_2V_2^\gamma$, and we know that $T_2 = 2T_1$. We want the factor by which p changes during this process, so we want p_2/p_1.

EXECUTE: From $pV = nRT$ we have $V = nRT/p$. Taking the ratio of the volumes gives $\dfrac{V_1}{V_2} = \dfrac{nRT_1/p_1}{nRT_2/p_2} = \left(\dfrac{T_1}{T_2}\right)\left(\dfrac{p_2}{p_1}\right)$. Now use $p_1V_1^\gamma = p_2V_2^\gamma$, which gives $\dfrac{p_2}{p_1} = \left(\dfrac{V_1}{V_2}\right)^\gamma$. Use the previous result for the volume ration to get $\dfrac{p_2}{p_1} = \left(\dfrac{T_1}{T_2}\cdot\dfrac{p_2}{p_1}\right)^\gamma$, which can be arranged to get $\dfrac{p_2}{p_1}\left(\dfrac{p_2}{p_1}\right)^{-\gamma} = \left(\dfrac{T_1}{T_2}\right)^\gamma$. Using $\gamma = 5/3$ and $T_1/T_2 = ½$, this becomes $\dfrac{p_2}{p_1} = \left(\dfrac{1}{2}\right)^{-5/2} = 4\sqrt{2}$.

EVALUATE: Look at the volume ratio V_2/V_1, which is $\dfrac{V_2}{V_1} = \dfrac{nRT_2/p_2}{nRT_1/p_1} = \left(\dfrac{T_2}{T_1}\right)\left(\dfrac{p_1}{p_2}\right)$, so $\dfrac{V_2}{V_1} = (2)\left(\dfrac{1}{4\sqrt{2}}\right) = \dfrac{\sqrt{2}}{4} \approx 0.354$, which means that the volume decreases. This is reasonable because the only way to increase the gas temperature adiabatically is to compress it.

19 34. IDENTIFY: We are looking at an adiabatic compression of an ideal diatomic gas in which the temperature increases.

SET UP: We want to find the change ΔU in the internal energy of the gas. $\Delta U = nC_V\Delta T$ for any process, and $C_V = \dfrac{5}{2}R$ for an ideal diatomic gas.

EXECUTE: $\Delta U = n\left(\dfrac{5}{2}R\right)\Delta T$. We need n. We know that 1 mol of a gas contains N_A molecules so the number N of molecules is nN_A. Therefore $n = \dfrac{N}{N_A} = \dfrac{3.01\times10^{20} \text{ molecules}}{6.022\times10^{23} \text{ molecules/mol}} = 4.99\times10^{-4}$ mol.

Now we use $\Delta U = n\left(\dfrac{5}{2}R\right)\Delta T$ with $\Delta T = 35.0$ K to get $\Delta U = 0.364$ J.

EVALUATE: For an adiabatic process, $\Delta U = Q - W = 0 - W$, which tells us that $W = -0.364$ J. Work was done *on* the gas which compressed it and increased its internal energy and therefore its temperature.

19.35. **IDENTIFY** and **SET UP:** For an ideal gas, $pV = nRT$. The work done is the area under the path in the pV-diagram.

EXECUTE: **(a)** The product pV increases and this indicates a temperature increase.

(b) The work is the area in the pV plane bounded by the blue line representing the process and the verticals at V_a and V_b. The area of this trapezoid is

$\frac{1}{2}(p_b + p_a)(V_b - V_a) = \frac{1}{2}(2.40\times10^5 \text{ Pa})(0.0400 \text{ m}^3) = 4800 \text{ J}.$

EVALUATE: The work done is the average pressure, $\frac{1}{2}(p_1 + p_2)$, times the volume increase.

19.36. **IDENTIFY:** Steam from boiling water slightly lifts the lid of a pot. This does work on the lid and therefore cools down the steam slightly. We want to find out the decrease in temperature of the steam.

SET UP and EXECUTE: For an adiabatic process, $Q = 0$ so $\Delta U = Q - W = -W$. $\Delta U = nC_V\Delta T$ where $C_V = \dfrac{5}{2}R$ for an ideal diatomic gas. Treat the air as N_2, which is diatomic.

(a) Estimate: Mass of the lie is 250 g = 0.250 kg.

(b) Estimate: Lid rises 0.50 cm = 0.0050 m.

(c) $W = mgh = (0.250 \text{ kg})(9.80 \text{ m/s}^2)(0.0050 \text{ m}) = 0.12 \text{ J}$.

(d) The expansion is adiabatic so $W = -\Delta U = -nC_V\Delta T = -n\left(\dfrac{5}{2}R\right)\Delta T$. Therefore

$\Delta T = -\dfrac{2W}{5nR} = -\dfrac{2(0.12 \text{ J})}{5\left(\dfrac{1}{11.2} \text{ mol}\right)(8.314 \text{ J/mol}\cdot\text{K})} = -0.06 \text{ K}$. The minus sign tells us that the temperature has dropped by 0.06 K = 0.06 C° ≈ 0.1 F.

EVALUATE: This is a very small temperature change, but based upon experience it seems reasonable.

19.37. **IDENTIFY:** We can read the values from the pV-diagram and apply the ideal gas law and the first law of thermodynamics.

SET UP: At each point $pV = nRT$, with $T = 85 \text{ K} + 273 \text{ K} = 358 \text{ K}$. For an isothermal process of an ideal gas, $W = nRT \ln(V_2/V_1)$. $\Delta U = nC_V\,\Delta T$ for any ideal gas process.

EXECUTE: **(a)** At point b, $p = 0.200 \text{ atm} = 2.026\times10^4 \text{ Pa}$ and $V = 0.100 \text{ m}^3$.

$$n = \frac{pV}{RT} = \frac{(2.026\times10^4 \text{ Pa})(0.100 \text{ m}^3)}{(8.315 \text{ J/mol}\cdot\text{K})(358 \text{ K})} = 0.681 \text{ moles.}$$

(b) n, R, and T are constant so $p_aV_a = p_bV_b$.

$$V_a = V_b\left(\frac{p_b}{p_a}\right) = (0.100 \text{ m}^3)\left(\frac{0.200 \text{ atm}}{0.600 \text{ atm}}\right) = 0.0333 \text{ m}^3.$$

(c) $W = nRT \ln(V_b/V_a) = (0.681 \text{ mol})(8.315 \text{ J/mol}\cdot\text{K})(358 \text{ K})\ln\left(\dfrac{0.100 \text{ m}^3}{0.0333 \text{ m}^3}\right) = 2230 \text{ J} = 2.23 \text{ kJ}.$

W is positive and corresponds to work done by the gas.

(d) $\Delta U = nC_V\,\Delta T$ so for an isothermal process $(\Delta T = 0)$, $\Delta U = 0$.

EVALUATE: W is positive when the volume increases, so the area under the curve is positive. For *any* isothermal process, $\Delta U = 0$.

19.38. **IDENTIFY:** Segment ab is isobaric, bc is isochoric, and ca is isothermal.

SET UP: He is a monatomic gas so $C_V = \frac{3}{2}R$ and $C_p = \frac{5}{2}R$. For any process of an ideal gas, $\Delta U = nC_V\Delta T$. For an isothermal process of an ideal gas, $\Delta U = 0$ so $Q = W = nRT\ln(V_2/V_1)$.

EXECUTE: **(a)** Apply $pV = nRT$ to states *a* and *c*. $T_a = T_c$ so *nRT* is constant and $p_aV_a = p_cV_c$.

$$p_a = p_c\left(\frac{V_c}{V_a}\right) = (2.0\times10^5\ \text{Pa})\left(\frac{0.040\ \text{m}^3}{0.010\ \text{m}^3}\right) = 8.0\times10^5\ \text{Pa}.$$

(b) $T_a = \dfrac{p_aV_a}{nR} = \dfrac{(8.0\times10^5\ \text{Pa})(0.010\ \text{m}^3)}{(3.25\ \text{mol})(8.315\ \text{J/mol}\cdot\text{K})} = 296\ \text{K};$

$$T_b = \frac{p_bV_b}{nR} = \frac{(8.0\times10^5\ \text{Pa})(0.040\ \text{m}^3)}{(3.25\ \text{mol})(8.315\ \text{J/mol}\cdot\text{K})} = 1184\ \text{K};$$

$$T_c = \frac{p_cV_c}{nR} = \frac{(2.0\times10^5\ \text{Pa})(0.040\ \text{m}^3)}{(3.25\ \text{mol})(8.315\ \text{J/mol}\cdot\text{K})} = 296\ \text{K} = T_a.$$

(c) <u>*ab*</u>: $Q = nC_p\Delta T = (3.25\ \text{mol})(\tfrac{5}{2})(8.315\ \text{J/mol}\cdot\text{K})(1184\ \text{K} - 296\ \text{K}) = 6.00\times10^4\ \text{J}$; heat enters the gas.

<u>*bc*</u>: $Q = nC_V\Delta T = (3.25\ \text{mol})(\tfrac{3}{2})(8.315\ \text{J/mol}\cdot\text{K})(296\ \text{K} - 1184\ \text{K}) = -3.60\times10^4\ \text{J}$; heat leaves the gas.

<u>*ca*</u>: $Q = nRT\ln\left(\dfrac{V_a}{V_c}\right) = (3.25\ \text{mol})(8.315\ \text{J/mol}\cdot\text{K})(296\ \text{K})\ln\left(\dfrac{0.010\ \text{m}^3}{0.040\ \text{m}^3}\right) = -1.11\times10^4\ \text{J}$; heat leaves the gas.

(d) <u>*ab*</u>: $\Delta U = nC_V\Delta T = (3.25\ \text{mol})(\tfrac{3}{2})(8.315\ \text{J/mol}\cdot\text{K})(1184\ \text{K} - 296\ \text{K}) = 3.60\times10^4\ \text{J}$; the internal energy increased.

<u>*bc*</u>: $\Delta U = nC_V\Delta T = (3.25\ \text{mol})(\tfrac{3}{2})(8.315\ \text{J/mol}\cdot\text{K})(296\ \text{K} - 1184\ \text{K}) = -3.60\times10^4\ \text{J}$; the internal energy decreased.

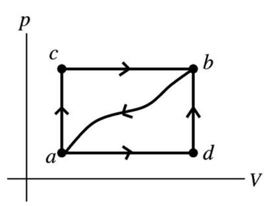
<u>*ca*</u>: $\Delta T = 0$ so $\Delta U = 0$.

EVALUATE: As we saw in (d), for any closed path on a *pV* diagram, $\Delta U = 0$ because we are back at the same values of *P*, *V*, and *T*.

19.39. **IDENTIFY:** Use $\Delta U = Q - W$ and the fact that ΔU is path independent.

$W > 0$ when the volume increases, $W < 0$ when the volume decreases, and $W = 0$ when the volume is constant. $Q > 0$ if heat flows into the system.

SET UP: The paths are sketched in Figure 19.39.



$Q_{acb} = +90.0\ \text{J}$ (positive since heat flows in)

$W_{acb} = +60.0\ \text{J}$ (positive since $\Delta V > 0$)

Figure 19.39

EXECUTE: **(a)** $\Delta U = Q - W$

ΔU is path independent; *Q* and *W* depend on the path.

$\Delta U = U_b - U_a$

This can be calculated for any path from *a* to *b*, in particular for path *acb*:

$\Delta U_{a\to b} = Q_{acb} - W_{acb} = 90.0\ \text{J} - 60.0\ \text{J} = 30.0\ \text{J}.$

Now apply $\Delta U = Q - W$ to path *adb*; $\Delta U = 30.0\ \text{J}$ for this path also.

$W_{adb} = +15.0\ \text{J}$ (positive since $\Delta V > 0$)

$\Delta U_{a\to b} = Q_{adb} - W_{adb}$ so $Q_{adb} = \Delta U_{a\to b} + W_{adb} = 30.0\ \text{J} + 15.0\ \text{J} = +45.0\ \text{J}.$

(b) Apply $\Delta U = Q - W$ to path *ba*: $\Delta U_{b\to a} = Q_{ba} - W_{ba}$

$W_{ba} = -35.0\text{ J}$ (negative since $\Delta V < 0$)

$\Delta U_{b\to a} = U_a - U_b = -(U_b - U_a) = -\Delta U_{a\to b} = -30.0\text{ J}$

Then $Q_{ba} = \Delta U_{b\to a} + W_{ba} = -30.0\text{ J} - 35.0\text{ J} = -65.0\text{ J}$.

($Q_{ba} < 0;$ the system liberates heat.)

(c) $U_a = 0,\ U_d = 8.0\text{ J}$

$\Delta U_{a\to b} = U_b - U_a = +30.0\text{ J}$, so $U_b = +30.0\text{ J}$.

<u>Process $a \to d$</u>:

$\Delta U_{a\to d} = Q_{ad} - W_{ad}$

$\Delta U_{a\to d} = U_d - U_a = +8.0\text{ J}$

$W_{adb} = +15.0\text{ J}$ and $W_{adb} = W_{ad} + W_{db}$. But the work W_{db} for the process $d \to b$ is zero since $\Delta V = 0$ for that process. Therefore $W_{ad} = W_{adb} = +15.0\text{ J}$.

Then $Q_{ad} = \Delta U_{a\to d} + W_{ad} = +8.0\text{ J} + 15.0\text{ J} = +23.0\text{ J}$ (positive implies heat absorbed).

<u>Process $d \to b$</u>:

$\Delta U_{d\to b} = Q_{db} - W_{db}$

$W_{db} = 0,$ as already noted.

$\Delta U_{d\to b} = U_b - U_d = 30.0\text{ J} - 8.0\text{ J} = +22.0\text{ J}$.

Then $Q_{db} = \Delta U_{d\to b} + W_{db} = +22.0\text{ J}$ (positive; heat absorbed).

EVALUATE: The signs of our calculated Q_{ad} and Q_{db} agree with the problem statement that heat is absorbed in these processes.

19.40. **IDENTIFY:** $\Delta U = Q - W$.

SET UP: $W = 0$ when $\Delta V = 0$.

EXECUTE: For each process, $Q = \Delta U + W$. No work is done in the processes *ab* and *dc*, and so $W_{bc} = W_{abc} = 450\text{ J}$ and $W_{ad} = W_{adc} = 120\text{ J}$. The heat flow for each process is: for *ab*, $Q = 90\text{ J}$. For *bc*, $Q = 440\text{ J} + 450\text{ J} = 890\text{ J}$. For *ad*, $Q = 180\text{ J} + 120\text{ J} = 300\text{ J}$. For *dc*, $Q = 350\text{ J}$. Heat is absorbed in each process. Note that the arrows representing the processes all point in the direction of increasing temperature (increasing *U*).

EVALUATE: ΔU is path independent so is the same for paths *adc* and *abc*.
$Q_{adc} = 300\text{ J} + 350\text{ J} = 650\text{ J}$. $Q_{abc} = 90\text{ J} + 890\text{ J} = 980\text{ J}$. *Q* and *W* are path dependent and are different for these two paths.

19.41. **IDENTIFY:** Use $pV = nRT$ to calculate T_c/T_a. Calculate ΔU and *W* and use $\Delta U = Q - W$ to obtain *Q*.

SET UP: For path *ac*, the work done is the area under the line representing the process in the *pV*-diagram.

EXECUTE: **(a)** $\dfrac{T_c}{T_a} = \dfrac{p_cV_c}{p_aV_a} = \dfrac{(1.0\times 10^5\text{ J})(0.060\text{ m}^3)}{(3.0\times 10^5\text{ J})(0.020\text{ m}^3)} = 1.00.\ T_c = T_a$.

(b) Since $T_c = T_a$, $\Delta U = 0$ for process *abc*. For *ab*, $\Delta V = 0$ and $W_{ab} = 0$. For *bc*, *p* is constant and $W_{bc} = p\Delta V = (1.0\times 10^5\text{ Pa})(0.040\text{ m}^3) = 4.0\times 10^3\text{ J}$. Therefore, $W_{abc} = +4.0\times 10^3\text{ J}$. Since $\Delta U = 0$, $Q = W = +4.0\times 10^3\text{ J}$. $4.0\times 10^3\text{ J}$ of heat flows into the gas during process *abc*.

(c) $W = \frac{1}{2}(3.0\times 10^5\text{ Pa} + 1.0\times 10^5\text{ Pa})(0.040\text{ m}^3) = +8.0\times 10^3\text{ J}$. $Q_{ac} = W_{ac} = +8.0\times 10^3\text{ J}$.

EVALUATE: The work done is path dependent and is greater for process *ac* than for process *abc*, even though the initial and final states are the same.

19.42. **IDENTIFY:** Apply the appropriate expression for W for each type of process. $pV = nRT$ and $C_p = C_V + R.$

SET UP: $R = 8.315$ J/mol·K.

EXECUTE: Path ac has constant pressure, so $W_{ac} = p\Delta V = nR\Delta T,$ and

$W_{ac} = nR(T_c - T_a) = (3\text{ mol})(8.3145\text{ J/mol}\cdot\text{K})(492\text{ K} - 300\text{ K}) = 4.789\times 10^3\text{ J}.$

Path cb is adiabatic $(Q = 0)$, so $W_{cb} = Q - \Delta U = -\Delta U = -nC_V\Delta T,$ and using $C_V = C_p - R,$

$W_{cb} = -n(C_p - R)(T_b - T_c) = -(3\text{ mol})(29.1\text{ J/mol}\cdot\text{K} - 8.3145\text{ J/mol}\cdot\text{K})(600\text{ K} - 492\text{ K}) = -6.735\times 10^3\text{ J}.$

Path ba has constant volume, so $W_{ba} = 0.$ So the total work done is

$$W = W_{ac} + W_{cb} + W_{ba} = 4.789\times 10^3\text{ J} - 6.735\times 10^3\text{ J} + 0 = -1.95\times 10^3\text{ J}.$$

EVALUATE: $W > 0$ when $\Delta V > 0,$ $W < 0$ when $\Delta V < 0$ and $W = 0$ when $\Delta V = 0.$

19.43. **IDENTIFY:** Segment ab is isochoric, bc is isothermal, and ca is isobaric.

SET UP: For bc, $\Delta T = 0,$ $\Delta U = 0,$ and $Q = W = nRT\ln(V_c/V_b).$ For ideal H_2 (diatomic), $C_V = \frac{5}{2}R$ and $C_p = \frac{7}{2}R.$ $\Delta U = nC_V\ \Delta T$ for any process of an ideal gas.

EXECUTE: **(a)** $T_b = T_c.$ For states b and c, $pV = nRT = \text{constant}$ so $p_bV_b = p_cV_c$ and

$$V_c = V_b\left(\frac{p_b}{p_c}\right) = (0.20\text{ L})\left(\frac{2.0\text{ atm}}{0.50\text{ atm}}\right) = 0.80\text{ L}.$$

(b) $T_a = \dfrac{p_aV_a}{nR} = \dfrac{(0.50\text{ atm})(1.013\times 10^5\text{ Pa/atm})(0.20\times 10^{-3}\text{ m}^3)}{(0.0040\text{ mol})(8.315\text{ J/mol}\cdot\text{K})} = 305\text{ K}.$ $V_a = V_b$ so for states a and b,

$$\frac{T}{p} = \frac{V}{nR} = \text{constant so } \frac{T_a}{p_a} = \frac{T_b}{p_b}.\ T_b = T_c = T_a\left(\frac{p_b}{p_a}\right) = (305\text{ K})\left(\frac{2.0\text{ atm}}{0.50\text{ atm}}\right) = 1220\text{ K};\ T_c = 1220\text{ K}.$$

(c) <u>ab</u>: $Q = nC_V\ \Delta T = n(\frac{5}{2}R)\ \Delta T,$ which gives

$Q = (0.0040\text{ mol})(\frac{5}{2})(8.315\text{ J/mol}\cdot\text{K})(1220\text{ K} - 305\text{ K}) = +76\text{ J}.$ Q is positive and heat goes into the gas.

<u>ca</u>: $Q = nC_p\ \Delta T = n(\frac{7}{2}R)\ \Delta T,$ which gives

$Q = (0.0040\text{ mol})(\frac{7}{2})(8.315\text{ J/mol}\cdot\text{K})(305\text{ K} - 1220\text{ K}) = -107\text{ J}.$ Q is negative and heat comes out of the gas.

<u>bc</u>: $Q = W = nRT\ln(V_c/V_b),$ which gives

$Q = (0.0040\text{ mol})(8.315\text{ J/mol}\cdot\text{K})(1220\text{ K})\ln(0.80\text{ L}/0.20\text{ L}) = 56\text{ J}.$ Q is positive and heat goes into the gas.

(d) <u>ab</u>: $\Delta U = nC_V\Delta T = n(\frac{5}{2}R)\Delta T,$ which gives

$\Delta U = (0.0040\text{ mol})(\frac{5}{2})(8.315\text{ J/mol}\cdot\text{K})(1220\text{ K} - 305\text{ K}) = +76\text{ J}.$ The internal energy increased.

<u>bc</u>: $\Delta T = 0$ so $\Delta U = 0.$ The internal energy does not change.

<u>ca</u>: $\Delta U = nC_V\Delta T = n(\frac{5}{2}R)\Delta T,$ which gives

$\Delta U = (0.0040\text{ mol})(\frac{5}{2})(8.315\text{ J/mol}\cdot\text{K})(305\text{ K} - 1220\text{ K}) = -76\text{ J}.$ The internal energy decreased.

EVALUATE: The net internal energy change for the complete cycle $a \to b \to c \to a$ is $\Delta U_{\text{tot}} = +76\text{ J} + 0 + (-76\text{ J}) = 0.$ For any complete cycle the final state is the same as the initial state and the net internal energy change is zero. For the cycle the net heat flow is $Q_{\text{tot}} = +76\text{ J} + (-107\text{ J}) + 56\text{ J} = +25\text{ J}.$ $\Delta U_{\text{tot}} = 0$ so $Q_{\text{tot}} = W_{\text{tot}}.$ The net work done in the cycle is positive and this agrees with our result that the net heat flow is positive.

19.44 **IDENTIFY:** The segments *ab* and *bc* are not any of the familiar ones, such as isothermal, isobaric, or isochoric, but *ac* is isobaric.

SET UP: For helium, $C_V = 12.47\text{ J/mol}\cdot\text{K}$ and $C_p = 20.78\text{ J/mol}\cdot\text{K}$. $\Delta U = Q - W$. *W* is the area under the *p* versus *V* curve. $\Delta U = nC_V\Delta T$ for any process of an ideal gas.

EXECUTE: **(a)** $W = \frac{1}{2}(1.0\times10^5\text{ Pa} + 3.5\times10^5\text{ Pa})(0.0060\text{ m}^3 - 0.0020\text{ m}^3)$

$+\frac{1}{2}(1.0\times10^5\text{ Pa} + 3.5\times10^5\text{ Pa})(0.0100\text{ m}^3 - 0.0060\text{ m}^3) = 1800\text{ J}.$

Find $\Delta T = T_c - T_a$. *p* is constant so $\Delta T = \dfrac{p\Delta V}{nR} = \dfrac{(1.0\times10^5\text{ Pa})(0.0100\text{ m}^3 - 0.0020\text{ m}^3)}{\left(\frac{1}{3}\text{ mol}\right)(8.315\text{ J/mol}\cdot\text{K})} = 289\text{ K}.$

Then

$\Delta U = nC_V\Delta T = (\frac{1}{3}\text{ mol})(12.47\text{ J/mol}\cdot\text{K})(289\text{ K}) = 1.20\times10^3\text{ J}.$

$Q = \Delta U + W = 1.20\times10^3\text{ J} + 1800\text{ J} = 3.00\times10^3\text{ J}$. $Q > 0$, so this heat is transferred into the gas.

(b) This process is isobaric, so $Q = nC_p\Delta T = \left(\frac{1}{3}\text{ mol}\right)(20.78\text{ J/mol}\cdot\text{K})(289\text{ K}) = 2.00\times10^3\text{ J}$. $Q > 0$, so this heat is transferred into the gas.

(c) Q is larger in part (a).

EVALUATE: ΔU is the same in parts (a) and (b) because the initial and final states are the same, but in (a) more work is done.

19.45. **IDENTIFY** and **SET UP:** We have information on the pressure and volume of the gas during the process, but we know almost nothing else about the gas. We do know that the first law of thermodynamics must apply to the gas during this process, so $Q = \Delta U + W$, and the work done by the g as is $W = \int_{V_1}^{V_2} p\,dV$. If *W* is positive, the gas does work, but if *W* is negative, work is done on the gas.

EXECUTE: **(a)** Figure 19.45 shows the *pV*-diagram for this process. On the *pV*-diagram, we see that the graph is a closed figure; the gas begins and ends in the same state.

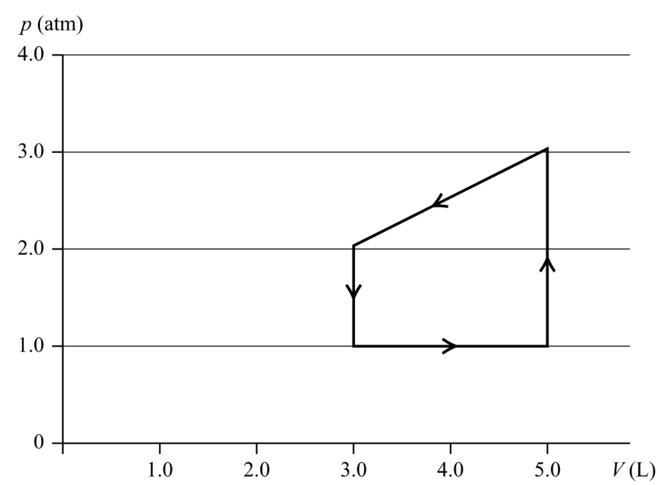


Figure 19.45

(b) Applying $Q = \Delta U + W$, we see that $\Delta U = 0$ because the gas ends up at the same state from which it began. Therefore $Q = W$. $W = \int_{V_1}^{V_2} p\,dV$, so the work is the area under the curve on a *pV*-diagram. For a closed cycle such as this one, the work is the area enclosed within the diagram. We calculate this work geometrically: $|W|$ = area (rectangle) + area (triangle) = (2.0 L)(1.0 atm) + $\frac{1}{2}$ (2.0 L)(1.0 atm) = 3.0

$\text{L}\cdot\text{atm} = 300$ J. But the net work is negative, so $Q = -3.0\ \text{L}\cdot\text{atm} = -300$ J. Since Q is negative, heat flows out of the gas.

EVALUATE: We know that the work is negative because in the upper part of the diagram, the volume is decreasing, which means that the gas is being compressed.

19.46. IDENTIFY: For a constant pressure process, $Q = nC_p\Delta T$. $\Delta U = Q - W$. $\Delta U = nC_V\Delta T$ for any ideal gas process.

SET UP: For N_2, $C_V = 20.76\ \text{J/mol}\cdot\text{K}$ and $C_p = 29.07\ \text{J/mol}\cdot\text{K}$. $Q < 0$ if heat comes out of the gas.

EXECUTE: **(a)** $n = \dfrac{Q}{C_p\Delta T} = \dfrac{-2.5\times10^4\ \text{J}}{(29.07\ \text{J/mol}\cdot\text{K})(-40.0\ \text{K})} = 21.5\ \text{mol}.$

(b) $\Delta U = nC_V\Delta T = Q(C_V/C_p) = (-2.5\times10^4\ \text{J})(20.76/29.07) = -1.79\times10^4\ \text{J}.$

(c) $W = Q - \Delta U = -7.15\times10^3\ \text{J}.$

(d) ΔU is the same for both processes, and if $\Delta V = 0$, $W = 0$ and $Q = \Delta U = -1.79\times10^4$ J.

EVALUATE: For a given ΔT, Q is larger in magnitude when the pressure is constant than when the volume is constant.

19.47. IDENTIFY: $pV = nRT$. For an isothermal process $W = nRT\ln(V_2/V_1)$. For a constant pressure process, $W = p\Delta V$.

SET UP: $1\ \text{L} = 10^{-3}\ \text{m}^3$.

EXECUTE: **(a)** The pV-diagram is sketched in Figure 19.47.

(b) At constant temperature, the product pV is constant, so

$V_2 = V_1(p_1/p_2) = (1.5\ \text{L})\left(\dfrac{1.00\times10^5\ \text{Pa}}{2.50\times10^4\ \text{Pa}}\right) = 6.00\ \text{L}.$ The final pressure is given as being the same as $p_3 = p_2 = 2.5\times10^4$ Pa. The final volume is the same as the initial volume, so $T_3 = T_1(p_3/p_1) = 75.0\ \text{K}.$

(c) Treating the gas as ideal, the work done in the first process is $W = nRT\ln(V_2/V_1) = p_1V_1\ln(p_1/p_2)$.

$$W = (1.00\times10^5\ \text{Pa})(1.5\times10^{-3}\ \text{m}^3)\ln\left(\frac{1.00\times10^5\ \text{Pa}}{2.50\times10^4\ \text{Pa}}\right) = 208\ \text{J}.$$

For the second process, $W = p_2(V_3 - V_2) = p_2(V_1 - V_2) = p_2V_1[1 - (p_1/p_2)]$.

$$W = (2.50\times10^4\ \text{Pa})(1.5\times10^{-3}\ \text{m}^3)\left(1 - \frac{1.00\times10^5\ \text{Pa}}{2.50\times10^4\ \text{Pa}}\right) = -113\ \text{J}.$$

The total work done is $208\ \text{J} - 113\ \text{J} = 95\ \text{J}$.

(d) Heat at constant volume. No work would be done by the gas or on the gas during this process.

EVALUATE: When the volume increases, $W > 0$. When the volume decreases, $W < 0$.

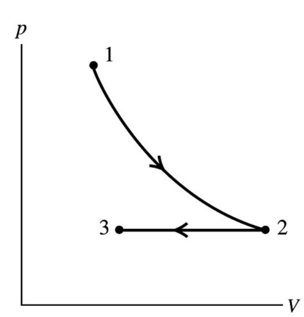

Figure 19.47

19.48. **IDENTIFY:** We are looking at the effect of gas compression on the buoyant force as a gas container descends in the ocean.

SET UP: As the inverted drum descends in the ocean, the water pressure increases and compresses the air in the drum. The pressure at a depth y in the ocean is $p = p_0 + \rho g y$. The temperature decreases linearly with depth from 23.0°C at the water surface to 3.0°C at a depth of 1000 m. The graph in Fig. 19.48 shows the temperature T as a function of depth y. This graph shows a line with a slope of –(20.0 C°)/(1000 m) = –0.0200 C°/m. The line intercepts the T axis at 23.0°C (y = 0 at the surface). Using the slope-intercept form of the equation, the equation is $T = T_0 - By$, where T_0 = 23.0°C = 296 K and B = 0.0200 C°/m.

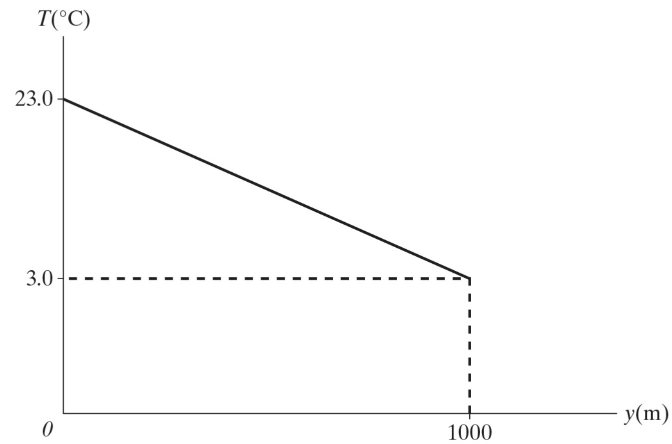

Figure 19.48

EXECUTE: **(a)** and **(b)** We want to find the depth for neutral buoyancy of the drum and the volume of the air in the drum at that depth. For neutral buoyancy, the buoyant force B on the drum must be equal to its weight mg, so $B = mg$. By Archimedes's principle, the buoyant force is equal to the weight of water displaced by the drum. At depth y the air in the drum has volume V_y, so $\rho g V_y = mg$. In this equation ρ is the density of seawater (1025 kg/m^3) and V_y is the volume of water displaced by the drum at depth y, which is the same as the volume of air in the drum. From $\rho g V_y = mg$ we get

$$V_y = \frac{m}{\rho} = \frac{17.3\text{ kg}}{1025\text{ kg/m}^3} = 0.0169\text{ m}^3.$$

We now want to find the depth y at which the air volume in the drum is 0.0169 m^3. At the water surface the volume of the air is the volume of the drum, which is $V_0 = \pi r^2 L$, which gives $V_0 = \pi(0.305\text{ m})^2(0.880\text{ m}) = 0.2572\text{ m}^3$. Therefore at this depth y we know $\frac{V_y}{V_0} = \frac{0.0169\text{ m}^3}{0.2572\text{ m}^3} = 0.06571$. We now look at the gas pressure at depth y. We do this because that pressure must be equal to the water pressure at the same depth. Using $pV = nRT$ gives

$$\frac{p_y}{p_0} = \left(\frac{T_y}{T_0}\right)\left(\frac{V_0}{V_y}\right) = \left(\frac{T_0 - By}{T_0}\right)\left(\frac{1}{0.06571}\right) = 15.219\left(\frac{T_0 - By}{T_0}\right),$$ from which we get

$$p_y = (15.219)p_0\left(\frac{T_0 - By}{T_0}\right).$$ Now equate this pressure to the water pressure at depth y, which is

$p = p_0 + \rho g y$, giving $p_0 + \rho g y = (15.219)p_0\left(\frac{T_0 - By}{T_0}\right)$. This gives $y = \frac{14.219 p_0}{\rho g + 15.219 p_0 B / T_0}$. Using $p_0 = 101\times10^3$ Pa, T_0 = 296 K, B = 0.0200 K/m and ρ = 1025 kg/m^3, we get y = 142 m.

EVALUATE: The compression of the air in the drum is *not* adiabatic because the air is in contact with the water so heat can flow out of the air as it moves to colder water at depth. In this process, none of the variables (p, V, and T) remained constant.

19.49. IDENTIFY: For an adiabatic process of an ideal gas, $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$. $pV = nRT$.

SET UP: For air, $\gamma = 1.40 = \frac{7}{5}$.

EXECUTE: **(a)** As the air moves to lower altitude its density increases; under an adiabatic compression, the temperature rises. If the wind is fast-moving, Q is not as likely to be significant, and modeling the process as adiabatic (no heat loss to the surroundings) is more accurate.

(b) $V = \dfrac{nRT}{p}$, so $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$ gives $T_1^{\gamma}p_1^{1-\gamma} = T_2^{\gamma}p_2^{1-\gamma}$. The temperature at the higher pressure is

$T_2 = T_1(p_1/p_2)^{(\gamma-1)/\gamma} = (258.15\text{ K})\left[(8.12\times10^4\text{ Pa})/(5.60\times10^4\text{ Pa})\right]^{2/7} = 287.1\text{ K} = 13.9°\text{C}$ so the temperature would rise by $11.9\ \text{C}°$.

EVALUATE: In an adiabatic compression, $Q = 0$ but the temperature rises because of the work done on the gas.

19.50. IDENTIFY: The process is adiabatic. Apply $p_1V_1^{\gamma} = p_2V_2^{\gamma}$ and $pV = nRT$. $Q = 0$ so

$$\Delta U = -W = -\frac{1}{\gamma-1}(p_1V_1 - p_2V_2).$$

SET UP: For ideal monatomic helium, $\gamma = 5/3 = 1.667$. $p_1 = 1.00\text{ atm} = 1.013\times10^5\text{ Pa}$.

$V_1 = 2.00\times10^3\text{ m}^3$. $p_2 = 0.900\text{ atm} = 9.117\times10^4\text{ Pa}$. $T_1 = 288.15\text{ K}$.

EXECUTE: **(a)** $V_2^{\gamma} = V_1^{\gamma}\left(\dfrac{p_1}{p_2}\right)$. $V_2 = V_1\left(\dfrac{p_1}{p_2}\right)^{1/\gamma} = (2.00\times10^3\text{ m}^3)\left(\dfrac{1.00\text{ atm}}{0.900\text{ atm}}\right)^{1/1.67} = 2.13\times10^3\text{ m}^3$.

(b) $pV = nRT$ gives $\dfrac{T_1}{p_1V_1} = \dfrac{T_2}{p_2V_2}$.

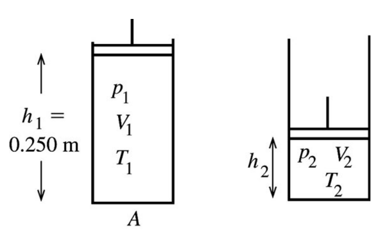
$$T_2 = T_1\left(\frac{p_2}{p_1}\right)\left(\frac{V_2}{V_1}\right) = (288.15\text{ K})\left(\frac{0.900\text{ atm}}{1.00\text{ atm}}\right)\left(\frac{2.13\times10^3\text{ m}^3}{2.00\times10^3\text{ m}^3}\right) = 276.2\text{ K} = 3.0°\text{C}.$$

(c) $\Delta U = -\dfrac{(1.013\times10^5\text{ Pa})(2.00\times10^3\text{ m}^3) - (9.117\times10^4\text{ Pa})(2.13\times10^3\text{ m}^3)}{1.667-1} = -1.25\times10^7\text{ J}$.

EVALUATE: The internal energy decreases when the temperature decreases.

19.51. IDENTIFY: Assume that the gas is ideal and that the process is adiabatic. Apply $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$ and $p_1V_1^{\gamma} = p_2V_2^{\gamma}$ to relate pressure and volume and temperature and volume. The distance the piston moves is related to the volume of the gas. Use $W = nC_V(T_1 - T_2)$ to calculate W.

(a) SET UP: $\gamma = C_p/C_V = (C_V + R)/C_V = 1 + R/C_V = 1.40$. The two positions of the piston are shown in Figure 19.51.



$p_1 = 1.01\times10^5\text{ Pa}$

$p_2 = 3.80\times10^5\text{ Pa} + p_{\text{air}} = 4.81\times10^5\text{ Pa}$

$V_1 = h_1A$

$V_2 = h_2A$

Figure 19.51

EXECUTE: For an adiabatic process of an ideal gas, $p_1V_1^\gamma = p_2V_2^\gamma$.

$p_1h_1^\gamma A^\gamma = p_2h_2^\gamma A^\gamma$

$$h_2 = h_1\left(\frac{p_1}{p_2}\right)^{1/\gamma} = (0.250\text{ m})\left(\frac{1.01\times10^5\text{ Pa}}{4.81\times10^5\text{ Pa}}\right)^{1/1.40} = 0.08199\text{ m}$$

The piston has moved a distance $h_1 - h_2 = 0.250\text{ m} - 0.08199\text{ m} = 0.168\text{ m}$.

(b) SET UP: $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$

$T_1h_1^{\gamma-1}A^{\gamma-1} = T_2h_2^{\gamma-1}A^{\gamma-1}$

EXECUTE: $T_2 = T_1\left(\dfrac{h_1}{h_2}\right)^{\gamma-1} = 300.1\text{ K}\left(\dfrac{0.250\text{ m}}{0.08199\text{ m}}\right)^{0.40} = 468.7\text{ K} = 196°\text{C}$.

(c) SET UP and **EXECUTE:** $W = nC_V(T_1 - T_2)$ gives

$W = (20.0\text{ mol})(20.8\text{ J/mol}\cdot\text{K})(300.1\text{ K} - 468.7\text{ K}) = -7.01\times10^4\text{ J} = -70.1\text{ kJ}$. This is the work done *by* the gas. The work done *on* the gas by the pump is +70.1 kJ.

EVALUATE: In an adiabatic compression of an ideal gas the temperature increases. In any compression the work W done by the gas is negative.

19.52. IDENTIFY: For constant pressure, $W = p\Delta V$. For an adiabatic process of an ideal gas,

$W = \dfrac{C_V}{R}(p_1V_1 - p_2V_2)$ and $p_1V_1^\gamma = p_2V_2^\gamma$.

SET UP: $\gamma = \dfrac{C_p}{C_V} = \dfrac{C_p + C_V}{C_V} = 1 + \dfrac{R}{C_V}$.

EXECUTE: **(a)** The pV-diagram is sketched in Figure 19.52.

(b) The work done is $W = p_0(2V_0 - V_0) + \dfrac{C_V}{R}(p_0(2V_0) - p_3(4V_0))$. $p_3 = p_0(2V_0/4V_0)^\gamma$ and so

$W = p_0V_0\left[1 + \dfrac{C_V}{R}(2 - 2^{2-\gamma})\right]$. Note that p_0 is the absolute pressure.

(c) The most direct way to find the temperature is to find the ratio of the final pressure and volume to the original and treat the air as an ideal gas. $p_3 = p_2\left(\dfrac{V_2}{V_3}\right)^\gamma = p_1\left(\dfrac{V_2}{V_3}\right)^\gamma$, since $p_1 = p_2$. Then

$$T_3 = T_0\frac{p_3V_3}{p_1V_1} = T_0\left(\frac{V_2}{V_3}\right)^\gamma\left(\frac{V_3}{V_1}\right) = T_0\left(\frac{1}{2}\right)^\gamma 4 = T_0(2)^{2-\gamma}.$$

(d) Since $n = \dfrac{p_0V_0}{RT_0}, Q = \dfrac{p_0V_0}{RT_0}(C_V + R)(2T_0 - T_0) = p_0V_0\left(\dfrac{C_V}{R} + 1\right)$. This amount of heat flows into the gas, since $Q > 0$.

EVALUATE: In the isobaric expansion the temperature doubles and in the adiabatic expansion the temperature decreases. If the gas is diatomic, with $\gamma = \frac{7}{5}$, $2 - \gamma = \frac{3}{5}$ and $T_3 = 1.52T_0$, $W = 2.21p_0V_0$, and $Q = 3.50p_0V_0$. $\Delta U = 1.29p_0V_0$. $\Delta U > 0$ and this is consistent with an increase in temperature.

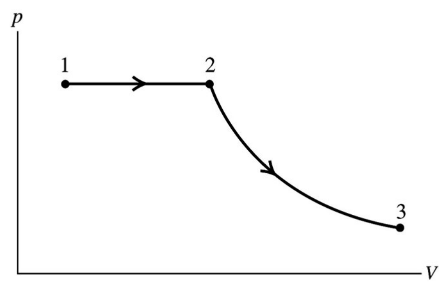


Figure 19.52

19.53. IDENTIFY: In each case calculate either ΔU or Q for the specific type of process and then apply the first law.

(a) SET UP: <u>Isothermal</u>: $(\Delta T = 0)$ $\Delta U = Q - W$; $W = +450$ J. For any process of an ideal gas, $\Delta U = nC_V \Delta T$.

EXECUTE: Therefore, for an ideal gas, if $\Delta T = 0$ then $\Delta U = 0$ and $Q = W = +450$ J.

(b) SET UP: <u>Adiabatic</u>: $(Q = 0)$

$\Delta U = Q - W;$ $W = +450$ J.

EXECUTE: $Q = 0$ says $\Delta U = -W = -450$ J.

(c) SET UP: <u>Isobaric</u>: $\Delta p = 0$

Use W to calculate ΔT and then calculate Q.

EXECUTE: $W = p\Delta V = nR\Delta T$; $\Delta T = W/nR$

$Q = nC_p \Delta T$ and for a monatomic ideal gas $C_p = \frac{5}{2}R$.

Thus $Q = n\frac{5}{2}R\Delta T = (5Rn/2)(W/nR) = 5W/2 = +1125$ J.

$\Delta U = nC_V \Delta T$ for any ideal gas process and $C_V = C_p - R = \frac{3}{2}R$.

Thus $\Delta U = 3W/2 = +675$ J.

EVALUATE: 450 J of energy leaves the gas when it performs expansion work. In the isothermal process this energy is replaced by heat flow into the gas and the internal energy remains the same. In the adiabatic process the energy used in doing the work decreases the internal energy. In the isobaric process 1125 J of heat energy enters the gas, 450 J leaves as the work done and 675 J remains in the gas as increased internal energy.

19.54. IDENTIFY: $pV = nRT$. For the isobaric process, $W = p\Delta V = nR\Delta T$. For the isothermal process, $W = nRT\ln\left(\frac{V_2}{V_1}\right)$.

SET UP: $R = 8.315$ J/mol·K.

EXECUTE: **(a)** The pV diagram for these processes is sketched in Figure 19.54.

(b) Find T_2. For process $1 \to 2$, n, R and p are constant so $\frac{T}{V} = \frac{p}{nR} = \text{constant}$. $\frac{T_1}{V_1} = \frac{T_2}{V_2}$ and

$T_2 = T_1\left(\frac{V_2}{V_1}\right) = (355\text{ K})(2) = 710\text{ K}.$

(c) The maximum pressure is for state 3. For process $2 \to 3$, n, R and T are constant. $p_2V_2 = p_3V_3$ and

$p_3 = p_2\left(\frac{V_2}{V_3}\right) = (2.40\times 10^5\text{ Pa})(2) = 4.80\times 10^5\text{ Pa}.$

(d) <u>Proces $1 \to 2$</u>: $W = p\Delta V = nR\Delta T = (0.250\text{ mol})(8.315\text{ J/mol}\cdot\text{K})(710\text{ K} - 355\text{ K}) = 738\text{ K}.$

<u>Proces 2 → 3</u>: $W = nRT\ln\left(\frac{V_3}{V_2}\right) = (0.250 \text{ mol})(8.315 \text{ J/mol}\cdot\text{K})(710 \text{ K})\ln\left(\frac{1}{2}\right) = -1023 \text{ J}.$

<u>Proces 3 → 1</u>: $\Delta V = 0$ and $W = 0.$

The total work done is $738 \text{ J} + (-1023 \text{ J}) = -285 \text{ J}.$ This is the work done by the gas. The work done on the gas is 285 J.

EVALUATE: The final pressure and volume are the same as the initial pressure and volume, so the final state is the same as the initial state. For the cycle, $\Delta U = 0$ and $Q = W = -285 \text{ J}.$ During the cycle, 285 J of heat energy must leave the gas.

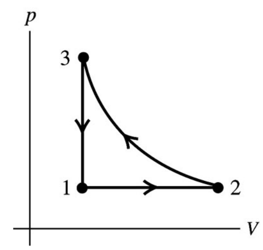

Figure 19.54

19.55. **IDENTIFY** and **SET UP:** Use the ideal gas law, the first law of thermodynamics, and expressions for Q and W for specific types of processes.

EXECUTE: **(a)** initial expansion (state 1 → state 2)

$p_1 = 2.40\times10^5 \text{ Pa},\ T_1 = 355 \text{ K},\ p_2 = 2.40\times10^5 \text{ Pa},\ V_2 = 2V_1$

$pV = nRT;\ T/V = p/nR = \text{constant, so } T_1/V_1 = T_2/V_2 \text{ and } T_2 = T_1(V_2/V_1) = 355 \text{ K}(2V_1/V_1) = 710 \text{ K}$

$\Delta p = 0$ so $W = p\Delta V = nR\Delta T = (0.250 \text{ mol})(8.3145 \text{ J/mol}\cdot\text{K})(710 \text{ K} - 355 \text{ K}) = +738 \text{ J}$

$Q = nC_p\Delta T = (0.250 \text{ mol})(29.17 \text{ J/mol}\cdot\text{K})(710 \text{ K} - 355 \text{ K}) = +2590 \text{ J}$

$\Delta U = Q - W = 2590 \text{ J} - 738 \text{ J} = 1850 \text{ J}$

(b) At the beginning of the final cooling process (cooling at constant volume), $T = 710$ K. The gas returns to its original volume and pressure, so also to its original temperature of 355 K.

$\Delta V = 0$ so $W = 0$

$Q = nC_V\Delta T = (0.250 \text{ mol})(20.85 \text{ J/mol}\cdot\text{K})(355 \text{ K} - 710 \text{ K}) = -1850 \text{ J}$

$\Delta U = Q - W = -1850 \text{ J}.$

(c) For any ideal gas process $\Delta U = nC_V\Delta T.$ For an isothermal process $\Delta T = 0,$ so $\Delta U = 0.$

EVALUATE: The three processes return the gas to its initial state, so $\Delta U_{\text{total}} = 0;$ our results agree with this.

19.56. **IDENTIFY:** $pV = nRT.$ For an adiabatic process of an ideal gas, $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}.$

SET UP: For N_2, $\gamma = 1.40.$

EXECUTE: **(a)** The pV-diagram is sketched in Figure 19.56.

(b) At constant pressure, halving the volume halves the Kelvin temperature, and the temperature at the beginning of the adiabatic expansion is 150 K. The volume doubles during the adiabatic expansion, and from Eq. (19.22), the temperature at the end of the expansion is $(150 \text{ K})(1/2)^{0.40} = 114 \text{ K}.$

(c) The minimum pressure occurs at the end of the adiabatic expansion (state 3). During the final heating the volume is held constant, so the minimum pressure is proportional to the Kelvin temperature, $p_{\min} = (1.80\times10^5 \text{ Pa})(114\text{K}/300 \text{ K}) = 6.82\times10^4 \text{ Pa}.$

EVALUATE: In the adiabatic expansion the temperature decreases.

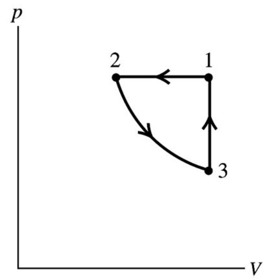

Figure 19.56

19.57. **IDENTIFY:** Use the appropriate expressions for Q, W, and ΔU for each type of process. $\Delta U = Q - W$ can also be used.

SET UP: For N_2, $C_V = 20.76 \text{ J/mol} \cdot \text{K}$ and $C_p = 29.07 \text{ J/mol} \cdot \text{K}$.

EXECUTE: **(a)** $W = p\Delta V = nR\Delta T = (0.150 \text{ mol})(8.3145 \text{ J/mol} \cdot \text{K})(-150 \text{ K}) = -187 \text{ J}$,

$Q = nC_p\Delta T = (0.150 \text{ mol})(29.07 \text{ mol} \cdot \text{K})(-150 \text{ K}) = -654 \text{ J}$, $\Delta U = Q - W = -467 \text{ J}$.

(b) From Eq. (19.26), using the expression for the temperature found in Problem 19.56,

$W = \dfrac{1}{0.40}(0.150 \text{ mol})(8.3145 \text{ J/mol} \cdot \text{K})(150 \text{ K})[1 - (1/2^{0.40})] = 113 \text{ J}$. $Q = 0$ for an adiabatic process,

and $\Delta U = Q - W = -W = -113 \text{ J}$.

(c) $\Delta V = 0$, so $W = 0$. Using the temperature change as found in Problem 19.66 part (b),

$Q = nC_V\Delta T = (0.150 \text{ mol})(20.76 \text{ J/mol} \cdot \text{K})(300 \text{ K} - 113.7 \text{ K}) = 580 \text{ J}$ and $\Delta U = Q - W = Q = 580 \text{ J}$.

EVALUATE: For each process we could also use $\Delta U = nC_V\Delta T$ to calculate ΔU.

19.58. **IDENTIFY:** Use the appropriate expression for W for each type of process.

SET UP: For a monatomic ideal gas, $\gamma = 5/3$ and $C_V = 3R/2$.

EXECUTE: **(a)** $W = nRT \ln(V_2/V_1) = nRT \ln(3) = 3.29 \times 10^3 \text{ J}$.

(b) $Q = 0$ so $W = -\Delta U = -nC_V\Delta T$. $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$ gives $T_2 = T_1(1/3)^{2/3}$. Then

$W = nC_VT_1(1 - (1/3^{2/3})) = 2.33 \times 10^3 \text{ J}$.

(c) $V_2 = 3V_1$, so $W = p\Delta V = 2pV_1 = 2nRT_1 = 6.00 \times 10^3 \text{ J}$.

(d) Each process is shown in Figure 19.58. The most work done is in the isobaric process, as the pressure is maintained at its original value. The least work is done in the adiabatic process.

(e) The isobaric process involves the most work and the largest temperature increase, and so requires the most heat. Adiabatic processes involve no heat transfer, and so the magnitude is zero.

(f) The isobaric process doubles the Kelvin temperature, and so has the largest change in internal energy. The isothermal process necessarily involves no change in internal energy.

EVALUATE: The work done is the area under the path for the process in the pV-diagram. Figure 19.58 shows that the work done is greatest in the isobaric process and least in the adiabatic process.

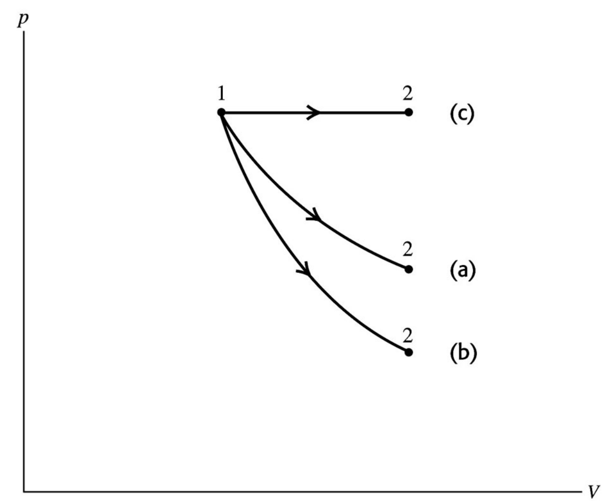

Figure 19.58

19.59. **IDENTIFY:** For an adiabatic process, no heat enters or leaves the gas. An isochoric process takes place at constant volume, and an isoboric process takes place at constant pressure. The first law of thermodynamics applies.

SET UP: For any process, including an isochoric process, $Q = nC_V\Delta T$, and for an isobaric process, $Q = nC_p\Delta T$. $Q = \Delta U + W$.

EXECUTE: **(a)** Process *a* is adiabatic since no heat goes into or out of the system. In processes *b* and *c*, the temperature change is the same, but more heat goes into the gas for process *c*. Since the change in internal energy is the same for both *b* and *c*, some of the heat in *c* must be doing work, but not in *b*. Therefore *b* is isochoric and *c* is isobaric. To summarize: *a* is adiabatic, *b* is isochoric, *c* is isobaric.

(b) $Q_b = nC_V\Delta T$ and $Q_c = nC_p\Delta T$. Subtracting gives

$Q_c - Q_b = nC_p\ \Delta T - nC_V\Delta T = n(C_p - C_V)\ \Delta T = nR\Delta T = 20$ J. Solving for ΔT gives

$\Delta T = (20\text{ J})/nR = (20\text{ J})/[(0.300\text{ mol})(8.314\text{ J/mol}\cdot\text{K})] = 8.0\ \text{C}°$, so $T_2 = 20.0°\text{C} + 8.0°\text{C} = 28.0°\text{C}$.

(c) $\dfrac{Q_c}{Q_b} = \dfrac{nC_p\Delta T}{nC_V\Delta T} = \dfrac{C_p}{C_V} = \gamma = \dfrac{50\text{ J}}{30\text{ J}} = \dfrac{5}{3}$. Since $\gamma = 5/3$, the gas must be monatomic, in which case we have $C_V = 3/2\ R$ and $C_p = 5/2\ R$. Therefore

Process *a*: $Q = \Delta U + W$ gives $0 = nC_V\Delta T + W$.

$W = -n(3/2\ R)\ \Delta T = -(0.300\text{ mol})(3/2)(8.314\text{ J/mol}\cdot\text{K})(8.0\text{ K}) = -30$ J.

Process *b*: The volume is constant, so $W = 0$.

Process *c*: $Q = \Delta U + W$. ΔU is the same as for process *a* because ΔT is the same, so we have $50\text{ J} = 30\text{ J} + W$, which gives $W = 20$ J.

(d) The greatest work has the greatest volume change. Using the results of part (c), process *a* has the greatest amount of work and hence the greatest volume change.

(e) The volume is increasing if *W* is positive. Therefore

Process *a*: *W* is negative, so the volume decreases.

Process *b*: $W = 0$ so the volume stays the same.

Process *c*: *W* is positive, so the volume increases.

EVALUATE: In Process *a*, no heat enters the gas, yet its temperature increases. This means that work must have been done on the gas, as we found.

19.60. **IDENTIFY** and **SET UP:** The cylinder is insulated, so no heat can go into or out of the gas, which makes this an adiabatic process. For an adiabatic process, $pV^\gamma = \text{constant}$, and the ideal gas law, $pV = nRT$, also applies.

EXECUTE: **(a)** The graph of log p versus log V is shown in Figure 19.60.

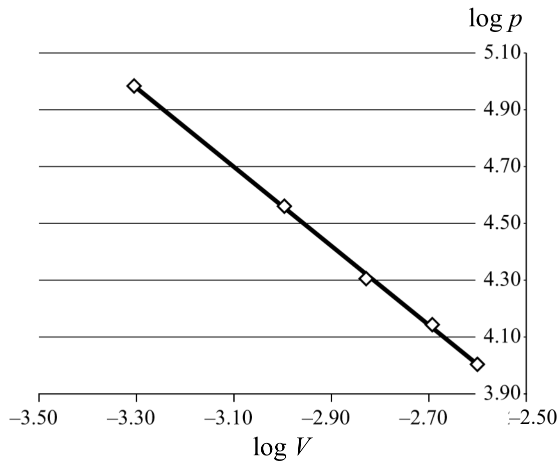

Figure 19.60

For an adiabatic process, $pV^{\gamma} = \text{constant}$. Taking logs of both sides of this equation gives $\log(pV^{\gamma}) = \log p + \log V^{\gamma} = \log p + \gamma \log V = \log(\text{constant})$. Solving for log p gives $\log p = -\gamma \log V + \log(\text{constant})$. Therefore a graph of log p versus log V should be a straight line having a slope equal to $-\gamma$.

(b) The equation of the best-fit line in the graph is log p = –1.3946 log$V$ + 0.381, so $-\gamma$ = –1.3946, so γ = 1.4. This is the adiabatic constant for a diatomic gas, so this gas must be diatomic.

(c) The ideal gas law gives $pV = nRT$, so $nR = pV/T$. Using the first set of data points in the table gives $nR = (0.101 \text{ atm})(2.50 \text{ L})/(293.15 \text{ K}) = 8.61 \times 10^{-4} \text{ L} \cdot \text{atm/K}$, so $1/nR = 1160 \text{ K/L} \cdot \text{atm}$. Using this number, we can calculate T for the rest of the pairs of points in the table. For example, for the next set of points, we have $T = pV/nR = (1160 \text{ K/L} \cdot \text{atm})(2.02 \text{ L})(0.139 \text{ atm}) = 326 \text{ K}$. We do likewise for the other pairs of points. The results are:

For 1.48 L, 0.202 atm: T = 347 K.

For 1.01 L, 0.361 atm: T = 423 K.

For 0.50 L, 0.952 atm: T = 553 K.

As the volume decreases, the temperature is increasing, so the temperature is increasing during compression.

EVALUATE: This result confirms that during an adiabatic compression, the gas temperature increases because work is being done on the gas.

19.61. **IDENTIFY:** The air in a cylinder can be compressed by a moveable piston at one end. It goes through a cycle that ends in the same state at which it began. The compression ratio v is defined as $V_{max}/V_{min} = v$.

SET UP: Summarize the steps of the cycle and make a pV-diagram of the process, shown in Fig. 19.61.

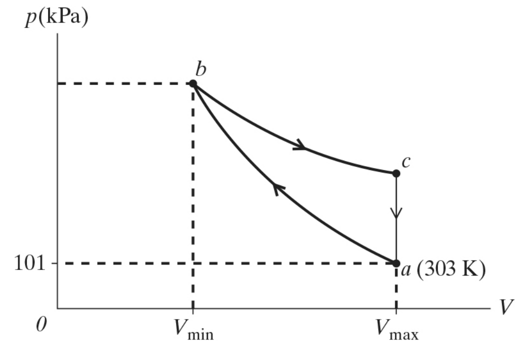

Figure 19.61

<u>Segment *ab*</u>: Beginning at ambient temperature, an adiabatic compression quickly increases the air temperature.
<u>Segment *bc*</u>: Isorthermal expansion to maximum volume
<u>Segment *ca*</u>: Isochoric cooling back to ambient temperature
We know the following things about this system: For diatomic air $C_V = 20.8\ \text{J/mol}\cdot\text{K}$ and $\gamma = 1.40$. The volume of the air in the cylinder is $V = AL$, where A is the area of the faces and L is the length of the gas-containing part of the cylinder. $L_{\max} = 30.0\text{ cm} = 0.300\text{ m}$ and $L_{\min} = L_{\max}/v = (0.300\text{ m})/v$. The cycle starts at point a with $T_a = 30.0°\text{C} = 303\text{ K}$, $p_a = 101\text{ kPa}$, and $V_a = L_{\max}A = (0.300\text{ m})A$, where $A = \pi r^2$.

EXECUTE: (a) We want the work done by the air for a complete cycle *abc*. We need to break this process up into its three segments, so $W_{\text{tot}} = W_{ab} + W_{bc} + W_{ca}$. Segment *ab* is an adiabatic compression, so $W_{ab} = \dfrac{1}{\gamma-1}\left(p_aV_a - p_bV_b\right)$. Using $p_aV_a^\gamma = p_bV_b^\gamma$ with $V_b = V_a/v$, this becomes

$$W_{ab} = \frac{1}{\gamma-1}\left[p_aV_a - p_aV_b\left(\frac{V_a}{V_b}\right)^\gamma\right] = \frac{p_a}{\gamma-1}\left[V_a - v^\gamma(V_a/v)\right] = \frac{p_aV_a}{\gamma-1}\left(1-v^\gamma/v\right) = \frac{p_aV_a}{\gamma-1}\left(1-v^{\gamma-1}\right).$$

Segment *bc* is isothermal, so T = constant = T_b. Using $pV = nRT$ and $W_{bc} = \int_b^c p\,dV$, we have $W_{bc} = \int_b^c \frac{nRT_b}{V}dV = nRT_b\ln\left(V_c/V_b\right)$. But $V_c = V_a$ and $V_b = V_a/v$, so $V_c/V_b = v$, so W_{bc} is $W_{bc} = nRT_b\ln v = p_bV_b\ln v$. From $p_aV_a^\gamma = p_bV_b^\gamma$ we have $p_b = p_a\left(\frac{V_a}{V_b}\right)^\gamma$, and we also know that $V_b = V_a/v$, so $W_{bc} = p_a\left(\frac{V_a}{V_b}\right)^\gamma\frac{V_a}{v}\ln v = p_aV_av^\gamma\frac{1}{v}\ln v = p_aV_av^{\gamma-1}\ln v$. The work during segment *ca* is 0 because the volume is constant. $V_a = (0.300\text{ m})A = (0.300\text{ m})\pi(0.0150\text{ m})^2 = 2.1205\times10^{-4}\text{ m}^3$. Using the values for p_a, V_a, and γ we get $W_{ab} = (53.5\text{ J})\left(1-v^{0.40}\right)$ and $W_{bc} = (21.4\text{ J})v^{0.40}\ln v$.

$$W_{\text{tot}} = 53.5\text{ J} + v^{0.40}\left[(21.42\text{ J})\ln v - 53.5\text{ J}\right].$$

(b) We want the maximum integer value of v so that maximum temperature is no greater than 400°C. The maximum temperature occurs along segment *bc*, so the maximum that T_b can be is 400°C = 673 K. Using $T_bV_b^{\gamma-1} = T_aV_a^{\gamma-1}$ gives $T_b = T_a\left(\frac{V_a}{V_b}\right)^{\gamma-1} = T_a\left(\frac{vV_b}{V_b}\right)^{\gamma-1} = T_av^{\gamma-1}$. This gives $v^{0.40} = 673/303$, so $v = (673/303)^{1/0.400} = 7.35$. Since v must be an integer, $v_{\max} = 7$. The temperature at b for this value of v is $T_b = T_av^{\gamma-1} = (303\text{ K})7^{0.40} = 660\text{ K} = 387°\text{C}$. (Note that this is *not* 400°C, but the requirement was that the maximum temperature be *no greater than* 400°C, not that it be *equal to* 400°C.)

(c) We want the minimum value of v so that the gas does at least 25.0 J of work per cycle. Using $W_{\text{tot}} = 53.5\text{ J} + v^{0.40}\left[(21.42\text{ J})\ln v - 53.5\text{ J}\right] = 25.0\text{ J}$ gives $-28.55\text{ J} = v^{0.40}\left[(21.42\text{ J})\ln v - 53.5\text{ J}\right]$. The LHS of this equation is negative, so the RHS must also be negative. The only way this is possible is for $\left[(21.42\text{ J})\ln v - 53.5\text{ J}\right]$ to be negative. This tells us that ln v < 53.5/21.42, so v < 12.18. Since v must be an integer, v < 12. But in part (b) we saw that $v \le 7$. We try $v = 7$ to see how much work is done. Using $v = 7$ in $W_{\text{tot}} = 53.5\text{ J} + v^{0.40}\left[(21.42\text{ J})\ln v - 53.5\text{ J}\right]$ gives $= 27.7$ J, which is acceptable since it is more than 25.0 J. Now try $v = 6$, which gives $W_{\text{tot}} = 22.5$ J. This is not acceptable since it is less than 25.0 J, and no smaller integers would be acceptable either. Therefore $v_{\text{min}} = 7$.

(d) $v \ge 7$ and $v \le 7$, so $v = 7$.

(e) We want the heat that leaves the gas during the isochoric segment, which is *ca*. The work is zero, so $\Delta U = Q - W = Q$. Therefore $Q = \Delta U = nC_V\Delta T$. First we need n. Using $pV = nRT$ gives $n = p_aV_a/RT_a$, which gives $n = 8.50\times10^{-3}$ mol. Now we can use $Q = \Delta U = nC_V\Delta T$. This gives $Q =$ $(8.50\times10^{-3}\text{ mol})(20.8\text{ J/mol}\cdot\text{K})(303\text{ K} - 660\text{ K}) = -63.1$ J. The minus sign tells us that the heat comes *out of* the air.

EVALUATE: This device does 27.7 J of work per cycle operating between a high temperature of 660 K (387°C) and low temperature of 303 K (30°C).

19.62. IDENTIFY: $m = \rho V$. The density of air is given by $\rho = \dfrac{pM}{RT}$. For an adiabatic process, $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$. $pV = nRT$.

SET UP: Using $V = \dfrac{nRT}{p}$ in $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$ gives $T_1p_1^{1-\gamma} = T_2p_2^{1-\gamma}$.

EXECUTE: **(a)** The pV-diagram is sketched in Figure 19.62.

(b) The final temperature is the same as the initial temperature, and the density is proportional to the absolute pressure. The mass needed to fill the cylinder is then

$$m = \rho_0 V\frac{p}{p_{\text{air}}} = (1.23\text{ kg/m}^3)(575\times10^{-6}\text{ m}^3)\frac{1.45\times10^5\text{ Pa}}{1.01\times10^5\text{ Pa}} = 1.02\times10^{-3}\text{ kg}.$$

Without the turbocharger or intercooler the mass of air at $T = 15.0°\text{C}$ and $p = 1.01\times10^5$ Pa in a cylinder is $m = \rho_0 V = 7.07\times10^{-4}$ kg. The increase in power is proportional to the increase in mass of air in the cylinder; the percentage increase is $\dfrac{1.02\times10^{-3}\text{ kg}}{7.07\times10^{-4}\text{ kg}} - 1 = 0.44 = 44\%$.

(c) The temperature after the adiabatic process is $T_2 = T_1\left(\dfrac{p_2}{p_1}\right)^{(\gamma-1)/\gamma}$. The density becomes

$$\rho = \rho_0\left(\frac{T_1}{T_2}\right)\left(\frac{p_2}{p_1}\right) = \rho_0\left(\frac{p_2}{p_1}\right)^{(1-\gamma)/\gamma}\left(\frac{p_2}{p_1}\right) = \rho_0\left(\frac{p_2}{p_1}\right)^{1/\gamma}.$$ The mass of air in the cylinder is

$$m = (1.23\text{ kg/m}^3)(575\times10^{-6}\text{ m}^3)\left(\frac{1.45\times10^5\text{ Pa}}{1.01\times10^5\text{ Pa}}\right)^{1/1.40} = 9.16\times10^{-4}\text{ kg},$$

The percentage increase in power is $\dfrac{9.16\times10^{-4}\text{ kg}}{7.07\times10^{-4}\text{ kg}} - 1 = 0.30 = 30\%$.

EVALUATE: The turbocharger and intercooler each have an appreciable effect on the engine power.

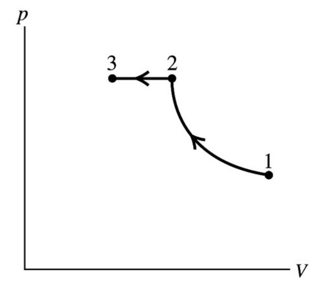

Figure 19.62

19.63. **IDENTIFY and SET UP:** The gas is cooled at constant volume. The ideal gas law applies, so $pV = nRT$.

At constant volume, this becomes $\frac{p_1}{T_1} = \frac{p_2}{T_2}$.

EXECUTE: Solving $\frac{p_1}{T_1} = \frac{p_2}{T_2}$ for p_2 gives $p_2 = p_1\frac{T_2}{T_1} = (2000 \text{ psi})\frac{268 \text{ K}}{293 \text{ K}} = 1830 \text{ psi}$, which is choice (c).

EVALUATE: As the temperature decreases, the pressure decreases, as expected.

19.64. **IDENTIFY and SET UP:** The rapid expansion of the gas is an adiabatic process.
EXECUTE: The work the gas does comes from its internal energy, so its temperature decreases, causing some of it to condense. Therefore choice (d) is correct.
EVALUATE: This is the same principle used by snow-making machines.

19.65. **IDENTIFY and SET UP:** The gas is initially a gauge pressure of 2000 psi (absolute pressure of 2014.7 psi). It will continue to flow out until it is at the same absolute pressure as the outside air, which is 1.0 atm, or 14.7 psi. So we need to find the volume the gas would occupy at 1.0 atm of absolute pressure. The ideal gas law, $pV = nRT$, applies to the gas, and the temperature is constant during this process.

EXECUTE: For an isothermal process, T is constant, so $pV = nRT$ can be put into the form

$V_2 = V_1\frac{p_1}{p_2} = (500 \text{ L})\frac{2014.7 \text{ psi}}{14.7 \text{ psi}} = 6.85\times10^4 \text{ L}$. The volume of gas lost is therefore

$6.85\times10^4 \text{ L} - 500 \text{ L} = 6.80\times10^4 \text{ L}$. The gas flows at a constant rate of 8.2 L/min, so

$(8.2 \text{ L/min})t = 6.80\times10^4 \text{ L}$, which gives t = 8300 min = 140 h, which is choice (d).

EVALUATE: The rate of flow might not be uniform as the gas approaches 1.0 atm, but for most of the time under high pressure, it should be reasonable to assume that the flow rate can be held constant.

19.66. **IDENTIFY and SET UP:** The oxygen and the N_2O are at the same temperature in the same container. Therefore to have a 50%/50% mixture by volume, they should have equal numbers of moles. $pV = nRT$ applies.

EXECUTE: The molecular mass of N_2O is (28 + 16) g/mol = 44 g/mol. The amount present is 1.7 kg = 1700 g, which is 1700/44 = 38.64 mol. Therefore the O_2 must also contain 38.64 mol. The temperature is 20°C = 293 K. The pressure is 50 psi + 14.7 psi = 64.7 psi. Since 1.0 atm = 14.7 psi = 1.01×10^5 Pa, converting gives 64.7 psi = 4.445×10^5 Pa. Using $pV = nRT$, we have

$V = nRT/p = (38.64 \text{ mol})(8.314 \text{ J/mol}\cdot\text{K})(293 \text{ K})/(4.445 \times 10^5 \text{ Pa}) = 0.21 \text{ m}^3$, which is choice (a).

EVALUATE: The mixture is 50%/50% by volume, but not by weight, since N_2O is heavier than O_2.

20

THE SECOND LAW OF THERMODYNAMICS

VP20.1.1. **IDENTIFY:** We are dealing the efficiency of a diesel engine.

SET UP: Efficiency = $e = W/Q_H$ and $Q_H = W + Q_C$.

EXECUTE: **(a)** We want the heat taken in, which is Q_H. Solve $e = W/Q_H$ for Q_H giving

$$Q_H = \frac{W}{e} = \frac{1.24\times10^4 \text{ J}}{0.180} = 6.89\times10^4 \text{ J}.$$

(b) $Q_C = W + Q_H = 6.89\times10^4 \text{ J} - 1.24\times10^4 \text{ J} = 5.65\times10^4 \text{ J}$.

EVALUATE: Only 18% of the heat taken in is converted to work. This is around the efficiency of automobile engines.

VP20.1.2. **IDENTIFY:** We are dealing with the efficiency of a heat engine.

SET UP and EXECUTE: $e = 1 - \left|\frac{Q_C}{Q_H}\right| = 1 - \frac{3.16\times10^4 \text{ J}}{3.82\times10^4 \text{ J}} = 0.173.$

EVALUATE: Only 17.3% of the heat input is converted to work; the rest is rejected from the engine as waste heat.

VP20.1.3. **IDENTIFY:** We are dealing with the efficiency of a gasoline heat engine.

SET UP: The efficiency is $e = 0.196$ and $Q_C = 4.96\times10^8 \text{ J}$ in 20 min.

EXECUTE: **(a)** We want to find Q_H. $e = 1 - \left|\frac{Q_C}{Q_H}\right| = 1 - \frac{4.96\times10^8 \text{ J}}{Q_H} = 0.196$. $Q_H = 6.17\times10^8 \text{ J}$.

(b) We want the work W. $W = Q_H - Q_C = 6.17\times10^8 \text{ J} - 4.96\times10^8 \text{ J} = 1.21\times10^8 \text{ J}$.

EVALUATE: The power output is $P = W/t = (1.21\times10^8 \text{ J})/[(20)(60) \text{ s}] = 1.01\times10^5 \text{ W} = 101 \text{ kW}$.

VP20.1.4. **IDENTIFY:** A heat engine has a power output of 1.10×10^5 W and gets its heat input from the combustion of gasoline.

SET UP and EXECUTE: The heat of combustion of gasoline is 5.0×10^7 J/kg.

(a) We want to see how much work this engine does in one hour. The power output is the rate at which the engine does work, so the work it does in one hour is $W = Pt = (1.10\times10^5 \text{ W})(3600 \text{ s}) = 3.96\times10^8 \text{ J}$.

(b) We want the heat input. $Q_H = (34 \text{ kg})(5.0\times10^7 \text{ J/kg}) = 1.7\times10^9 \text{ J}$.

(c) We want the efficiency. $e = \frac{W}{Q_H} = \frac{3.96\times10^8 \text{ J}}{1.7\times10^9 \text{ J}} = 0.23.$

EVALUATE: The heat wasted each hour is $Q_H - W = 1.7\times10^9 \text{ J} - 3.96\times10^8 \text{ J} = 1.3\times10^9 \text{ J}$.

VP20.4.1. **IDENTIFY:** Th3is problem deals with a Carnot heat engine.

SET UP: For any heat engine $e = W/Q_H$ and $Q_H = W + Q_C$, and for a Carnot engine $e = 1 - \dfrac{T_C}{T_H}$.

EXECUTE: **(a)** We want the efficiency. $e = \dfrac{W}{Q_H} = \dfrac{1.68\times 10^4 \text{ J}}{8.00\times 10^4 \text{ J}} = 0.210.$

(b) We want Q_C. $Q_H = W + Q_C$, so $Q_C = 8.00\times 10^4 \text{ J} - 1.68\times 10^4 \text{ J} = 6.32\times 10^4 \text{ J}$.

(c) We want T_H. $e = 1 - \dfrac{T_C}{T_H}$ gives $0.210 = 1 - \dfrac{298 \text{ K}}{T_H}$. $T_H = 377$ K = 104°C.

EVALUATE: The temperature must be in Kelvins to use these formulas.

VP20.4.2. **IDENTIFY:** We are analyzing a Carnot heat engine.

SET UP and EXECUTE: **(a)** We want the efficiency. $e = 1 - \dfrac{T_C}{T_H}$ = 1 – (200 K)/(500 K) = 0.60.

(b) Segment ab is the same as in Example 20.3, so W_{ab} = 576 J.
$W_{bc} = nC_V(T_H - T_C)$ = (0.200 mol)(20.8 J/mol·K) (500 K – 200 K) = 1250 J.
$W_{cd} = nRT_C\ln(V_d/V_c)$ = (0.200 mol)(8.314 J/mol·K)(200 K) ln(1/2) = –231 J.
$W_{da} = nC_V(T_C - T_H)$ = (0.200 mol)(20.8 J/mol·K) (200 K – 500 K) = –1250 J.

EVALUATE: The total work is 576 J + 1250 J – 231 J – 1250 J = 345 J. This is much more work than in Example 20.3 due to the greater temperature difference between the hot and cold reservoirs. We get much more work from the same heat input of 576 J.

VP20.4.3. **IDENTIFY:** This problem is about a refrigerator operating on a Carnot cycle. T_C = –10.0°C = 263.15 K and T_H = 25.0°C = 298.15 K.

SET UP and EXECUTE: **(a)** We want the coefficient of performance K.

$$K = \frac{T_C}{T_H - T_C} = \frac{263.15 \text{ K}}{298 \text{ K} - 263 \text{ K}} = 7.52.$$

(b) We want the work input. $K = \dfrac{|Q_C|}{|Q_H| - |Q_C|} = \dfrac{|Q_C|}{W}$. $W = \dfrac{|Q_C|}{K} = \dfrac{4.00\times 10^6 \text{ J}}{7.52} = 5.32\times 10^5 \text{ J}$.

EVALUATE: $Q_H = W + |Q_C| = 5.32\times 10^5 \text{ J} + 4.00\times 10^6 \text{ J} = 4.53\times 10^6 \text{ J}$. Each cycle this refrigerator discharges 4.53×10^6 J of heat into the room.

VP20.4.4. **IDENTIFY:** We are dealing with a Carnot heat engine. We know that $V_b = 2V_a$.

SET UP and EXECUTE: **(a)** We want the work done during the isothermal expansion ab.

$$W_{ab} = \int_a^b p\,dV = \int_a^b \frac{nRT}{V}dV = nRT_H \ln(V_b/V_a) = nRT_H \ln 2.$$

(b) We want the work done during the adiabatic expansion bc. $Q = 0$, so $W_{bc} = Q_{bc}$. So

$$W_{bc} = nC_V\Delta T_{bc} = n\left(\frac{3}{2}R\right)(T_H - T_C) = \frac{3}{2}nR(T_H - T_C).$$

(c) Given that $W_{ab} = W_{bc}$, we want e and the ratio of the cold to hot temperatures. Using the results from parts (a) and (b) gives $nRT_H \ln 2 = \dfrac{3}{2}nR(T_H - T_C)$, which gives $\dfrac{T_C}{T_H} = 1 - \dfrac{2}{3}\ln 2$. The efficiency is

$$e = 1 - \frac{T_C}{T_H} = 1 - \left(1 - \frac{2}{3}\ln 2\right) = \frac{2}{3}\ln 2 = 0.462.$$

EVALUATE: This is quite an efficient engine. It is not necessarily true that $W_{ab} = W_{bc}$ for any Carnot engine.

VP20.10.1. **IDENTIFY:** We want to calculate the entropy changes due to melting, boiling, and temperature change.

SET UP and EXECUTE: For constant temperature $\Delta S = \dfrac{Q}{T}$, and for changing temperature $\Delta S = \int \dfrac{dQ}{T}$.

We want the entropy change in each case.

(a) The temperature stays constant, so $\Delta S = \dfrac{Q}{T} = \dfrac{mL_\text{f}}{T} = \dfrac{(1.00\text{ kg})(1.042\times10^5\text{ J/kg})}{159\text{ K}} = 655\text{ J/K}.$

(b) The temperature increases, so $\Delta S = \int \dfrac{dQ}{T} = \int_{T_1}^{T_2} \dfrac{mcdT}{T} = mc\ln\left(T_2/T_1\right) =$ 1920 J/K using T_1 = 159 K, T_2 = 159 K, m = 1.00 kg, and $c = 2428\text{ J/kg}\cdot\text{K}$.

(c) The temperature stays constant, so $\Delta S = \dfrac{Q}{T} = \dfrac{mL_\text{v}}{T} = \dfrac{(1.00\text{ kg})(8.54\times10^5\text{ J/kg})}{351\text{ K}} = 2430\text{ J/K}.$

EVALUATE: The greatest increase is for boiling because $L_\text{v} >> L_\text{f}$.

VP20.10.2. **IDENTIFY:** This problem involves the entropy change due to helium expansion by two different processes. We want to compare the entropy change in the two cases.

SET UP and EXECUTE: For constant temperature $\Delta S = \dfrac{Q}{T}$, and for changing temperature $\Delta S = \int \dfrac{dQ}{T}$.

(a) For an isothermal expansion we use $\Delta S = \dfrac{Q}{T}$. Since T is constant, $\Delta U = 0$, so $Q = W$. This gives $Q = W = \int_{V_1}^{V_2} pdV = \int_{V_1}^{V_2} \dfrac{nRT}{V} dV = nRT\ln(V_2/V_1).$ $\Delta S = \dfrac{Q}{T} = \dfrac{nRT\ln(V_2/V_1)}{T} = nR\ln(V_2/V_1).$ Putting in the numbers gives $\Delta S = (5.00\text{ mol})(8.314\text{ J/mol}\cdot\text{K})\ln\left(\dfrac{0.360\text{ m}^3}{0.120\text{ m}^3}\right) = 45.7\text{ J/K}.$

(b) Start with a pV-diagram showing the process (Fig. VP20.10.2). Break the process into its two segments: ab is isobaric and bc is isochoric. We know that $T_a = T_c = 20.0°\text{C}$ and $V_c = V_b = 3V_a$.

Segment ab (constant pressure): The temperature is not constant, so we use $\Delta S = \int \dfrac{dQ}{T}$. The first law of thermodynamics (in its differential form) gives $dQ = dU + dW$. The pressure is constant, so $pV = nRT$ gives $pdV = nRdT$. Using this in the entropy calculation gives

$dS_{ab} = \dfrac{dQ}{T} = \dfrac{dU + dW}{T} = \dfrac{nC_V dT}{T} + \dfrac{pdV}{T} = \dfrac{nC_V dT}{T} + \dfrac{nRdT}{T}.$ Integrating gives

$$\Delta S_{ab} = \int_{T_a}^{T_b} \left(\frac{nC_V}{T} + \frac{nR}{T}\right) dT = nC_V\ln(T_b/T_a) + nR\ln(T_b/T_a).$$

Segment bc (constant volume): Since the volume is constant, $dW = 0$, so $dQ = dU = nC_V dT$. Therefore

$$\Delta S_{bc} = \int \frac{dQ}{T} = \int \frac{dU}{T} = \int_{T_b}^{T_c} \frac{nC_V dT}{T} = nC_V\ln(T_c/T_b).$$

The total entropy change is $\Delta S_{ac} = \Delta S_{ab} + \Delta S_{bc} = nC_V\ln(T_b/T_a) + nR\ln(T_b/T_a) + nC_V\ln(T_c/T_b)$. But $T_a = T_c = 20.0°\text{C}$, so $T_c/T_b = T_a/T_b$ which means that the first and third terms in the last sum are equal but have opposite signs, so they cancel. This leaves $\Delta S_{ac} = nR\ln(T_b/T_a)$. Using $pV = nRT$ for constant pressure tells us that $\dfrac{T_b}{T_a} = \dfrac{V_b}{V_a} = 3.$ Thus the total entropy change is

$$\Delta S_{ac} = nR\ln 3 = (5.00\text{ mol})(8.314\text{ J/mol}\cdot\text{K})\ln 3 = 45.7\text{ J/K}.$$

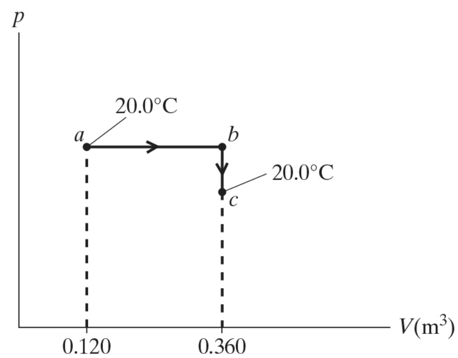

Figure VP20 10.2

EVALUATE: Notice that the entropy change is the same for both paths between the same initial and final states.

VP20.10.3. **IDENTIFY:** We are dealing the entropy change of a heat engine that is *not* using a Carnot cycle.

SET UP: For a constant temperature process $\Delta S = \frac{Q}{T}$. For one cycle, we want the entropy changes of the gas in the engine, the hot reservoir, and the cold reservoir. The two reservoirs are assumed to be so large that they do not change their temperatures as the engine runs. T_H = 260°C = 533.15 K and T_C = 20°C = 293.15 K.

EXECUTE: **(a)** $\Delta S = 0$ for a reversible cycle.

(b) The engine takes a quantity of heat Q_H *out* of the hot reservoir, so

$$\Delta S_{\text{hot res}} = \frac{Q}{T} = \frac{-Q_H}{T_H} = \frac{-8.00\times 10^4\ \text{J}}{533.15\ \text{K}} = -150\ \text{J/K}.$$

(b) The engine transfers a quantity of heat Q_C *into* the hot reservoir, so

$$\Delta S_{\text{cold res}} = \frac{Q}{T} = \frac{+Q_C}{T_H} = \frac{+6.40\times 10^4\ \text{J}}{293.15\ \text{K}} = +218\ \text{J/K}.$$

(c) $\Delta S_{\text{tot}} = \Delta S_{\text{engine}} + \Delta S_{\text{hot res}} + \Delta S_{\text{cold res}} = 0 - 150\ \text{J/K} + 218\ \text{J/K} = +68\ \text{J/K}$. The entropy of the system *increases*.

EVALUATE: The entropy of the universe (that is, the total entropy) increases.

VP20.10.4. **IDENTIFY:** We are looking at the entropy change for an *irreversible* process.

SET UP: For ice melting at constant temperature $\Delta S = \frac{Q}{T}$, and for water changing temperature $\Delta S = \int \frac{dQ}{T}$. We want the entropy change of the ice and of the water and the total entropy change for the entire system. T_1 = 0.0°C = 273 K and T_2 = 95.0°C = 368 K.

EXECUTE: **(a)** $\Delta S_{\text{ice}} = \frac{Q}{T} = \frac{mL_f}{T} = \frac{(1.00\ \text{kg})(3.34\times 10^5\ \text{J/kg})}{273.15\ \text{K}} = +1220\ \text{J/K}.$

(b) $\Delta S_{\text{water}} = \int \frac{dQ}{T} = \int_{368\ \text{K}}^{273\ \text{K}} \frac{mcdT}{T} = (0.839\ \text{kg})(4190\ \text{J/kg}\cdot\text{K})\ln\left(\frac{273\ \text{K}}{368\ \text{K}}\right) = -1050\ \text{J/K}.$

(c) $\Delta S_{\text{system}} =$ +1220 J/K – 1050 J/K = +170 J/K. The entropy increases.

EVALUATE: This is an irreversible process so the entropy should increase, as we've found.

20.1. **IDENTIFY:** For a heat engine, $W = |Q_H| - |Q_C|$. $e = \frac{W}{Q_H}$. $Q_H > 0$, $Q_C < 0$.

SET UP: $W = 2200$ J. $|Q_C| = 4300$ J.

EXECUTE: (a) $Q_H = W + |Q_C| = 6500\ \text{J}.$

(b) $e = \dfrac{2200\ \text{J}}{6500\ \text{J}} = 0.34 = 34\%.$

EVALUATE: Since the engine operates on a cycle, the net Q equal the net W. But to calculate the efficiency we use the heat energy input, Q_H.

20.2. **IDENTIFY:** For a heat engine, $W = |Q_H| - |Q_C|$. $e = \dfrac{W}{Q_H}$. $Q_H > 0,\ Q_C < 0.$

SET UP: $|Q_H| = 9000\ \text{J}$. $|Q_C| = 6400\ \text{J}.$

EXECUTE: (a) $W = 9000\ \text{J} - 6400\ \text{J} = 2600\ \text{J}.$

(b) $e = \dfrac{W}{Q_H} = \dfrac{2600\ \text{J}}{9000\ \text{J}} = 0.29 = 29\%.$

EVALUATE: Since the engine operates on a cycle, the net Q equal the net W. But to calculate the efficiency we use the heat energy input, Q_H.

20.3. **IDENTIFY** and **SET UP:** The problem deals with a heat engine. $W = +3700\ \text{W}$ and $Q_H = +16{,}100\ \text{J}.$
Use $e = \dfrac{W}{Q_H} = 1 - \left|\dfrac{Q_C}{Q_H}\right|$ to calculate the efficiency e and $W = |Q_H| - |Q_C|$ to calculate $|Q_C|$.
Power $= W/t$.

EXECUTE: (a) $e = \dfrac{\text{work output}}{\text{heat energy input}} = \dfrac{W}{Q_H} = \dfrac{3700\ \text{J}}{16{,}100\ \text{J}} = 0.23 = 23\%.$

(b) $W = Q = |Q_H| - |Q_C|$
Heat discarded is $|Q_C| = |Q_H| - W = 16{,}100\ \text{J} - 3700\ \text{J} = 12{,}400\ \text{J}.$

(c) Q_H is supplied by burning fuel; $Q_H = mL_c$ where L_c is the heat of combustion.

$m = \dfrac{Q_H}{L_c} = \dfrac{16{,}100\ \text{J}}{4.60\times10^4\ \text{J/g}} = 0.350\ \text{g}.$

(d) $W = 3700$ J per cycle
In $t = 1.00\ \text{s}$ the engine goes through 60.0 cycles.
$P = W/t = 60.0(3700\ \text{J})/1.00\ \text{s} = 222\ \text{kW}$

$P = (2.22\times10^5\ \text{W})(1\ \text{hp}/746\ \text{W}) = 298\ \text{hp}$

EVALUATE: $Q_C = -12{,}400\ \text{J}$. In one cycle $Q_{tot} = Q_C + Q_H = 3700\ \text{J}$. This equals W_{tot} for one cycle.

20.4. **IDENTIFY:** $W = |Q_H| - |Q_C|$. $e = \dfrac{W}{Q_H}$. $Q_H > 0,\ Q_C < 0.$

SET UP: For 1.00 s, $W = 180\times10^3\ \text{J}.$

EXECUTE: (a) $Q_H = \dfrac{W}{e} = \dfrac{180\times10^3\ \text{J}}{0.280} = 6.43\times10^5\ \text{J}.$

(b) $|Q_C| = |Q_H| - W = 6.43\times10^5\ \text{J} - 1.80\times10^5\ \text{J} = 4.63\times10^5\ \text{J}.$

EVALUATE: Of the 6.43×10^5 J of heat energy supplied to the engine each second, 1.80×10^5 J is converted to mechanical work and the remaining 4.63×10^5 J is discarded into the low temperature reservoir.

20.5. **IDENTIFY:** This cycle involves adiabatic (ab), isobaric (bc), and isochoric (ca) processes.
SET UP: ca is at constant volume, ab has $Q = 0$, and bc is at constant pressure. For a constant pressure process $W = p\Delta V$ and $Q = nC_p\,\Delta T$. $pV = nRT$ gives $n\Delta T = \dfrac{p\Delta V}{R}$, so $Q = \left(\dfrac{C_p}{R}\right)p\Delta V$. If $\gamma = 1.40$

the gas is diatomic and $C_p = \frac{7}{2}R$. For a constant volume process $W = 0$ and $Q = nC_V\ \Delta T$. $pV = nRT$ gives $n\Delta T = \dfrac{V\Delta p}{R}$, so $Q = \left(\dfrac{C_V}{R}\right)V\Delta p$. For a diatomic ideal gas $C_V = \frac{5}{2}R$. $1\text{ atm} = 1.013\times10^5$ Pa.

EXECUTE: **(a)** $V_b = 9.0\times10^{-3}\text{ m}^3$, $p_b = 1.5$ atm and $V_a = 2.0\times10^{-3}\text{ m}^3$. For an adiabatic process $p_aV_a^\gamma = p_bV_b^\gamma$. $p_a = p_b\left(\dfrac{V_b}{V_a}\right)^\gamma = (1.5\text{ atm})\left(\dfrac{9.0\times10^{-3}\text{ m}^3}{2.0\times10^{-3}\text{ m}^3}\right)^{1.4} = 12.3$ atm.

(b) Heat enters the gas in process ca, since T increases.

$Q = \left(\dfrac{C_V}{R}\right)V\Delta p = \left(\dfrac{5}{2}\right)(2.0\times10^{-3}\text{ m}^3)(12.3\text{ atm} - 1.5\text{ atm})(1.013\times10^5\text{ Pa/atm}) = 5470\text{ J}$. $Q_\text{H} = 5470$ J.

(c) Heat leaves the gas in process bc, since T decreases.

$Q = \left(\dfrac{C_p}{R}\right)p\Delta V = \left(\dfrac{7}{2}\right)(1.5\text{ atm})(1.013\times10^5\text{ Pa/atm})(-7.0\times10^{-3}\text{ m}^3) = -3723\text{ J}$. $Q_\text{C} = -3723$ J.

(d) $W = Q_\text{H} + Q_\text{C} = +5470\text{ J} + (-3723\text{ J}) = 1747\text{ J}$.

(e) $e = \dfrac{W}{Q_\text{H}} = \dfrac{1747\text{ J}}{5470\text{ J}} = 0.319 = 31.9\%$.

EVALUATE: We did not use the number of moles of the gas.

20.6. **IDENTIFY and SET UP:** This problem deals with the work done by a heat engine. We want to find the work done during 100 cycles. $|Q_\text{H}| = W + |Q_\text{C}|$. $Q_\text{C} = mL_\text{f}$. We know that $Q_\text{H} = 8000$ J.

EXECUTE: $Q_\text{C} = mL_\text{f} = (0.0180\text{ kg})(334{,}000\text{ J/kg}) = 6012$ J. $W = |Q_\text{H}| - |Q_\text{C}| = 8000\text{ J} - 6012\text{ J} = 1990$ J.

EVALUATE: The efficiency of this engine is $e = W/Q_\text{H} = (1990\text{ J})/(8000\text{ J}) = 0.249$, which is typical of many engines.

20.7. **IDENTIFY and SET UP:** We are dealing with an engine operating on the Otto cycle for which $\gamma = 7/5$ and $e = 0.63$. The compression ration r, which we want to find, is given by $\dfrac{1}{r^{\gamma-1}} = 1 - e$.

EXECUTE: **(a)** We want r. Solving $\dfrac{1}{r^{\gamma-1}} = 1 - e$ for r gives $r^{\gamma-1} = \dfrac{1}{1-e}$, so $r^{7/5-1} = \dfrac{1}{1-0.63}$, which gives $r = 12$.

(b) We want the rejected and absorbed heat if the engine does 12.6 kJ of work per cycle. Solving $e = W/Q_\text{H}$ for Q_H gives $Q_\text{H} = W/e = (12.6\text{ kJ})/(0.63) = 20$ kJ.

Using $|Q_\text{H}| = W + |Q_\text{C}|$ gives $Q_\text{C} = Q_\text{H} - W = 20\text{ kJ} - 12.6\text{ kJ} = 7.4$ kJ.

EVALUATE: This engine is indeed very efficient at 63%.

20.8. **IDENTIFY:** Apply $e = 1 - \dfrac{1}{r^{\gamma-1}}$. $e = 1 - \dfrac{|Q_\text{C}|}{|Q_\text{H}|}$.

SET UP: In part (b), $Q_\text{H} = 10{,}000$ J. The heat discarded is $|Q_\text{C}|$.

EXECUTE: **(a)** $e = 1 - \dfrac{1}{9.50^{0.40}} = 0.594 = 59.4\%$.

(b) $|Q_\text{C}| = |Q_\text{H}|(1-e) = (10{,}000\text{ J})(1 - 0.594) = 4060\text{ J}$.

EVALUATE: The work output of the engine is $W = |Q_\text{H}| - |Q_\text{C}| = 10{,}000\text{ J} - 4060\text{ J} = 5940\text{ J}$.

20.9. **IDENTIFY:** For the Otto-cycle engine, $e = 1 - r^{1-\gamma}$.

SET UP: r is the compression ratio.

EXECUTE: **(a)** $e = 1 - (8.8)^{-0.40} = 0.581$, which rounds to 58%.

(b) $e = 1 - (9.6)^{20.40} = 0.595$ an increase of 1.4%.

EVALUATE: An increase in *r* gives an increase in *e*.

20.10. **IDENTIFY:** $|Q_\text{H}| = |Q_\text{C}| + |W|$. $K = \dfrac{|Q_\text{C}|}{W}$.

SET UP: For water, $c_\text{w} = 4190\ \text{J/kg} \cdot \text{K}$ and $L_\text{f} = 3.34 \times 10^5\ \text{J/kg}$. For ice, $c_\text{ice} = 2100\ \text{J/kg} \cdot \text{K}$.

EXECUTE: **(a)** $Q = mc_\text{ice}\Delta T_\text{ice} - mL_\text{f} + mc_\text{w}\Delta T_\text{w}$.

$$Q = (1.80\ \text{kg})\left[(2100\ \text{J/kg} \cdot \text{K})(-5.0\ \text{C}°) - 3.34 \times 10^5\ \text{J/kg} + (4190\ \text{J/kg} \cdot \text{K})(-25.0\ \text{C}°)\right] = -8.09 \times 10^5\ \text{J}$$

$Q = -8.09 \times 10^5$ J. Q is negative for the water since heat is removed from it.

(b) $|Q_\text{C}| = 8.09 \times 10^5$ J. $W = \dfrac{|Q_\text{C}|}{K} = \dfrac{8.09 \times 10^5\ \text{J}}{2.40} = 3.37 \times 10^5$ J.

(c) $|Q_\text{H}| = 8.09 \times 10^5\ \text{J} + 3.37 \times 10^5\ \text{J} = 1.15 \times 10^6$ J.

EVALUATE: For this device, $Q_\text{C} > 0$ and $Q_\text{H} < 0$. More heat is rejected to the room than is removed from the water.

20.11. **IDENTIFY:** The heat $Q = mc\Delta T$ that comes out of the water to cool it to 5.0°C is Q_C for the refrigerator.

SET UP: For water 1.0 L has a mass of 1.0 kg and $c = 4.19 \times 10^3\ \text{J/kg} \cdot \text{C}°$. $P = \dfrac{|W|}{t}$. The coefficient of performance is $K = \dfrac{|Q_\text{C}|}{|W|}$.

EXECUTE: $Q = mc\Delta T = (12.0\ \text{kg})(4.19 \times 10^3\ \text{J/kg} \cdot \text{C}°)(5.0°\text{C} - 31°\text{C}) = -1.31 \times 10^6$ J. $|Q_\text{C}| = 1.31 \times 10^6$ J.

$$K = \frac{|Q_\text{C}|}{|W|} = \frac{|Q_\text{C}|}{Pt} \text{ so } t = \frac{|Q_\text{C}|}{PK} = \frac{1.31 \times 10^6\ \text{J}}{(135\ \text{W})(2.25)} = 4313\ \text{s} = 71.88\ \text{min} = 1.20\ \text{h}.$$

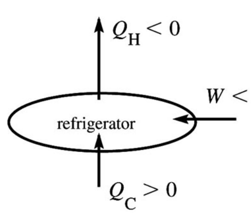
EVALUATE: 1.2 h seems like a reasonable time to cool down the dozen bottles.

20.12. **IDENTIFY** and **SET UP:** For the refrigerator $K = 2.10$ and $Q_\text{C} = +3.1 \times 10^4$ J. Use $K = Q_\text{C}/|W|$ to calculate $|W|$ and then $W = Q_\text{C} + Q_\text{H}$ to calculate Q_H.

EXECUTE: **(a)** Coefficient of performance: $K = Q_\text{C}/|W|$.

$|W| = Q_\text{C}/K = 3.10 \times 10^4\ \text{J}/2.10 = 1.48 \times 10^4$ J.

(b) The operation of the device is illustrated in Figure 20.12.



$W = Q_\text{C} + Q_\text{H}$

$Q_\text{H} = W - Q_\text{C}$

$Q_\text{H} = -1.48 \times 10^4\ \text{J} - 3.10 \times 10^4\ \text{J} = -4.58 \times 10^4$ J (negative because heat goes out of the system)

Figure 20.12

EVALUATE: $|Q_\text{H}| = |W| + |Q_\text{C}|$. The heat $|Q_\text{H}|$ delivered to the high temperature reservoir is greater than the heat taken in from the low temperature reservoir.

20.13. **IDENTIFY:** The hot reservoir of a Carnot engine is 72.0 C° higher than the cold reservoir and this engine is 12.5% efficient. We want the temperature of the two reservoirs.

SET UP: For a Carnot engine $e = 1 - \dfrac{T_\text{C}}{T_\text{H}}$. $T_\text{C} = T_\text{H} - 72.0$ K.

EXECUTE: $e = 1 - \dfrac{T_C}{T_H} = 1 - \dfrac{T_H - 72.0\text{ K}}{T_H} = 0.125$ gives $T_H = 576$ K, so $T_C = 576\text{ K} - 72\text{ K} = 504$ K.

EVALUATE: Careful! The 72.0 C° is a temperature *difference*. Since Kelvin and Celsius degrees are the same size, so $\Delta T_K = \Delta T_C$. We should *not* convert the 72.0 C° to get 345 K.

20.14. **IDENTIFY:** $|W| = |Q_H| - |Q_C|$. $Q_C < 0$, $Q_H > 0$. $e = \dfrac{W}{Q_H}$. For a Carnot cycle, $\dfrac{Q_C}{Q_H} = -\dfrac{T_C}{T_H}$.

SET UP: $T_C = 300$ K, $T_H = 520$ K. $|Q_H| = 6.45\times10^3$ J.

EXECUTE: **(a)** $Q_C = -Q_H\left(\dfrac{T_C}{T_H}\right) = -(6.45\times10^3\text{ J})\left(\dfrac{300\text{ K}}{520\text{ K}}\right) = -3.72\times10^3$ J.

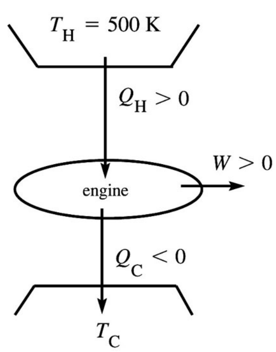
(b) $|W| = |Q_H| - |Q_C| = 6.45\times10^3\text{ J} - 3.72\times10^3\text{ J} = 2.73\times10^3$ J.

(c) $e = \dfrac{W}{Q_H} = \dfrac{2.73\times10^3\text{ J}}{6.45\times10^3\text{ J}} = 0.423 = 42.3\%$.

EVALUATE: We can verify that $e = 1 - T_C/T_H$ also gives $e = 42.3\%$.

20.15. **IDENTIFY** and **SET UP:** Use $W = Q_C + Q_H$ to calculate $|W|$. Since it is a Carnot device we can use $\dfrac{|Q_C|}{|Q_H|} = \dfrac{T_C}{T_H}$ to relate the heat flows out of the reservoirs. The reservoir temperatures can be used in $e_{\text{Carnot}} = 1 - \dfrac{T_C}{T_H}$ to calculate e.

EXECUTE: **(a)** The operation of the device is sketched in Figure 20.15.



$W = Q_C + Q_H$
$W = -335\text{ J} + 550\text{ J} = 215\text{ J}$

Figure 20.15

(b) For a Carnot cycle, $\dfrac{|Q_C|}{|Q_H|} = \dfrac{T_C}{T_H}$, which gives

$$T_C = T_H\frac{|Q_C|}{|Q_H|} = 620\text{ K}\left(\frac{335\text{ J}}{550\text{ J}}\right) = 378\text{ K}.$$

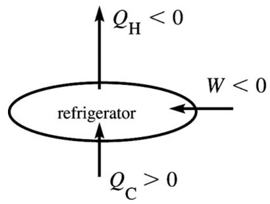
(c) $e_{\text{Carnot}} = 1 - T_C/T_H = 1 - 378\text{ K}/620\text{ K} = 0.390 = 39.0\%$.

EVALUATE: We could use the fundamental definition of e, $e = \dfrac{W}{Q_H}$:

$e = W/Q_H = (215\text{ J})/(550\text{ J}) = 39\%$, which checks.

20.16. **IDENTIFY** and **SET UP:** The device is a Carnot refrigerator.
We can use $W = Q_C + Q_H$ and $|Q_C|/|Q_H| = T_C/T_H$.

(a) The operation of the device is sketched in Figure 20.16.



$T_H = 24.0°C = 297$ K
$T_C = 0.0°C = 273$ K

Figure 20.16

The amount of heat taken out of the water to make the liquid $\rightarrow$ solid phase change is $Q = -mL_f = -(85.0\text{ kg})(334\times10^3\text{ J/kg}) = -2.84\times10^7$ J. This amount of heat must go into the working substance of the refrigerator, so $Q_C = +2.84\times10^7$ J. For Carnot cycle $|Q_C|/|Q_H| = T_C/T_H$.

EXECUTE: $|Q_H| = |Q_C|(T_H/T_C) = 2.84\times10^7\text{ J}(297\text{ K}/273\text{ K}) = 3.09\times10^7$ J.

(b) $W = Q_C + Q_H = +2.84\times10^7\text{ J} - 3.09\times10^7\text{ J} = -2.5\times10^6$ J

EVALUATE: W is negative because this much energy must be supplied to the refrigerator rather than obtained from it. Note that in $W = Q_C + Q_H$ we must use Kelvin temperatures.

20.17. IDENTIFY: $e = \dfrac{W}{Q_H}$ for any engine. For the Carnot cycle, $\dfrac{Q_C}{Q_H} = -\dfrac{T_C}{T_H}$.

SET UP: $T_C = 20.0°C + 273.15\text{ K} = 293.15$ K

EXECUTE: **(a)** $Q_H = \dfrac{W}{e} = \dfrac{2.5\times10^4\text{ J}}{0.66} = 3.79\times10^4$ J, which rounds to 3.8×10^4 J.

(b) $W = Q_H + Q_C$ so $Q_C = W - Q_H = 2.5\times10^4\text{ J} - 3.79\times10^4\text{ J} = -1.29\times10^4$ J.

$$T_H = -T_C\frac{Q_H}{Q_C} = -(293.15\text{ K})\left(\frac{3.79\times10^4\text{ J}}{-1.29\times10^4\text{ J}}\right) = 861\text{ K} = 590°C.$$

EVALUATE: For a heat engine, $W > 0$, $Q_H > 0$ and $Q_C < 0$.

20.18. IDENTIFY: The theoretical maximum performance coefficient is a $K_{\text{Cannot}} = \dfrac{T_C}{T_H - T_C}$. $K = \dfrac{|Q_C|}{|W|}$. $|Q_C|$ is the heat removed from the water to convert it to ice. For the water, $|Q| = mc_w\Delta T + mL_f$.

SET UP: $T_C = -5.0°C = 268$ K. $T_H = 20.0°C = 293$ K. $c_w = 4190\text{ J/kg}\cdot\text{K}$ and $L_f = 334\times10^3$ J/kg.

EXECUTE: **(a)** In one year the freezer operates $(5\text{ h/day})(365\text{ days}) = 1825$ h.

$$P = \frac{730\text{ kWh}}{1825\text{ h}} = 0.400\text{ kW} = 400\text{ W}.$$

(b) $K_{\text{Carnot}} = \dfrac{268\text{ K}}{293\text{ K} - 268\text{ K}} = 10.7.$

(c) $|W| = Pt = (400\text{ W})(3600\text{ s}) = 1.44\times10^6$ J. $|Q_C| = K|W| = 1.54\times10^7$ J. $|Q| = mc_w\Delta T + mL_f$ gives

$$m = \frac{|Q_C|}{c_w\Delta T + L_f} = \frac{1.54\times10^7\text{ J}}{(4190\text{ J/kg}\cdot\text{K})(20.0\text{ K}) + 334\times10^3\text{ J/kg}} = 36.9\text{ kg}.$$

EVALUATE: For any actual device, $K < K_{\text{Carnot}}$, $|Q_C|$ is less than we calculated and the freezer makes less ice in one hour than the mass we calculated in part (c).

20.19. IDENTIFY: $|Q_H| = |W| + |Q_C|$. $Q_H < 0$, $Q_C > 0$. $K = \dfrac{|Q_C|}{|W|}$. For a Carnot cycle, $\dfrac{Q_C}{Q_H} = -\dfrac{T_C}{T_H}$.

SET UP: $T_C = 270$ K, $T_H = 320$ K. $|Q_C| = 415$ J.

EXECUTE: **(a)** $Q_H = -\left(\frac{T_H}{T_C}\right)Q_C = -\left(\frac{320\text{ K}}{270\text{ K}}\right)(415\text{ J}) = -492\text{ J}.$

(b) For one cycle, $|W| = |Q_H| - |Q_C| = 492\text{ J} - 415\text{ J} = 77\text{ J}.$ $P = \frac{(165)(77\text{ J})}{60\text{ s}} = 212\text{ W}.$

(c) $K = \frac{|Q_C|}{|W|} = \frac{415\text{ J}}{77\text{ J}} = 5.4.$

EVALUATE: The amount of heat energy $|Q_H|$ delivered to the high-temperature reservoir is greater than the amount of heat energy $|Q_C|$ removed from the low-temperature reservoir.

20.20. **IDENTIFY:** $W = Q_C + Q_H$. For a Carnot cycle, $\frac{Q_C}{Q_H} = -\frac{T_C}{T_H}$. For the ice to liquid water phase transition, $Q = mL_f$.

SET UP: For water, $L_f = 334\times10^3$ J/kg.

EXECUTE: $Q_C = -mL_f = -(0.0400\text{ kg})(334\times10^3\text{ J/kg}) = -1.336\times10^4\text{ J}.$ $\frac{Q_C}{Q_H} = -\frac{T_C}{T_H}$ gives

$Q_H = -(T_H/T_C)Q_C = -(-1.336\times10^4\text{ J})\left[(373.15\text{ K})/(273.15\text{ K})\right] = +1.825\times10^4\text{ J}.$

$W = Q_C + Q_H = 4.89\times10^3\text{ J}.$

EVALUATE: For a heat engine, Q_C is negative and Q_H is positive. The heat that comes out of the engine $(Q < 0)$ goes into the ice $(Q > 0)$.

20.21. **IDENTIFY and SET UP:** We are looking at two refrigerators, *A* and *B*, operating on a Carnot cycle. The coefficient of performance of a Carnot refrigerator is $K_{\text{Carnot}} = \frac{T_C}{T_H - T_C} = \frac{T_C}{\Delta T}$. We know that $K_A = K_B + 0.16K_B = 1.16K_B$, $\Delta T_B = \Delta T_A + 0.30\Delta T_A = 1.30\Delta T_A$, and $T_C(B)$ = 180 K. We want to find the cold reservoir temperature for *A*, $T_C(A)$.

EXECUTE: $K_A = \frac{T_C(A)}{\Delta T_A}$ and $K_B = \frac{T_C(B)}{\Delta T_B}$, so $\frac{K_A}{K_B} = \frac{\frac{T_C(A)}{\Delta T_A}}{\frac{T_C(B)}{\Delta T_B}}$. Using the given information, we have

$\frac{1.16K_B}{K_B} = \frac{T_C(A)}{T_C(B)}\frac{\Delta T_B}{\Delta T_A} = \frac{T_C(A)}{T_C(B)}\frac{1.30\Delta T_A}{\Delta T_A}$. This gives $1.16 = \frac{1.30T_C(A)}{180\text{ K}}$, so $T_C(A)$ = 161 K.

EVALUATE: All temperatures must be in Kelvins.

20.22. **IDENTIFY:** Apply $Q_{\text{system}} = 0$ to calculate the final temperature. $Q = mc\Delta T$. $\Delta S = mc\ln(T_2/T_1)$ when an object undergoes a temperature change.

SET UP: For water $c = 4190\text{ J/kg}\cdot\text{K}$. Boiling water has $T = 100.0°\text{C} = 373\text{ K}$.

EXECUTE: **(a)** The heat transfer between 100°C water and 30°C water occurs over a finite temperature difference and the process is irreversible.

(b) $(195\text{ kg})c(T_2 - 30.0°\text{C}) + (5.00\text{ kg})c(T_2 - 100°\text{C}) = 0.$ $T_2 = 31.75°\text{C} = 304.90\text{ K}.$

(c) $\Delta S = (195\text{ kg})(4190\text{ J/kg}\cdot\text{K})\ln\left(\frac{304.90\text{ K}}{303.15\text{ K}}\right) + (5.00\text{ kg})(4190\text{ J/kg}\cdot\text{K})\ln\left(\frac{304.90\text{ K}}{373.15\text{ K}}\right) = 471\text{ J/K}.$

EVALUATE: $\Delta S_{\text{system}} > 0$, as it should for an irreversible process.

20.23. **IDENTIFY:** $\Delta S = \frac{Q}{T}$ for each object, where *T* must be in kelvins. The temperature of each object remains constant.

SET UP: For water, $L_f = 3.34\times10^5$ J/kg.

EXECUTE: **(a)** The heat flow into the ice is $Q = mL_f = (0.350\text{ kg})(3.34\times10^5\text{ J/kg}) = 1.17\times10^5\text{ J}$. The heat flow occurs at $T = 273$ K, so $\Delta S = \dfrac{Q}{T} = \dfrac{1.17\times10^5\text{ J}}{273\text{ K}} = 429$ J/K. Q is positive and ΔS is positive.

(b) $Q = -1.17\times10^5$ J flows out of the heat source, at $T = 298$ K. $\Delta S = \dfrac{Q}{T} = \dfrac{-1.17\times10^5\text{ J}}{298\text{ K}} = -393$ J/K. Q is negative and ΔS is negative.

(c) $\Delta S_{\text{tot}} = 429\text{ J/K} + (-393\text{ J/K}) = +36\text{ J/K}$.

EVALUATE: For the total isolated system, $\Delta S > 0$ and the process is irreversible.

20.24. IDENTIFY: $Q = mc\Delta T$ for the water. $\Delta S = mc\ln(T_2/T_1)$ when an object undergoes a temperature change. $\Delta S = Q/T$ for an isothermal process.

SET UP: For water, $c = 4190\text{ J/kg}\cdot\text{K}$. $85.0°\text{C} = 358.2$ K. $20.0°\text{C} = 293.2$ K.

EXECUTE: **(a)** $\Delta S = mc\ln\left(\dfrac{T_2}{T_1}\right) = (0.250\text{ kg})(4190\text{ J/kg}\cdot\text{K})\ln\left(\dfrac{293.2\text{ K}}{358.2\text{ K}}\right) = -210$ J/K. Heat comes out of the water and its entropy decreases.

(b) $Q = mc\Delta T = (0.250)(4190\text{ J/kg}\cdot\text{K})(-65.0\text{ K}) = -6.81\times10^4$ J. The amount of heat that goes into the air is $+6.81\times10^4$ J. For the air, $\Delta S = \dfrac{Q}{T} = \dfrac{+6.81\times10^4\text{ J}}{293.1\text{ K}} = +232$ J/K.

$\Delta S_{\text{system}} = -210\text{ J/K} + 232\text{ J/K} = +22\text{ J/K}$.

EVALUATE: $\Delta S_{\text{system}} > 0$ and the process is irreversible.

20.25. IDENTIFY: The process is at constant temperature, so $\Delta S = \dfrac{Q}{T}$. $\Delta U = Q - W$.

SET UP: For an isothermal process of an ideal gas, $\Delta U = 0$ and $Q = W$. For a compression, $\Delta V < 0$ and $W < 0$.

EXECUTE: $Q = W = -1850$ J. $\Delta S = \dfrac{-1850\text{ J}}{293\text{ K}} = -6.31$ J/K.

EVALUATE: The entropy change of the gas is negative. Heat must be removed from the gas during the compression to keep its temperature constant and therefore the gas is not an isolated system.

20.26. IDENTIFY and SET UP: The initial and final states are at the same temperature, at the normal boiling point of 4.216 K. Calculate the entropy change for the irreversible process by considering a reversible isothermal process that connects the same two states, since ΔS is path independent and depends only on the initial and final states. For the reversible isothermal process we can use $\Delta S = Q/T$.

The heat flow for the helium is $Q = -mL_v$, negative since in condensation heat flows out of the helium.

The heat of vaporization L_v is given in Table 17.4 and is $L_v = 20.9\times10^3$ J/kg.

EXECUTE: $Q = -mL_v = -(0.130\text{ kg})(20.9\times10^3\text{ J/kg}) = -2717$ J

$\Delta S = Q/T = -2717\text{ J}/4.216\text{ K} = -644$ J/K.

EVALUATE: The system we considered is the 0.130 kg of helium; ΔS is the entropy change of the helium. This is not an isolated system since heat must flow out of it into some other material. Our result that $\Delta S < 0$ doesn't violate the second law since it is not an isolated system. The material that receives the heat that flows out of the helium would have a positive entropy change and the total entropy change would be positive.

20.27. IDENTIFY: Each phase transition occurs at constant temperature and $\Delta S = \dfrac{Q}{T}$. $Q = mL_{\text{v}}$.

SET UP: For vaporization of water, $L_{\text{v}} = 2256\times10^3$ J/kg.

EXECUTE: **(a)** $\Delta S = \dfrac{Q}{T} = \dfrac{mL\text{v}}{T} = \dfrac{(1.00\text{ kg})(2256\times10^3\text{ J/kg})}{(373.15\text{ K})} = 6.05\times10^3$ J/K. Note that this is the change of entropy of the water as it changes to steam.

(b) The magnitude of the entropy change is roughly five times the value found in Example 20.5.

EVALUATE: Water is less ordered (more random) than ice, but water is far less random than steam; a consideration of the density changes indicates why this should be so.

20.28. IDENTIFY and SET UP: **(a)** The velocity distribution of the Maxwell-Boltzmann distribution, $f(v) = 4\pi\left(\dfrac{m}{2\pi kT}\right)^{3/2} v^2 e^{-mv^2/2kT}$, depends only on T, so in an isothermal process it does not change.

(b) EXECUTE: Calculate the change in the number of available microscopic states and apply Eq. (20.23). Following the reasoning of Example 20.11, the number of possible positions available to each molecule is altered by a factor of 3 (becomes larger). Hence the number of microscopic states the gas occupies at volume $3V$ is $w_2 = (3)^N w_1$, where N is the number of molecules and w_1 is the number of possible microscopic states at the start of the process, where the volume is V. Then, using $\Delta S = k\ln(w_2/w_1)$, we have $\Delta S = k\ln(w_2/w_1) = k\ln(3)^N = Nk\ln(3) = nN_{\text{A}}k\ln(3) = nR\ln(3)$.

$\Delta S = (2.00\text{ mol})(8.3145\text{ J/mol}\cdot\text{K})\ln(3) = +18.3$ J/K.

(c) IDENTIFY and SET UP: For an isothermal reversible process $\Delta S = Q/T$.

EXECUTE: Calculate W and then use the first law to calculate Q.

$\Delta T = 0$ implies that $\Delta U = 0$, since system is an ideal gas.

Then by $\Delta U = Q - W$, $Q = W$.

For an isothermal process, $W = \int_{V_1}^{V_2} p\,dV = \int_{V_1}^{V_2} (nRT/V)\,dV = nRT\ln(V_2/V_1)$.

Thus $Q = nRT\ln(V_2/V_1)$ and $\Delta S = Q/T = nR\ln(V_2/V_1)$.

$\Delta S = (2.00\text{ mol})(8.3145\text{ J/mol}\cdot\text{K})\ln(3V_1/V_1) = +18.3$ J/K.

EVALUATE: This is the same result as obtained in part (b).

20.29. IDENTIFY: For a free expansion, $\Delta S = nR\ln(V_2/V_1)$.

SET UP: $V_1 = 2.40\text{ L} = 2.40\times10^{-3}\text{ m}^3$.

EXECUTE: $\Delta S = (0.100\text{ mol})(8.314\text{ J/mol}\cdot\text{K})\ln\left(\dfrac{425\text{ m}^3}{2.40\times10^{-3}\text{ m}^3}\right) = 10.0$ J/K.

EVALUATE: $\Delta S_{\text{system}} > 0$ and the free expansion is irreversible.

20.30. IDENTIFY: For a Carnot engine, $\dfrac{Q_{\text{C}}}{Q_{\text{H}}} = -\dfrac{T_{\text{C}}}{T_{\text{H}}}$. $e_{\text{Carnot}} = 1 - \dfrac{T_{\text{C}}}{T_{\text{H}}}$. $|W| = |Q_{\text{H}}| - |Q_{\text{C}}|$. $Q_{\text{H}} > 0$, $Q_{\text{C}} < 0$. $pV = nRT$.

SET UP: The work done by the engine each cycle is $mg\Delta y$, with $m = 15.0$ kg and $\Delta y = 2.00$ m. $T_{\text{H}} = 773$ K. $Q_{\text{H}} = 500$ J.

EXECUTE: **(a)** The pV diagram is sketched in Figure 20.30.

(b) $W = mg\Delta y = (15.0\text{ kg})(9.80\text{ m/s}^2)(2.00\text{ m}) = 294$ J. $|Q_{\text{C}}| = |Q_{\text{H}}| - |W| = 500\text{ J} - 294\text{ J} = 206$ J, and $Q_{\text{C}} = -206$ J.

$$T_{\text{C}} = -T_{\text{H}}\left(\frac{Q_{\text{C}}}{Q_{\text{H}}}\right) = -(773\text{ K})\left(\frac{-206\text{ J}}{500\text{ J}}\right) = 318\text{ K} = 45°\text{C}.$$

(c) $e = 1 - \dfrac{T_\text{C}}{T_\text{H}} = 1 - \dfrac{318\text{ K}}{773\text{ K}} = 0.589 = 58.9\%.$

(d) $|Q_\text{C}| = 206\text{ J}.$

(e) The maximum pressure is for state a. This is also where the volume is a minimum, so $V_a = 5.00\text{ L} = 5.00\times10^{-3}\text{ m}^3.$ $T_a = T_\text{H} = 773\text{ K}.$

$$p_a = \frac{nRT_a}{V_a} = \frac{(2.00\text{ mol})(8.315\text{ J/mol}\cdot\text{K})(773\text{ K})}{5.00\times10^{-3}\text{ m}^3} = 2.57\times10^6\text{ Pa}.$$

EVALUATE: We can verify that $e = \dfrac{W}{Q_\text{H}}$ gives the same value for e as calculated in part (c).

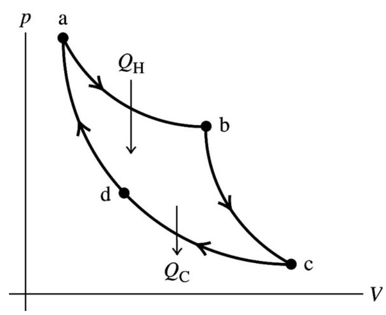


Figure 20.30

20.31. **IDENTIFY:** The total work that must be done is $W_\text{tot} = mg\Delta y$. $|W| = |Q_\text{H}| - |Q_\text{C}|$. $Q_\text{H} > 0$, $W > 0$ and $Q_\text{C} < 0$. For a Carnot cycle, $\dfrac{Q_\text{C}}{Q_\text{H}} = -\dfrac{T_\text{C}}{T_\text{H}}$.

SET UP: $T_\text{C} = 373\text{ K}$, $T_\text{H} = 773\text{ K}$. $|Q_\text{H}| = 250\text{ J}$.

EXECUTE: **(a)** $Q_\text{C} = -Q_\text{H}\left(\dfrac{T_\text{C}}{T_\text{H}}\right) = -(250\text{ J})\left(\dfrac{373\text{ K}}{773\text{ K}}\right) = -121\text{ J}.$

(b) $|W| = 250\text{ J} - 121\text{ J} = 129\text{ J}$. This is the work done in one cycle.

$W_\text{tot} = (500\text{ kg})(9.80\text{ m/s}^2)(100\text{ m}) = 4.90\times10^5\text{ J}$. The number of cycles required is

$\dfrac{W_\text{tot}}{|W|} = \dfrac{4.90\times10^5\text{ J}}{129\text{ J/cycle}} = 3.80\times10^3$ cycles.

EVALUATE: In $\dfrac{Q_\text{C}}{Q_\text{H}} = -\dfrac{T_\text{C}}{T_\text{H}}$, the temperatures must be in kelvins.

20.32. **IDENTIFY:** The same amount of heat that enters the person's body also leaves the body, but these transfers of heat occur at different temperatures, so the person's entropy changes.

SET UP: We are asked to find the entropy change of the person. The person is not an isolated system. In 1.0 s, $0.80(80\text{ J}) = 64\text{ J}$ of heat enters the person's body at $37°\text{C} = 310\text{ K}$. This amount of heat leaves the person at a temperature of $30°\text{C} = 303\text{ K}$. $\Delta S = \dfrac{Q}{T}$.

EXECUTE: For the person, $\Delta S = \dfrac{+64\text{ J}}{310\text{ K}} + \dfrac{-64\text{ J}}{303\text{ K}} = -4.8\times10^{-3}\text{ J/K}.$

EVALUATE: The entropy of the person can decrease without violating the second law of thermodynamics because the person isn't an isolated system.

20.33. **IDENTIFY:** We know the efficiency of this Carnot engine, the heat it absorbs at the hot reservoir and the temperature of the hot reservoir.

SET UP: For a heat engine $e = \dfrac{W}{|Q_H|}$ and $Q_H + Q_C = W$. For a Carnot cycle, $\dfrac{Q_C}{Q_H} = -\dfrac{T_C}{T_H}$. $Q_C < 0$, $W >$ 0, and $Q_H > 0$. $T_H = 135°\text{C} = 408\text{ K}$. In each cycle, $|Q_H|$ leaves the hot reservoir and $|Q_C|$ enters the cold reservoir. The work done on the water equals its increase in gravitational potential energy, *mgh*.

EXECUTE: **(a)** $e = \dfrac{W}{Q_H}$ so $W = eQ_H = (0.220)(410\text{ J}) = 90.2\text{ J}$.

(b) $Q_C = W - Q_H = 90.2\text{ J} - 410\text{ J} = -319.85\text{ J}$, which rounds to –320 J.

(c) $\dfrac{Q_C}{Q_H} = -\dfrac{T_C}{T_H}$ so $T_C = -T_H\left(\dfrac{Q_C}{Q_H}\right) = -(408\text{ K})\left(\dfrac{-319.8\text{ J}}{410\text{ J}}\right) = 318\text{ K} = 45°\text{C}$.

(d) $\Delta S = \dfrac{-|Q_H|}{T_H} + \dfrac{|Q_C|}{T_C} = \dfrac{-410\text{ J}}{408\text{ K}} + \dfrac{319.8\text{ J}}{318\text{ K}} = 0$. The Carnot cycle is reversible and $\Delta S = 0$.

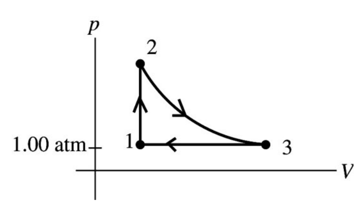
(e) $W = mgh$ so $m = \dfrac{W}{gh} = \dfrac{90.2\text{ J}}{(9.80\text{ m/s}^2)(35.0\text{ m})} = 0.263\text{ kg} = 263\text{ g}$.

EVALUATE: The Carnot cycle is reversible so $\Delta S = 0$ for the world. However some parts of the world gain entropy while other parts lose it, making the sum equal to zero.

20.34. **IDENTIFY:** Use the ideal gas law to calculate *p* and *V* for each state. Use the first law and specific expressions for *Q*, *W*, and ΔU for each process. Use $e = \dfrac{W}{Q_H} = 1 - \left|\dfrac{Q_C}{Q_H}\right|$ to calculate *e*. Q_H is the net heat flow into the gas.

SET UP: $\gamma = 1.40$

$C_V = R/(\gamma - 1) = 20.79\text{ J/mol}\cdot\text{K}$; $C_p = C_V + R = 29.10\text{ J/mol}\cdot\text{K}$. The cycle is sketched in Figure 20.34.



$T_1 = 300\text{ K}$
$T_2 = 600\text{ K}$
$T_3 = 492\text{ K}$

Figure 20.34

EXECUTE: **(a)** Point 1:

$p_1 = 1.00\text{ atm} = 1.013\times10^5\text{ Pa}$ (given); $pV = nRT$;

$$V_1 = \frac{nRT_1}{p_1} = \frac{(0.350\text{ mol})(8.3145\text{ J/mol}\cdot\text{K})(300\text{ K})}{1.013\times10^5\text{ Pa}} = 8.62\times10^{-3}\text{ m}^3$$

Point 2:

Process $1 \to 2$ is at constant volume so $V_2 = V_1 = 8.62\times10^{-3}\text{ m}^3$

$pV = nRT$ and *n*, *R*, *V* constant implies $p_1/T_1 = p_2/T_2$

$p_2 = p_1(T_2/T_1) = (1.00\text{ atm})(600\text{ K}/300\text{ K}) = 2.00\text{ atm} = 2.03\times10^5\text{ Pa}$

Point 3:

Consider the process $3 \to 1$, since it is simpler than $2 \to 3$.

Process $3 \to 1$ is at constant pressure so $p_3 = p_1 = 1.00\text{ atm} = 1.013\times10^5\text{ Pa}$

$pV = nRT$ and n, R, p constant implies $V_1/T_1 = V_3/T_3$

$V_3 = V_1(T_3/T_1) = (8.62\times10^{-3}\ \text{m}^3)(492\ \text{K}/300\ \text{K}) = 14.1\times10^{-3}\ \text{m}^3$

(b) Process $1\to2$:

Constant volume $(\Delta V = 0)$

$Q = nC_V\Delta T = (0.350\ \text{mol})(20.79\ \text{J/mol}\cdot\text{K})(600\ \text{K} - 300\ \text{K}) = 2180\ \text{J}$

$\Delta V = 0$ and $W = 0$. Then $\Delta U = Q - W = 2180\ \text{J}$

Process $2\to3$:

Adiabatic means $Q = 0$.

$\Delta U = nC_V\Delta T$ (any process), so

$\Delta U = (0.350\ \text{mol})(20.79\ \text{J/mol}\cdot\text{K})(492\ \text{K} - 600\ \text{K}) = -780\ \text{J}$

Then $\Delta U = Q - W$ gives $W = Q - \Delta U = 1780\ \text{J}$. (It is correct for W to be positive since ΔV is positive.)

Process $3\to1$:

For constant pressure

$W = p\Delta V = (1.013\times10^5\ \text{Pa})(8.62\times10^{-3}\ \text{m}^3 - 14.1\times10^{-3}\ \text{m}^3) = -560\ \text{J}$

or $W = nR\Delta T = (0.350\ \text{mol})(8.3145\ \text{J/mol}\cdot\text{K})(300\ \text{K} - 492\ \text{K}) = -560\ \text{J}$, which checks. (It is correct for W to be negative, since ΔV is negative for this process.)

$Q = nC_p\Delta T = (0.350\ \text{mol})(29.10\ \text{J/mol}\cdot\text{K})(300\ \text{K} - 492\ \text{K}) = -1960\ \text{J}$

$\Delta U = Q - W = -1960\ \text{J} - (-560\ \text{K}) = -1400\ \text{J}$

or $\Delta U = nC_V\Delta T = (0.350\ \text{mol})(20.79\ \text{J/mol}\cdot\text{K})(300\ \text{K} - 492\ \text{K}) = -1400\ \text{J}$, which checks.

(c) $W_{\text{net}} = W_{1\to2} + W_{2\to3} + W_{3\to1} = 0 + 780\ \text{J} - 560\ \text{J} = +220\ \text{J}$

(d) $Q_{\text{net}} = Q_{1\to2} + Q_{2\to3} + Q_{3\to1} = 2180\ \text{J} + 0 - 1960\ \text{J} = +220\ \text{J}$

(e) $e = \dfrac{\text{work output}}{\text{heat energy input}} = \dfrac{W}{Q_\text{H}} = \dfrac{220\ \text{J}}{2180\ \text{J}} = 0.101 = 10.1\%.$

$e(\text{Carnot}) = 1 - T_\text{C}/T_\text{H} = 1 - 300\ \text{K}/600\ \text{K} = 0.500.$

EVALUATE: For a cycle $\Delta U = 0$, so by $\Delta U = Q - W$ it must be that $Q_{\text{net}} = W_{\text{net}}$ for a cycle. We can also check that $\Delta U_{\text{net}} = 0$: $\Delta U_{\text{net}} = \Delta U_{1\to2} + \Delta U_{2\to3} + \Delta U_{3\to1} = 2180\ \text{J} - 1050\ \text{J} - 1130\ \text{J} = 0$

$e < e(\text{Carnot})$, as it must.

20.35. **IDENTIFY:** The same amount of heat that enters the person's body also leaves the body, but these transfers of heat occur at different temperatures, so the person's entropy changes.

SET UP: 1 food calorie = 1000 cal = 4186 J. The heat enters the person's body at 37°C = 310 K and leaves at a temperature of 30°C = 303 K. $\Delta S = \dfrac{Q}{T}$.

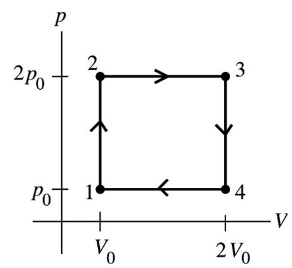
EXECUTE: $|Q| = (0.80)(2.50\ \text{g})(9.3\ \text{food calorie/g})\left(\dfrac{4186\ \text{J}}{1\ \text{food calorie}}\right) = 7.79\times10^4\ \text{J}.$

$\Delta S = \dfrac{+7.79\times10^4\ \text{J}}{310\ \text{K}} + \dfrac{-7.79\times10^4\ \text{J}}{303\ \text{K}} = -5.8\ \text{J/K}.$ Your body's entropy decreases.

EVALUATE: The entropy of your body can decrease without violating the second law of thermodynamics because you are not an isolated system.

20.36. **IDENTIFY:** Use $e = \dfrac{W}{Q_\text{H}}$ to calculate e.

SET UP: The cycle is sketched in Figure 20.36.



$C_V = 5R/2$

for an ideal gas $C_p = C_V + R = 7R/2$

Figure 20.36

SET UP: Calculate Q and W for each process.

Process $1 \to 2$:

$\Delta V = 0$ implies $W = 0$

$\Delta V = 0$ implies $Q = nC_V \Delta T = nC_V (T_2 - T_1)$

But $pV = nRT$ and V constant says $p_1 V = nRT_1$ and $p_2 V = nRT_2$.

Thus $(p_2 - p_1)V = nR(T_2 - T_1)$; $V\Delta p = nR\Delta T$ (true when V is constant).

Then $Q = nC_V \Delta T = nC_V (V\Delta p/nR) = (C_V/R)V\Delta p = (C_V/R)V_0(2p_0 - p_0) = (C_V/R)p_0V_0$. ($Q > 0$; heat is absorbed by the gas.)

Process $2 \to 3$:

$\Delta p = 0$ so $W = p\Delta V = p(V_3 - V_2) = 2p_0(2V_0 - V_0) = 2p_0V_0$ (W is positive since V increases.)

$\Delta p = 0$ implies $Q = nC_p \Delta T = nC_p(T_2 - T_1)$.

But $pV = nRT$ and p constant says $pV_1 = nRT_1$ and $pV_2 = nRT_2$.

Thus $p(V_2 - V_1) = nR(T_2 - T_1)$; $p\Delta V = nR\Delta T$ (true when p is constant).

Then $Q = nC_p \Delta T = nC_p(p\Delta V/nR) = (C_p/R)p\Delta V = (C_p/R)2p_0(2V_0 - V_0) = (C_p/R)2p_0V_0$. ($Q > 0$; heat is absorbed by the gas.)

Process $3 \to 4$:

$\Delta V = 0$ implies $W = 0$

$\Delta V = 0$ so

$Q = nC_V \Delta T = nC_V(V\Delta p/nR) = (C_V/R)(2V_0)(p_0 - 2p_0) = -2(C_V/R)p_0V_0$

($Q < 0$ so heat is rejected by the gas.)

Process $4 \to 1$:

$\Delta p = 0$ so $W = p\Delta V = p(V_1 - V_4) = p_0(V_0 - 2V_0) = -p_0V_0$ (W is negative since V decreases)

$\Delta p = 0$ so $Q = nC_p \Delta T = nC_p(p\Delta V/nR) = (C_p/R)p\Delta V = (C_p/R)p_0(V_0 - 2V_0) = -(C_p/R)p_0V_0$ ($Q < 0$ so heat is rejected by the gas.)

Total work performed by the gas during the cycle:

$W_{\text{tot}} = W_{1\to 2} + W_{2\to 3} + W_{3\to 4} + W_{4\to 1} = 0 + 2p_0V_0 + 0 - p_0V_0 = p_0V_0$

(Note that W_{tot} equals the area enclosed by the cycle in the pV-diagram.)

Total heat absorbed by the gas during the cycle (Q_{H}):

Heat is absorbed in processes $1 \to 2$ and $2 \to 3$.

$$Q_{\text{H}} = Q_{1\to 2} + Q_{2\to 3} = \frac{C_V}{R}p_0V_0 + 2\frac{C_p}{R}p_0V_0 = \left(\frac{C_V + 2C_p}{R}\right)p_0V_0$$

But $C_p = C_V + R$ so $Q_{\text{H}} = \dfrac{C_V + 2(C_V + R)}{R}p_0V_0 = \left(\dfrac{3C_V + 2R}{R}\right)p_0V_0$.

Total heat rejected by the gas during the cycle (Q_{C}):

Heat is rejected in processes $3 \to 4$ and $4 \to 1$.

$$Q_{\text{C}} = Q_{3\to4} + Q_{4\to1} = -2\frac{C_V}{R}p_0V_0 - \frac{C_p}{R}p_0V_0 = -\left(\frac{2C_V + C_p}{R}\right)p_0V_0$$

But $C_p = C_V + R$ so $Q_{\text{C}} = -\dfrac{2C_V + (C_V + R)}{R}p_0V_0 = -\left(\dfrac{3C_V + R}{R}\right)p_0V_0.$

Efficiency: $e = \dfrac{W}{Q_{\text{H}}} = \dfrac{p_0V_0}{[(3C_V + 2R)/R](p_0V_0)} = \dfrac{R}{3C_V + 2R} = \dfrac{R}{3(5R/2) + 2R} = \dfrac{2}{19}.$ $e = 0.105 = 10.5\%.$

EVALUATE: As a check on the calculations note that

$Q_{\text{C}} + Q_{\text{H}} = -\left(\dfrac{3C_V + R}{R}\right)p_0V_0 + \left(\dfrac{3C_V + 2R}{R}\right)p_0V_0 = p_0V_0 = W,$ as it should.

20.37. **IDENTIFY:** $pV = nRT$, so pV is constant when T is constant. Use the appropriate expression to calculate Q and W for each process in the cycle. $e = \dfrac{W}{Q_{\text{H}}}.$

SET UP: For an ideal diatomic gas, $C_V = \frac{5}{2}R$ and $C_p = \frac{7}{2}R.$

EXECUTE: **(a)** $p_aV_a = 2.0\times10^3$ J. $p_bV_b = 2.0\times10^3$ J. $pV = nRT$ so $p_aV_a = p_bV_b$ says $T_a = T_b.$

(b) For an isothermal process, $Q = W = nRT\ln(V_2/V_1)$. ab is a compression, with $V_b < V_a$, so $Q < 0$ and heat is rejected. bc is at constant pressure, so $Q = nC_p\Delta T = \dfrac{C_p}{R}p\Delta V.$ ΔV is positive, so $Q > 0$ and heat is absorbed. ca is at constant volume, so $Q = nC_V\Delta T = \dfrac{C_V}{R}V\Delta p.$ Δp is negative, so $Q < 0$ and heat is rejected.

(c) $T_a = \dfrac{p_aV_a}{nR} = \dfrac{2.0\times10^3\text{ J}}{(1.00)(8.314\text{ J/mol}\cdot\text{K})} = 241\text{ K}.$ $T_b = \dfrac{p_bV_b}{nR} = T_a = 241\text{ K}.$

$$T_c = \frac{p_cV_c}{nR} = \frac{4.0\times10^3\text{ J}}{(1.00)(8.314\text{ J/mol}\cdot\text{K})} = 481\text{ K}.$$

(d) $Q_{ab} = nRT\ln\left(\dfrac{V_b}{V_a}\right) = (1.00\text{ mol})(8.314\text{ J/mol}\cdot\text{K})(241\text{ K})\ln\left(\dfrac{0.0050\text{ m}^3}{0.010\text{ m}^3}\right) = -1.39\times10^3\text{ J}.$

$$Q_{bc} = nC_p\Delta T = (1.00)\left(\frac{7}{2}\right)(8.314\text{ J/mol}\cdot\text{K})(241\text{ K}) = 7.01\times10^3\text{ J}.$$

$$Q_{ca} = nC_V\Delta T = (1.00)\left(\frac{5}{2}\right)(8.314\text{ J/mol}\cdot\text{K})(-241\text{ K}) = -5.01\times10^3\text{ J}.$$

$Q_{\text{net}} = Q_{ab} + Q_{bc} + Q_{ca} = 610$ J. $W_{\text{net}} = Q_{\text{net}} = 610$ J.

(e) $e = \dfrac{W}{Q_{\text{H}}} = \dfrac{610\text{ J}}{7.01\times10^3\text{ J}} = 0.087 = 8.7\%.$

EVALUATE: We can calculate W for each process in the cycle. $W_{ab} = Q_{ab} = -1.39\times10^3$ J. $W_{bc} = p\Delta V = (4.0\times10^5\text{ Pa})(0.0050\text{ m}^3) = 2.00\times10^3$ J. $W_{ca} = 0.$ $W_{\text{net}} = W_{ab} + W_{bc} + W_{ca} = 610$ J, which does equal Q_{net}.

20.38. **IDENTIFY and SET UP:** This problem involves the entropy change of ice water and the surrounding air in a room. Estimate: The cup is ¼ ice and ¾ water all at 0°C when we go to bed. Convert pints to liters and cubic meters: 1 gal = 3.788 L and 8 pints = 1 gal, so 1 pint = (3.788 L)/8 = 0.474 L = $4.74\times10^{-4}\text{ m}^3$. From Table 12.1, $\rho_{\text{w}} = 1000\text{ kg/m}^3$ and $\rho_{\text{ice}} = 920\text{ kg/m}^3$, so the masses are m_{ice} = (920 kg/m³)(¼)($4.74\times10^{-4}\text{ m}^3$) = 0.109 kg, m_{w} = (1000 kg/m³)(¾)($4.74\times10^{-4}\text{ m}^3$) = 0.355 kg. In the morning, the cup is full of liquid water at 22.2°C. During the night, the water-ice mixture went from 0.0°C to 22.2°C. $\Delta S = Q/T$ (for constant temperature) and $\Delta S = \int \frac{dQ}{T}$ (if the temperature varies).

EXECUTE: **(a)** We want the entropy change of the ice-water mixture. It starts at 0.0°C and ends up at 22.2°C. $\Delta S_{\text{tot}} = \Delta S_{\text{ice}} + \Delta S_{\text{water}}$. The entropy change of the original ice is the sum of the entropy change as it melts and the entropy change of the resulting water as it increases from 0.0°C to 22.2°C.

$$\Delta S_{\text{melt ice}} = \frac{Q}{T} = \frac{mL_{\text{f}}}{T} = \frac{(0.109\text{ kg})(334\times10^3\text{ J/kg})}{273\text{ K}} = +133.2\text{ J/kg}.$$

$\Delta S_{\text{melted ice}} = \int_{T_1}^{T_2} \frac{dQ}{T} = \int_{T_1}^{T_2} \frac{m_{\text{i}}c_{\text{w}}dT}{T} = m_{\text{i}}c_{\text{w}} \ln(T_2/T_1)$. Using m_{i} = 0.109 kg, c_{w} = 4190 J/kg · K , T_1 = 0.0°C = 273.15 K, T_2 = 22.2°C = 295.35 K, we get $\Delta S_{\text{melted ice}} = 35.7$ J/K. The total entropy change of the ice is $\Delta S_{\text{ice}} =$ 133.2 J/K + 35.7 J/K = 169 J/K. The entropy change of the original water in the glass is

$\Delta S_{\text{water}} = \int_{T_1}^{T_2} \frac{dQ}{T} = \int_{T_1}^{T_2} \frac{m_{\text{w}}c_{\text{w}}dT}{T} = m_{\text{w}}c_{\text{w}} \ln T_2/T_1$. Using T_1 = 0.0°C = 273.15 K, T_2 = 22.2°C = 295.35 K, m_{w} = 0.355 kg, we get $\Delta S_{\text{water}} =$ 116.2 J/K. The total entropy change is $\Delta S_{\text{tot}} = \Delta S_{\text{ice}} + \Delta S_{\text{water}}$ = 169 J/K + 116 J/K = +285 J/K.

(b) The air remains at a constant 22.2°C = 295.35 K, so $\Delta S_{\text{air}} = Q/T_{\text{air}}$. Q is the *total* heat that flows out of the air into the ice-water mixture in the plastic cup. This heat melts the ice and then increases the temperature of *all* the water from 0.0°C to 22.2°C. Therefore $Q = Q_{\text{melt ice}} + Q_{\text{heat all water to 22.2°C}} = m_{\text{i}}L_{\text{f}} + m_{\text{all water}}c_{\text{w}}\Delta T_{\text{w}}$. This gives

Q = (0.109 kg + 0.355 kg)(4190 J/kg · K)(22.2°C) = 7.96×10^4 J. This heat comes *out* of the air, so

$\Delta S_{\text{air}} = \frac{Q}{T_{\text{air}}} = \frac{-7.96\times10^4\text{ J}}{285.35\text{ K}} = -279$ J/K. The total entropy change is –279 J/K + 285 J/K = +6 J/K, a positive change.

EVALUATE: The heating of the ice/water mixture is irreversible, so $\Delta S > 0$.

20.39. **IDENTIFY:** $T_b = T_c$ and is equal to the maximum temperature. Use the ideal gas law to calculate T_a. Apply the appropriate expression to calculate Q for each process. $e = \frac{W}{Q_{\text{H}}}$. $\Delta U = 0$ for a complete cycle and for an isothermal process of an ideal gas.

SET UP: For helium, $C_V = 3R/2$ and $C_p = 5R/2$. The maximum efficiency is for a Carnot cycle, and $e_{\text{Carnot}} = 1 - T_{\text{C}}/T_{\text{H}}$.

EXECUTE: **(a)** $Q_{\text{in}} = Q_{ab} + Q_{bc}$. $Q_{\text{out}} = Q_{ca}$. $T_{\max} = T_b = T_c = 327°\text{C} = 600\text{ K}$.

$$\frac{p_aV_a}{T_a} = \frac{p_bV_b}{T_b} \to T_a = \frac{p_a}{p_b}T_b = \frac{1}{3}(600\text{ K}) = 200\text{ K}.$$

$$p_bV_b = nRT_b \to V_b = \frac{nRT_b}{p_b} = \frac{(2\text{ moles})(8.31\text{ J/mol}\cdot\text{K})(600\text{ K})}{3.0\times10^5\text{ Pa}} = 0.0332\text{ m}^3.$$

$$\frac{p_bV_b}{T_b} = \frac{p_cV_c}{T_c} \to V_c = V_b\frac{p_b}{p_c} = (0.0332\text{ m}^3)\left(\frac{3}{1}\right) = 0.0997\text{ m}^3 = V_a.$$

$$Q_{ab} = nC_V\Delta T_{ab} = (2\text{ mol})\left(\frac{3}{2}\right)(8.31\text{ J/mol}\cdot\text{K})(400\text{ K}) = 9.97\times10^3\text{ J}.$$

$$Q_{bc} = W_{bc} = \int_b^c p\,dV = \int_b^c \frac{nRT_b}{V}dV = nRT_b \ln\frac{V_c}{V_b} = nRT_b \ln 3.$$

$Q_{bc} = (2.00\text{ mol})(8.31\text{ J/mol}\cdot\text{K})(600\text{ K})\ln 3 = 1.10\times10^4\text{ J}$. $Q_{\text{in}} = Q_{ab} + Q_{bc} = 2.10\times10^4\text{ J}$.

$$Q_{\text{out}} = Q_{ca} = nC_p\Delta T_{ca} = (2.00\text{ mol})\left(\frac{5}{2}\right)(8.31\text{ J/mol}\cdot\text{K})(400\text{ K}) = 1.66\times10^4\text{ J}.$$

(b) $Q = \Delta U + W = 0 + W \to W = Q_{\text{in}} - Q_{\text{out}} = 2.10\times10^4\text{ J} - 1.66\times10^4\text{ J} = 4.4\times10^3\text{ J}$.

$$e = W/Q_{\text{in}} = \frac{4.4\times10^3\text{ J}}{2.10\times10^4\text{ J}} = 0.21 = 21\%.$$

(c) $e_{\text{max}} = e_{\text{Carnot}} = 1 - \dfrac{T_C}{T_H} = 1 - \dfrac{200\text{ k}}{600\text{ k}} = 0.67 = 67\%$.

Evaluate: The thermal efficiency of this cycle is about one-third of the efficiency of a Carnot cycle that operates between the same two temperatures.

20.40. **Identify:** Since there is temperature difference between the inside and outside of your body, you can use it as a heat engine.

Set Up: For a heat engine $e = \dfrac{W}{Q_H}$. For a Carnot engine $e = 1 - \dfrac{T_C}{T_H}$. Gravitational potential energy is $U_{\text{grav}} = mgh$. 1 food calorie = 1000 cal = 4186 J.

Execute: **(a)** $e = 1 - \dfrac{T_C}{T_H} = 1 - \dfrac{303\text{ K}}{310\text{ K}} = 0.0226 = 2.26\%$. This engine has a very low thermal efficiency.

(b) $U_{\text{grav}} = mgh = (2.50\text{ kg})(9.80\text{ m/s}^2)(1.20\text{ m}) = 29.4\text{ J}$. This equals the work output of the engine.

$e = \dfrac{W}{Q_H}$ so $Q_H = \dfrac{W}{e} = \dfrac{29.4\text{ J}}{0.0226} = 1.30\times10^3\text{ J}$.

(c) Since 80% of food energy goes into heat, you must eat food with a food energy of $\dfrac{1.30\times10^3\text{ J}}{0.80} = 1.63\times10^3\text{ J}$. Each candy bar gives $(350\text{ food calorie})(4186\text{ J/food calorie}) = 1.47\times10^6\text{ J}$.

The number of candy bars required is $\dfrac{1.63\times10^3\text{ J}}{1.47\times10^6\text{ J/candy bar}} = 1.11\times10^{-3}$ candy bars.

Evaluate: A large amount of mechanical work must be done to use up the energy from one candy bar.

20.41. **Identify:** $e_{\text{max}} = e_{\text{Carnot}} = 1 - T_C/T_H$. $e = \dfrac{W}{Q_H} = \dfrac{W/t}{Q_H/t}$. $W = Q_H + Q_C$ so $\dfrac{W}{t} = \dfrac{Q_C}{t} + \dfrac{Q_H}{t}$. For a temperature change $Q = mc\Delta T$.

Set Up: $T_H = 300.15\text{ K}$, $T_C = 279.15\text{ K}$. For water, $\rho = 1000\text{ kg/m}^3$, so a mass of 1 kg has a volume of 1 L. For water, $c = 4190\text{ J/kg}\cdot\text{K}$.

Execute: **(a)** $e = 1 - \dfrac{279.15\text{K}}{300.15\text{K}} = 7.0\%$.

(b) $\dfrac{Q_H}{t} = \dfrac{P_{\text{out}}}{e} = \dfrac{210\text{ kW}}{0.070} = 3.0\text{ MW}$. $\dfrac{|Q_C|}{t} = \dfrac{Q_H}{t} - \dfrac{W}{t} = 3.0\text{ MW} - 210\text{ kW} = 2.8\text{ MW}$.

(c) $\dfrac{m}{t} = \dfrac{|Q_C|/t}{c\Delta T} = \dfrac{(2.8\times10^6\text{ W})(3600\text{ s/h})}{(4190\text{ J/kg}\cdot\text{K})(4\text{ K})} = 6\times10^5\text{ kg/h} = 6\times10^5\text{ L/h}$.

Evaluate: The efficiency is small since T_C and T_H don't differ greatly.

20.42. **IDENTIFY:** Use $\Delta U = Q - W$ and the appropriate expressions for Q, W and ΔU for each type of process. $pV = nRT$ relates ΔT to p and V values. $e = \dfrac{W}{Q_H}$, where Q_H is the heat that enters the gas during the cycle.

SET UP: For a monatomic ideal gas, $C_p = \frac{5}{2}R$ and $C_V = \frac{3}{2}R$.

(a) *ab*: The temperature changes by the same factor as the volume, and so

$$Q = nC_p\Delta T = \frac{C_p}{R}p_a(V_a - V_b) = (2.5)(3.00\times10^5 \text{ Pa})(0.300 \text{ m}^3) = 2.25\times10^5 \text{ J}.$$

The work $p\Delta V$ is the same except for the factor of $\frac{5}{2}$, so $W = 0.90\times10^5$ J.

$\Delta U = Q - W = 1.35\times10^5$ J.

bc: The temperature now changes in proportion to the pressure change, and $Q = \frac{3}{2}(p_c - p_b)V_b = (1.5)(-2.00\times10^5 \text{ Pa})(0.800 \text{ m}^3) = -2.40\times10^5$ J, and the work is zero $(\Delta V = 0)$. $\Delta U = Q - W = -2.40\times10^5$ J.

ca: The easiest way to do this is to find the work done first; W will be the negative of area in the *p-V* plane bounded by the line representing the process *ca* and the verticals from points *a* and *c*. The area of this trapezoid is $\frac{1}{2}(3.00\times10^5 \text{ Pa} + 1.00\times10^5 \text{ Pa})(0.800 \text{ m}^3 - 0.500 \text{ m}^3) = 6.00\times10^4$ J and so the work is -0.60×10^5 J. ΔU must be 1.05×10^5 J (since $\Delta U = 0$ for the cycle, anticipating part (b)), and so Q must be $\Delta U + W = 0.45\times10^5$ J.

(b) See above; $Q = W = 0.30\times10^5$ J, $\Delta U = 0$.

(c) The heat added, during process *ab* and *ca*, is $2.25\times10^5 \text{ J} + 0.45\times10^5 \text{ J} = 2.70\times10^5$ J and the efficiency is $e = \dfrac{W}{Q_H} = \dfrac{0.30\times10^5}{2.70\times10^5} = 0.111 = 11.1\%$.

EVALUATE: For any cycle, $\Delta U = 0$ and $Q = W$.

20.43. **IDENTIFY:** Use $pV = nRT$. Apply the expressions for Q and W that apply to each type of process. $e = \dfrac{W}{Q_H}$.

SET UP: For O_2, $C_V = 20.85$ J/mol·K and $C_p = 29.17$ J/mol·K.

EXECUTE: **(a)** $p_1 = 2.00$ atm, $V_1 = 4.00$ L, $T_1 = 300$ K.

$p_2 = 2.00$ atm. $\dfrac{V_1}{T_1} = \dfrac{V_2}{T_2}$. $V_2 = \left(\dfrac{T_2}{T_1}\right)V_1 = \left(\dfrac{450 \text{ K}}{300 \text{ K}}\right)(4.00 \text{ L}) = 6.00$ L.

$V_3 = 6.00$ L. $\dfrac{p_2}{T_2} = \dfrac{p_3}{T_3}$. $p_3 = \left(\dfrac{T_3}{T_2}\right)p_2 = \left(\dfrac{250 \text{ K}}{450 \text{ K}}\right)(2.00 \text{ atm}) = 1.11$ atm.

$V_4 = 4.00$ L. $p_3V_3 = p_4V_4$. $p_4 = p_3\left(\dfrac{V_3}{V_4}\right) = (1.11 \text{ atm})\left(\dfrac{6.00 \text{ L}}{4.00 \text{ L}}\right) = 1.67$ atm.

These processes are shown in Figure 20.43.

(b) $n = \dfrac{p_1V_1}{RT_1} = \dfrac{(2.00 \text{ atm})(4.00 \text{ L})}{(0.08206 \text{ L}\cdot\text{atm/mol}\cdot\text{K})(300 \text{ K})} = 0.325$ mol

Process $1 \to 2$: $W = p\Delta V = nR\Delta T = (0.325 \text{ mol})(8.315 \text{ J/mol}\cdot\text{K})(150 \text{ K}) = 405$ J.

$Q = nC_p\Delta T = (0.325 \text{ mol})(29.17 \text{ J/mol}\cdot\text{K})(150 \text{ K}) = 1422$ J.

Process $2 \to 3$: $W = 0$. $Q = nC_V\Delta T = (0.325 \text{ mol})(20.85 \text{ J/mol}\cdot\text{K})(-200 \text{ K}) = -1355$ J.

Process $3 \to 4$: $\Delta U = 0$ and

$$Q = W = nRT_3 \ln\left(\frac{V_4}{V_3}\right) = (0.325 \text{ mol})(8.315 \text{ J/mol}\cdot\text{K})(250 \text{ K})\ln\left(\frac{4.00 \text{ L}}{6.00 \text{ L}}\right) = -274 \text{ J}.$$

Process $4 \to 1$: $W = 0$. $Q = nC_V\Delta T = (0.325 \text{ mol})(20.85 \text{ J/mol}\cdot\text{K})(50 \text{ K}) = 339 \text{ J}$.

(c) $W = 405 \text{ J} - 274 \text{ J} = 131 \text{ J}$.

(d) $e = \dfrac{W}{Q_\text{H}} = \dfrac{131 \text{ J}}{1422 \text{ J} + 339 \text{ J}} = 0.0744 = 7.44\%$.

$e_\text{Carnot} = 1 - \dfrac{T_\text{C}}{T_\text{H}} = 1 - \dfrac{250 \text{ K}}{450 \text{ K}} = 0.444 = 44.4\%$; e_Carnot is much larger.

Evaluate: $Q_\text{tot} = +1422 \text{ J} + (-1355 \text{ J}) + (-274 \text{ J}) + 339 \text{ J} = 132 \text{ J}$. This is equal to W_tot, apart from a slight difference due to rounding. For a cycle, $W_\text{tot} = Q_\text{tot}$, since $\Delta U = 0$.

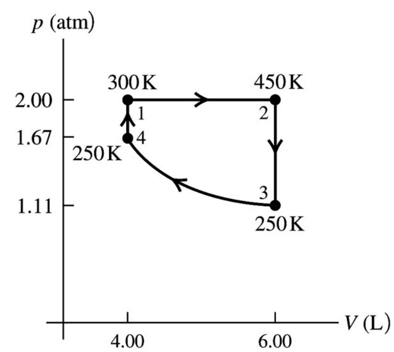


Figure 20.43

20.44. Identify: $e = \dfrac{W}{Q_\text{H}}$. 1 day $= 8.64\times10^4$ s. For the river water, $Q = mc\Delta T$, where the heat that goes into the water is the heat Q_C rejected by the engine. The density of water is 1000 kg/m^3. When an object undergoes a temperature change, $\Delta S = mc\ln(T_2/T_1)$.

Set Up: $18.0°\text{C} = 291.1 \text{ K}$. $18.5°\text{C} = 291.6 \text{ K}$.

Execute: **(a)** $Q_\text{H} = \dfrac{W}{e}$ so $P_\text{H} = \dfrac{P_\text{W}}{e} = \dfrac{1000 \text{ MW}}{0.40} = 2.50\times10^3 \text{ MW}$.

(b) The heat input in one day is $(2.50\times10^9 \text{ W})(8.64\times10^4 \text{ s}) = 2.16\times10^{14} \text{ J}$. The mass of coal used per day is $\dfrac{2.16\times10^{14} \text{ J}}{2.65\times10^7 \text{ J/kg}} = 8.15\times10^6 \text{ kg}$.

(c) $|Q_\text{H}| = |W| + |Q_\text{C}|$. $|Q_\text{C}| = |Q_\text{H}| - |W|$. $P_\text{C} = P_\text{H} - P_\text{W} = 2.50\times10^3 \text{ MW} - 1000 \text{ MW} = 1.50\times10^3 \text{ MW}$.

(d) The heat input to the river is 1.50×10^9 J/s. $Q = mc\Delta T$ and $\Delta T = 0.5 \text{ C°}$ gives

$m = \dfrac{Q}{c\Delta T} = \dfrac{1.50\times10^9 \text{ J}}{(4190 \text{ J/kg}\cdot\text{K})(0.5 \text{ K})} = 7.16\times10^5 \text{ kg}$. $V = \dfrac{m}{\rho} = 716 \text{ m}^3$. The river flow rate must be $716 \text{ m}^3/\text{s}$.

(e) In one second, 7.16×10^5 kg of water goes from 291.1 K to 291.6 K.

$$\Delta S = mc\ln\left(\frac{T_2}{T_1}\right) = (7.16\times10^5 \text{ kg})(4190 \text{ J/kg}\cdot\text{K})\ln\left(\frac{291.6 \text{ K}}{291.1 \text{ K}}\right) = 5.1\times10^6 \text{ J/K}.$$

Evaluate: The entropy of the river increases because heat flows into it. The mass of coal used per second is huge.

20.45. IDENTIFY: The efficiency of the composite engine is $e_{12} = \dfrac{W_1 + W_2}{Q_{\text{H1}}}$, where Q_{H1} is the heat input to the first engine and W_1 and W_2 are the work outputs of the two engines. For any heat engine, $W = Q_\text{C} + Q_\text{H}$, and for a Carnot engine, $\dfrac{Q_{\text{low}}}{Q_{\text{high}}} = -\dfrac{T_{\text{low}}}{T_{\text{high}}}$, where Q_{low} and Q_{high} are the heat flows at the two reservoirs that have temperatures T_{low} and T_{high}.

SET UP: $Q_{\text{high,2}} = -Q_{\text{low,1}}$. $T_{\text{low,1}} = T'$, $T_{\text{high,1}} = T_\text{H}$, $T_{\text{low,2}} = T_\text{C}$ and $T_{\text{high,2}} = T'$.

EXECUTE: $e_{12} = \dfrac{W_1 + W_2}{Q_{\text{H1}}} = \dfrac{Q_{\text{high,1}} + Q_{\text{low,1}} + Q_{\text{high,2}} + Q_{\text{low,2}}}{Q_{\text{high,1}}}$. Since $Q_{\text{high,2}} = -Q_{\text{low,1}}$, this reduces to

$e_{12} = 1 + \dfrac{Q_{\text{low,2}}}{Q_{\text{high,1}}}$. $Q_{\text{low,2}} = -Q_{\text{high,2}}\dfrac{T_{\text{low,2}}}{T_{\text{high,2}}} = Q_{\text{low,1}}\dfrac{T_\text{C}}{T'} = -Q_{\text{high,1}}\left(\dfrac{T_{\text{low,1}}}{T_{\text{high,1}}}\right)\dfrac{T_\text{C}}{T'} = -Q_{\text{high,1}}\left(\dfrac{T'}{T_\text{H}}\right)\dfrac{T_\text{C}}{T'}$. This gives

$e_{12} = 1 - \dfrac{T_\text{C}}{T_\text{H}}$. The efficiency of the composite system is the same as that of the original engine.

EVALUATE: The overall efficiency is independent of the value of the intermediate temperature T'.

20.46. IDENTIFY: We are dealing with the efficiency of an automobile engine.

SET UP: **(a)** Estimate: 45 miles/gallon (a Prius).

EXECUTE: **(b)** The combustion releases 120 MJ/gal. At 40 mph the engine is turning at 3000 rpm which is 3000 cycles/min. We want to know how many joules/cycle are released. At 40 mph, the time to travel 45 mi is $t = x/v$ = (45 mi)/(40 mi/h) = 1.125 h = 67.5 min. The energy released during this time is 1 gal = 120 MJ. In 67.5 min the number of cycles the engine turns through is (3000 cyles/min)(67.5 min) = 2.025×10^5 cycles. The energy per cycle is $\dfrac{120 \text{ MJ}}{2.025\times10^5 \text{ cycles}} = 593$ J/cycle.

(c) We want the power the car engine supplies at 40 mph. The power P is the energy E divided by the time t, so $P = E/t$. At 20% efficiency, E = (0.20)(593 J/cycle) = 118.5 J/cycle and 3000 cycles/min = 50 cycles/s, so the time for one cycle is t = 1/50 s. So $P = E/t$ = (118.5 J)/(1/50 s) = 5900 W.

(d) Convert to horsepower: (5900 W)(1 hp/746 W) = 7.9 hp.

EVALUATE: Based on the "power climb" in Example 6.10, the car power is about $\dfrac{5900 \text{ W}}{241 \text{ W}}$ = 24 times as great as the power climber.

20.47. (a) IDENTIFY and SET UP: Calculate e from $e = 1 - 1/(r^{\gamma-1})$, Q_C from $e = (Q_\text{H} + Q_\text{C})/Q_\text{H}$, and then W from $W = Q_\text{C} + Q_\text{H}$.

EXECUTE: $e = 1 - 1/(r^{\gamma-1}) = 1 - 1/(10.6^{0.4}) = 0.6111$

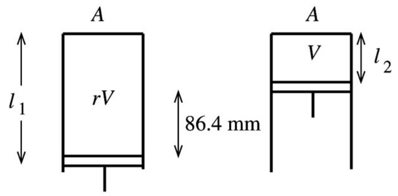
$e = (Q_\text{H} + Q_\text{C})/Q_\text{H}$ and we are given $Q_\text{H} = 200$ J; calculate Q_C.

$Q_\text{C} = (e-1)Q_\text{H} = (0.6111 - 1)(200\text{ J}) = -78$ J. (negative, since corresponds to heat leaving)

Then $W = Q_\text{C} + Q_\text{H} = -78\text{ J} + 200\text{ J} = 122$ J. (positive, in agreement with Figure 20.6 in the text)

EVALUATE: Q_H, $W > 0$, and $Q_\text{C} < 0$ for an engine cycle.

(b) IDENTIFY and SET UP: The stoke times the bore equals the change in volume. The initial volume is the final volume V times the compression ratio r. Combining these two expressions gives an equation for V. For each cylinder of area $A = \pi(d/2)^2$ the piston moves 0.0864 m and the volume changes from rV to V, as shown in Figure 20.47a.



$l_1 A = rV$

$l_2 A = V$

and $l_1 - l_2 = 86.4\times10^{-3}$ m

Figure 20.47a

EXECUTE: $l_1 A - l_2 A = rV - V$ and $(l_1 - l_2)A = (r-1)V$

$$V = \frac{(l_1 - l_2)A}{r-1} = \frac{(86.4\times10^{-3}\ \text{m})\pi(41.25\times10^{-3}\ \text{m})^2}{10.6-1} = 4.811\times10^{-5}\ \text{m}^3$$

At point a the volume is $rV = 10.6(4.811\times10^{-5}\ \text{m}^3) = 5.10\times10^{-4}\ \text{m}^3$.

(c) IDENTIFY and **SET UP:** The processes in the Otto cycle are either constant volume or adiabatic. Use the Q_H that is given to calculate ΔT for process bc. Use $T_1V_1^{\gamma-1} = T_2V_2^{\gamma-1}$ and $pV = nRT$ to relate p, V and T for the adiabatic processes ab and cd.

EXECUTE: <u>Point a</u>: $T_a = 300$ K, $p_a = 8.50\times10^4$ Pa and $V_a = 5.10\times10^{-4}\ \text{m}^3$.

<u>Point b</u>: $V_b = V_a/r = 4.81\times10^{-5}\ \text{m}^3$. Process $a \to b$ is adiabatic, so $T_aV_a^{\gamma-1} = T_bV_b^{\gamma-1}$.

$T_a(rV)^{\gamma-1} = T_bV^{\gamma-1}$

$T_b = T_ar^{\gamma-1} = 300\ \text{K}(10.6)^{0.4} = 771$ K

$pV = nRT$ so $pV/T = nR = \text{constant}$, so $p_aV_a/T_a = p_bV_b/T_b$

$p_b = p_a(V_a/V_b)(T_b/T_a) = (8.50\times10^4\ \text{Pa})(rV/V)(771\ \text{K}/300\ \text{K}) = 2.32\times10^6$ Pa

<u>Point c</u>: Process $b \to c$ is at constant volume, so $V_c = V_b = 4.81\times10^{25}\ \text{m}^3$

$Q_\text{H} = nC_V\Delta T = nC_V(T_c - T_b)$. The problem specifies $Q_\text{H} = 200$ J; use to calculate T_c. First use the p, V, T values at point a to calculate the number of moles n.

$$n = \frac{pV}{RT} = \frac{(8.50\times10^4\ \text{Pa})(5.10\times10^{-4}\ \text{m}^3)}{(8.3145\ \text{J/mol}\cdot\text{K})(300\ \text{K})} = 0.01738\ \text{mol}$$

Then $T_c - T_b = \dfrac{Q_\text{H}}{nC_V} = \dfrac{200\ \text{J}}{(0.01738\ \text{mol})(20.5\ \text{J/mol}\cdot\text{K})} = 561.3$ K, and

$T_c = T_b + 561.3\ \text{K} = 771\ \text{K} + 561\ \text{K} = 1332$ K

$p/T = nR/V = \text{constant}$ so $p_b/T_b = p_c/T_c$

$p_c = p_b(T_c/T_b) = (2.32\times10^6\ \text{Pa})(1332\ \text{K}/771\ \text{K}) = 4.01\times10^6$ Pa

<u>Point d</u>: $V_d = V_a = 5.10\times10^{-4}\ \text{m}^3$

Process $c \to d$ is adiabatic, so $T_dV_d^{\gamma-1} = T_cV_c^{\gamma-1}$

$T_d(rV)^{\gamma-1} = T_cV^{\gamma-1}$

$T_d = T_c/r^{\gamma-1} = 1332\ \text{K}/10.6^{0.4} = 518$ K

$p_cV_c/T_c = p_dV_d/T_d$

$p_d = p_c(V_c/V_d)(T_d/T_c) = (4.01\times10^6\ \text{Pa})(V/rV)(518\ \text{K}/1332\ \text{K}) = 1.47\times10^5$ Pa

EVALUATE: Can look at process $d \to a$ as a check.

$Q_\text{C} = nC_V(T_a - T_d) = (0.01738\ \text{mol})(20.5\ \text{J/mol}\cdot\text{K})(300\ \text{K} - 518\ \text{K}) = -78$ J, which agrees with part (a).

The cycle is sketched in Figure 20.47b.

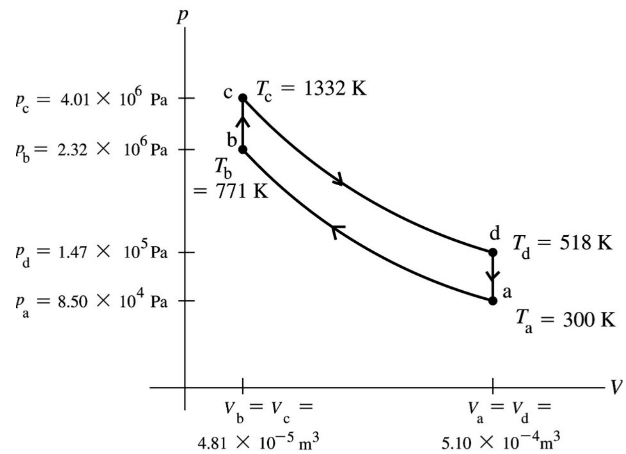


Figure 20.47b

(d) IDENTIFY and **SET UP:** The Carnot efficiency is given by $e_{\text{Carnot}} = 1 - \dfrac{T_\text{C}}{T_\text{H}}$. T_H is the highest temperature reached in the cycle and T_C is the lowest.

EXECUTE: From part (a) the efficiency of this Otto cycle is $e = 0.611 = 61.1\%$.
The efficiency of a Carnot cycle operating between 1332 K and 300 K is
$e_{\text{Carnot}} = 1 - T_\text{C}/T_\text{H} = 1 - 300\text{ K}/1332\text{ K} = 0.775 = 77.5\%$, which is larger.

EVALUATE: The second law of thermodynamics requires that $e \le e_{\text{Carnot}}$, and our result obeys this law.

20.48. **IDENTIFY:** We want to estimate the entropy of the air in a typical room.
SET UP: **(a)** Estimate: My office volume is $V = (12\text{ ft})(15\text{ ft})(8.0\text{ ft}) = 1440\text{ ft}^3 = 41\text{ m}^3$.
EXECUTE: **(b)** $n/(41\text{ m}^3) = (1\text{ mol})/(22.4\text{ L})$, which gives $n = 1800$ mol.
(c) $N = nN_\text{A} = (1800\text{ mol})(6.022\times10^{23}\text{ molecules/mol}) = 1.1\times10^{27}$ molecules.
(d) $S = k \ln w$. In this case, $N^N = w$, so $S = k \ln N^N = kN \ln N$. For the numbers here, we get
$S = (1.38\times10^{-23}\text{ J/K})(1.1\times10^{27})\ln(1.1\times10^{27}) = 9.3\times10^5\text{ J/K}$.
EVALUATE: As N increases, there are more possible states, so S also increases.

20.49. **IDENTIFY** and **SET UP:** A refrigerator is like a heat engine run in reverse. In the pV-diagram shown with the figure, heat enters the gas during parts *ab* and *bc* of the cycle, and leaves during *ca*. Treating H_2 as a diatomic gas, we know that $C_V = \frac{5}{2}R$ and $C_p = \frac{7}{2}R$. Segment *bc* is isochoric, so $Q_{bc} = nC_V\Delta T$. Segment *ca* is isobaric, so $Q_{ca} = nC_p\Delta T$. Segment *ab* is isothermal, so $Q_{ab} = nRT\ln(V_b/V_a)$. The coefficient of performance of a refrigerator is $K = \dfrac{|Q_\text{C}|}{|W|} = \dfrac{|Q_\text{C}|}{|Q_\text{H}| - |Q_\text{C}|}$, and $pV = nRT$ applies.

Calculate the values for Q_C and Q_H and use the definition of K. Use 1000 L = 1 m^3 and work in units of $\text{L}\cdot\text{atm}$.
EXECUTE: Use $pV = nRT$ to find p_b. Since *ab* is isothermal, $p_aV_a = p_bV_b$, which gives
$p_b = (0.700\text{ atm})(0.0300\text{ m}^3)/(0.100\text{ m}^3) = 0.210$ atm.
$Q_\text{C} = Q_{ab} + Q_{bc}$, so we need to calculate these quantities.
$Q_{ab} = nRT\ln(V_b/V_a) = p_aV_a\ln(V_b/V_a) = (0.700\text{ atm})(30.0\text{ L})\ln[(100\text{ L})/(30\text{ L})] = 25.2834\ \text{L}\cdot\text{atm}$.
$Q_{bc} = nC_V\Delta T_{bc} = n(\frac{5}{2}R)\ \Delta T_{bc} = \frac{5}{2} V_b\Delta p_{bc} = (5/2)(100\text{ L})(0.700\text{ atm} - 0.210\text{ atm}) = 122.5\ \text{L}\cdot\text{atm}$.
Therefore $Q_\text{C} = Q_{ab} + Q_{bc} = 25.2834\ \text{L}\cdot\text{atm} + 122.500\ \text{L}\cdot\text{atm} = 147.7834\ \text{L}\cdot\text{atm}$.

$Q_H = Q_{ca} = nC_p\Delta T_{ca} = n\left(\frac{7}{2}R\right)\Delta T_{ca} = \frac{7}{2}p_c\Delta T_{ca}$ = (7/2)(0.700 atm)(30.0 L – 100.0 L) =–171.500 L · atm.

Now get K: $K = \dfrac{|Q_C|}{|Q_H| - |Q_C|} = \dfrac{147.7834 \text{ L}\cdot\text{atm}}{(171.500 \text{ L}\cdot\text{atm} - 147.7834 \text{ L}\cdot\text{atm}} = 6.23.$

EVALUATE: K is greater than 1, which it must be. Efficiencies are less than 1.

20.50. **IDENTIFY** and **SET UP:** A person radiates heat from the surface of her body which is at a constant temperature of T = 30.0°C into air at T_s = 20.0°C. In 1.0 s, heat $Ae\sigma tT^4$ flows from the person into the room and heat $Ae\sigma tT_s^4$ flows out of the room into the person. The heat flows into and out of the room occur at a temperature of T_s. At constant temperature, $\Delta S = Q/T$.

EXECUTE: For the room,

$$\Delta S = \frac{Ae\sigma tT^4}{T_s} - \frac{Ae\sigma tT_s^4}{T_s} = \frac{Ae\sigma t(T^4 - T_s^4)}{T_s}$$

$$\Delta S = \frac{(1.85 \text{ m}^2)(1.00)(5.67\times10^{-8} \text{ W/m}^2\cdot\text{K}^4)(1.0)[(303 \text{ K})^4 - (293 \text{ K})^4]}{293 \text{ K}} = 0.379 \text{ J/K}$$

EVALUATE: The entropy change is positive since the air in the room becomes more disordered. In addition, this process is irreversible; heat from the cool room will not spontaneously flow into the warmer person and increase her temperature even further. Heat flows only from hot to cold.

20.51. **IDENTIFY:** Use $\Delta S = mc\ln(T_2/T_1)$ for an isothermal process. For the value of T for which ΔS is a maximum, $d(\Delta S)/dT = 0$.

SET UP: The heat flow for a temperature change is $Q = mc\Delta T$.

EXECUTE: **(a)** As in Example 20.10, the entropy change of the first object is $m_1c_1\ln(T/T_1)$ and that of the second is $m_2c_2\ln(T'/T_2)$, and so the net entropy change is as given. Neglecting heat transfer to the surroundings, $Q_1 + Q_2 = 0, m_1c_1(T - T_1) + m_2c_2(T' - T_2) = 0,$ which is the given expression.

(b) Solving the energy-conservation relation for T' and substituting into the expression for ΔS gives $\Delta S = m_1c_1\ln\left(\frac{T}{T_1}\right) + m_2c_2\ln\left(1 - \frac{m_1c_1}{m_2c_2}\left(\frac{T}{T_2} - \frac{T_1}{T_2}\right)\right)$. Differentiating with respect to T and setting the derivative equal to 0 gives $0 = \dfrac{m_1c_1}{T} + \dfrac{(m_2c_2)(m_1c_1/m_2c_2)(-1/T_2)}{\left(1 - (m_1c_1/m_2c_2)\left(\frac{T}{T_2} - \frac{T_1}{T_2}\right)\right)}$. This may be solved for

$T = \dfrac{m_1c_1T_1 + m_2c_2T_2}{m_1c_1 + m_2c_2}$. Using this value for T in the conservation of energy expression in part (a) and solving for T' gives $T' = \dfrac{m_1c_1T_1 + m_2c_2T_2}{m_1c_1 + m_2c_2}$. Therefore, $T = T'$ when ΔS is a maximum.

EVALUATE: **(c)** The final state of the system will be that for which no further entropy change is possible. If $T < T'$, it is possible for the temperatures to approach each other while increasing the total entropy, but when $T = T'$, no further spontaneous heat exchange is possible.

20.52. **IDENTIFY:** Use the expression derived in Example 20.6 for the entropy change in a temperature change.

SET UP: For water, $c = 4190$ J/kg · K. 20°C = 293.15 K, 78°C = 351.15 K and 120°C = 393.15 K.

EXECUTE:

(a) $\Delta S = mc\ln(T_2/T_1) = (250\times10^{-3} \text{ kg})(4190 \text{ J/kg}\cdot\text{K})\ln(351.15 \text{ K}/293.15 \text{ K}) = 189 \text{ J/K}.$

(b) $\Delta S = \dfrac{-mc\Delta T}{T_{\text{element}}} = \dfrac{-(250\times10^{-3} \text{ kg})(4190 \text{ J/kg}\cdot\text{K})(351.15 \text{ K} - 293.15 \text{ K})}{393.15 \text{ K}} = -155 \text{ J/K}.$

(c) The sum of the result of parts (a) and (b) is $\Delta S_{\text{system}} = 34.6$ J/K. (Carry extra figures when subtraction is involved.)

EVALUATE: **(d)** Heating a liquid is not reversible. Whatever the energy source for the heating element, heat is being delivered at a higher temperature than that of the water, and the entropy loss of the source will be less in magnitude than the entropy gain of the water. The net entropy change is positive.

20.53. **IDENTIFY** and **SET UP:** The most efficient heat engine operating between any two given temperatures is the Carnot engine, and its efficiency is $e_{\text{Carnot}} = 1 - \frac{T_C}{T_H}$.

EXECUTE: **(a)** For prototype A, $e_{max} = e_{\text{Carnot}} = 1 - \frac{T_C}{T_H}$ = 1 – (320 K)/(450 K) = 0.289 = 28.9%. By similar calculations, we get the following:

A: e_{max} = 0.289 = 28.9%
B: e_{max} = 0.383 = 38.3%
C: e_{max} = 0.538 = 53.8%
D: e_{max} = 0.244 = 24.4%

(b) Engine C claims a maximum efficiency of 56%, which is greater than the maximum possible for its temperature range, so it is impossible.

(c) We get the following ratios:

A: $e_{claimed}/e_{max}$ = 0.21/0.289 = 0.73
B: $e_{claimed}/e_{max}$ = 0.35/0.383 = 0.90
D: $e_{claimed}/e_{max}$ = 0.20/0.244 = 0.82

In decreasing order, we have B, D, A.

EVALUATE: Engine B is not only the most efficient, it is also closest to its maximum possible efficiency for its temperature range. Engines A and D have nearly the same efficiency, but D comes somewhat closer to its theoretical maximum than does A.

20.54. **IDENTIFY** and **SET UP:** In terms of power, $K = \frac{|Q_C|/t}{|W|/t}$. 1 Btu = 1055 J and $1\ \text{W}\cdot\text{h} = 3600$ J.

EXECUTE: **(a)** $1\ \text{W}\cdot\text{h}$ = (3600 J)(1 Btu/1055 J) = 3.412 Btu, so EER = $(3.412\ \text{Btu/W}\cdot\text{h})K$.

(b) T_H = 95°F = 35°C = 308.1 K; T_C = 80°F = 26.7°C = 299.8 K.

For a Carnot air conditioner, $K = T_C/(T_H - T_C)$ = (299.8 K)/(308.1 K – 299.8 K) = 36. The corresponding EER is

EER = $(3.412\ \text{Btu/W}\cdot\text{h})(36) = 120\ \text{Btu/W}\cdot\text{h}$.

(c) K = EER/3.412 = 10.9/3.412 = 3.195

$|W| = |Q_C|/K = (1.9\times10^{10}\ \text{J})/(3.195) = 5.95\times10^{9}\ \text{J}\ [(1\ \text{kWh})/(3.6\times10^{6}\ \text{J})] = 1650$ kWh. The cost is $0.153(1650 kWh) = $253.

(d) Using the same approach as in (c) gives the following values:

K = 4.279, W = 1233 kWh, cost = $189, savings = $253 – $189 = $64 per year.

EVALUATE: Whether it is worth it to replace your air conditioner depends on what it costs. In 10 years you would save $640 (probably more since utility rates tend to rise over time). But would the unit last10 years?

20.55. **IDENTIFY** and **SET UP:** The cycle consists of two isochoric processes (*ab* and *cd*) and two isobaric processes (*bc* and *da*). Use $Q = nC_V\Delta T$ and $Q = nC_p\Delta T$ for these processes. For an ideal monatomic gas (argon), $C_V = \frac{3}{2}R$ and $C_p = \frac{5}{2}R$. Use $R = 8.3145\ \text{J/mol}\cdot\text{K}$.

EXECUTE: **(a)** Using the equations listed above, the heat transfers are as follows:

Q_{ab} = (3/2)(4.00 mol)(8.3145 J/mol·K)(300.0 K – 250.0 K) = 2.494 kJ

Q_{bc} = (5/2)(4.00 mol)(8.3145 J/mol·K)(380.0 K – 300.0 K) = 6.652 kJ

Q_{cd} = (3/2)(4.00 mol) (8.3145 J/mol · K) (316.7 K – 380.0 K) = –3.158 kJ

Q_{da} = (5/2)(4.00 mol) (8.3145 J/mol · K) (250.0 K – 316.7 K) = –5.546 kJ

The efficiency of this cycle is $e = \dfrac{W}{|Q_{\text{in}}|} = \dfrac{|Q_{\text{in}}| - |Q_{\text{out}}|}{|Q_{\text{in}}|} = 1 - \dfrac{|Q_{\text{out}}|}{|Q_{\text{in}}|}$. This gives

$e = 1 - \dfrac{3.158\text{ kJ} + 5.546\text{ kJ}}{2.494\text{ kJ} + 6.652\text{ kJ}} = 0.0483 = 4.83\%.$

(b) If we double the number of moles, all the values of Q will double, but the factor of 2 cancels out, so the efficiency remains the same.

(c) Using the same procedure as in (a), the revised numbers are

Q_{ab} = 2.494 kJ (unchanged)

Q_{bc} = 38.247 kJ

Q_{cd} = –6.316 kJ

Q_{da} = –31.878 kJ

As in part (a), the efficiency of this cycle is $e = 1 - \dfrac{|Q_{\text{out}}|}{|Q_{\text{in}}|}$, which gives

$e = 1 - \dfrac{31.878\text{ kJ} + 6.316\text{ kJ}}{38.247\text{ kJ} + 2.494\text{ kJ}} = 0.0625 = 6.25\%.$

(d) In symbolic form, we have Q_{ab} = +2.494 kJ (unchanged)

Q_{bc} = (5/2)(4.00 mol) (8.3145 J/mol · K) (T_c – 300.0 K), which is positive.

Q_{cd} = (3/2)(4.00 mol) (8.3145 J/mol · K) (T_d – T_c), which is negative.

Q_{da} = (5/2)(4.00 mol) (8.3145 J/mol · K) (250.0 K – T_d), which is positive.

Using these values, the efficiency becomes $e = 1 - \dfrac{3(T_c - T_d) + 5(T_d - 250.0\text{ K})}{150 + 5(T_c - 300.0\text{ K})}$. Using the fact that T_c = 1.20T_d and simplifying, we get $e = \dfrac{0.40T_d - 100\text{ K}}{6.00T_d - 1350\text{ K}}$. As $T_d \to \infty$, $e \to$ 0.40/6.00 = 0.0667 = 6.67%.

EVALUATE: In (c), the Carnot efficiency for the temperature extremes given would be $e_{\text{Carnot}} = 1 - \dfrac{T_{\text{C}}}{T_{\text{H}}} =$ 1 – (250 K)/(760 K) = 0.67 = 67%, which is 10 times the maximum efficiency of your engine. Maybe you need a new design!

20.56. **IDENTIFY:** We are dealing with an ideal Stirling heat engine.

SET UP: First make a pV-diagram, as shown in Fig. 20.56.

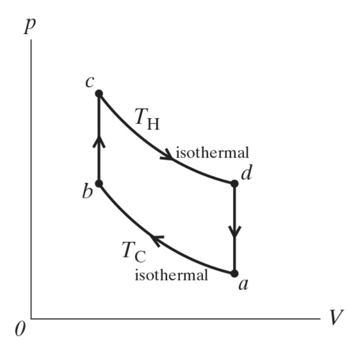

Figure 20.56

EXECUTE: **(a)** Both ab and cd are isothermal, and both bc and da are isochoric. Using $pV = nRT$ and taking ratios gives

<u>bc</u>: $\dfrac{p_cV_c}{p_bV_b} = \dfrac{T_c}{T_b} = \dfrac{T_H}{T_C}$. Since $V_b = V_c$, we have $\dfrac{p_c}{p_b} = \dfrac{T_H}{T_C}$.

<u>da</u>: Since $V_d = V_a$, we get $\dfrac{p_d}{p_a} = \dfrac{T_H}{T_C}$.

Equating the two expressions for T_H/T_C gives $\dfrac{p_d}{p_a} = \dfrac{p_c}{p_b}$. Rearranging gives $\dfrac{p_b}{p_a} = \dfrac{p_c}{p_d} =$ CR.

(b) We want the work done in segment *cd*. $W_{cd} = \int_c^d p\,dV = \int_c^d \dfrac{nRT_H}{V} dV = nRT_H \ln(V_d / V_c)$. Using $pV = nRT$ we have $\dfrac{V_d}{V_c} = \dfrac{nRT_H / p_d}{nRT_H / p_c} = \dfrac{p_c}{p_d} = \text{CR}$. Using this result we get $W_{cd} = nRT_H \ln(\text{CR})$.

(c) We want W_{ab}. $W_{ab} = \int_a^b p\,dV = \int_a^b \dfrac{nRT_C}{V} dV = nRT_C \ln(V_b / V_a)$. As in part (b), we take ratios giving $\dfrac{V_b}{V_a} = \dfrac{nRT_b / p_b}{nRT_a / p_a} = \dfrac{p_a}{p_b} = \dfrac{1}{\text{CR}}$. So $W_{ab} = nRT_C \ln(1/\text{CR}) = -nRT_C \ln(\text{CR})$.

(d) We want the power output of the engine, which is the rate at which it does work, so $P = W/t$. With a frequency of operation of 100 Hz, each cycle takes 1/100 s. Work is done only in segments *ab* and *cd* since the other segments are isochoric. Using our results from parts (b) and (c) gives $W_{tot} = W_{cd} + W_{ab} = nRT_H \ln(\text{CR}) - nRT_C \ln(\text{CR}) = nR \ln(\text{CR})(T_H - T_C)$, so the power output is $P = W/t = nR \ln(\text{CR})(T_H - T_C)/t$. Using $n = 1$ mol, CR = 10, $T_C = 20°\text{C} = 293$ K, $T_H = 100°\text{C} = 373$ K, and $t = 1/100$ s, we get $P = 1.53\times10^5$ W = 153 kW.

EVALUATE: If this were are a Carnot engine operating between the same temperature extremes, its efficiency would be $e = 1 - (293\text{ K})/(373\text{ K}) = 0.214$. For the Stirling engine, heat enters the gas during segments *bc* and *cd*, so $Q_{in} = Q_{bc} + Q_{cd}$. Using the numbers for part (c), we have $Q_{bc} = nC_V(T_H - T_C) = n(3/2\,R)(T_H - T_C) = 997.7$ J. During segment *cd*, *T* is constant so the internal energy *U* is constant. By the first law of thermodynamics, this means that $Q_{in} = Q_{cd} = W_{cd} = nRT_H \ln(\text{CR}) = 7141$ J. Thus during one cycle $Q_{in} = 997.7\text{ J} + 7141\text{ J} = 8138$ J. The work during one cycle is $W = Pt = (153\text{ kW})(1/100\text{ s}) = 1530$ J. So the efficiency is $e = W/Q_{in} = \dfrac{1530\text{ J}}{8138\text{ J}} = 0.188$. As expected, this engine is not as efficient as a Carnot engine operating between the same temperature extremes.

20.57. **IDENTIFY and SET UP:** Once you cut through all the extraterrestrial description, this problem boils down to an ordinary Carnot heat engine. First list all the known information and then summarize it on a *pV*-diagram as shown in Fig. 20.57. We know the following information:

$T_d = 123$ K = ambient temperature = T_a

$p_b = 20.3$ kPa

p_d = ambient pressure because the gauge pressure is zero at *d*

Trigger volume is V_a.

Combustion starts at point *b*.

$r_a = 1/3\, r_d \;\rightarrow\; r_d = 3r_a \rightarrow V_d = 27V_a$

$V_b = ½\, V_a \;\rightarrow\; V_a = 2V_b$

$\gamma = 1.30$

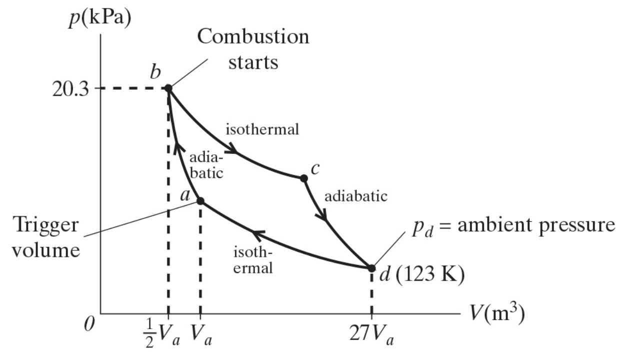

Figure 20.57

EXECUTE: **(a)** We want the combustion temperature, which is T_b. Since da is isothermal, $T_a = T_d =$ 123 K. Since ab is adiabatic, we know that $T_a V_a^{\gamma-1} = T_b V_b^{\gamma-1}$. Using $V_b = ½ V_a$, we have

$$T_b = T_a(V_a/V_b)^{\gamma-1} = (123\text{ K})\left(\frac{2V_b}{V_b}\right)^{1.30-1} = 151\text{ K}.$$

(b) We want the ambient pressure, which is p_d. Since ab is adiabatic, we use $p_a V_a^{\gamma} = p_b V_b^{\gamma}$ to get p_a. Then use $p_aV_a = p_dV_d$ to find p_d since da is isothermal.

Find p_a: $p_a = p_b(V_b/V_a)^{\gamma} = (20.3\text{ kPa})\left(\frac{V_b}{2V_b}\right)^{1.30} = 8.244\text{ kPa}.$

Find p_d: $p_d = p_a\left(\frac{V_a}{V_d}\right) = (8.244\text{ kPa})\left(\frac{V_a}{27V_a}\right) = 0.305\text{ kPa} = 305\text{ Pa}.$ At point d the gauge pressure is zero, so 305 Pa is the ambient pressure.

(c) We want the heat input Q_{in} each minute. The work that is done is W = 60 kJ/h = 1.00 kJ/min. For a Carnot engine $e = \frac{W}{Q_{in}} = 1 - \frac{T_C}{T_H} = 1 - \frac{T_d}{T_b}$. Using the result from part (a) and the given information, we have $\frac{1.00\text{ kJ}}{Q_{in}} = 1 - \frac{123\text{ K}}{151\text{ K}}$, so Q_{in} = 5.39 kJ.

(d) We want the heat rejected Q_{out} each minute. $Q_{in} = W + Q_{out}$, so 5.39 kJ = 1.00 kJ + Q_{out}, which gives Q_{out} = 4.39 kJ.

EVALUATE: The efficiency of this engine is $e = W/Q_{in}$ = (1.00 kJ)/(5.39 kJ) = 0.185. Sporons are about as efficient at doing work as automobile engines on Earth.

20.58. **IDENTIFY:** Calculate Q_C and Q_H in terms of p and V at each point. Use the ideal gas law and the pressure-volume relation for adiabatic processes for an ideal gas. $e = 1 - \frac{|Q_C|}{|Q_H|}$.

SET UP: For an ideal gas, $C_p = C_V + R$, and taking air to be diatomic, $C_p = \frac{7}{2}R, C_V = \frac{5}{2}R$, and $\gamma = \frac{7}{5}$.

EXECUTE: **(a)** Referring to Figure 20.7 in the textbook, $Q_H = n\frac{7}{2}R(T_c - T_b) = \frac{7}{2}(p_cV_c - p_bV_b)$. Similarly, $Q_C = n\frac{5}{2}R(p_aV_a - p_dV_d)$. What needs to be done is to find the relations between the product of the pressure and the volume at the four points. For an ideal gas, $\frac{p_cV_c}{T_c} = \frac{p_bV_b}{T_b}$ so $p_cV_c = p_aV_a\left(\frac{T_c}{T_a}\right)$. For a compression ratio r, and given that for the Diesel cycle the process ab is adiabatic,

$p_bV_b = p_aV_a\left(\frac{V_a}{V_b}\right)^{\gamma-1} = p_aV_ar^{\gamma-1}$. Similarly, $p_dV_d = p_cV_c\left(\frac{V_c}{V_a}\right)^{\gamma-1}$. Note that the last result uses the fact that process da is isochoric, and $V_d = V_a$; also, $p_c = p_b$ (process bc is isobaric), and so $V_c = V_b\left(\dfrac{T_c}{T_a}\right)$.

Then,

$$\frac{V_c}{V_a} = \frac{T_c}{T_b}\cdot\frac{V_b}{V_a} = \frac{T_b}{T_a}\cdot\frac{T_a}{T_b}\cdot\frac{V_a}{V_b} = \frac{T_c}{T_a}\cdot\left(\frac{T_a V_a^{\gamma-1}}{T_b V_b^{\gamma-1}}\right)\left(\frac{V_a}{V_b}\right)^{-\gamma} = \frac{T_c}{T_a}r^{\gamma}$$

Combining the above results, $p_d V_d = p_a V_a\left(\dfrac{T_c}{T_a}\right)^{\gamma} r^{\gamma-\gamma^2}$. Substitution of the above results into

$e = 1 - \dfrac{|Q_{\text{C}}|}{|Q_{\text{H}}|}$ gives $e = 1 - \dfrac{5}{7}\left[\dfrac{\left(\dfrac{T_c}{T_a}\right)^{\gamma} r^{\gamma-\gamma^2} - 1}{\left(\dfrac{T_c}{T_a}\right) - r^{\gamma-1}}\right]$.

(b) $e = 1 - \dfrac{1}{1.4}\left[\dfrac{(5.002)r^{-0.56} - 1}{(3.167) - r^{0.40}}\right]$, where $\dfrac{T_c}{T_a} = 3.167$ and $\gamma = 1.40$ have been used. Substitution of $r = 21.0$ yields $e = 0.708 = 70.8\%$.

EVALUATE: The efficiency for an Otto cycle with $r = 21.0$ and $\gamma = 1.40$ is $e = 1 - r^{1-\gamma} = 1 - (21.0)^{-0.40} = 70.4\%$. This efficiency is very close to the value for the Diesel cycle.

20.59. **IDENTIFY** and **SET UP:** The Carnot efficiency is $e_{\text{Carnot}} = 1 - \dfrac{T_{\text{C}}}{T_{\text{H}}}$. Solve for T_{C} to get the temperature for the desired efficiency. Then use the graph to find the depth at which the water is at that temperature.

EXECUTE: Solving $e_{\text{Carnot}} = 1 - \dfrac{T_{\text{C}}}{T_{\text{H}}}$ for T_{C} gives $T_{\text{C}} = T_{\text{H}}(1 - e) = (300\text{ K})(1 - 0.065) = 280.5\text{ K} = 7.5°\text{C}$. From the graph, we see that this temperature occurs at a depth of about 400 m, which is choice (b).

EVALUATE: This depth is over 1200 ft, so deep water is essential for such a power plant.

20.60. **IDENTIFY** and **SET UP:** This power plant produces energy (i.e., does work) at a rate of 10 MW and is 6.5% efficient. This means that the 10 MW is 6.5% of the heat input, Q_{H}, per second.

EXECUTE: $W/t = 0.065Q_{\text{H}}/t$, so $Q_{\text{H}}/t = (10\text{ MW})/(0.065)$. The entropy change per second is $[Q/T_{\text{H}}]/t = [(10\text{ MW})/(0.065)]/(300\text{ K}) = 5.1 \times 10^5$ J/K, which is choice (b).

EVALUATE: The entropy increases because the ammonia gets more disordered as it vaporizes, so our answer is plausible.

20.61. **IDENTIFY** and **SET UP:** Both the warm and cold reservoirs are so large that they do not change temperature as heat is added or lost, so $\Delta S = Q/T$. For a Carnot engine, $|Q_{\text{C}}/Q_{\text{H}}| = |T_{\text{C}}/T_{\text{H}}|$.

EXECUTE: $\Delta S_{\text{warm}} = Q_{\text{H}}/T_{\text{H}}$ and $\Delta S_{\text{cold}} = Q_{\text{C}}/T_{\text{C}}$. But for a Carnot engine, $|Q_{\text{H}}/T_{\text{H}}| = |Q_{\text{C}}/T_{\text{C}}|$. Therefore $\Delta S_{\text{warm}} = -\Delta S_{\text{cold}}$, which is choice (d).

EVALUATE: Our result means that the net entropy change for a cycle is zero. An ideal Carnot engine is reversible, so the entropy change in a cycle is zero, which agrees with our result.

20.62. **IDENTIFY** and **SET UP:** For a cycle, $Q_{\text{H}} = W + Q_{\text{C}}$ and $e = W/Q_{\text{H}}$.

EXECUTE: For this engine, W/t =10 MW and $Q_{\text{C}}/t = 165$ MW, so $Q_{\text{H}}/t = W/t + Q_{\text{C}}/t = 175$ W. The efficiency is $e = (W/t)/(Q_{\text{C}}/t) = (10\text{ MW})/(175\text{ MW}) = 0.057 = 5.7\%$, choice (a).

EVALUATE: An actual heat engine is always less efficient than the theoretical limit due to friction as well as internal effects in the gas which prevent it from behaving exactly like an ideal gas.

21

ELECTRIC CHARGE AND ELECTRIC FIELD

VP21.4.1. **IDENTIFY:** In this problem we use Coulomb's law to calculate the electric force between charges.

SET UP: $F = \dfrac{1}{4\pi\epsilon_0}\dfrac{|qQ|}{r^2}$. We want the total force on q_3. Start with a sketch showing the charge arrangement, as in Fig. VP21.4.1a.

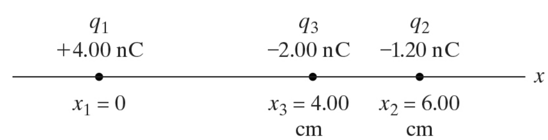

Figure VP21.4.1a

EXECUTE: We know that q_1 attracts q_3 because they have opposite signs, and q_2 repels q_3 because they have the same sign (both are negative). Sketch the forces on q_3 due to the other charges (see Fig. VP21.4.1b). Using $F = \dfrac{1}{4\pi\epsilon_0}\dfrac{|qQ|}{r^2}$, we add the forces since they are both in the same direction. $F_{\text{tot}} =$ $F_{1\text{ on }3} + F_{2\text{ on }3} = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_1q_3|}{r_{13}^2} + \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_2q_3|}{r_{23}^2} = \dfrac{|q_3|}{4\pi\epsilon_0}\left(\dfrac{|q_1|}{r_{13}^2} + \dfrac{|q_2|}{r_{23}^2}\right)$. Using the given charges, $r_{13} =$ 4.00 cm = 0.0400 m, and r_{23} = 2.00 cm = 0.0200 m gives $F_{\text{tot}} = 9.89\times10^{-5}$ N = 98.9 μN. This force is in the $-x$ direction, so we can express it as $98.9\ \mu\text{N}\hat{\boldsymbol{i}}$.

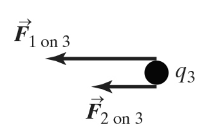

Figure VP21.4.1b

EVALUATE: It is always very helpful to make sketches like those shown here to get charge arrangements, distances, and force directions clear.

VP21.4.2. **IDENTIFY:** This problem requires the calculation of the electric force between charges, so we use Coulomb's law.

SET UP: $F = \dfrac{1}{4\pi\epsilon_0}\dfrac{|qQ|}{r^2}$. Start with a sketch showing the charge arrangement, as in Fig. VP21.4.2a.

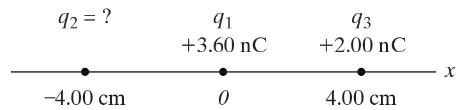

Figure VP21.4.2a

EXECUTE: **(a)** We want the force that q_1 exerts on q_3.
$F_{1\text{ on }3} = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_1 q_3|}{r_{13}^2} = \dfrac{1}{4\pi\epsilon_0}\dfrac{(3.60\text{ nC})(2.00\text{ nC})}{(0.0400\text{ m})^2} = 40.5\ \mu\text{N}$. The direction is to the right (+x). Now sketch the forces on q_3 (Fig. 21.4.2b).

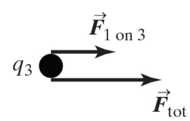

Figure VP21.4.2b

(b) We want the force that q_2 exerts on q_3. $F_{2\text{ on }3} = 54.0\ \mu\text{N} - 40.5\ \mu\text{N} = 13.5\ \mu\text{N}$ in the +x direction.
(c) We want q_2. $F_{2\text{ on }3} = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_2 q_3|}{r_{23}^2}$. Since q_2 repels q_3, q_2 must be positive. Solving for q_2 and using $r_{23} = 8.00\text{ cm} = 0.0800\text{ m}$, $q_3 = 2.00\text{ nC}$, and the result from part (b) gives $q_2 = +4.82\text{ nC}$.
EVALUATE: Always make sketches like those shown here to get charge arrangements, distances, and force directions clear.

VP21.4.3. **IDENTIFY:** This problem requires the calculation of the electric force between charges, so we use Coulomb's law.
SET UP: $F = \dfrac{1}{4\pi\epsilon_0}\dfrac{|qQ|}{r^2}$. Start with a sketch showing the charge arrangement, as in Fig. VP21.4.3a.

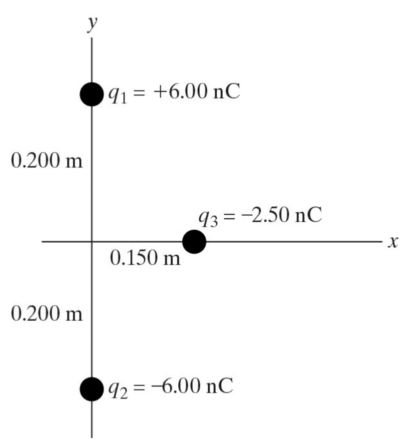

Figure VP21.4.3a

EXECUTE: Start with a careful sketch showing the forces on q_3 shown in Fig. VP21.4.3b. Since q_1 and q_2 have the same magnitude, the figure shows that the x components cancel and the y components add. So $F_{tot} = 2F_{1 \text{ on } 3}\sin\theta = \dfrac{2}{4\pi\epsilon_0}\dfrac{|q_1q_3|}{r_{13}^2}\sin\theta.$ $\theta = \arctan\left(\dfrac{0.200 \text{ m}}{0.150 \text{ m}}\right) = 53.13°.$

$r_{13}^2 = (0.150 \text{ m})^2 + (0.200 \text{ m})^2 = 0.625 \text{ m}^2.$ Using these results, $q_1 = 6.00$ nC, and $q_3 = -2.50$ nC gives $F_{tot} = 3.45$ N in the $+y$ direction.

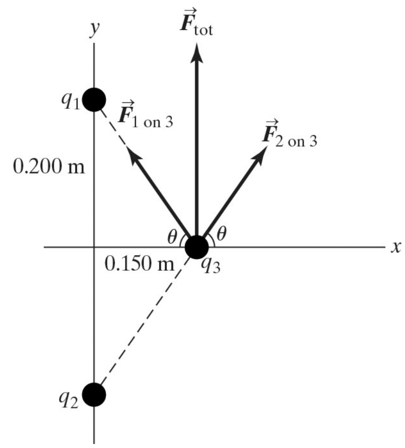

Figure VP21.4.3b

EVALUATE: Before doing any calculations, always make a vector drawing as in the figure. It can save a lot of unnecessary arithmetic and algebra.

VP21.4.4. **IDENTIFY:** We use Coulomb's law to calculate electric forces between point charges. Begin with a clear sketch of the charge arrangement, as in Fig. VP21.4.4a.

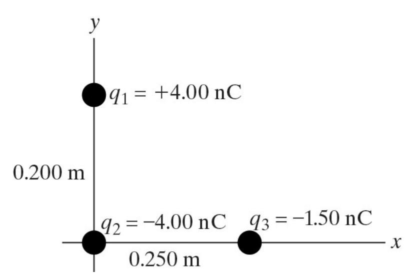

Figure VP21.4.4a

SET UP: $F = \dfrac{1}{4\pi\epsilon_0}\dfrac{|qQ|}{r^2}$. We want the components of the total electric force on q_3. Fig. VP21.4.4b shows the two forces on q_3.

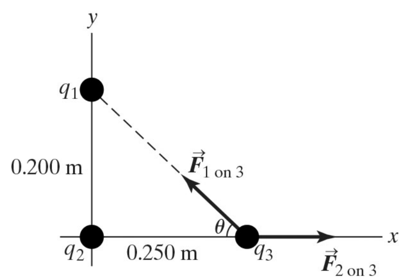

Figure VP21.4.4b

EXECUTE: $F_x = F_{2\text{ on }3} - F_{1\text{ on }3}\cos\theta$. Using Coulomb's law gives

$F_x = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_2q_3|}{r_{23}^2} - \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_1q_3|}{r_{13}^2}\cos\theta$. $r_{13}^2 = (0.250\text{ m})^2 + (0.200\text{ m})^2 = 0.1025\text{ m}^2$.

$\theta = \arctan\left(\dfrac{0.200\text{ m}}{0.250\text{ m}}\right) = 38.66°$. Using $r_{23} = 0.250$ m and the given charges, gives $F_x = 0.451\ \mu$N.

$F_y = F_{1\text{ on }3}\sin\theta = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_1q_3|}{r_{13}^2}\sin\theta = 0.329\ \mu\text{N}$.

EVALUATE: Always start with careful sketches showing the charges and the force vectors.

VP21.10.1 **IDENTIFY:** We want to find the total electric field due to two point charges.

SET UP: $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$.

EXECUTE: **(a)** First sketch the charge arrangement and the electric fields at the point (0, 0.100 m) (Fig. VP21.10.1a). Both fields point in the $-y$ direction, so $E_y = E_1 + E_2$ and $E_x = 0$. Using $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$

gives $E_y = -\dfrac{1}{4\pi\epsilon_0}\dfrac{|q_1|}{r_1^2} - \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_2|}{r_2^2}$. Using the given charges and $r_1 = r_2 = 0.100$ m gives

$E_y = -8090$ N/C.

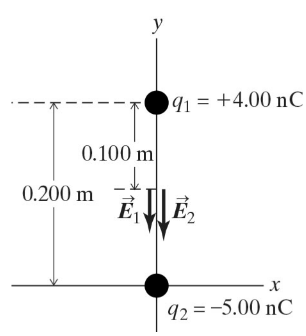

Figure VP21.10.1a

(b) Sketch the electric fields at the point (0, 0.400 m) as in Fig. VP21.10.1b. As in part (a), $E_x = 0$. Now the fields point in opposite directions, so $E_y = E_1 - E_2$. This gives $E_y = -\dfrac{1}{4\pi\epsilon_0}\dfrac{|q_1|}{r_1^2} - \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_2|}{r_2^2}$.

Using $r_1 = 0.200$ m and $r_2 = 0.400$ m, we get $E_y = 618$ N/C.

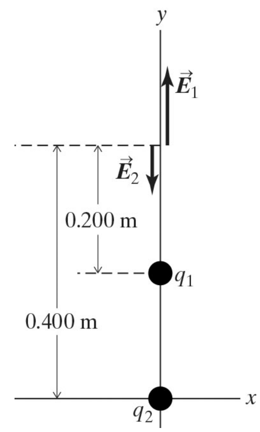

Figure VP21.10.1b

(c) Sketch the electric fields at the point (0.200 m, 0) as in Fig. VP21.10.1c. From this figure, we can see that $E_x = E_{1x} - |E_{2x}| = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_1|}{r_1^2}\cos\theta - \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_2|}{r_2^2}$. $\theta = \arctan\left(\dfrac{0.200\text{ m}}{0.20\text{ m}}\right) = 45.0°$.

$r_1^2 = (0.200\text{ m})^2 + (0.200\text{ m})^2 = 0.0800\text{ m}^2$. Using these results and $r_2 = 0.200$ m, we get $E_x = -806$ N/C. From the figure we see that $E_y = -|E_{1y}| = -E_1\sin\theta = -\dfrac{1}{4\pi\epsilon_0}\dfrac{|q_1|}{r_1^2}\sin\theta$. Using $r_1 =$ 0.0800 m gives $E_y = -318$ N/C.

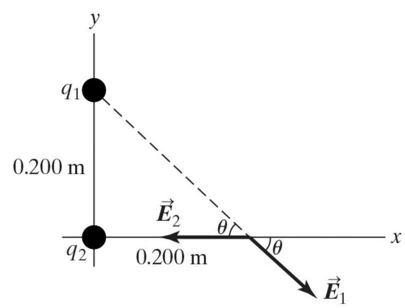

Figure VP21.10.1c

EVALUATE: Careful sketches are especially important when working with two-dimensional charge configurations.

VP21.10.2. **IDENTIFY:** We are dealing with the electric field due to two point charges.

SET UP: $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$. First sketch the charge arrangement, as in Fig. 21.10.2a.

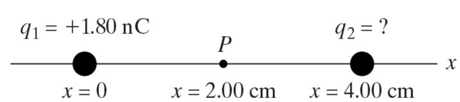

Figure VP21.10.2a

EXECUTE: **(a)** We want the field due to q_1 at point P. Using $q_1 = 1.80$ nC and $r_1 = 0.0200$ m, $E_1 = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_1|}{r_1^2}$ gives $E_1 = 4.05\times10^4$ N/C in the $+x$ direction.

(c) Fig. VP21.10b shows the known electric fields at P. We want to find E_2. $E_{tot} = E_1 - E_2$, which gives $E_2 = E_{tot} - E_1 = 6.75\times10^4\ \text{N/C} - 4.05\times10^4\ \text{N/C} = 2.70\times10^4\ \text{N/C}$ in the $+x$ direction.

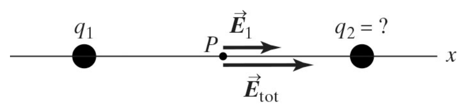

Figure VP21.10.2b

(c) The field E_2 must point in the $+x$ direction, which is toward q_2, so q_2 must be negative.
$E_2 = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_2|}{r_2^2}$. Solve for $|q_2|$, use $r_2 = 0.0200$ m and the result from part (b), so $q_2 = -1.20$ nC.

EVALUATE: Careful when finding electric fields. The components can be negative but the magnitude cannot be negative.

VP21.10.3. **IDENTIFY:** We view the hydrogen atom by modeling the orbital electron as a ring of charge centered on the proton.

SET UP: $E_x = \dfrac{1}{4\pi\epsilon_0}\dfrac{Qx}{(x^2+a^2)^{3/2}}$. The total electric field is the field of the electron and the proton. We want the total field at $x = a$.

EXECUTE: **(a)** Electron: $E_x = \dfrac{1}{4\pi\epsilon_0}\dfrac{Qx}{(x^2+a^2)^{3/2}} = \dfrac{1}{4\pi\epsilon_0}\dfrac{ea}{(a^2+a^2)^{3/2}} = \dfrac{1}{4\pi\epsilon_0}\dfrac{e}{2^{3/2}a^2}$. The electron is negative, so this field points *toward* the proton, which gives $E_x = -\dfrac{1}{4\pi\epsilon_0}\dfrac{e}{2^{3/2}a^2}$.

Proton: $E_x = \dfrac{1}{4\pi\epsilon_0}\dfrac{e}{a^2}$ away from the proton.

$E_{tot} = E_p + E_e = E_x = \dfrac{1}{4\pi\epsilon_0}\dfrac{e}{a^2} - \dfrac{1}{4\pi\epsilon_0}\dfrac{e}{2^{3/2}a^2} = \dfrac{e}{4\pi\epsilon_0 a^2}\left(1-\dfrac{1}{2\sqrt{2}}\right)$.

(b) $1-\dfrac{1}{2\sqrt{2}} > 0$, so the total field points *away from* the proton.

EVALUATE: The total field is less than the proton's field because the electron partially cancel it.

VP21.10.4. **IDENTIFY:** We want the electric field caused by a charged rod. We need calculus to do this calculation.
SET UP: Fig. VP21.10.4 shows the set up of the rod along the x-axis. The uniform linear charge density of the rod is Q/L.

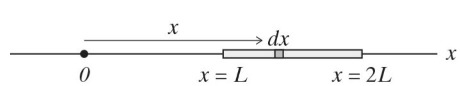

Figure VP21.10.4

EXECUTE: **(a)** $dq = (Q/L)dx$.
(b) $dE_x = -\dfrac{1}{4\pi\epsilon_0}\dfrac{dq}{x^2} = -\dfrac{1}{4\pi\epsilon_0}\dfrac{(Q/L)dx}{x^2}$. $dE_y = 0$.
(c) $E_x = \int dE_x = \int_L^{2L} -\dfrac{1}{4\pi\epsilon_0}\dfrac{(Q/L)dx}{x^2} = -\dfrac{Q}{8\pi\epsilon_0 L^2}$.

EVALUATE: If we treat the rod as a point charge at its center, we get $E_x = -\dfrac{Q}{4\pi\epsilon_0 (3L/2)^2} = -\dfrac{Q}{9\pi\epsilon_0 L^2}$, which is *not* the same as our result. So we cannot simplify the rod as a point charge.

VP21.14.1. **IDENTIFY:** This problem involves an electric dipole in an external electric field.

SET UP: We want the torque on the dipole and its potential energy.

EXECUTE: **(a)** $\tau = pE\sin\phi = (6.13\times10^{-30}\,\text{C}\cdot\text{m})(3.00\times10^5\ \text{N/C})\sin 50.0° = 1.41\times10^{-24}\ \text{N}\cdot\text{m}$.

(b) $U = -pE\cos\phi = -1.18\times10^{-24}$ J, using the same values as in part (a).

EVALUATE: These results are very small, but a molecule consists of very small charges that are very close together.

VP21.14.2. **IDENTIFY** This problem involves an electric dipole in an external electric field.

SET UP: We want the charges that make up the dipole. $\tau = pE\sin\phi$ where $p = qd$.

EXECUTE: Solve for q: $q = \dfrac{\tau}{dE\sin\phi} = \dfrac{6.60\times10^{-26}\ \text{N}\cdot\text{m}}{(1.10\times10^{-10}\ \text{m})(8.50\times10^4\ \text{N/C})(\sin 90°)} = 7.06\times10^{-21}$ C.

EVALUATE: Each end of the dipole has charge of this magnitude but opposite signs.

VP21.14.3. **IDENTIFY:** We are dealing with the potential energy of an electric dipole in an external electric field.

SET UP: $U = -pE\cos\phi$.

EXECUTE: We want p. $\Delta U = U_2 - U_1 = -pE\cos 0° = (-pE\cos 180°) = -2pE$, so the work required is $W = +2pE$. Therefore $p = \dfrac{W}{2E} = \dfrac{4.60\times10^{-25}\ \text{J}}{2(1.20\times10^5\ \text{N/C})} = 1.92\times10^{-30}\ \text{C}\cdot\text{m}$.

EVALUATE: If the charges are 0.50×10^{-11} m apart (about 1/10 the radius of an atom), the charges are each $q = p/d =$ $(1.92\times10^{-30}\ \text{C}\cdot\text{m})/(0.50\times10^{-11}\ \text{m}) = 3.8\times10^{-19}$ C.

VP21.14.4. **IDENTIFY:** We are looking at a KBr dipole having a dipole moment of $p = 3.50\times10^{-29}\ \text{C}\cdot\text{m}$.

SET UP and EXECUTE: **(a)** We want the distance between the ions. $p = qd = ed$, so $d = p/e$. Using the given p gives $d = 2.19\times10^{-10}$ m.

(b) We want to find the point on the dipole axis where the electric field is $E = 8.00\times10^4$ N/C. There are two possibilities to consider: the point is between the ions or it is outside the dipole. Between the ions: The field is weakest midway between the ions. At that point

$$E_{\text{min}} = 2\left(\frac{1}{4\pi\epsilon_0}\frac{e}{(d/2)^2}\right) = 2.40\times10^{11}\ \text{N/C}$$

This is less than 8.00×10^4 N/C, so the point must be *outside* the dipole.

Outside the dipole: In this case the fields due to the two ions point in opposite directions. Call x the distance from the center of the dipole to the desired point and $2a$ the length of the dipole. The total field is $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{e}{(x-a)^2} - \dfrac{1}{4\pi\epsilon_0}\dfrac{e}{(x+a)^2} = \dfrac{e}{4\pi\epsilon_0}\dfrac{4ax}{(x+a)^2(x-a)^2}$. The electric field at this point is 8.00×10^4 N/C, which is much much less than E_{min} inside the dipole. Therefore this point must be very far from the center of the dipole, so $x >> a$. In this case, $x + a \approx x$ and $x - a \approx x$, so the equation for E simplifies to $E \approx \dfrac{e}{4\pi\epsilon_0}\dfrac{4ax}{x^4} = \dfrac{ea}{\pi\epsilon_0 x^3}$. Using $a = d/2$ and solving for x gives $x = \left(\dfrac{ed/2}{\pi\epsilon_0 E}\right)^{1/3}$. Using $d = 2.19\times10^{-10}$ m and $E = 8.00\times10^4$ N/C gives $x = 1.99\times10^{-8}$ m.

EVALUATE: Between the ions of the dipole the field is very strong since we are very close to the charges and the fields point in the same direction. Outside the dipole the fields are in opposite directions and partially cancel each other so the net field is much weaker. Our approximation in part (b) that $x <<$ a is reasonable $x \approx 100d$.

21.1. **(a) IDENTIFY and SET UP:** Use the charge of one electron $(-1.602\times10^{-19}\text{ C})$ to find the number of electrons required to produce the net charge.

EXECUTE: The number of excess electrons needed to produce net charge q is

$$\frac{q}{-e} = \frac{-3.20\times10^{-9}\text{ C}}{-1.602\times10^{-19}\text{ C/electron}} = 2.00\times10^{10}\text{ electrons.}$$

(b) IDENTIFY and SET UP: Use the atomic mass of lead to find the number of lead atoms in 8.00×10^{-3} kg of lead. From this and the total number of excess electrons, find the number of excess electrons per lead atom.

EXECUTE: The atomic mass of lead is $207\times10^{-3}\text{ kg/mol}$, so the number of moles in 8.00×10^{-3} kg is $n = \dfrac{m_{\text{tot}}}{M} = \dfrac{8.00\times10^{-3}\text{ kg}}{207\times10^{-3}\text{ kg/mol}} = 0.03865\text{ mol.}$ N_A (Avogadro's number) is the number of atoms in 1 mole, so the number of lead atoms is

$N = nN_A = (0.03865\text{ mol})(6.022\times10^{23}\text{ atoms/mol}) = 2.328\times10^{22}\text{ atoms.}$ The number of excess electrons per lead atom is $\dfrac{2.00\times10^{10}\text{ electrons}}{2.328\times10^{22}\text{ atoms}} = 8.59\times10^{-13}$.

EVALUATE: Even this small net charge corresponds to a large number of excess electrons. But the number of atoms in the sphere is much larger still, so the number of excess electrons per lead atom is very small.

21.2. **IDENTIFY:** The charge that flows is the rate of charge flow times the duration of the time interval.

SET UP: The charge of one electron has magnitude $e = 1.60\times10^{-19}$ C.

EXECUTE: The rate of charge flow is $20{,}000\text{ C/s}$ and $t = 100\ \mu\text{s} = 1.00\times10^{-4}\text{ s}$.

$Q = (20{,}000\text{ C/s})(1.00\times10^{-4}\text{ s}) = 2.00\text{ C}$. The number of electrons is $n_e = \dfrac{Q}{1.60\times10^{-19}\text{ C}} = 1.25\times10^{19}$.

EVALUATE: This is a very large amount of charge and a large number of electrons.

21.3. **IDENTIFY and SET UP:** A proton has charge $+e$ and an electron has charge $-e$, with $e = 1.60\times10^{-19}$ C. The force between them has magnitude $F = k\dfrac{|q_1q_2|}{r^2} = k\dfrac{e^2}{r^2}$ and is attractive since the charges have opposite sign. A proton has mass $m_p = 1.67\times10^{-27}$ kg and an electron has mass 9.11×10^{-31} kg. The acceleration is related to the net force $\vec{F}$ by $\vec{F} = m\vec{a}$.

EXECUTE: $F = k\dfrac{e^2}{r^2} = (8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\dfrac{(1.60\times10^{-19}\text{ C})^2}{(2.0\times10^{-10}\text{ m})^2} = 5.75\times10^{-9}\text{ N.}$

Proton: $a_p = \dfrac{F}{m_p} = \dfrac{5.75\times10^{-9}\text{ N}}{1.67\times10^{-27}\text{ kg}} = 3.4\times10^{18}\text{ m/s}^2$.

Electron: $a_e = \dfrac{F}{m_e} = \dfrac{5.75\times10^{-9}\text{ N}}{9.11\times10^{-31}\text{ kg}} = 6.3\times10^{21}\text{ m/s}^2$

The proton has an initial acceleration of $3.4\times10^{18}\text{ m/s}^2$ toward the electron and the electron has an initial acceleration of $6.3\times10^{21}\text{ m/s}^2$ toward the proton.

EVALUATE: The force the electron exerts on the proton is equal in magnitude to the force the proton exerts on the electron, but the accelerations of the two particles are very different because their masses are very different.

21.4. **IDENTIFY:** Apply Coulomb's law and find the vector sum of the two forces on q_2.

SET UP: $\vec{F}_{2\text{ on }1}$ is in the $+y$-direction.

EXECUTE: $F_{2\text{ on }1} = \dfrac{(9.0\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(2.0\times10^{-6}\ \text{C})(2.0\times10^{-6}\ \text{C})}{(0.60\ \text{m})^2} = 0.100\ \text{N}$. $(F_{2\text{ on }1})_x = 0$ and $(F_{2\text{ on }1})_y = +0.100\ \text{N}$. $F_{Q\text{ on }1}$ is equal and opposite to $F_{1\text{ on }Q}$ (Example 21.4), so $(F_{Q\text{ on }1})_x = -0.23\ \text{N}$ and . $(F_{Q\text{ on }1})_y = 0.17\ \text{N}$. . $F_x = (F_{2\text{ on }1})_x + (F_{Q\text{ on }1})_x = -0.23\ \text{N}$.
$F_y = (F_{2\text{ on }1})_y + (F_{Q\text{ on }1})_y = 0.100\ \text{N} + 0.17\ \text{N} = 0.27\ \text{N}$. The magnitude of the total force is $F = \sqrt{(0.23\ \text{N})^2 + (0.27\ \text{N})^2} = 0.35\ \text{N}$. $\tan^{-1}\dfrac{0.23}{0.27} = 40°$, so $\vec{F}$ is $40°$ counterclockwise from the $+y$-axis, or $130°$ counterclockwise from the $+x$- axis.

EVALUATE: Both forces on q_1 are repulsive and are directed away from the charges that exert them.

21.5. **IDENTIFY:** Each ion carries charge as it enters the axon.

SET UP: The total charge Q is the number N of ions times the charge of each one, which is e. So $Q = Ne$, where $e = 1.60\times10^{-19}\ \text{C}$.

EXECUTE: The number N of ions is $N = (5.6\times10^{11}\ \text{ions/m})(1.5\times10^{-2}\ \text{m}) = 8.4\times10^9$ ions. The total charge Q carried by these ions is $Q = Ne = (8.4\times10^9)(1.60\times10^{-19}\ \text{C}) = 1.3\times10^{-9}\ \text{C} = 1.3\ \text{nC}$.

EVALUATE: The amount of charge is small, but these charges are close enough together to exert large forces on nearby charges.

21.6. **IDENTIFY:** Apply Coulomb's law and calculate the net charge q on each sphere.

SET UP: The magnitude of the charge of an electron is $e = 1.60\times10^{-19}\ \text{C}$.

EXECUTE: $F = k\dfrac{|q_1q_2|}{r^2}$ gives

$|q| = \sqrt{4\pi\epsilon_0\, Fr^2} = \sqrt{4\pi\epsilon_0\,(3.33\times10^{-21}\ \text{N})(0.200\ \text{m})^2} = 1.217\times10^{-16}\ \text{C}$. Therefore, the total number of electrons required is $n = |q|/e = (1.217\times10^{-16}\ \text{C})/(1.60\times10^{-19}\ \text{C/electron}) = 760$ electrons.

EVALUATE: Each sphere has 760 excess electrons and each sphere has a net negative charge. The two like charges repel.

21.7. **IDENTIFY:** Apply $F = \dfrac{k|q_1q_2|}{r^2}$ and solve for r.

SET UP: $F = 650\ \text{N}$.

EXECUTE: $r = \sqrt{\dfrac{k|q_1q_2|}{F}} = \sqrt{\dfrac{(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(1.0\ \text{C})^2}{650\ \text{N}}} = 3.7\times10^3\ \text{m} = 3.7\ \text{km}$

EVALUATE: Charged objects typically have net charges much less than 1 C.

21.8. **IDENTIFY:** Use the mass of a sphere and the atomic mass of aluminum to find the number of aluminum atoms in one sphere. Each atom has 13 electrons. Apply Coulomb's law and calculate the magnitude of charge $|q|$ on each sphere.

SET UP: $N_\text{A} = 6.02\times10^{23}$ atoms/mol. $|q| = n'_\text{e}e$, where n'_e is the number of electrons removed from one sphere and added to the other.

EXECUTE: **(a)** The total number of electrons on each sphere equals the number of protons.

$$n_\text{e} = n_\text{p} = (13)(N_\text{A})\left(\frac{0.0250\ \text{kg}}{0.026982\ \text{kg/mol}}\right) = 7.25\times10^{24}\ \text{electrons}.$$

(b) For a force of 1.00×10^4 N to act between the spheres, $F = 1.00\times10^4\ \text{N} = \dfrac{1}{4\pi\epsilon_0}\dfrac{q^2}{r^2}$. This gives

$|q| = \sqrt{4\pi\epsilon_0\,(1.00\times10^4\ \text{N})(0.800\ \text{m})^2} = 8.43\times10^{-4}$ C. The number of electrons removed from one sphere and added to the other is $n'_e = |q|/e = 5.27\times10^{15}$ electrons.

(c) $n'_e/n_e = 7.27\times10^{-10}$.

EVALUATE: When ordinary objects receive a net charge, the fractional change in the total number of electrons in the object is very small.

21.9. IDENTIFY: Apply Coulomb's law.

SET UP: Consider the force on one of the spheres.

EXECUTE: **(a)** $q_1 = q_2 = q$ and $F = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_1q_2|}{r^2} = \dfrac{q^2}{4\pi\epsilon_0 r^2}$, so

$$q = r\sqrt{\frac{F}{(1/4\pi\epsilon_0)}} = 0.150\ \text{m}\sqrt{\frac{0.220\ \text{N}}{8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2}} = 7.42\times10^{-7}\ \text{C (on each)}.$$

(b) $q_2 = 4q_1$

$$F = \frac{1}{4\pi\epsilon_0}\frac{|q_1q_2|}{r^2} = \frac{4q_1^2}{4\pi\epsilon_0 r^2}\ \text{so}\ q_1 = r\sqrt{\frac{F}{4(1/4\pi\epsilon_0)}} = \frac{1}{2}r\sqrt{\frac{F}{(1/4\pi\epsilon_0)}} = \frac{1}{2}(7.42\times10^{-7}\ \text{C}) = 3.71\times10^{-7}\ \text{C}.$$

And then $q_2 = 4q_1 = 1.48\times10^{-6}$ C.

EVALUATE: The force on one sphere is the same magnitude as the force on the other sphere, whether the spheres have equal charges or not.

21.10. IDENTIFY: Apply $F = k\dfrac{|qq'|}{r^2}$ to each pair of charges. The net force is the vector sum of the forces due to q_1 and q_2.

SET UP: Like charges repel and unlike charges attract. The charges and their forces on q_3 are shown in Figure 21.10.

EXECUTE: $F_1 = k\dfrac{|q_1q_3|}{r_1^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{(4.00\times10^{-9}\ \text{C})(6.00\times10^{-9}\ \text{C})}{(0.200\ \text{m})^2} = 5.394\times10^{-6}$ N.

$$F_2 = k\frac{|q_2q_3|}{r_2^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(5.00\times10^{-9}\ \text{C})(6.00\times10^{-9}\ \text{C})}{(0.300\ \text{m})^2} = 2.997\times10^{-6}\ \text{N}.$$

$F_x = F_{1x} + F_{2x} = +F_1 - F_2 = 2.40\times10^{-6}$ N. The net force has magnitude 2.40×10^{-6} N and is in the $+x$-direction.

EVALUATE: Each force is attractive, but the forces are in opposite directions because of the placement of the charges. Since the forces are in opposite directions, the net force is obtained by subtracting their magnitudes.

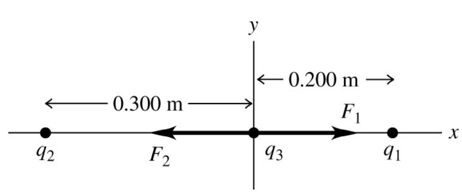

Figure 21.10

21.11. IDENTIFY: In a space satellite, the only force accelerating the free proton is the electrical repulsion of the other proton.

SET UP: Coulomb's law gives the force, and Newton's second law gives the acceleration: $a = F/m = (1/4\pi\epsilon_0)(e^2/r^2)/m.$

EXECUTE:

(a) $a = (9.00\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(1.60\times10^{-19}\ \text{C})^2/[(0.00250\ \text{m})^2(1.67\times10^{-27}\ \text{kg})] = 2.21\times10^4\ \text{m/s}^2.$

(b) The graphs are sketched in Figure 21.11.

EVALUATE: The electrical force of a single stationary proton gives the moving proton an initial acceleration about 20,000 times as great as the acceleration caused by the gravity of the entire earth. As the protons move farther apart, the electrical force gets weaker, so the acceleration decreases. Since the protons continue to repel, the velocity keeps increasing, but at a decreasing rate.

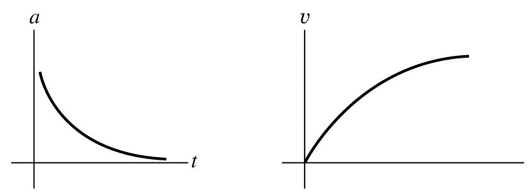

Figure 21.11

21.12. IDENTIFY: Apply Coulomb's law.

SET UP: Like charges repel and unlike charges attract.

EXECUTE: **(a)** $F = \frac{1}{4\pi\epsilon_0}\frac{|q_1q_2|}{r^2}$ gives $0.600\ \text{N} = \frac{1}{4\pi\epsilon_0}\frac{(0.550\times10^{-6}\ \text{C})|q_2|}{(0.30\ \text{m})^2}$ and

$|q_2| = +1.09\times10^{-5}\ \text{C} = 10.9\ \mu\text{C}$. The force is attractive and $q_1 < 0$, so $q_2 = +1.09\times10^{-5}\ \text{C} = +10.9\mu\text{C}$.

(b) $F = 0.600\ \text{N}$. The force is attractive, so is downward.

EVALUATE: The forces between the two charges obey Newton's third law.

21.13. IDENTIFY: Apply Coulomb's law. The two forces on q_3 must have equal magnitudes and opposite directions.

SET UP: Like charges repel and unlike charges attract.

EXECUTE: The force $\vec{F}_2$ that q_2 exerts on q_3 has magnitude $F_2 = k\frac{|q_2q_3|}{r_2^2}$ and is in the +x-direction. $\vec{F}_1$ must be in the –x-direction, so q_1 must be positive. $F_1 = F_2$ gives $k\frac{|q_1||q_3|}{r_1^2} = k\frac{|q_2||q_3|}{r_2^2}$.

$$|q_1| = |q_2|\left(\frac{r_1}{r_2}\right)^2 = (3.00\ \text{nC})\left(\frac{2.00\ \text{cm}}{4.00\ \text{cm}}\right)^2 = 0.750\ \text{nC}.$$

EVALUATE: The result for the magnitude of q_1 doesn't depend on the magnitude of q_3.

21.14. IDENTIFY: Apply Coulomb's law and find the vector sum of the two forces on Q.

SET UP: The force that q_1 exerts on Q is repulsive, as in Example 21.4, but now the force that q_2 exerts is attractive.

EXECUTE: The x-components cancel. We only need the y-components, and each charge contributes equally. $F_{1y} = F_{2y} = -\frac{1}{4\pi\epsilon_0}\frac{(2.0\times10^{-6}\ \text{C})(4.0\times10^{-6}\ \text{C})}{(0.500\ \text{m})^2}\sin\alpha = -0.173\ \text{N}$ (since $\sin\alpha = 0.600$).

Therefore, the total force is $2F = 0.35\ \text{N}$, in the $-y$-direction.

EVALUATE: If q_1 is $-2.0\ \mu\text{C}$ and q_2 is $+2.0\ \mu\text{C}$, then the net force is in the $+y$-direction.

21.15. **IDENTIFY:** Apply Coulomb's law and find the vector sum of the two forces on q_1.

SET UP: Like charges repel and unlike charges attract, so $\vec{F}_2$ and $\vec{F}_3$ are both in the $+x$-direction.

EXECUTE: $F_2 = k\dfrac{|q_1q_2|}{r_{12}^2} = 6.749\times10^{-5}\text{ N}$, $F_3 = k\dfrac{|q_1q_3|}{r_{13}^2} = 1.124\times10^{-4}\text{ N}$. $F = F_2 + F_3 = 1.8\times10^{-4}\text{ N}$.

$F = 1.8\times10^{-4}$ N and is in the $+x$-direction.

EVALUATE: Comparing our results to those in Example 21.3, we see that $\vec{F}_{1\text{ on }3} = -\vec{F}_{3\text{ on }1}$, as required by Newton's third law.

21.16. **IDENTIFY** and **SET UP:** Apply Coulomb's law to calculate the force exerted by q_2 and q_3 on q_1. Add these forces as vectors to get the net force. The target variable is the x-coordinate of q_3.

EXECUTE: $\vec{F}_2$ is in the x-direction.

$F_2 = k\dfrac{|q_1q_2|}{r_{12}^2} = 3.37\text{ N}$, so $F_{2x} = +3.37\text{ N}$

$F_x = F_{2x} + F_{3x}$ and $F_x = -7.00\text{ N}$

$F_{3x} = F_x - F_{2x} = -7.00\text{ N} - 3.37\text{ N} = -10.37\text{ N}$

For F_{3x} to be negative, q_3 must be on the $-x$-axis.

$F_3 = k\dfrac{|q_1q_3|}{x^2}$, so $|x| = \sqrt{\dfrac{k|q_1q_3|}{F_3}} = 0.144\text{ m}$, so $x = -0.144\text{ m}$

EVALUATE: q_2 attracts q_1 in the $+x$-direction so q_3 must attract q_1 in the $-x$-direction, and q_3 is at negative x.

21.17. **IDENTIFY:** Apply Coulomb's law to calculate the force each of the two charges exerts on the third charge. Add these forces as vectors.

SET UP: The three charges are placed as shown in Figure 21.17a.

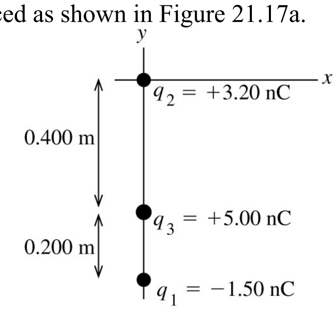

Figure 21.17a

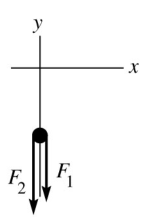
EXECUTE: Like charges repel and unlike attract, so the free-body diagram for q_3 is as shown in Figure 21.17b.



$$F_1 = \frac{1}{4\pi\epsilon_0}\frac{|q_1q_3|}{r_{13}^2}$$

$$F_2 = \frac{1}{4\pi\epsilon_0}\frac{|q_2q_3|}{r_{23}^2}$$

Figure 21.17b

$$F_1 = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(1.50\times10^{-9}\ \text{C})(5.00\times10^{-9}\ \text{C})}{(0.200\ \text{m})^2} = 1.685\times10^{-6}\ \text{N}$$

$$F_2 = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(3.20\times10^{-9}\ \text{C})(5.00\times10^{-9}\ \text{C})}{(0.400\ \text{m})^2} = 8.988\times10^{-7}\ \text{N}$$

The resultant force is $\vec{R} = \vec{F}_1 + \vec{F}_2$.

$R_x = 0$.

$R_y = -(F_1 + F_2) = -(1.685\times10^{-6}\ \text{N} + 8.988\times10^{-7}\ \text{N}) = -2.58\times10^{-6}\ \text{N}$.

The resultant force has magnitude $2.58\times10^{-6}\ \text{N}$ and is in the $-y$-direction.

EVALUATE: The force between q_1 and q_3 is attractive and the force between q_2 and q_3 is repulsive.

21.18. **IDENTIFY:** We use Coulomb's law to find each electrical force and combine these forces to find the net force.

SET UP: In the O-H-N combination the O^- is 0.170 nm from the H^+ and 0.280 nm from the N^-. In the N-H-N combination the N^- is 0.190 nm from the H^+ and 0.300 nm from the other N^-. Like charges repel and unlike charges attract. The net force is the vector sum of the individual forces. The force due to each pair of charges is $F = k\frac{|q_1 q_2|}{r^2} = k\frac{e^2}{r^2}$.

EXECUTE: **(a)** $F = k\frac{|q_1 q_2|}{r^2} = k\frac{e^2}{r^2}$.

O-H-N:

O^-- H^+: $F = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\ \text{C})^2}{(0.170\times10^{-9}\ \text{m})^2} = 7.96\times10^{-9}\ \text{N}$, attractive

O^-- N^-: $F = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\ \text{C})^2}{(0.280\times10^{-9}\ \text{m})^2} = 2.94\times10^{-9}\ \text{N}$, repulsive

N-H-N:

N^-- H^+: $F = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\ \text{C})^2}{(0.190\times10^{-9}\ \text{m})^2} = 6.38\times10^{-9}\ \text{N}$, attractive

N^-- N^-: $F = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\ \text{C})^2}{(0.300\times10^{-9}\ \text{m})^2} = 2.56\times10^{-9}\ \text{N}$, repulsive

The total attractive force is $1.43\times10^{-8}\ \text{N}$ and the total repulsive force is $5.50\times10^{-9}\ \text{N}$. The net force is attractive and has magnitude $1.43\times10^{-8}\ \text{N} - 5.50\times10^{-9}\ \text{N} = 8.80\times10^{-9}\ \text{N}$.

(b) $F = k\frac{e^2}{r^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\ \text{C})^2}{(0.0529\times10^{-9}\ \text{m})^2} = 8.22\times10^{-8}\ \text{N}$.

EVALUATE: The bonding force of the electron in the hydrogen atom is a factor of 10 larger than the bonding force of the adenine-thymine molecules.

21.19. **IDENTIFY:** We use Coulomb's law to find each electrical force and combine these forces to find the net force.

SET UP: In the O-H-O combination the O^- is 0.180 nm from the H^+ and 0.290 nm from the other O^-. In the N-H-N combination the N^- is 0.190 nm from the H^+ and 0.300 nm from the other N^-. In the O-H-N combination the O^- is 0.180 nm from the H^+ and 0.290 nm from the other N^-. Like charges repel and unlike charges attract. The net force is the vector sum of the individual forces. The force due to each pair of charges is $F = k\frac{|q_1 q_2|}{r^2} = k\frac{e^2}{r^2}$.

EXECUTE: Using $F = k\frac{|q_1 q_2|}{r^2} = k\frac{e^2}{r^2}$, we find that the attractive forces are: $O^- - H^+$, 7.10×10^{-9} N; $N^- - H^+$, 6.37×10^{-9} N; $O^- - H^+$, 7.10×10^{-9} N. The total attractive force is 2.06×10^{-8} N. The repulsive forces are: $O^- - O^-$, 2.74×10^{-9} N; $N^- - N^-$, 2.56×10^{-9} N; $O^- - N^-$, 2.74×10^{-9} N. The total repulsive force is 8.04×10^{-9} N. The net force is attractive and has magnitude 1.26×10^{-8} N.

EVALUATE: The net force is attractive, as it should be if the molecule is to stay together.

21.20. IDENTIFY: Apply constant acceleration equations to the motion of the proton. $E = F/|q|$.

SET UP: A proton has mass $m_p = 1.67\times10^{-27}$ kg and charge $+e$. Let $+x$ be in the direction of motion of the proton.

EXECUTE: **(a)** $v_{0x} = 0$. $a = \frac{eE}{m_p}$. $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $x - x_0 = \frac{1}{2}a_x t^2 = \frac{1}{2}\frac{eE}{m_p}t^2$. Solving for E gives $E = \frac{2(0.0160\text{ m})(1.67\times10^{-27}\text{ kg})}{(1.60\times10^{-19}\text{ C})(3.20\times10^{-6}\text{ s})^2} = 32.6\text{ N/C}$.

(b) $v_x = v_{0x} + a_x t = \frac{eE}{m_p}t = \frac{e}{m_p}\left(\frac{2(x-x_0)m_p}{et^2}\right)t = \frac{2(x-x_0)}{t} = \frac{2(0.0160\text{ m})}{3.20\times10^{-6}\text{ s}} = 1.00\times10^4\text{ m/s}$.

EVALUATE: The electric field is directed from the positively charged plate toward the negatively charged plate and the force on the proton is also in this direction.

21.21. IDENTIFY: $F = |q|E$. Since the field is uniform, the force and acceleration are constant and we can use a constant acceleration equation to find the final speed.

SET UP: A proton has charge $+e$ and mass 1.67×10^{-27} kg.

EXECUTE: **(a)** $F = (1.60\times10^{-19}\text{ C})(2.75\times10^3\text{ N/C}) = 4.40\times10^{-16}\text{ N}$.

(b) $a = \frac{F}{m} = \frac{4.40\times10^{-16}\text{ N}}{1.67\times10^{-27}\text{ kg}} = 2.63\times10^{11}\text{ m/s}^2$.

(c) $v_x = v_{0x} + a_x t$ gives $v = (2.63\times10^{11}\text{ m/s}^2)(1.00\times10^{-6}\text{ s}) = 2.63\times10^5\text{ m/s}$.

EVALUATE: The acceleration is very large and the gravity force on the proton can be ignored.

21.22. IDENTIFY: For a point charge, $E = k\frac{|q|}{r^2}$.

SET UP: $\vec{E}$ is toward a negative charge and away from a positive charge.

EXECUTE: **(a)** The field is toward the negative charge so is downward.

$$E = (8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\frac{5.00\times10^{-9}\text{ C}}{(0.250\text{ m})^2} = 719\text{ N/C}.$$

(b) $r = \sqrt{\frac{k|q|}{E}} = \sqrt{\frac{(8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(5.00\times10^{-9}\text{ C})}{12.0\text{ N/C}}} = 1.94\text{ m}$.

EVALUATE: At different points the electric field has different directions, but it is always directed toward the negative point charge.

21.23. IDENTIFY: The acceleration that stops the charge is produced by the force that the electric field exerts on it. Since the field and the acceleration are constant, we can use the standard kinematics formulas to find acceleration and time.

(a) SET UP: First use kinematics to find the proton's acceleration. $v_x = 0$ when it stops. Then find the electric field needed to cause this acceleration using the fact that $F = qE$.

EXECUTE: $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$. $0 = (4.50\times10^6\ \text{m/s})^2 + 2a(0.0320\ \text{m})$ and $a = 3.16\times10^{14}\ \text{m/s}^2$. Now find the electric field, with $q = e$. $eE = ma$ and

$E = ma/e = (1.67\times10^{-27}\ \text{kg})(3.16\times10^{14}\ \text{m/s}^2)/(1.60\times10^{-19}\ \text{C}) = 3.30\times10^6\ \text{N/C}$, to the left.

(b) SET UP: Kinematics gives $v = v_0 + at$, and $v = 0$ when the electron stops, so $t = v_0/a$.

EXECUTE: $t = v_0/a = (4.50\times10^6\ \text{m/s})/(3.16\times10^{14}\ \text{m/s}^2) = 1.42\times10^{-8}\ \text{s} = 14.2\ \text{ns}$.

(c) SET UP: In part (a) we saw that the electric field is proportional to *m*, so we can use the ratio of the electric fields. $E_e/E_p = m_e/m_p$ and $E_e = (m_e/m_p)E_p$.

EXECUTE: $E_e = [(9.11\times10^{-31}\ \text{kg})/(1.67\times10^{-27}\ \text{kg})](3.30\times10^6\ \text{N/C}) = 1.80\times10^3\ \text{N/C}$, to the right.

EVALUATE: Even a modest electric field, such as the ones in this situation, can produce enormous accelerations for electrons and protons.

21.24. IDENTIFY: Use constant acceleration equations to calculate the upward acceleration *a* and then apply $\vec{F} = q\vec{E}$ to calculate the electric field.

SET UP: Let +*y* be upward. An electron has charge $q = -e$.

EXECUTE: **(a)** $v_{0y} = 0$ and $a_y = a$, so $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $y - y_0 = \frac{1}{2}at^2$. Then

$$a = \frac{2(y - y_0)}{t^2} = \frac{2(4.50\ \text{m})}{(3.00\times10^{-6}\ \text{s})^2} = 1.00\times10^{12}\ \text{m/s}^2.$$

$$E = \frac{F}{q} = \frac{ma}{q} = \frac{(9.11\times10^{-31}\ \text{kg})(1.00\times10^{12}\ \text{m/s}^2)}{1.60\times10^{-19}\ \text{C}} = 5.69\ \text{N/C}$$

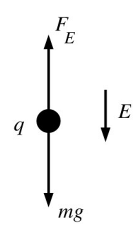
The force is up, so the electric field must be *downward* since the electron has negative charge.

(b) The electron's acceleration is $\sim 10^{11}g$, so gravity must be negligibly small compared to the electrical force.

EVALUATE: Since the electric field is uniform, the force it exerts is constant and the electron moves with constant acceleration.

21.25. IDENTIFY: The equation $\vec{F} = q\vec{E}$ relates the electric field, charge of the particle, and the force on the particle. If the particle is to remain stationary the net force on it must be zero.

SET UP: The free-body diagram for the particle is sketched in Figure 21.25. The weight is *mg*, downward. For the net force to be zero the force exerted by the electric field must be upward. The electric field is downward. Since the electric field and the electric force are in opposite directions the charge of the particle is negative.



$mg = |q|E$

Figure 21.25

EXECUTE: **(a)** $|q| = \dfrac{mg}{E} = \dfrac{(1.45\times10^{-3}\ \text{kg})(9.80\ \text{m/s}^2)}{650\ \text{N/C}} = 2.19\times10^{-5}\ \text{C}$ and $q = -21.9\ \mu\text{C}$.

(b) SET UP: The electrical force has magnitude $F_E = |q|E = eE$. The weight of a proton is $w = mg$. $F_E = w$ so $eE = mg$.

EXECUTE: $E = \dfrac{mg}{e} = \dfrac{(1.673\times10^{-27}\ \text{kg})(9.80\ \text{m/s}^2)}{1.602\times10^{-19}\ \text{C}} = 1.02\times10^{-7}\ \text{N/C}.$

This is a very small electric field.

EVALUATE: In both cases $|q|E = mg$ and $E = (m/|q|)g$. In part (b) the $m/|q|$ ratio is much smaller $(\sim10^{-8})$ than in part (a) $(\sim10^{2})$ so E is much smaller in (b). For subatomic particles gravity can usually be ignored compared to electric forces.

21.26. IDENTIFY: The net force on each charge must be zero.

SET UP: The force diagram for the $-6.50\ \mu\text{C}$ charge is given in Figure 21.26. *FE* is the force exerted on the charge by the uniform electric field. The charge is negative and the field is to the right, so the force exerted by the field is to the left. F_q is the force exerted by the other point charge. The two charges have opposite signs, so the force is attractive. Take the +*x*-axis to be to the right, as shown in the figure.

EXECUTE: **(a)** $F_E = |q|E = (6.50\times10^{-6}\ \text{C})(1.85\times10^{8}\ \text{N/C}) = 1.20\times10^{3}\ \text{N}$

$$F_q = k\frac{|q_1q_2|}{r^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(6.50\times10^{26}\ \text{C})(8.75\times10^{-6}\ \text{C})}{(0.0250\ \text{m})^2} = 8.18\times10^2\ \text{N}$$

$\sum F_x = 0$ gives $T + F_q - F_E = 0$ and $T = F_E - F_q = 382\ \text{N}.$

(b) Now F_q is to the left, since like charges repel.

$\sum F_x = 0$ gives $T - F_q - F_E = 0$ and $T = F_E + F_q = 2.02\times10^{3}\ \text{N}.$

EVALUATE: The tension is much larger when both charges have the same sign, so the force one charge exerts on the other is repulsive.

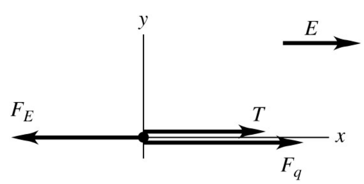


Figure 21.26

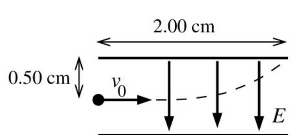
21.27. IDENTIFY: The equation $\vec{F} = q\vec{E}$ gives the force on the particle in terms of its charge and the electric field between the plates. The force is constant and produces a constant acceleration. The motion is similar to projectile motion; use constant acceleration equations for the horizontal and vertical components of the motion.

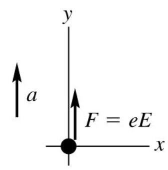
SET UP: The motion is sketched in Figure 21.27a.



For an electron $q = -e$.

Figure 21.27a

$\vec{F} = q\vec{E}$ and q negative gives that $\vec{F}$ and $\vec{E}$ are in opposite directions, so $\vec{F}$ is upward. The free-body diagram for the electron is given in Figure 21.27b.



EXECUTE: **(a)** $\sum F_y = ma_y$

$eE = ma$

Figure 21.27b

Solve the kinematics to find the acceleration of the electron: Just misses upper plate says that $x - x_0 = 2.00\text{ cm}$ when $y - y_0 = +0.500\text{ cm}$.

<u>x-component</u>:

$v_{0x} = v_0 = 1.60\times10^6\text{ m/s},\ a_x = 0,\ x - x_0 = 0.0200\text{ m},\ t = ?$

$x - x_0 = v_{0x}t + \tfrac{1}{2}a_x t^2$

$$t = \frac{x - x_0}{v_{0x}} = \frac{0.0200\text{ m}}{1.60\times10^6\text{ m/s}} = 1.25\times10^{-8}\text{ s}$$

In this same time t the electron travels 0.0050 m vertically.

<u>y-component</u>:

$t = 1.25\times10^{-8}\text{ s},\ v_{0y} = 0,\ y - y_0 = +0.0050\text{ m},\ a_y = ?$

$y - y_0 = v_{0y}t + \tfrac{1}{2}a_y t^2$

$$a_y = \frac{2(y - y_0)}{t^2} = \frac{2(0.0050\text{ m})}{(1.25\times10^{-8}\text{ s})^2} = 6.40\times10^{13}\text{ m/s}^2.$$

(This analysis is very similar to that used in Chapter 3 for projectile motion, except that here the acceleration is upward rather than downward.) This acceleration must be produced by the electric-field force: $eE = ma$.

$$E = \frac{ma}{e} = \frac{(9.109\times10^{-31}\text{ kg})(6.40\times10^{13}\text{ m/s}^2)}{1.602\times10^{-19}\text{ C}} = 364\text{ N/C}$$

Note that the acceleration produced by the electric field is <u>much</u> larger than g, the acceleration produced by gravity, so it is perfectly ok to neglect the gravity force on the electron in this problem.

(b) $a = \dfrac{eE}{m_\text{p}} = \dfrac{(1.602\times10^{-19}\text{ C})(364\text{ N/C})}{1.673\times10^{-27}\text{ kg}} = 3.49\times10^{10}\text{ m/s}^2.$

This is much less than the acceleration of the electron in part (a) so the vertical deflection is less and the proton won't hit the plates. The proton has the same initial speed, so the proton takes the same time $t = 1.25\times10^{-8}\text{ s}$ to travel horizontally the length of the plates. The force on the proton is downward (in the same direction as $\vec{E}$, since q is positive), so the acceleration is downward and $a_y = -3.49\times10^{10}\text{ m/s}^2$. $y - y_0 = v_{0y}t + \tfrac{1}{2}a_y t^2 = \tfrac{1}{2}(-3.49\times10^{10}\text{ m/s}^2)(1.25\times10^{-8}\text{ s})^2 = -2.73\times10^{-6}\text{ m}.$

The displacement is $2.73\times10^{-6}\text{ m}$, downward.

EVALUATE: **(c)** The displacements are in opposite directions because the electron has negative charge and the proton has positive charge. The electron and proton have the same magnitude of charge, so the force the electric field exerts has the same magnitude for each charge. But the proton has a mass larger by a factor of 1836 so its acceleration and its vertical displacement are smaller by this factor.

(d) In each case $a \gg g$ and it is reasonable to ignore the effects of gravity.

21.28. **IDENTIFY:** Apply constant acceleration equations to the motion of the electron.

SET UP: Let $+x$ be to the right and let $+y$ be downward. The electron moves 2.00 cm to the right and 0.50 cm downward.

EXECUTE: Use the horizontal motion to find the time when the electron emerges from the field. $x - x_0 = 0.0200$ m, $a_x = 0$, $v_{0x} = 1.60\times10^6$ m/s. $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $t = 1.25\times10^{-8}$ s. Since $a_x = 0$, $v_x = 1.60\times10^6$ m/s. $y - y_0 = 0.0050$ m, $v_{0y} = 0$, $t = 1.25\times10^{-8}$ s. $y - y_0 = \left(\dfrac{v_{0y} + v_y}{2}\right)t$ gives $v_y = 8.00\times10^5$ m/s. Then $v = \sqrt{v_x^2 + v_y^2} = 1.79\times10^6$ m/s.

EVALUATE: $v_y = v_{0y} + a_y t$ gives $a_y = 6.4\times10^{13}$ m/s^2. The electric field between the plates is $E = \dfrac{ma_y}{e} = \dfrac{(9.11\times10^{-31}\text{ kg})(6.4\times10^{13}\text{ m/s}^2)}{1.60\times10^{-19}\text{ C}} = 364$ N/C. This is not a very large field.

21.29. **IDENTIFY:** Find the angle θ that $\hat{\boldsymbol{r}}$ makes with the $+x$-axis. Then $\hat{\boldsymbol{r}} = (\cos\theta)\hat{\boldsymbol{i}} + (\sin\theta)\hat{\boldsymbol{j}}$.

SET UP: $\tan\theta = y/x$.

EXECUTE: **(a)** $\tan^{-1}\left(\dfrac{-1.35}{0}\right) = -\dfrac{\pi}{2}$ rad. $\hat{\boldsymbol{r}} = -\hat{\boldsymbol{j}}$.

(b) $\tan^{-1}\left(\dfrac{12}{12}\right) = \dfrac{\pi}{4}$ rad. $\hat{\boldsymbol{r}} = \dfrac{\sqrt{2}}{2}\hat{\boldsymbol{i}} + \dfrac{\sqrt{2}}{2}\hat{\boldsymbol{j}}$.

(c) $\tan^{-1}\left(\dfrac{2.6}{+1.10}\right) = 1.97\text{ rad} = 112.9°$. $\hat{\boldsymbol{r}} = -0.39\hat{\boldsymbol{i}} + 0.92\hat{\boldsymbol{j}}$ (Second quadrant).

EVALUATE: In each case we can verify that $\hat{\boldsymbol{r}}$ is a unit vector, because $\hat{\boldsymbol{r}}\cdot\hat{\boldsymbol{r}} = 1$.

21.30. **IDENTIFY** and **SET UP:** Use $\vec{E}$ in $\vec{E} = \dfrac{\vec{F}_0}{q_0}$ to calculate $\vec{F}$, $\vec{F} = m\vec{a}$ to calculate $\vec{a}$, and a constant acceleration equation to calculate the final velocity. Let $+x$ be east.

(a) EXECUTE: $F_x = |q|E = (1.602\times10^{-19}\text{ C})(1.50\text{ N/C}) = 2.403\times10^{-19}$ N.

$a_x = F_x/m = (2.403\times10^{-19}\text{ N})/(9.109\times10^{-31}\text{ kg}) = +2.638\times10^{11}\text{ m/s}^2$.

$v_{0x} = +4.50\times10^5$ m/s, $a_x = +2.638\times10^{11}$ m/s^2, $x - x_0 = 0.375$ m, $v_x = ?$

$v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives $v_x = 6.33\times10^5$ m/s.

EVALUATE: $\vec{E}$ is west and q is negative, so $\vec{F}$ is east and the electron speeds up.

(b) EXECUTE: $F_x = -|q|E = -(1.602\times10^{-19}\text{ C})(1.50\text{ N/C}) = -2.403\times10^{-19}$ N.

$a_x = F_x/m = (-2.403\times10^{-19}\text{ N})/(1.673\times10^{-27}\text{ kg}) = -1.436\times10^8\text{ m/s}^2$.

$v_{0x} = +1.90\times10^4$ m/s, $a_x = -1.436\times10^8$ m/s^2, $x - x_0 = 0.375$ m, $v_x = ?$

$v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives $v_x = 1.59\times10^4$ m/s.

EVALUATE: $q > 0$ so $\vec{F}$ is west and the proton slows down.

21.31. **IDENTIFY:** We want to find the force that a charged sphere exerts on a line of charge. By Newton's third law, this is also the force that the line exerts on the sphere, which is much easier to calculate. Fig. 21.31 shows the arrangement of the objects involved.

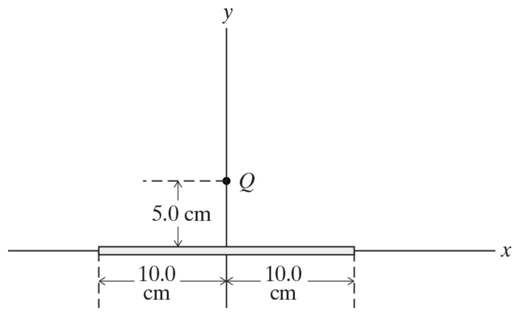


Figure 21.31

SET UP and EXECUTE: The small sphere is equivalent to a point charge. From the textbook we know that the electric field due to the line is $E = \frac{1}{2\pi\epsilon_0} \frac{\lambda}{x\sqrt{(x/a)^2+1}}$. The magnitude of the force that the line exerts on the sphere is $F_y = QE_y$. We know that $Q = -2.00\ \mu\text{C}$, $a = 10.0\text{ cm} = 0.100\text{ m}$, $x = 5.00\text{ cm} = 0.0500\text{ m}$, and $\lambda = 4.80\text{ nC/m}$. Using $F = \frac{Q}{2\pi\epsilon_0} \frac{\lambda}{x\sqrt{(x/a)^2+1}}$ for the given quantities, we get $F_y = 3.09 \times 10^{-3}$ N. The sphere is negative and the line is positive, so the sphere attracts the line, which means that the direction of the force is in the $+y$ direction.

EVALUATE: This is a small force, but for a very light line (such as a very thin wire) it could readily be observed.

21.32. **IDENTIFY:** The net electric field is the vector sum of the fields due to the individual charges.

SET UP: The electric field points toward negative charge and away from positive charge.

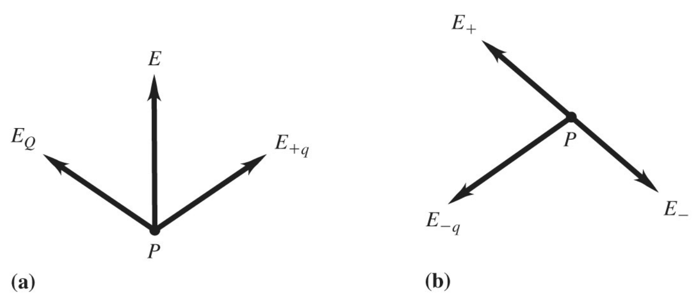

Figure 21.32

EXECUTE: **(a)** Figure 21.32(a) shows $\vec{E}_Q$ and $\vec{E}_{+q}$ at point P. $\vec{E}_Q$ must have the direction shown, to produce a resultant field in the specified direction. $\vec{E}_Q$ is toward Q, so Q is negative. In order for the horizontal components of the two fields to cancel, Q and q must have the same magnitude.

(b) No. If the lower charge were negative, its field would be in the direction shown in Figure 21.32(b). The two possible directions for the field of the upper charge, when it is positive ($\vec{E}_+$) or negative ($\vec{E}_-$), are shown. In neither case is the resultant field in the direction shown in the figure in the problem.

EVALUATE: When combining electric fields, it is always essential to pay attention to their directions.

21.33. **IDENTIFY and SET UP:** Two very long lines of charge are parallel to each other. At any point, the total electric field is the vector sum of the two fields. We want to find where the resultant field is zero. The resultant field can be zero only where the two fields have equal magnitudes but opposite directions.

Since the lines have opposite sign charge densities, in the region between the lines both fields point in the $+y$ direction, so they cannot cancel. Below the x-axis ($y < 0$) the fields are in opposite directions, but the field due to the lower line is always greater than the field due to the upper line, so they cannot cancel. For $y > 10.0$ cm, the fields are again in opposite directions. If we are close enough to the upper line, its field can equal in magnitude the field due to the lower line, so they can cancel. Call P the point on the y-axis at which the two field magnitudes are equal. Calling 1 the lower line and 2 the upper line, we have $|E_1| = |E_2|$ at point P. The field due to a very long line of charge is $E = \dfrac{\lambda}{2\pi\epsilon_0 x}$.

EXECUTE: Call y the y coordinate of P (and recalling that P is above the upper line), $|E_1| = |E_2|$ gives $\dfrac{\lambda_1}{2\pi\epsilon_0 y} = \dfrac{|\lambda_2|}{2\pi\epsilon_0 (y - 10.0\text{ cm})}$, which gives $\dfrac{8.00\,\mu\text{C/m}}{y} = \dfrac{4.00\,\mu\text{C/m}}{y - 10.0\text{ cm}}$, which gives $y = 20.0$ cm.

EVALUATE: If both lines had the same sign charge, the point of cancellation would be in the region between the lines.

21.34. **IDENTIFY:** Add the individual electric fields to obtain the net field.
SET UP: The electric field points away from positive charge and toward negative charge. The electric fields $\vec{E}_1$ and $\vec{E}_2$ add to form the net field $\vec{E}$.
EXECUTE: **(a)** The electric field is toward A at points B and C and the field is zero at A.
(b) The electric field is away from A at B and C. The field is zero at A.
(c) The field is horizontal and to the right at points A, B, and C.
EVALUATE: Compare your results to the field lines shown in Figure 21.28a and b in the textbook.

21.35. **IDENTIFY:** $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$ gives the electric field of each point charge. Use the principle of superposition and add the electric field vectors. In part (b) use $\vec{E} = \dfrac{\vec{F}_0}{q_0}$ to calculate the force, using the electric field calculated in part (a).
SET UP: The placement of charges is sketched in Figure 21.35a.

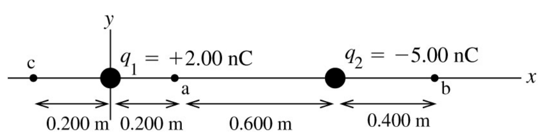

Figure 21.35a

The electric field of a point charge is directed away from the point charge if the charge is positive and toward the point charge if the charge is negative. The magnitude of the electric field is $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$, where r is the distance between the point where the field is calculated and the point charge.
(a) EXECUTE: (i) At point a the fields $\vec{E}_1$ of q_1 and $\vec{E}_2$ of q_2 are directed as shown in Figure 21.35b.

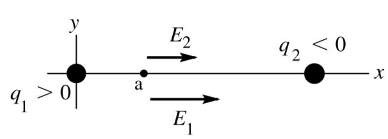

Figure 21.35b

$$E_1 = \frac{1}{4\pi\epsilon_0}\frac{|q_1|}{r_1^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{2.00\times10^{-9}\ \text{C}}{(0.200\ \text{m})^2} = 449.4\ \text{N/C}.$$

$$E_2 = \frac{1}{4\pi\epsilon_0}\frac{|q_2|}{r_2^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{5.00\times10^{-9}\ \text{C}}{(0.600\ \text{m})^2} = 124.8\ \text{N/C}.$$

$E_{1x} = 449.4$ N/C, $E_{1y} = 0$.

$E_{2x} = 124.8$ N/C, $E_{2y} = 0$.

$E_x = E_{1x} + E_{2x} = +449.4\ \text{N/C} + 124.8\ \text{N/C} = +574.2\ \text{N/C}.$

$E_y = E_{1y} + E_{2y} = 0.$

The resultant field at point a has magnitude 574 N/C and is in the $+x$-direction.

(ii) At point b the fields $\vec{E}_1$ of q_1 and $\vec{E}_2$ of q_2 are directed as shown in Figure 21.35c.

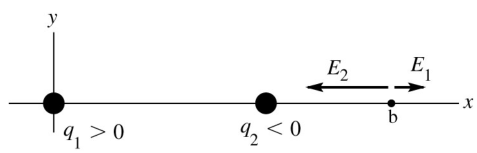

Figure 21.35c

$$E_1 = \frac{1}{4\pi\epsilon_0}\frac{|q_1|}{r_1^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{2.00\times10^{-9}\ \text{C}}{(1.20\ \text{m})^2} = 12.5\ \text{N/C}.$$

$$E_2 = \frac{1}{4\pi\epsilon_0}\frac{|q_2|}{r_2^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{5.00\times10^{-9}\ \text{C}}{(0.400\ \text{m})^2} = 280.9\ \text{N/C}.$$

$E_{1x} = 12.5$ N/C, $E_{1y} = 0$.

$E_{2x} = -280.9$ N/C, $E_{2y} = 0$.

$E_x = E_{1x} + E_{2x} = +12.5\ \text{N/C} - 280.9\ \text{N/C} = -268.4\ \text{N/C}.$

$E_y = E_{1y} + E_{2y} = 0.$

The resultant field at point b has magnitude 268 N/C and is in the $-x$-direction.

(iii) At point c the fields $\vec{E}_1$ of q_1 and $\vec{E}_2$ of q_2 are directed as shown in Figure 21.35d.

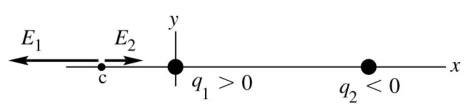

Figure 21.35d

$$E_1 = \frac{1}{4\pi\epsilon_0}\frac{|q_1|}{r_1^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{2.00\times10^{-9}\ \text{C}}{(0.200\ \text{m})^2} = 449.4\ \text{N/C}.$$

$$E_2 = \frac{1}{4\pi\epsilon_0}\frac{|q_2|}{r_2^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{5.00\times10^{-9}\ \text{C}}{(1.00\ \text{m})^2} = 44.9\ \text{N/C}.$$

$E_{1x} = -449.4$ N / C, $E_{1y} = 0$.

$E_{2x} = +44.9$ N / C, $E_{2y} = 0$.

$E_x = E_{1x} + E_{2x} = -449.4\ \text{N/C} + 44.9\ \text{N/C} = -404.5\ \text{N/C}.$

$E_y = E_{1y} + E_{2y} = 0.$

The resultant field at point b has magnitude 404 N/C and is in the $-x$-direction.

(b) Set Up: Since we have calculated $\vec{E}$ at each point the simplest way to get the force is to use $\vec{F} = -e\vec{E}$.

Execute: (i) $F = (1.602\times10^{-19}\ \text{C})(574.2\ \text{N/C}) = 9.20\times10^{-17}\ \text{N},\ -x\text{-direction}.$

(ii) $F = (1.602\times10^{-19}\ \text{C})(268.4\ \text{N/C}) = 4.30\times10^{-17}\ \text{N},\ +x\text{-direction}.$

(iii) $F = (1.602\times10^{-19}\ \text{C})(404.5\ \text{N/C}) = 6.48\times10^{-17}\ \text{N},\ +x\text{-direction}.$

Evaluate: The general rule for electric field direction is away from positive charge and toward negative charge. Whether the field is in the $+x$- or $-x$-direction depends on where the field point is relative to the charge that produces the field. In part (a), for (i) the field magnitudes were added because the fields were in the same direction and in (ii) and (iii) the field magnitudes were subtracted because the two fields were in opposite directions. In part (b) we could have used Coulomb's law to find the forces on the electron due to the two charges and then added these force vectors, but using the resultant electric field is much easier.

21.36. Identify: $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$ gives the electric field of each point charge. Use the principle of superposition and add the electric field vectors. In part (b) use $\vec{E} = \dfrac{\vec{F}_0}{q_0}$ to calculate the force, using the electric field calculated in part (a).

(a) Set Up: The placement of charges is sketched in Figure 21.36a.

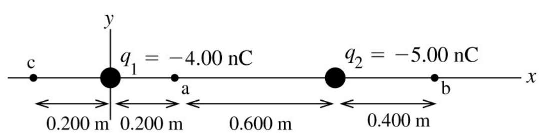

Figure 21.36a

The electric field of a point charge is directed away from the point charge if the charge is positive and toward the point charge if the charge is negative. The magnitude of the electric field is $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$, where r is the distance between the point where the field is calculated and the point charge.

(i) At point a the fields $\vec{E}_1$ of q_1 and $\vec{E}_2$ of q_2 are directed as shown in Figure 21.36b.

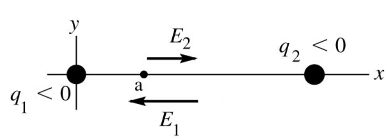

Figure 21.36b

Execute: $E_1 = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_1|}{r_1^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{4.00\times10^{-9}\ \text{C}}{(0.200\ \text{m})^2} = 898.8\ \text{N/C}.$

$E_2 = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_2|}{r_2^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{5.00\times10^{-9}\ \text{C}}{(0.600\ \text{m})^2} = 124.8\ \text{N/C}.$

$E_{1x} = 898.8\ \text{N/C},\ E_{1y} = 0.$

$E_{2x} = 124.8\ \text{N/C},\ E_{2y} = 0.$

$E_x = E_{1x} + E_{2x} = -898.8\ \text{N/C} + 124.8\ \text{N/C} = -774\ \text{N/C}.$

$E_y = E_{1y} + E_{2y} = 0.$

The resultant field at point a has magnitude 774 N/C and is in the –x-direction.

(ii) **SET UP:** At point b the fields $\vec{E}_1$ of q_1 and $\vec{E}_2$ of q_2 are directed as shown in Figure 21.36c.

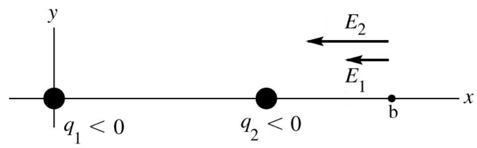

Figure 21.36c

EXECUTE: $E_1 = \frac{1}{4\pi\epsilon_0}\frac{|q_1|}{r_1^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{4.00\times10^{-9}\ \text{C}}{(1.20\ \text{m})^2} = 24.97\ \text{N/C}.$

$$E_2 = \frac{1}{4\pi\epsilon_0}\frac{|q_2|}{r_2^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{5.00\times10^{-9}\ \text{C}}{(0.400\ \text{m})^2} = 280.9\ \text{N/C}.$$

$E_{1x} = -24.97\ \text{N/C},\ E_{1y} = 0.$

$E_{2x} = -280.9\ \text{N/C},\ E_{2y} = 0.$

$E_x = E_{1x} + E_{2x} = -24.97\ \text{N/C} - 280.9\ \text{N/C} = -305.9\ \text{N/C}.$

$E_y = E_{1y} + E_{2y} = 0.$

The resultant field at point b has magnitude 306 N/C and is in the $-x$-direction.

(iii) **SET UP:** At point c the fields $\vec{E}_1$ of q_1 and $\vec{E}_2$ of q_2 are directed as shown in Figure 21.36d.

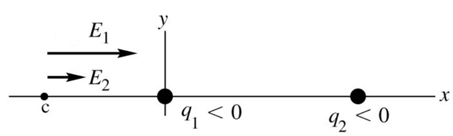

Figure 21.36d

EXECUTE: $E_1 = \frac{1}{4\pi\epsilon_0}\frac{|q_1|}{r_1^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{4.00\times10^{-9}\ \text{C}}{(0.200\ \text{m})^2} = 898.8\ \text{N/C}.$

$$E_2 = \frac{1}{4\pi\epsilon_0}\frac{|q_2|}{r_2^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{5.00\times10^{-9}\ \text{C}}{(1.00\ \text{m})^2} = 44.9\ \text{N/C}.$$

$E_{1x} = +898.8\ \text{N/C},\ E_{1y} = 0.$

$E_{2x} = +44.9\ \text{N/C},\ E_{2y} = 0.$

$E_x = E_{1x} + E_{2x} = +898.8\ \text{N/C} + 44.9\ \text{N/C} = +943.7\ \text{N/C}.$

$E_y = E_{1y} + E_{2y} = 0.$

The resultant field at point b has magnitude 944 N/C and is in the $+x$-direction.

(b) SET UP: Since we have calculated $\vec{E}$ at each point the simplest way to get the force is to use $\vec{F} = -e\vec{E}$.

EXECUTE: (i) $F = (1.602\times10^{-19}\ \text{C})(774\ \text{N/C}) = 1.24\times10^{-16}\ \text{N}$, +$x$-direction.

(ii) $F = (1.602\times10^{-19}\ \text{C})(305.9\ \text{N/C}) = 4.90\times10^{-17}\ \text{N}$, $+x$-direction.

(iii) $F = (1.602\times10^{-19}\ \text{C})(943.7\ \text{N/C}) = 1.51\times10^{-16}\ \text{N}$, $-x$-direction.

EVALUATE: The general rule for electric field direction is away from positive charge and toward negative charge. Whether the field is in the +*x*- or −*x*-direction depends on where the field point is relative to the charge that produces the field. In part (a), for (i) the field magnitudes were subtracted because the fields were in opposite directions and in (ii) and (iii) the field magnitudes were added because the two fields were in the same direction. In part (b) we could have used Coulomb's law to find the forces on the electron due to the two charges and then added these force vectors, but using the resultant electric field is much easier.

21.37. **IDENTIFY:** $E = k\dfrac{|q|}{r^2}$. The net field is the vector sum of the fields due to each charge.

SET UP: The electric field of a negative charge is directed toward the charge. Label the charges $q_1, q_2,$ and $q_3,$ as shown in Figure 21.37(a). This figure also shows additional distances and angles. The electric fields at point *P* are shown in Figure 21.37(b). This figure also shows the *xy*-coordinates we will use and the *x*- and *y*-components of the fields $\vec{E}_1,$ $\vec{E}_2,$ and $\vec{E}_3$.

EXECUTE: $E_1 = E_3 = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{5.00\times10^{-6}\ \text{C}}{(0.100\ \text{m})^2} = 4.49\times10^6\ \text{N/C}.$

$E_2 = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{2.00\times10^{-6}\ \text{C}}{(0.0600\ \text{m})^2} = 4.99\times10^6\ \text{N/C}.$

$E_y = E_{1y} + E_{2y} + E_{3y} = 0$ and $E_x = E_{1x} + E_{2x} + E_{3x} = E_2 + 2E_1\cos 53.1° = 1.04\times10^7\ \text{N/C}.$

$E = 1.04\times10^7\ \text{N/C},$ toward the $-2.00\ \mu\text{C}$ charge.

EVALUATE: The *x*-components of the fields of all three charges are in the same direction.

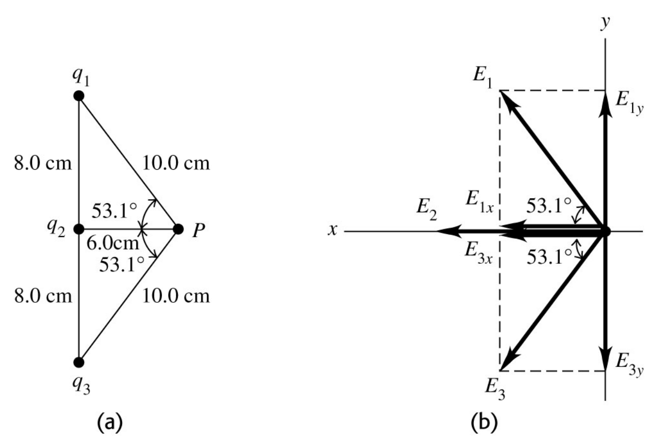

Figure 21.37

21.38. **IDENTIFY:** The net electric field is the vector sum of the individual fields.

SET UP: The distance from a corner to the center of the square is $r = \sqrt{(a/2)^2 + (a/2)^2} = a/\sqrt{2}$. The magnitude of the electric field due to each charge is the same and equal to $E_q = \dfrac{kq}{r^2} = 2\dfrac{kq}{a^2}$. All four *y*-components add and the *x*-components cancel.

EXECUTE: Each *y*-component is equal to $E_{qy} = -E_q\cos 45° = -\dfrac{E_q}{\sqrt{2}} = \dfrac{-2kq}{\sqrt{2}a^2} = -\dfrac{\sqrt{2}kq}{a^2}$. The resultant field is $\dfrac{4\sqrt{2}kq}{a^2}$, in the $-y$-direction.

EVALUATE: We must add the *y*-components of the fields, not their magnitudes.

21.39. **IDENTIFY:** For a point charge, $E = k\frac{|q|}{r^2}$. The net field is the vector sum of the fields produced by each charge. A charge q in an electric field $\vec{E}$ experiences a force $\vec{F} = q\vec{E}$.

SET UP: The electric field of a negative charge is directed toward the charge. Point A is 0.100 m from q_2 and 0.150 m from q_1. Point B is 0.100 m from q_1 and 0.350 m from q_2.

EXECUTE: **(a)** The electric fields at point A due to the charges are shown in Figure 21.39(a).

$$E_1 = k\frac{|q_1|}{r_{A1}^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{6.25\times10^{-9}\ \text{C}}{(0.150\ \text{m})^2} = 2.50\times10^3\ \text{N/C}.$$

$$E_2 = k\frac{|q_2|}{r_{A2}^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{12.5\times10^{-9}\ \text{C}}{(0.100\ \text{m})^2} = 1.124\times10^4\ \text{N/C}.$$

Since the two fields are in opposite directions, we subtract their magnitudes to find the net field.
$E = E_2 - E_1 = 8.74\times10^3\ \text{N/C},$ to the right.

(b) The electric fields at point B are shown in Figure 21.39(b).

$$E_1 = k\frac{|q_1|}{r_{B1}^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{6.25\times10^{-9}\ \text{C}}{(0.100\ \text{m})^2} = 5.619\times10^3\ \text{N/C}.$$

$$E_2 = k\frac{|q_2|}{r_{B2}^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{12.5\times10^{-9}\ \text{C}}{(0.350\ \text{m})^2} = 9.17\times10^2\ \text{N/C}.$$

Since the fields are in the same direction, we add their magnitudes to find the net field.
$E = E_1 + E_2 = 6.54\times10^3\ \text{N/C},$ to the right.

(c) At A, $E = 8.74\times10^3\ \text{N/C},$ to the right. The force on a proton placed at this point would be
$F = qE = (1.60\times10^{-19}\ \text{C})(8.74\times10^3\ \text{N/C}) = 1.40\times10^{-15}\ \text{N},$ to the right.

EVALUATE: A proton has positive charge so the force that an electric field exerts on it is in the same direction as the field.

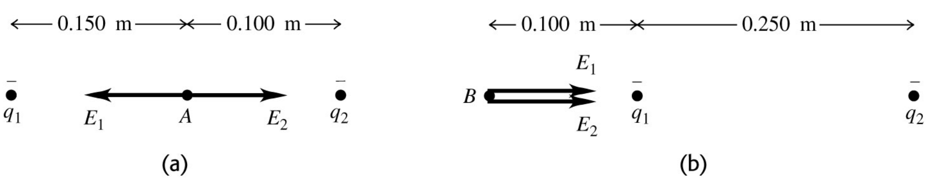

Figure 21.39

21.40. **IDENTIFY:** Apply $E = \frac{1}{4\pi\epsilon_0}\frac{|q|}{r^2}$ to calculate the electric field due to each charge and add the two field vectors to find the resultant field.

SET UP: For q_1, $\hat{r} = \hat{j}$. For q_2, $\hat{r} = \cos\theta\hat{i} + \sin\theta\hat{j}$, where θ is the angle between $\vec{E}_2$ and the $+x$-axis.

EXECUTE: **(a)** $\vec{E}_1 = \frac{q_1}{4\pi\epsilon_0 r_1^2}\hat{j} = \frac{(9.0\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(-5.00\times10^{-9}\ \text{C})}{(0.0400\ \text{m})^2}\hat{j} = (-2.813\times10^4\ \text{N/C})\ \hat{j}.$

$\left|\vec{E}_2\right| = \frac{q_2}{4\pi\epsilon_0 r_2^2} = \frac{(9.0\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(3.00\times10^{-9}\ \text{C})}{(0.0300\ \text{m})^2 + (0.0400\ \text{m})^2} = 1.080\times10^4\ \text{N/C}.$ The angle of $\vec{E}_2$, measured from the x-axis, is $180° - \tan^{-1}\left(\frac{4.00\ \text{cm}}{3.00\ \text{cm}}\right) = 126.9°$ Thus

$$\vec{E}_2 = (1.080\times10^4\ \text{N/C})(\hat{i}\cos126.9° + \hat{j}\sin126.9°) = (-6.485\times10^3\ \text{N/C})\hat{i} + (8.64\times10^3\ \text{N/C})\hat{j}.$$

(b) The resultant field is $\vec{E}_1 + \vec{E}_2 = (-6.485\times10^3\ \text{N/C})\hat{i} + (-2.813\times10^4\ \text{N/C} + 8.64\times10^3\ \text{N/C})\hat{j}$.

$$\vec{E}_1 + \vec{E}_2 = (-6.485\times10^3\ \text{N/C})\hat{i} - (1.95\times10^4\ \text{N/C})\hat{j}.$$

EVALUATE: $\vec{E}_1$ is toward q_1 since q_1 is negative. $\vec{E}_2$ is directed away from q_2, since q_2 is positive.

21.41. IDENTIFY: The forces the charges exert on each other are given by Coulomb's law. The net force on the proton is the vector sum of the forces due to the electrons.

SET UP: $q_e = -1.60\times10^{-19}$ C. $q_p = +1.60\times10^{-19}$ C. The net force is the vector sum of the forces exerted by each electron. Each force has magnitude $F = k\dfrac{|q_1 q_2|}{r^2} = k\dfrac{e^2}{r^2}$ and is attractive so is directed toward the electron that exerts it.

EXECUTE: Each force has magnitude

$F_1 = F_2 = k\dfrac{|q_1 q_2|}{r^2} = k\dfrac{e^2}{r^2} = \dfrac{(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(1.60\times10^{-19}\ \text{C})^2}{(1.50\times10^{-10}\ \text{m})^2} = 1.023\times10^{-8}$ N. The vector force diagram is shown in Figure 21.41.

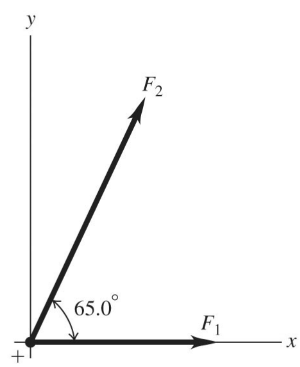

Figure 21. 41

Taking components, we get $F_{1x} = 1.023\times10^{-8}$ N; $F_{1y} = 0$. $F_{2x} = F_2 \cos 65.0° = 4.32\times10^{-9}$ N;

$F_{2y} = F_2 \sin 65.0° = 9.27\times10^{-9}$ N. $F_x = F_{1x} + F_{2x} = 1.46\times10^{-8}$ N; $F_y = F_{1y} + F_{2y} = 9.27\times10^{-9}$ N.

$F = \sqrt{F_x^2 + F_y^2} = 1.73\times10^{-8}$ N. $\tan\theta = \dfrac{F_y}{F_x} = \dfrac{9.27\times10^{-9}\ \text{N}}{1.46\times10^{-8}\ \text{N}} = 0.6349$ which gives

$\theta = 32.4°$. The net force is 1.73×10^{-8} N and is directed toward a point midway between the two electrons.

EVALUATE: Note that the net force is less than the algebraic sum of the individual forces.

21.42. IDENTIFY: We can model a segment of the axon as a point charge.

SET UP: If the axon segment is modeled as a point charge, its electric field is $E = k\dfrac{q}{r^2}$. The electric field of a point charge is directed away from the charge if it is positive.

EXECUTE: **(a)** 5.6×10^{11} Na^+ ions enter per meter so in a $0.10\ \text{mm} = 1.0\times10^{-4}$ m section, 5.6×10^7 Na^+ ions enter. This number of ions has charge $q = (5.6\times10^7)(1.60\times10^{-19}\ \text{C}) = 9.0\times10^{-12}$ C.

(b) $E = k\dfrac{|q|}{r^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{9.0\times10^{-12}\ \text{C}}{(5.00\times10^{-2}\ \text{m})^2} = 32$ N/C, directed away from the axon.

(c) $r = \sqrt{\dfrac{k|q|}{E}} = \sqrt{\dfrac{(8.99\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)(9.0\times10^{-12}\ \text{C})}{1.0\times10^{-6}\ \text{N/C}}} = 280\ \text{m}.$

EVALUATE: The field in (b) is considerably smaller than ordinary laboratory electric fields.

21.43. **IDENTIFY:** The electric field of a positive charge is directed radially outward from the charge and has magnitude $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$. The resultant electric field is the vector sum of the fields of the individual charges.

SET UP: The placement of the charges is shown in Figure 21.43a.

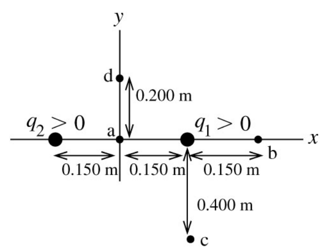

Figure 21.43a

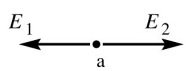
EXECUTE: **(a)** The directions of the two fields are shown in Figure 21.43b.

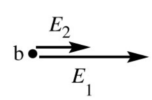


$E_1 = E_2 = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$ with $r = 0.150$ m.

$E = E_2 - E_1 = 0;\ E_x = 0,\ E_y = 0.$

Figure 21.43b

(b) The two fields have the directions shown in Figure 21.43c.



$E = E_1 + E_2$, in the $+x$-direction.

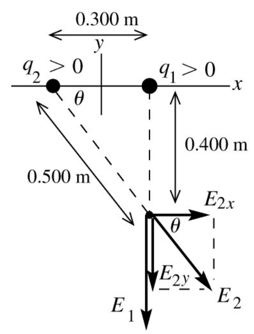
Figure 21.43c

$$E_1 = \frac{1}{4\pi\epsilon_0}\frac{|q_1|}{r_1^2} = (8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{6.00\times10^{-9}\ \text{C}}{(0.150\ \text{m})^2} = 2396.8\ \text{N/C}.$$

$$E_2 = \frac{1}{4\pi\epsilon_0}\frac{|q_2|}{r_2^2} = (8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{6.00\times10^{-9}\ \text{C}}{(0.450\ \text{m})^2} = 266.3\ \text{N/C}.$$

$E = E_1 + E_2 = 2396.8\ \text{N/C} + 266.3\ \text{N/C} = 2660\ \text{N/C};\ E_x = +2660\ \text{N/C},\ E_y = 0.$

(c) The two fields have the directions shown in Figure 21.43d.



$$\sin\theta = \frac{0.400\text{ m}}{0.500\text{ m}} = 0.800.$$

$$\cos\theta = \frac{0.300\text{ m}}{0.500\text{ m}} = 0.600.$$

Figure 21.43d

$$E_1 = \frac{1}{4\pi\epsilon_0}\frac{|q_1|}{r_1^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{6.00\times10^{-9}\ \text{C}}{(0.400\ \text{m})^2} = 337.1\ \text{N/C}.$$

$$E_2 = \frac{1}{4\pi\epsilon_0}\frac{|q_2|}{r_2^2} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{6.00\times10^{-9}\ \text{C}}{(0.500\ \text{m})^2} = 215.7\ \text{N/C}.$$

$E_{1x} = 0$, $E_{1y} = -E_1 = -337.1$ N/C.

$E_{2x} = +E_2\cos\theta = +(215.7\ \text{N/C})(0.600) = +129.4$ N/C.

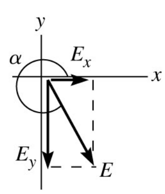
$E_{2y} = -E_2\sin\theta = -(215.7\ \text{N/C})(0.800) = -172.6$ N/C.

$E_x = E_{1x} + E_{2x} = +129$ N/C.

$E_y = E_{1y} + E_{2y} = -337.1\ \text{N/C} - 172.6\ \text{N/C} = -510$ N/C.

$$E = \sqrt{E_x^2 + E_y^2} = \sqrt{(129\ \text{N/C})^2 + (-510\ \text{N/C})^2} = 526\ \text{N/C}.$$

$\vec{E}$ and its components are shown in Figure 21.43e.



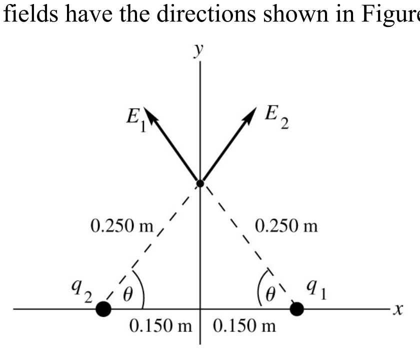
$$\tan\alpha = \frac{E_y}{E_x}.$$

$$\tan\alpha = \frac{-510\ \text{N/C}}{+129\ \text{N/C}} = -3.953.$$

$\alpha = 284°$, counterclockwise from $+x$-axis.

Figure 21.43e

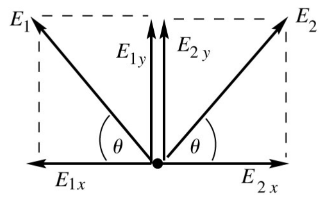
(d) The two fields have the directions shown in Figure 21.43f.



$$\sin\theta = \frac{0.200\text{ m}}{0.250\text{ m}} = 0.800.$$

Figure 21.43f

The components of the two fields are shown in Figure 21.43g.



$E_1 = E_2 = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$.

$E_1 = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{6.00\times10^{-9}\ \text{C}}{(0.250\ \text{m})^2}$.

$E_1 = E_2 = 862.8$ N/C.

Figure 21.43g

$E_{1x} = -E_1\cos\theta,\ E_{2x} = +E_2\cos\theta.$

$E_x = E_{1x} + E_{2x} = 0.$

$E_{1y} = +E_1\sin\theta,\ E_{2y} = +E_2\sin\theta.$

$E_y = E_{1y} + E_{2y} = 2E_{1y} = 2E_1\sin\theta = 2(862.8\ \text{N/C})(0.800) = 1380\ \text{N/C}.$

$E = 1380$ N/C, in the $+y$-direction.

EVALUATE: Point a is symmetrically placed between identical charges, so symmetry tells us the electric field must be zero. Point b is to the right of both charges and both electric fields are in the $+x$-direction and the resultant field is in this direction. At point c both fields have a downward component and the field of q_2 has a component to the right, so the net $\vec{E}$ is in the fourth quadrant. At point d both fields have an upward component but by symmetry they have equal and opposite x-components so the net field is in the $+y$-direction. We can use this sort of reasoning to deduce the general direction of the net field before doing any calculations.

21.44. **IDENTIFY:** Apply $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$ to calculate the field due to each charge and then calculate the vector sum of those fields.

SET UP: The fields due to q_1 and to q_2 are sketched in Figure 21.44.

EXECUTE: $\vec{E}_2 = \dfrac{1}{4\pi\epsilon_0}\dfrac{(6.00\times10^{-9}\ \text{C})}{(0.6\ \text{m})^2}(-\hat{i}) = -150\hat{i}\ \text{N/C}.$

$$\vec{E}_1 = \frac{1}{4\pi\epsilon_0}(4.00\times10^{-9}\ \text{C})\left(\frac{1}{(1.00\ \text{m})^2}(0.600)\hat{i} + \frac{1}{(1.00\ \text{m})^2}(0.800)\hat{j}\right) = (21.6\hat{i} + 28.8\hat{j})\text{N/C}.$$

$\vec{E} = \vec{E}_1 + \vec{E}_2 = (-128.4\ \text{N/C})\hat{i} + (28.8\ \text{N/C})\hat{j}$. $E = \sqrt{(128.4\ \text{N/C})^2 + (28.8\ \text{N/C})^2} = 131.6\ \text{N/C}$ at $\theta = \tan^{-1}\left(\dfrac{28.8}{128.4}\right) = 12.6°$ above the $-x$-axis and therefore $167.4°$ counterclockwise from the $+x$-axis.

EVALUATE: $\vec{E}_1$ is directed toward q_1 because q_1 is negative and $\vec{E}_2$ is directed away from q_2 because q_2 is positive.

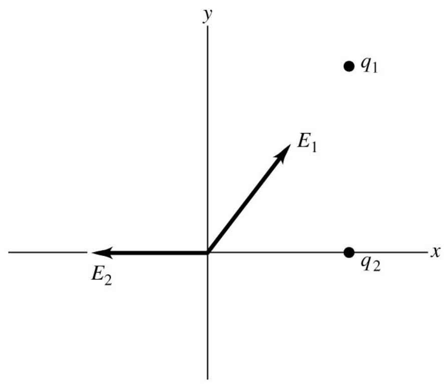


Figure 21.44

21.45. **IDENTIFY and SET UP:** We are dealing with the net electric field produced by three very large sheets of charge. The magnitude of the field due to each sheet is $E = \sigma / 2\epsilon_0$ and is independent of the distance from the sheet. $\vec{E}_A$ points away from sheet A, $\vec{E}_B$ points toward sheet B, and $\vec{E}_C$ points away from sheet C. Draw the sheet arrangement, locate point P midway between B and C, and show the fields at P (see Fig. 21.45). All the fields are along the x-axis.

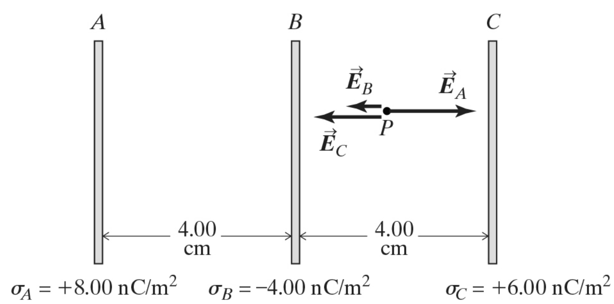

Figure 21.45

EXECUTE: Using the directions shown in the figure, we have $E_{Px} = \dfrac{|\sigma_A|}{2\epsilon_0} - \dfrac{|\sigma_B|}{2\epsilon_0} - \dfrac{|\sigma_C|}{2\epsilon_0} =$

$\dfrac{8.00 \text{ nC/m}^2 - 4.00 \text{ nC/m}^2 - 6.00 \text{ nC/m}^2}{2\epsilon_0} = -113$ N/C. The magnitude is 113 N/C and the direction is in the $-x$ direction (to the left).

EVALUATE: Since the electric fields are independent of distance from the sheet, the resultant field would would be the same *anywhere* between sheets B and C.

21.46. **IDENTIFY and SET UP:** We are dealing with the electric fields of two point charges. First sketch the charge arrangement as in Fig. 21.46. We want to find q_2 so that the resultant electric field at point P is zero. The magnitude of the field due to a point charge is $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$. The two fields at P cancel, so $E_1 = E_2$.

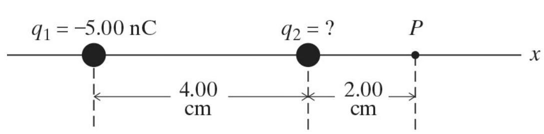

Figure 21.46

EXECUTE: $\dfrac{1}{4\pi\epsilon_0}\dfrac{|q_1|}{r_1^2}=\dfrac{1}{4\pi\epsilon_0}\dfrac{|q_2|}{r_2^2}$ gives $\dfrac{5.00\text{ nC}}{(6.00\text{ cm})^2}=\dfrac{q_2}{(2.00\text{ cm})^2}$, so $q_2 = +0.556$ nC. At point P E_1 points to the left, so E_2 must point to the right, which tells us that q_2 is positive.

EVALUATE: There was no need to convert to standard SI units because most of the quantities cancel.

21.47. IDENTIFY: We are dealing with the resultant electric field of two point charges. Sketch the charge arrangement as in Fig. 21.47.

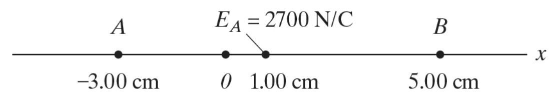

Figure 21.47

SET UP: We know that $|q_A| = 2|q_B|$, $E_A = 2700$ N/C (magnitude only) at $x = 1.00$ cm, and $E=\dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$. In each case, we want to find the resultant electric field at the origin.

EXECUTE: **(a)** Both A and B are positive. First find q_A: $E_A=\dfrac{1}{4\pi\epsilon_0}\dfrac{q_A}{r^2}=2700\text{ N/C}$, and $r = 4.00$ cm = 0.0400 m, which gives $q_A = 0.48053$ nC. Therefore $q_B = 2q_A = 0.96106$ nC. At the origin, the two fields point in opposite directions, so $E = E_A - E_B = \dfrac{1}{4\pi\epsilon_0}\left[\dfrac{0.48053\text{ nC}}{(0.0300\text{ m})^2}-\dfrac{0.96106\text{ nC}}{(0.0500\text{ m})^2}\right] = 1340\text{ N/C}$, in the $+x$ direction.

(b) Both A and B are negative. The calculation is the same as in part (a) except the field is in the opposite direction: $E = 1340$ N/C in the $-x$ direction.

(c) A is positive and B is negative. Both fields point in the $+x$ direction, so the magnitudes add, giving $E = E_A + E_B = \dfrac{1}{4\pi\epsilon_0}\left[\dfrac{0.48053\text{ nC}}{(0.0300\text{ m})^2}+\dfrac{0.96106\text{ nC}}{(0.0500\text{ m})^2}\right] = 8260$ N/C in the $+x$ direction.

(d) A is negative and B is positive. Both fields point in the $-x$ direction but E has the same magnitude as in part (c), so $E = 8260$ N/C in the $-x$ direction.

EVALUATE: It is always best to sketch the charge arrangement to visualize the direction of the electric fields.

21.48. IDENTIFY: For a long straight wire, $E=\dfrac{\lambda}{2\pi\epsilon_0 r}$.

SET UP: $\dfrac{1}{2\pi\epsilon_0}=1.80\times10^{10}\ \text{N}\cdot\text{m}^2/\text{C}^2$.

EXECUTE: Solve $E=\dfrac{\lambda}{2\pi\epsilon_0 r}$ for r: $r=\dfrac{3.20\times10^{-10}\text{ C/m}}{2\pi\epsilon_0\,(2.50\text{ N/C})}=2.30\text{ m}$.

EVALUATE: For a point charge, E is proportional to $1/r^2$. For a long straight line of charge, E is proportional to $1/r$.

21.49. IDENTIFY: For a ring of charge, the magnitude of the electric field is given by $E_x=\dfrac{1}{4\pi\epsilon_0}\dfrac{Qx}{(x^2+a^2)^{3/2}}$. Use $\vec{F}=q\vec{E}$. In part (b) use Newton's third law to relate the force on the ring to the force exerted by the ring.

SET UP: $Q=0.125\times10^{-9}$ C, $a=0.025$ m and $x=0.400$ m.

EXECUTE: **(a)** $\vec{E}=\dfrac{1}{4\pi\epsilon_0}\dfrac{Qx}{(x^2+a^2)^{3/2}}\hat{i}=(7.0\text{ N/C})\hat{i}$.

(b) $\vec{F}_{\text{on ring}} = -\vec{F}_{\text{on q}} = -q\vec{E} = -(-2.50\times10^{-6}\ \text{C})(7.0\ \text{N/C})\hat{i} = (1.75\times10^{-5}\ \text{N})\hat{i}$.

EVALUATE: Charges q and Q have opposite sign, so the force that q exerts on the ring is attractive.

21.50. **(a) IDENTIFY:** The field is caused by a finite uniformly charged wire.

SET UP: The field for such a wire a distance x from its midpoint is

$$E = \frac{1}{2\pi\epsilon_0}\frac{\lambda}{x\sqrt{(x/a)^2+1}} = 2\left(\frac{1}{4\pi\epsilon_0}\right)\frac{\lambda}{x\sqrt{(x/a)^2+1}}.$$

EXECUTE: $E = \dfrac{(18.0\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(175\times10^{-9}\ \text{C/m})}{(0.0600\ \text{m})\sqrt{\left(\dfrac{6.00\ \text{cm}}{4.25\ \text{cm}}\right)^2+1}} = 3.03\times10^4\ \text{N/C},\ \text{directed upward.}$

(b) IDENTIFY: The field is caused by a uniformly charged circular wire.

SET UP: The field for such a wire a distance x from its midpoint is $E_x = \dfrac{1}{4\pi\epsilon_0}\dfrac{Qx}{(x^2+a^2)^{3/2}}$. We first find the radius a of the circle using $2\pi a = l$.

EXECUTE: Solving for a gives $a = l/2\pi = (8.50\ \text{cm})/2\pi = 1.353\ \text{cm}$.

The charge on this circle is $Q = \lambda l = (175\ \text{nC/m})(0.0850\ \text{m}) = 14.88\ \text{nC}$.

The electric field is

$$E = \frac{1}{4\pi\epsilon_0}\frac{Qx}{(x^2+a^2)^{3/2}} = \frac{(9.00\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(14.88\times10^{-9}\ \text{C/m})(0.0600\ \text{m})}{\left[(0.0600\ \text{m})^2+(0.01353\ \text{m})^2\right]^{3/2}}$$

$$E = 3.45\times10^4\ \text{N/C},\ \text{upward.}$$

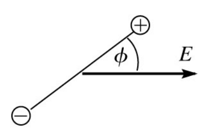
EVALUATE: In both cases, the fields are of the same order of magnitude, but the values are different because the charge has been bent into different shapes.

21.51. **(a) IDENTIFY and SET UP:** Use $p = qd$ to relate the dipole moment to the charge magnitude and the separation d of the two charges. The direction is from the negative charge toward the positive charge.

EXECUTE: $p = qd = (4.5\times10^{-9}\ \text{C})(3.1\times10^{-3}\ \text{m}) = 1.4\times10^{-11}\ \text{C}\cdot\text{m}$. The direction of $\vec{p}$ is from q_1 toward q_2.

(b) IDENTIFY and SET UP: Use $\tau = pE\sin\phi$ to relate the magnitudes of the torque and field.

EXECUTE: $\tau = pE\sin\phi$, with ϕ as defined in Figure 21.51, so



$$E = \frac{\tau}{p\sin\phi}.$$

$$E = \frac{7.2\times10^{-9}\ \text{N}\cdot\text{m}}{(1.4\times10^{-11}\ \text{C}\cdot\text{m})\sin36.9^\circ} = 860\ \text{N/C}.$$

Figure 21. 51

EVALUATE: The equation $\tau = pE\sin\phi$ gives the torque about an axis through the center of the dipole. But the forces on the two charges form a couple and the torque is the same for any axis parallel to this one. The force on each charge is $|q|E$ and the maximum moment arm for an axis at the center is $d/2$, so the maximum torque is $2(|q|E)(d/2) = 1.2\times10^{-8}\ \text{N}\cdot\text{m}$. The torque for the orientation of the dipole in the problem is less than this maximum.

21.52. **(a) IDENTIFY:** The potential energy is given by $U(\phi) = -\vec{p}\cdot\vec{E} = -pE\cos\phi.$

SET UP: $U(\phi) = -\vec{p}\cdot\vec{E} = -pE\cos\phi$, where ϕ is the angle between $\vec{p}$ and $\vec{E}$.

EXECUTE: parallel: $\phi = 0$ and $U(0°) = -pE$.
perpendicular: $\phi = 90°$ and $U(90°) = 0$.

$\Delta U = U(90°) - U(0°) = pE = (5.0\times10^{-30}\ \text{C}\cdot\text{m})(1.6\times10^{6}\ \text{N/C}) = 8.0\times10^{-24}\ \text{J}$.

(b) $\frac{3}{2}kT = \Delta U$ so $T = \dfrac{2\Delta U}{3k} = \dfrac{2(8.0\times10^{-24}\ \text{J})}{3(1.381\times10^{-23}\ \text{J/K})} = 0.39\ \text{K}$.

EVALUATE: Only at very low temperatures are the dipoles of the molecules aligned by a field of this strength. A much larger field would be required for alignment at room temperature.

21.53. **IDENTIFY:** The torque on a dipole in an electric field is given by $\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{p}}\times\vec{\boldsymbol{E}}$.

SET UP: $\tau = pE\sin\phi$, where ϕ is the angle between the direction of $\vec{\boldsymbol{p}}$ and the direction of $\vec{\boldsymbol{E}}$.

EXECUTE: **(a)** The torque is zero when $\vec{\boldsymbol{p}}$ is aligned either in the *same* direction as $\vec{\boldsymbol{E}}$ or in the *opposite* direction, as shown in Figure 21.53(a).
(b) The stable orientation is when $\vec{\boldsymbol{p}}$ is aligned in the *same* direction as $\vec{\boldsymbol{E}}$. In this case a small rotation of the dipole results in a torque directed so as to bring $\vec{\boldsymbol{p}}$ back into alignment with $\vec{\boldsymbol{E}}$. When $\vec{\boldsymbol{p}}$ is directed opposite to $\vec{\boldsymbol{E}}$, a small displacement results in a torque that takes $\vec{\boldsymbol{p}}$ farther from alignment with $\vec{\boldsymbol{E}}$.
(c) Field lines for E_{dipole} in the stable orientation are sketched in Figure 21.53(b).

EVALUATE: The field of the dipole is directed from the + charge toward the − charge.

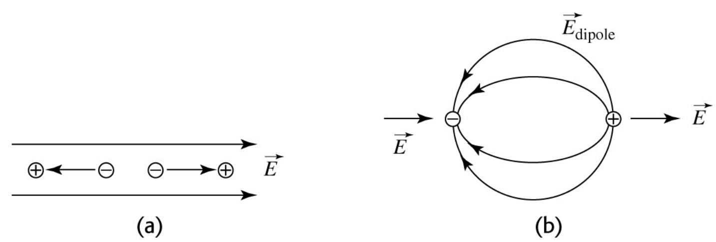


Figure 21. 53

21.54. **IDENTIFY:** Calculate the electric field due to the dipole and then apply $\vec{\boldsymbol{F}} = q\vec{\boldsymbol{E}}$.

SET UP: The field of a dipole is $E_{\text{dipole}}(x) = \dfrac{p}{2\pi\epsilon_0 x^3}$.

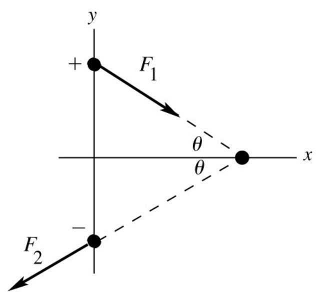
EXECUTE: $E_{\text{dipole}} = \dfrac{6.17\times10^{-30}\ \text{C}\cdot\text{m}}{2\pi\epsilon_0 (3.0\times10^{-9}\ \text{m})^3} = 4.11\times10^{6}\ \text{N/C}$. The electric force is

$F = qE = (1.60\times10^{-19}\ \text{C})(4.11\times10^{6}\ \text{N/C}) = 6.58\times10^{-13}\ \text{N}$ and is toward the water molecule (negative x-direction).

EVALUATE: $\vec{\boldsymbol{E}}_{\text{dipole}}$ is in the direction of $\vec{\boldsymbol{p}}$, so is in the $+x$-direction. The charge q of the ion is negative, so $\vec{\boldsymbol{F}}$ is directed opposite to $\vec{\boldsymbol{E}}$ and is therefore in the $-x$-direction.

21.55. **(a) IDENTIFY:** Use Coulomb's law to calculate each force and then add them as vectors to obtain the net force. Torque is force times moment arm.

SET UP: The two forces on each charge in the dipole are shown in Figure 21.55a.



$\sin\theta = 1.50/2.00$ so $\theta = 48.6°$.

Opposite charges attract and like charges repel.

$F_x = F_{1x} + F_{2x} = 0.$

Figure 21. 55a

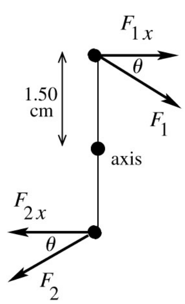
EXECUTE: $F_1 = k\dfrac{|qq'|}{r^2} = k\dfrac{(5.00\times10^{-6}\ \text{C})(10.0\times10^{-6}\ \text{C})}{(0.0200\ \text{m})^2} = 1.124\times10^3\ \text{N}.$

$F_{1y} = -F_1\sin\theta = -842.6\ \text{N}.$

$F_{2y} = -842.6\ \text{N}$ so $F_y = F_{1y} + F_{2y} = -1680\ \text{N}$ (in the direction from the $+5.00$-μC charge toward the -5.00-μC charge).

EVALUATE: The x-components cancel and the y-components add.

(b) SET UP: Refer to Figure 21.55b.



The y-components have zero moment arm and therefore zero torque.

F_{1x} and F_{2x} both produce clockwise torques.

Figure 21. 55b

EXECUTE: $F_{1x} = F_1\cos\theta = 743.1\ \text{N}.$

$\tau = 2(F_{1x})(0.0150\ \text{m}) = 22.3\ \text{N}\cdot\text{m}$, clockwise.

EVALUATE: The electric field produced by the $-10.00\ \mu$C charge is not uniform so $\tau = pE\sin\phi$ does not apply.

21.56. IDENTIFY: An electric dipole is in an external electric field. We want to know about the torque on this dipole and its electric potential energy due to this field.

SET UP: The torque is $\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{p}}\times\vec{\boldsymbol{E}}$ and the potential energy is $U = -\vec{\boldsymbol{p}}\cdot\vec{\boldsymbol{E}} = -pE\cos\phi$.

EXECUTE: **(a)** We want the orientation of the dipole that will produce the maximum torque into the paper. Fig. 21.56a shows the orientation so that the torque will be into the page. The magnitude of the torque is $\tau = pE\sin\phi$, which is a maximum when $\phi = 90°$. Fig. 21.56b shows this orientation, for which $\vec{\boldsymbol{p}}$ is downward. The potential energy at this angle is $U = -pE\cos\phi = -pE\cos 90° = 0$.

Figures 21.56a and 21.56b

(b) We want the orientation so that the torque is zero and the potential energy is a maximum. The magnitude of the torque is $\tau = pE\sin\phi$, which is zero for $\phi = 0°$ or 180°.

For $\phi = 0°$: $U = -pE \cos 0° = -pE$.

For $\phi = 180°$: $U = -pE \cos 180° = +pE$.

As we can see, the orientation for maximum potential energy is $\phi = 180°$. At this angle, $\vec{p}$ points opposite to the electric field. To find the type of equilibrium, imagine displacing the dipole a small angle from the $\phi = 180°$ equilibrium position. Fig. 21.56c shows the dipole and the electric forces on the dipole. As the figure shows, the torques tend to rotate the dipole *away from* the equilibrium position, so this is an *unstable* equilibrium.

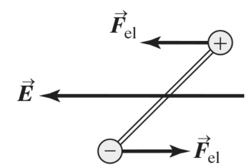


Figure 21.56c

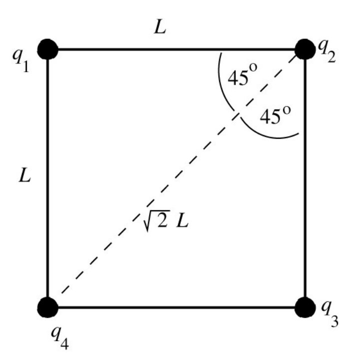
EVALUATE: A system is in a stable equilibrium state when its potential energy is a minimum (like a ball in a valley) and an unstable state when the potential energy is a maximum (like a ball at the top of a peak). In our case, $U = +pE$ (a maximum) when $\phi = 180°$, so this is an unstable equilibrium. The state $U = -pE$ (a minimum) when $\phi = 0°$ is a stable state. To show this, use the procedure we followed with Fig. 21.56c except displace the dipole a small angle from the $\phi = 0°$ state to see which way the torques tend to turn the dipole.

21.57. **IDENTIFY:** Apply Coulomb's law to calculate the force exerted on one of the charges by each of the other three and then add these forces as vectors.

SET UP: The charges are placed as shown in Figure 21.57a.



$q_1 = q_2 = q_3 = q_4 = Q$

Figure 21.57a

Consider forces on q_4. The free-body diagram is given in Figure 21.57b. Take the y-axis to be parallel to the diagonal between q_2 and q_4 and let $+y$ be in the direction away from q_2. Then $\vec{F}_2$ is in the $+y$-direction.

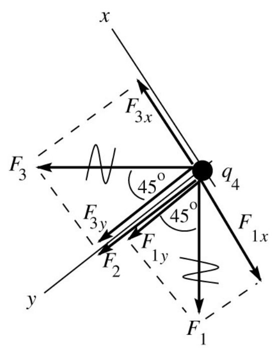


Figure 21.57b

EXECUTE: **(a)** $F_3 = F_1 = \dfrac{1}{4\pi\epsilon_0}\dfrac{Q^2}{L^2}$.

$F_2 = \dfrac{1}{4\pi\epsilon_0}\dfrac{Q^2}{2L^2}$.

$F_{1x} = -F_1 \sin 45° = -F_1/\sqrt{2}$.

$F_{1y} = +F_1 \cos 45° = +F_1/\sqrt{2}$.

$F_{3x} = +F_3 \sin 45° = +F_3/\sqrt{2}$.

$F_{3y} = +F_3 \cos 45° = +F_3/\sqrt{2}$.

$F_{2x} = 0, F_{2y} = F_2$.

(b) $R_x = F_{1x} + F_{2x} + F_{3x} = 0$.

$R_y = F_{1y} + F_{2y} + F_{3y} = (2/\sqrt{2})\dfrac{1}{4\pi\epsilon_0}\dfrac{Q^2}{L^2} + \dfrac{1}{4\pi\epsilon_0}\dfrac{Q^2}{2L^2} = \dfrac{Q^2}{8\pi\epsilon_0 L^2}(1+2\sqrt{2})$.

$R = \dfrac{Q^2}{8\pi\epsilon_0 L^2}(1+2\sqrt{2})$. Same for all four charges.

EVALUATE: In general the resultant force on one of the charges is directed away from the opposite corner. The forces are all repulsive since the charges are all the same. By symmetry the net force on one charge can have no component perpendicular to the diagonal of the square.

21.58. **IDENTIFY:** Apply $F = \dfrac{k|qq'|}{r^2}$ to find the force of each charge on $+q$. The net force is the vector sum of the individual forces.

SET UP: Let $q_1 = +2.50\ \mu\text{C}$ and $q_2 = -3.50\ \mu\text{C}$. The charge $+q$ must be to the left of q_1 or to the right of q_2 in order for the two forces to be in opposite directions. But for the two forces to have equal magnitudes, $+q$ must be closer to the charge q_1, since this charge has the smaller magnitude. Therefore, the two forces can combine to give zero net force only in the region to the left of q_1. Let $+q$ be a distance d to the left of q_1, so it is a distance $d + 0.600$ m from q_2.

EXECUTE: $F_1 = F_2$ gives $\dfrac{kq|q_1|}{d^2} = \dfrac{kq|q_2|}{(d+0.600\text{ m})^2}$.

$d = \pm\sqrt{\dfrac{|q_1|}{|q_2|}}(d + 0.600\text{ m}) = \pm(0.8452)(d + 0.600\text{ m})$. d must be positive, so

$d = \dfrac{(0.8452)(0.600\text{ m})}{1-0.8452} = 3.27$ m. The net force would be zero when $+q$ is at $x = -3.27$ m.

EVALUATE: When $+q$ is at $x = -3.27$ m, $\vec{F}_1$ is in the $-x$-direction and $\vec{F}_2$ is in the $+x$-direction.

21.59. **IDENTIFY:** Apply $F = k\dfrac{|qq'|}{r^2}$ for each pair of charges and find the vector sum of the forces that q_1 and q_2 exert on q_3.

SET UP: Like charges repel and unlike charges attract. The three charges and the forces on q_3 are shown in Figure 21.59.

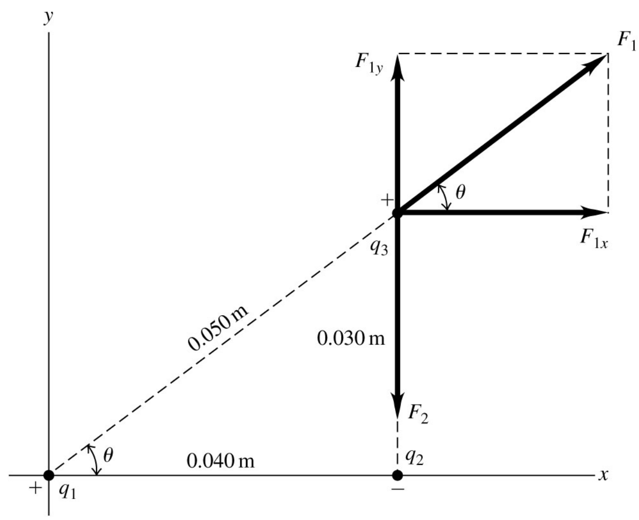

Figure 21.59

EXECUTE: **(a)** $F_1 = k\dfrac{|q_1 q_3|}{r_1^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{(5.00\times10^{-9}\ \text{C})(6.00\times10^{-9}\ \text{C})}{(0.0500\ \text{m})^2} = 1.079\times10^{-4}\ \text{N}.$

$\theta = 36.9°$. $F_{1x} = +F_1\cos\theta = 8.63\times10^{-5}\ \text{N}$. $F_{1y} = +F_1\sin\theta = 6.48\times10^{-5}\ \text{N}$.

$F_2 = k\dfrac{|q_2 q_3|}{r_2^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{(2.00\times10^{-9}\ \text{C})(6.00\times10^{-9}\ \text{C})}{(0.0300\ \text{m})^2} = 1.20\times10^{-4}\ \text{N}.$

$F_{2x} = 0$, $F_{2y} = -F_2 = -1.20\times10^{-4}\ \text{N}$. $F_x = F_{1x} + F_{2x} = 8.63\times10^{-5}\ \text{N}$.

$F_y = F_{1y} + F_{2y} = 6.48\times10^{-5}\ \text{N} + (-1.20\times10^{-4}\ \text{N}) = -5.52\times10^{-5}\ \text{N}.$

(b) $F = \sqrt{F_x^2 + F_y^2} = 1.02\times10^{-4}\ \text{N}$. $\tan\phi = \left|\dfrac{F_y}{F_x}\right| = 0.640$. $\phi = 32.6°$, below the +x-axis.

EVALUATE: The individual forces on q_3 are computed from Coulomb's law and then added as vectors, using components.

21.60. **IDENTIFY:** Apply $\sum F_x = 0$ and $\sum F_y = 0$ to one of the spheres.

SET UP: The free-body diagram is sketched in Figure 21.60. F_e is the repulsive Coulomb force between the spheres. For small θ, $\sin\theta \approx \tan\theta$.

EXECUTE: $\sum F_x = T\sin\theta - F_\text{e} = 0$ and $\sum F_y = T\cos\theta - mg = 0$. So $\dfrac{mg\sin\theta}{\cos\theta} = F_\text{e} = \dfrac{kq^2}{d^2}$. But

$\tan\theta \approx \sin\theta = \dfrac{d}{2L}$, so $d^3 = \dfrac{2kq^2L}{mg}$ and $d = \left(\dfrac{q^2 L}{2\pi\epsilon_0\, mg}\right)^{1/3}$.

EVALUATE: d increases when q increases.

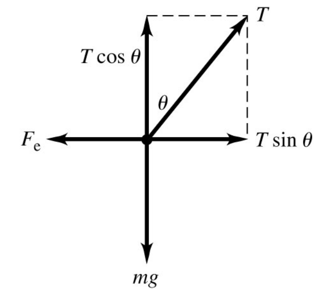

Figure 21.60

21.61. **IDENTIFY:** Use Coulomb's law for the force that one sphere exerts on the other and apply the first condition of equilibrium to one of the spheres.
SET UP: The placement of the spheres is sketched in Figure 21.61a.

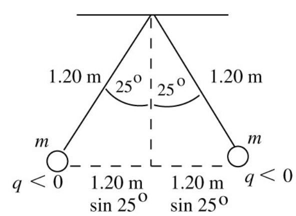

Figure 21.61a

EXECUTE: **(a)** The free-body diagrams for each sphere are given in Figure 21.61b.

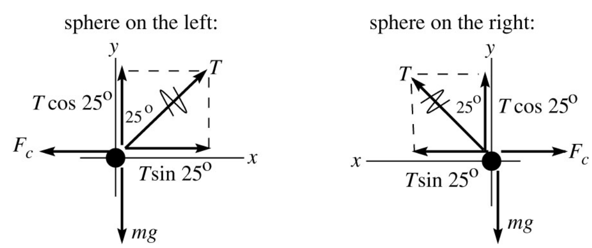

Figure 21.61b

F_c is the repulsive Coulomb force exerted by one sphere on the other.
(b) From either force diagram in part (a): $\sum F_y = ma_y$.

$T\cos 25.0° - mg = 0$ and $T = \dfrac{mg}{\cos 25.0°}$.

$\sum F_x = ma_x$.

$T\sin 25.0° - F_c = 0$ and $F_c = T\sin 25.0°$.

Use the first equation to eliminate T in the second: $F_c = (mg/\cos 25.0°)(\sin 25.0°) = mg\tan 25.0°$.

$$F_c = \frac{1}{4\pi\epsilon_0}\frac{|q_1 q_2|}{r^2} = \frac{1}{4\pi\epsilon_0}\frac{q^2}{r^2} = \frac{1}{4\pi\epsilon_0}\frac{q^2}{[2(1.20\text{ m})\sin 25.0°]^2}.$$

Combine this with $F_c = mg\tan 25.0°$ and get $mg\tan 25.0° = \dfrac{1}{4\pi\epsilon_0}\dfrac{q^2}{[2(1.20\text{ m})\sin 25.0°]^2}$.

$q = (2.40\text{ m})\sin 25.0°\sqrt{\dfrac{mg\tan 25.0°}{(1/4\pi\epsilon_0)}}.$

$q = (2.40\text{ m})\sin 25.0°\sqrt{\dfrac{(15.0\times 10^{-3}\text{ kg})(9.80\text{ m/s}^2)\tan 25.0°}{8.988\times 10^9\text{ N}\cdot\text{m}^2/\text{C}^2}} = 2.80\times 10^{-6}\text{ C}.$

(c) The separation between the two spheres is given by $2L\sin\theta$. $q = 2.80\mu\text{C}$ as found in part (b).
$F_c = (1/4\pi\epsilon_0)q^2/(2L\sin\theta)^2$ and $F_c = mg\tan\theta$. Thus $(1/4\pi\epsilon_0)q^2/(2L\sin\theta)^2 = mg\tan\theta$.

$(\sin\theta)^2\tan\theta = \dfrac{1}{4\pi\epsilon_0}\dfrac{q^2}{4L^2mg} =$

$(8.988\times 10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\dfrac{(2.80\times 10^{-6}\text{ C})^2}{4(0.600\text{ m})^2(15.0\times 10^{-3}\text{ kg})(9.80\text{ m/s}^2)} = 0.3328.$

Solve this equation by trial and error. This will go quicker if we can make a good estimate of the value of θ that solves the equation. For θ small, $\tan\theta \approx \sin\theta$. With this approximation the equation becomes $\sin^3\theta = 0.3328$ and $\sin\theta = 0.6930$, so $\theta = 43.9°$. Now refine this guess:

θ	$\sin^2\theta\tan\theta$	
45.0°	0.5000	
40.0°	0.3467	
39.6°	0.3361	
39.5°	0.3335	
39.4°	0.3309	so $\theta = 39.5°$.

EVALUATE: The expression in part (c) says $\theta \to 0$ as $L \to \infty$ and $\theta \to 90°$ as $L \to 0$. When L is decreased from the value in part (a), θ increases.

21.62. IDENTIFY and SET UP: The horizontal electric field exerts a force on the moving sphere. The field is in the same direction as the velocity of the sphere, so it will increase the sphere's speed as the sphere falls. We want to know the magnitude E of the electric field. It points toward the east, so it does not affect the vertical velocity of the sphere. It does, however, give the sphere horizontal acceleration. We know the initial and final speeds of the sphere.

EXECUTE: First find the time to fall 60.0 cm from rest. Then use that time to find the vertical velocity v_y just as the sphere reaches the ground. Using $y = \frac{1}{2}gt^2$ gives $t = \sqrt{\dfrac{2y}{g}} = \sqrt{\dfrac{2(0.600\text{ m})}{9.80\text{ m/s}^2}} = 0.3499\text{ s}$. $v_y = gt = (9.80\text{ m/s}^2)(0.3499\text{ s}) = 3.429\text{ m/s}$. Now find v_x just as the sphere reaches the ground. Using $\Sigma F_x = ma_x$ and $F_x = qE$ gives $a_x = qE/m$. The horizontal velocity is $v_x = v_{0x} + a_xt = v_0 + (qE/m)t$. At ground level $v = 5.00$ m/s, so $\sqrt{v_x^2 + v_y^2} = 5.00\text{ m/s}$. Squaring gives $v_x^2 + v_y^2 = 25.0\text{ m}^2/\text{s}^2$. Using our results for v_x and v_y, this becomes $\left(v_0 + qEt/m\right)^2 + v_y^2 = 25.0\text{ m}^2/\text{s}^2$. Solving for E gives

$E = \dfrac{m}{qt}\left(\sqrt{25.0\text{ m}^2/\text{s}^2 - v_y^2} - v_0\right)$. Using $m = 0.500\text{ g} = 5.00\times 10^{-4}\text{ kg}$, $q = 5.00\ \mu\text{C}$, $t = 0.3499$ s, $v_y = 3.429$ m/s, and $v_0 = 2.00$ m/s, we get $E = 468\text{ N/C}$.

EVALUATE: We can check using the work-energy theorem. $W_{tot} = W_g + W_E$. $W_g = mgy = (0.500\text{ g})(9.80\text{ m/s}^2)(0.600\text{ m}) = 2.94\times 10^{-3}\text{ J}$. $W_E = qEx$, where $x = v_0t + \frac{1}{2}a_xt^2$. Using $a_x = qE/m$ and putting in $q = 5.00\ \mu$C, $E = 468$ N/C, and $m = 0.500$ g, we get $x = 0.986$ m. Therefore $W_E = (0.500\ \mu\text{C})(468\text{ N/C})(0.986\text{ m}) = 2.308\times 10^{-3}\text{ J}$. Adding gives $W_{tot} = 5.25\times 10^{-3}\text{ J}$. The kinetic energy change is $K_2 - K_1 = \dfrac{1}{2}mv^2 - \dfrac{1}{2}mv_0^2 = \dfrac{1}{2}m\left(v^2 - v_0^2\right)$, which gives

$\Delta K = \frac{1}{2}(0.500\text{ g})\left[(5.00\text{ m/s})^2 - (2.00\text{ m/s})^2\right] = 5.25\times10^{-3}$ J. Our result is consistent with the work-energy theorem.

21.63. **IDENTIFY:** The electric field exerts a horizontal force away from the wall on the ball. When the ball hangs at rest, the forces on it (gravity, the tension in the string, and the electric force due to the field) add to zero.

SET UP: The ball is in equilibrium, so for it $\sum F_x = 0$ and $\sum F_y = 0$. The force diagram for the ball is given in Figure 21.63. F_E is the force exerted by the electric field. $\vec{F} = q\vec{E}$. Since the electric field is horizontal, $\vec{F}_E$ is horizontal. Use the coordinates shown in the figure. The tension in the string has been replaced by its x- and y-components.

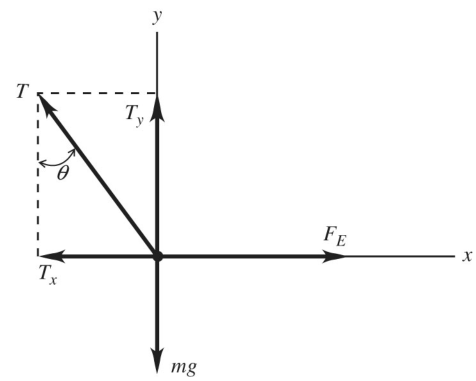

Figure 21.63

EXECUTE: $\sum F_y = 0$ gives $T_y - mg = 0$. $T\cos\theta - mg = 0$ and $T = \dfrac{mg}{\cos\theta}$. $\sum F_x = 0$ gives $F_E - T_x = 0$. $F_E - T\sin\theta = 0$. Combing the equations and solving for F_E gives

$F_E = \left(\dfrac{mg}{\cos\theta}\right)\sin\theta = mg\tan\theta = (12.3\times10^{-3}\text{ kg})(9.80\text{ m/s}^2)(\tan 17.4°) = 3.78\times10^{-2}$ N. $F_E = |q|E$ so

$E = \dfrac{F_E}{|q|} = \dfrac{3.78\times10^{-2}\text{ N}}{1.11\times10^{-6}\text{ C}} = 3.41\times10^4$ N/C. Since q is negative and $\vec{F}_E$ is to the right, $\vec{E}$ is to the left in the figure.

EVALUATE: The larger the electric field E the greater the angle the string makes with the wall.

21.64. **IDENTIFY:** A charged sphere is released in a vertical electric field and accelerates upward.

SET UP: We want the time it takes the sphere to travel upward a distance d. The forces on it are mg downward and qE upward. $\sum F_y = ma_y$ applies to the sphere.

EXECUTE: The vertical distance it travels in time t is $d = \frac{1}{2}at^2$. Using $\sum F_y = ma_y$ we get $qE - mg = ma$, so $a = \dfrac{qE - mg}{m}$. Therefore $d = \frac{1}{2}at^2 = \frac{1}{2}\left(\dfrac{qE - mg}{m}\right)t^2$. Solving for t gives $t = \sqrt{\dfrac{2md}{qE - mg}}$.

EVALUATE: We must have $qE > mg$ or the sphere would not travel upward.

21.65. **IDENTIFY and SET UP:** We model the interaction as being due to a negative charge on the balloon and an equal positive charge in the ceiling due to the positive charge left behind when the negative charge on the comb repels electrons in the ceiling. We are assuming that the negative charge in the ceiling is far enough away to be ignored. Furthermore, we model both of these charges as point charges separated by 500 μm and apply Coulomb's law to find the magnitude of the electric force. $F = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_1 q_2|}{r^2}$.

EXECUTE: **(a)** $F_{\text{el}} = mg$. $\dfrac{1}{4\pi\epsilon_0}\dfrac{q^2}{r^2} = mg$. $q = \sqrt{\dfrac{mgr^2}{1/4\pi\epsilon_0}}$. Using m = 0.004 kg and r = 500 μm gives q = 1 nC.

(b) $Q = 10q = 10.0$ nC $= Ne$, so $N = Q/e$ (10 nC)/ (1.6×10^{-19} C) $\approx 6\times 10^{10}$ electrons.

EVALUATE: This is a very rough approximation because the charges in the ceiling and balloon are not concentrated to a point as we assumed in our model, and the negative charges in the ceiling are not really far enough away to be ignored.

21.66. **IDENTIFY:** We want to estimate the amount of charge in a penny made of zinc with a mass of 2.5 g.

SET UP: The gram atomic mass of zinc is 65.38 g/mol, and a zinc atom contains 30 electrons.

EXECUTE: **(a)** $(2.5\text{ g})\left(\dfrac{1\text{ mol}}{65.38\text{ g}}\right)\left(\dfrac{6.022\times 10^{23}\text{ atoms}}{\text{mol}}\right)\left(\dfrac{30\text{ electrons}}{\text{atom}}\right) = 6.9\times 10^{23}$ electrons.

(b) $q = (6.9\times 10^{23}\text{ electrons})\left(\dfrac{1.60\times 10^{-19}\text{ C}}{\text{electron}}\right) = 1.1\times 10^{5}\text{ C}.$

(c) Coulomb's law: $F = \dfrac{1}{4\pi\epsilon_0}\dfrac{q^2}{r^2} = \dfrac{1}{4\pi\epsilon_0}\dfrac{(1.1\times 10^{5}\text{ C})^2}{(0.020\text{ m})^2} = 2.7\times 10^{23}\text{ N}.$

(d) Estimate: 2 million leaves.

(e) There would be 6.9×10^{23} leaves and each tree would contain 2×10^{6} leaves, so the number of trees in the forest would be $(6.9\times 10^{23}\text{ leaves})\left(\dfrac{1\text{ tree}}{2\times 10^{6}\text{ leaves}}\right) = 3.5\times 10^{17}$ trees. Think of each tree as being at the center of a 10 m by 10 m square, so the area for each tree would be 100 m^2. The area of this forest would be $(3.5\times 10^{17}\text{ trees})\left(\dfrac{100\text{ m}^2}{1\text{ tree}}\right) = 3.5\times 10^{19}\text{ m}^2$.

(f) $\dfrac{A_{\text{trees}}}{A_{\text{earth}}} = \dfrac{3.5\times 10^{19}\text{ m}^2}{4\pi(6.37\times 10^{6}\text{ m}^2)} \approx 70{,}000$. The trees would occupy an area about 70,000 times the surface area of the earth.

EVALUATE: The penny contains about 110,000 C of negative charge, but it also contains 110,000 C of positive charge. That is why it doesn't blow itself apart.

21.67. **IDENTIFY:** For a point charge, $E = k\dfrac{|q|}{r^2}$. For the net electric field to be zero, $\vec{E}_1$ and $\vec{E}_2$ must have equal magnitudes and opposite directions.

SET UP: Let $q_1 = +0.500$ nC and $q_2 = +8.00$ nC. $\vec{E}$ is toward a negative charge and away from a positive charge.

EXECUTE: The two charges and the directions of their electric fields in three regions are shown in Figure 21.67. Only in region II are the two electric fields in opposite directions. Consider a point a distance x from q_1 so a distance $1.20\text{ m} - x$ from q_2. $E_1 = E_2$ gives $k\dfrac{0.500\text{ nC}}{x^2} = k\dfrac{8.00\text{ nC}}{(1.20\text{ m} - x)^2}$.

$16x^2 = (1.20\text{ m} - x)^2$. $4x = \pm(1.20\text{ m} - x)$ and $x = 0.24$ m is the positive solution. The electric field is zero at a point between the two charges, 0.24 m from the 0.500 nC charge and 0.96 m from the 8.00 nC charge.

EVALUATE: There is only one point along the line connecting the two charges where the net electric field is zero. This point is closer to the charge that has the smaller magnitude.

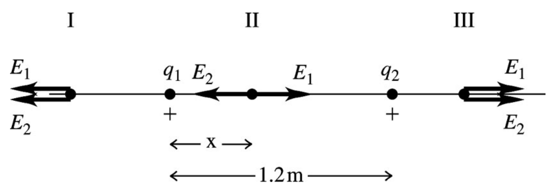

Figure 21.67

21.68. IDENTIFY: The net electric field at the origin is the vector sum of the fields due to the two charges.

SET UP: $E = k\dfrac{|q|}{r^2}$. $\vec{E}$ is toward a negative charge and away from a positive charge. At the origin, $\vec{E}_1$ due to the -3.00 nC charge is in the $+x$-direction, toward the charge.

EXECUTE: (a)

$E_1 = (8.99\times 10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{(3.00\times 10^{-9}\ \text{C})}{(1.20\ \text{m})^2} = 18.73\ \text{N/C}$, so $E_{1x} = +18.73\ \text{N/C}$. $E_x = E_{1x} + E_{2x}$.

$E_x = +45.0\ \text{N/C}$, so $E_{2x} = E_x - E_{1x} = +45.0\ \text{N/C} - 18.73\ \text{N/C} = 26.27\ \text{N/C}$. $\vec{E}$ is away from Q so Q is positive. Using $E_2 = k\dfrac{|Q|}{r^2}$ gives $|Q| = \dfrac{E_2 r^2}{k} = \dfrac{(26.27\ \text{N/C})(0.600\ \text{m})^2}{8.99\times 10^9\ \text{N}\cdot\text{m}^2/\text{C}^2} = 1.05\times 10^{-9}\ \text{C} = 1.05\ \text{nC}$. Since Q is positive, $Q = +1.05$ nC.

(b) $E_x = -45.0\ \text{N/C}$, so $E_{2x} = E_x - E_{1x} = -45.0\ \text{N/C} - 18.73\ \text{N/C} = -63.73\ \text{N/C}$. $\vec{E}$ is toward Q so Q is negative. $|Q| = \dfrac{E_2 r^2}{k} = \dfrac{(63.73\ \text{N/C})(0.600\ \text{m})^2}{8.99\times 10^9\ \text{N}\cdot\text{m}^2/\text{C}^2} = 2.55\times 10^{-9}\ \text{C} = 2.55\ \text{nC}$. Since Q is negative, we have $Q = -2.55$ nC.

EVALUATE: The equation $E = k\dfrac{|q|}{r^2}$ gives only the *magnitude* of the electric field. When combining fields, you still must figure out whether to add or subtract the magnitudes depending on the direction in which the fields point.

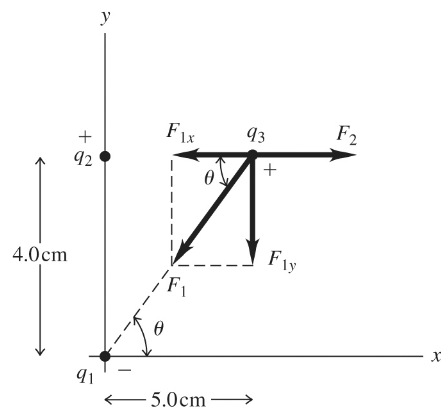
21.69. IDENTIFY: For equilibrium, the forces must balance. The electrical force is given by Coulomb's law.

SET UP: Set up axes so that the charge $+Q$ is located at $x = 0$, the charge $+4Q$ is located at $x = d$, and the unknown charge that is required to produce equilibrium, q, is located at a position $x = a$. Apply $F = k\dfrac{|q_1 q_2|}{r^2}$ to each pair of charges to obtain eqilibrium.

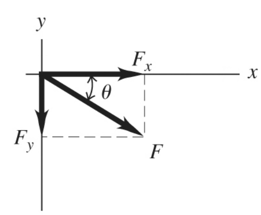
EXECUTE: For a charge q to be in equilbrium, it must be placed between the two given positive charges $(0 < a < d)$ and the magnitude of the force between q and $+Q$ must be equal to the magnitude of the force between q and $+4Q$: $k\dfrac{|q|Q}{a^2} = k\dfrac{4|q|Q}{(d-a)^2}$. Solving for a we obtain $(d-a) = \pm 4a$, which has $a = \dfrac{d}{3}$ as its only root in the required interval $(0 < a < d)$. Furthermore, to conteract the repulsive force between $+Q$ and $+4Q$ the charge q must be negative $(q = -|q|)$. The condition that $+Q$ is in equilibrium gives us $k\dfrac{-qQ}{(d/3)^2} = k\dfrac{4Q^2}{d^2}$. Solving for q we obtain $q = -\dfrac{4}{9}Q$.

EVALUATE: We have shown that both q and $+Q$ are in equilibrium provided that $a = \frac{d}{3}$ and $q = -\frac{4}{9}Q$. To make sure that the problem is well posed, we should check that these conditions also place the charge $+4Q$ is in equilbrium. We can do this by showing that $k\frac{-4qQ}{(d-a)^2}$ is equal to $k\frac{4Q^2}{d^2}$ when the given values for both a and q are substituted.

21.70. **IDENTIFY** and **SET UP:** Like charges repel and unlike charges attract, and Coulomb's law applies. The positions of the three charges are sketched in Figure 21.70(a) and each force acting on q_3 is shown. The distance between q_1 and q_3 is 5.00 cm.



(a)



(b)

Figure 21.70

EXECUTE: **(a)** $F_1 = k\frac{|q_1 q_3|}{r_1^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(3.00\times10^{-9}\ \text{C})(5.00\times10^{-9}\ \text{C})}{(5.00\times10^{-2}\ \text{m})^2} = 5.394\times10^{-5}\ \text{N}.$

$F_{1x} = -F_1\cos\theta = -(5.394\times10^{-5}\ \text{N})(0.600) = -3.236\times10^{-5}\ \text{N}.$

$F_{1y} = -F_1\sin\theta = -(5.394\times10^{-5}\ \text{N})(0.800) = -4.315\times10^{-5}\ \text{N}.$

$F_2 = k\frac{|q_2 q_3|}{r_2^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(2.00\times10^{-9}\ \text{C})(5.00\times10^{-9}\ \text{C})}{(3.00\times10^{-2}\ \text{m})^2} = 9.989\times10^{-5}\ \text{N}.$

$F_{2x} = 9.989\times10^{-5}\ \text{N};\ F_{2y} = 0.$

$F_x = F_{1x} + F_{2x} = 9.989\times10^{-5}\ \text{N} + (-3.236\times10^{-5}\ \text{N}) = 6.75\times10^{-5}\ \text{N};$

$F_y = F_{1y} + F_{2y} = -4.32\times10^{-5}\ \text{N}.$

(b) $\vec{F}$ and its components are shown in Figure 21.70(b).

$F=\sqrt{F_x^2+F_y^2}=8.01\times10^{-5}$ N. $\tan\theta=\left|\dfrac{F_y}{F_x}\right|=0.640$ and $\theta=32.6°$. $\vec{F}$ is 327° counterclockwise from the $+x$-axis.

EVALUATE: The equation $F=k\dfrac{|q_1q_2|}{r^2}$ gives only the magnitude of the force. We must find the direction by deciding if the force between the charges is attractive or repulsive.

21.71. **IDENTIFY:** Use Coulomb's law to calculate the forces between pairs of charges and sum these forces as vectors to find the net charge.

(a) SET UP: The forces are sketched in Figure 21.71a.

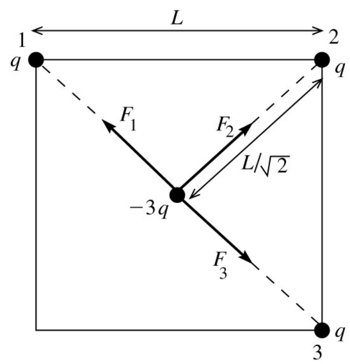


Figure 21. 71a

EXECUTE: $\vec{F}_1+\vec{F}_3=0$, so the net force is $\vec{F}=\vec{F}_2$.

$$F=\frac{1}{4\pi\epsilon_0}\frac{q(3q)}{(L/\sqrt{2})^2}=\frac{6q^2}{4\pi\epsilon_0 L^2},$$ away from the vacant corner.

(b) SET UP: The forces are sketched in Figure 21.71b.

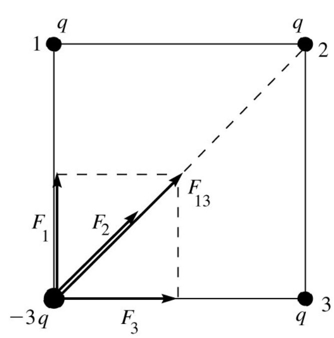

Figure 21. 71b

EXECUTE: $$F_2=\frac{1}{4\pi\epsilon_0}\frac{q(3q)}{(\sqrt{2}L)^2}=\frac{3q^2}{4\pi\epsilon_0(2L^2)}.$$

$$F_1=F_3=\frac{1}{4\pi\epsilon_0}\frac{q(3q)}{L^2}=\frac{3q^2}{4\pi\epsilon_0 L^2}.$$

The vector sum of F_1 and F_3 is $F_{13}=\sqrt{F_1^2+F_3^2}$.

$F_{13}=\sqrt{2}F_1=\dfrac{3\sqrt{2}q^2}{4\pi\epsilon_0 L^2}$; $\vec{F}_{13}$ and $\vec{F}_2$ are in the same direction.

$F=F_{13}+F_2=\dfrac{3q^2}{4\pi\epsilon_0 L^2}\left(\sqrt{2}+\dfrac{1}{2}\right)$, and is directed toward the center of the square.

EVALUATE: By symmetry the net force is along the diagonal of the square. The net force is only slightly larger when the $-3q$ charge is at the center. Here it is closer to the charge at point 2 but the other two forces cancel.

21.72. **IDENTIFY:** For the acceleration (and hence the force) on Q to be upward, as indicated, the forces due to q_1 and q_2 must have equal strengths, so q_1 and q_2 must have equal magnitudes. Furthermore, for the force to be upward, q_1 must be positive and q_2 must be negative.

SET UP: Since we know the acceleration of Q, Newton's second law gives us the magnitude of the force on it. We can then add the force components using $F = F_{Qq_1}\cos\theta + F_{Qq_2}\cos\theta = 2F_{Qq_1}\cos\theta$. The electrical force on Q is given by Coulomb's law, $F_{Qq_1} = \dfrac{1}{4\pi\epsilon_0}\dfrac{|Qq_1|}{r^2}$ (for q_1) and likewise for q_2.

EXECUTE: First find the net force: $F = ma =$ $(0.00500\text{ kg})(324\text{ m/s}^2) = 1.62\text{ N}$. Now add the force components, calling θ the angle between the line connecting q_1 and q_2 and the line connecting q_1 and Q. $F = F_{Qq_1}\cos\theta + F_{Qq_2}\cos\theta = 2F_{Qq_1}\cos\theta$ and $F_{Qq_1} = \dfrac{F}{2\cos\theta} = \dfrac{1.62\text{ N}}{2\left(\dfrac{2.25\text{ cm}}{3.00\text{ cm}}\right)} = 1.08\text{ N}$. Now find the charges by solving for q_1 in Coulomb's law and use the fact that q_1 and q_2 have equal magnitudes but opposite signs. $F_{Qq_1} = \dfrac{1}{4\pi\epsilon_0}\dfrac{|Q|q_1}{r^2}$ and

$$q_1 = \frac{r^2 F_{Qq_1}}{\dfrac{1}{4\pi\epsilon_0}|Q|} = \frac{(0.0300\text{ m})^2(1.08\text{ N})}{(9.00\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(1.75\times10^{-6}\text{ C})} = 6.17\times10^{-8}\text{ C}.$$

$q_2 = -q_1 = -6.17\times10^{-8}$ C.

EVALUATE: Simple reasoning allows us first to conclude that q_1 and q_2 must have equal magnitudes but opposite signs, which makes the equations much easier to set up than if we had tried to solve the problem in the general case. As Q accelerates and hence moves upward, the magnitude of the acceleration vector will change in a complicated way.

21.73. **IDENTIFY:** The small bags of protons behave like point-masses and point-charges since they are extremely far apart.

SET UP: For point-particles, we use Newton's formula for universal gravitation $(F = Gm_1m_2/r^2)$ and Coulomb's law. The number of protons is the mass of protons in the bag divided by the mass of a single proton.

EXECUTE: **(a)** $(0.0010\text{ kg})/(1.67\times10^{-27}\text{ kg}) = 6.0\times10^{23}$ protons.

(b) Using Coulomb's law, where the separation is twice the radius of the earth, we have
$F_{\text{electrical}} = (9.00\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(6.0\times10^{23}\times1.60\times10^{-19}\text{ C})^2/(2\times6.37\times10^6\text{ m})^2 = 5.1\times10^5\text{ N}.$
$F_{\text{grav}} = (6.67\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(0.0010\text{ kg})^2/(2\times6.37\times10^6\text{ m})^2 = 4.1\times10^{-31}\text{ N}.$

EVALUATE: **(c)** The electrical force (≈200,000 lb!) is certainly large enough to feel, but the gravitational force clearly is not since it is about 10^{36} times weaker.

21.74. **IDENTIFY:** The positive sphere will be deflected in the direction of the electric field but the negative sphere will be deflected in the direction opposite to the electric field. Since the spheres hang at rest, they are in equilibrium so the forces on them must balance. The external forces on each sphere are gravity, the tension in the string, the force due to the uniform electric field and the electric force due to the other sphere.

SET UP: The electric force on one sphere due to the other is $F_C = k\dfrac{|q^2|}{r^2}$ in the horizontal direction, the force on it due to the uniform electric field is $F_E = qE$ in the horizontal direction, the gravitational force is mg vertically downward and the force due to the string is T directed along the string. For equilibrium $\sum F_x = 0$ and $\sum F_y = 0$.

EXECUTE: **(a)** The positive sphere is deflected in the same direction as the electric field, so the one that is deflected to the left is positive.

(b) The separation between the two spheres is $2(0.530\text{ m})\sin 29.0^\circ = 0.5139\text{ m}$.

$F_C = k\dfrac{|q^2|}{r^2} = \dfrac{(8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(72.0\times10^{-9}\text{ C})^2}{(0.5139\text{ m})^2} = 1.765\times10^{-4}\text{ N}$. $F_E = qE$. $\sum F_y = 0$ gives

$T\cos 29.0^\circ - mg = 0$ so $T = \dfrac{mg}{\cos 29.0^\circ}$. $\sum F_x = 0$ gives $T\sin 29.0^\circ + F_C - F_E = 0$.

$mg\tan 29.0^\circ + F_C = qE$. Combining the equations and solving for E gives

$$E = \frac{mg\tan 29.0^\circ + F_C}{q} = \frac{(6.80\times10^{-6}\text{ kg})(9.80\text{ m/s}^2)\tan 29.0^\circ + 1.765\times10^{-4}\text{ N}}{72.0\times10^{-9}\text{ C}} = 2.96\times10^3\text{ N/C}.$$

EVALUATE: Since the charges have opposite signs, they attract each other, which tends to reduce the angle between the strings. Therefore if their charges were negligibly small, the angle between the strings would be greater than 58.0°.

21.75. **IDENTIFY:** The only external force acting on the electron is the electrical attraction of the proton, and its acceleration is toward the center of its circular path (that is, toward the proton). Newton's second law applies to the electron and Coulomb's law gives the electrical force on it due to the proton.

SET UP: Newton's second law gives $F_C = m\dfrac{v^2}{r}$. Using the electrical force for F_C gives $k\dfrac{e^2}{r^2} = m\dfrac{v^2}{r}$.

EXECUTE: Solving for v gives $v = \sqrt{\dfrac{ke^2}{mr}} = \sqrt{\dfrac{(8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(1.60\times10^{-19}\text{ C})^2}{(9.109\times10^{-31}\text{ kg})(5.29\times10^{-11}\text{ m})}} = 2.19\times10^6\text{ m/s}$.

EVALUATE: This speed is less than 1% the speed of light, so it is reasonably safe to use Newtonian physics.

21.76. **IDENTIFY:** A uniformly charged horizontal disk exerts an upward electric force on a small charged sphere. Gravity exerts a downward force on the sphere.

SET UP: The magnitude of the electric force on the sphere is $F = QE$, where E is the electric field a distance z above the center of the disk and is given by $E = \dfrac{\sigma}{2\epsilon_0}\left(1 - \dfrac{1}{\sqrt{(R/z)^2+1}}\right)$.

EXECUTE: **(a)** The net upward force is $F = F_{\text{el}} + F_{\text{g}} = \dfrac{Q\sigma}{2\epsilon_0}\left(1 - \dfrac{1}{\sqrt{(R/z)^2+1}}\right) - Mg$.

(b) We want the height h above the disk at which the sphere hovers. This will occur when the electric force is equal to the weight of the sphere, so $\dfrac{Q\sigma}{2\epsilon_0}\left(1 - \dfrac{1}{\sqrt{(R/z)^2+1}}\right) - Mg = 0$. Now solve for z.

Rearranging gives $1 - \dfrac{1}{\sqrt{(R/z)^2+1}} = \dfrac{2Mg\epsilon_0}{Q\sigma} \equiv v$, where we have used the v defined in the problem.

We now need to solve the equation $1 - v = \dfrac{1}{\sqrt{(R/h)^2+1}}$ for h, where h is the height at which the sphere hovers. Doing some algebra yields $h = \dfrac{R}{\sqrt{1/(1-v)^2 - 1}} = \dfrac{R(1-v)}{\sqrt{v(2-v)}}$.

(c) We want to find h if $M = 100$ g $= 0.100$ kg, $Q = 1.00\ \mu$C, $R = 5.00$ cm $= 0.0500$ m, and $\sigma = 10.0\ \text{nC/cm}^2 = 1.00\times10^{-4}\ \text{C/m}^2$. Using $v = \dfrac{2Mg\epsilon_0}{Q\sigma}$ and $h = \dfrac{R(1-v)}{\sqrt{v(2-v)}}$ with these numbers, we get $v = 0.1735$, which gives $h = 0.0734$ m $= 7.34$ cm.

EVALUATE: A 100-gram object hovering about 7 cm from the disk could easily be observed in a student laboratory.

21.77. **IDENTIFY:** $\vec{E} = \dfrac{\vec{F}_0}{q_0}$ gives the force exerted by the electric field. This force is constant since the electric field is uniform and gives the proton a constant acceleration. Apply the constant acceleration equations for the x- and y-components of the motion, just as for projectile motion.

SET UP: The electric field is upward so the electric force on the positively charged proton is upward and has magnitude $F = eE$. Use coordinates where positive y is downward. Then applying $\sum\vec{F} = m\vec{a}$ to the proton gives that $a_x = 0$ and $a_y = -eE/m$. In these coordinates the initial velocity has components $v_x = +v_0\cos\alpha$ and $v_y = +v_0\sin\alpha$, as shown in Figure 21.77a.

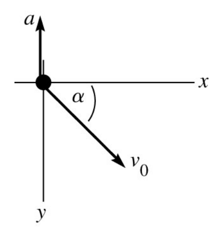

Figure 21.77a

EXECUTE: **(a)** Finding $h_{\max}$: At $y = h_{\max}$ the y-component of the velocity is zero.

$v_y = 0, v_{0y} = v_0\sin\alpha, a_y = -eE/m, y - y_0 = h_{\max} = ?$

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0).$

$$y - y_0 = \frac{v_y^2 - v_{0y}^2}{2a_y}.$$

$$h_{\max} = \frac{-v_0^2\sin^2\alpha}{2(-eE/m)} = \frac{mv_0^2\sin^2\alpha}{2eE}.$$

(b) Use the vertical motion to find the time t: $y - y_0 = 0, v_{0y} = v_0\sin\alpha, a_y = -eE/m, t = ?$

$$y - y_0 = v_{0y}t + \frac{1}{2}a_yt^2.$$

With $y - y_0 = 0$ this gives $t = -\dfrac{2v_{0y}}{a_y} = -\dfrac{2(v_0\sin\alpha)}{-eE/m} = \dfrac{2mv_0\sin\alpha}{eE}.$

Then use the x-component motion to find d: $a_x = 0, v_{0x} = v_0\cos\alpha, t = 2mv_0\sin\alpha/eE, x - x_0 = d = ?$

$x - x_0 = v_{0x}t + \frac{1}{2}a_xt^2$ gives $d = v_0\cos\alpha\left(\dfrac{2mv_0\sin\alpha}{eE}\right) = \dfrac{mv_0^2 2\sin\alpha\cos\alpha}{eE} = \dfrac{mv_0^2\sin2\alpha}{eE}.$

(c) The trajectory of the proton is sketched in Figure 21.77b.

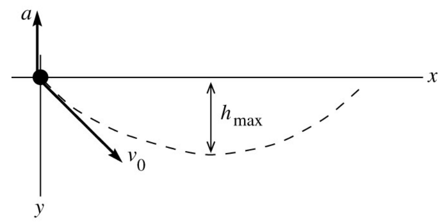

Figure 21.77b

(d) Use the expression in part (a): $h_{max} = \dfrac{[(4.00\times10^5 \text{ m/s})(\sin 30.0°)]^2(1.673\times10^{-27} \text{ kg})}{2(1.602\times10^{-19} \text{ C})(500 \text{ N/C})} = 0.418 \text{ m}.$

Use the expression in part (b): $d = \dfrac{(1.673\times10^{-27} \text{ kg})(4.00\times10^5 \text{ m/s})^2 \sin 60.0°}{(1.602\times10^{-19} \text{ C})(500 \text{ N/C})} = 2.89 \text{ m}.$

EVALUATE: In part (a), $a_y = -eE/m = -4.8\times10^{10} \text{ m/s}^2$. This is much larger in magnitude than g, the acceleration due to gravity, so it is reasonable to ignore gravity. The motion is just like projectile motion, except that the acceleration is upward rather than downward and has a much different magnitude. h_{max} and d increase when α or v_0 increase and decrease when E increases.

21.78. **IDENTIFY:** The electric field is vertically downward and the charged object is deflected downward, so it must be positively charged. While the object is between the plates, it is accelerated downward by the electric field. Once it is past the plates, it moves downward with a constant vertical velocity which is the same downward velocity it acquired while between the plates. Its horizontal velocity remains constant at v_0 throughout its motion. The forces on the object are all constant, so its acceleration is constant; therefore we can use the standard kinematics equations. Newton's second law applies to the object.

SET UP: Call the x-axis positive to the right and the y-axis positive downward. The equations $\vec{E} = \dfrac{\vec{F}_0}{q_0}$, $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$, $v_y = v_{0y} + a_y t$, $x = v_x t$, and $\Sigma F_y = ma_y$ all apply. $v_x = v_0$ = constant.

EXECUTE: *Time through the plates:* $t = x/v_x = x/v_0$ = (0.260 m)/(5000 m/s) = 5.20×10^{-5} s.

Vertical deflection between the plates: $\Delta y_1 = y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = \frac{1}{2}a_y t^2 = \frac{1}{2}(qE/m)t^2$

$\Delta y_1 = \frac{1}{2}(800 \text{ N/C})(5.20 \times10^{-5} \text{ s})^2(q/m) = (1.0816 \times10^{-6} \text{ kg}\cdot\text{m/C})(q/m).$

v_y as the object just emerges from the plates:
$v_y = v_{0y} + a_y t = (qE/m)t = (q/m)(800 \text{ N/C})(5.20 \times10^{-5} \text{ s}) = (0.04160 \text{ kg}\cdot\text{m/C}\cdot\text{s})(q/m)$. (This is the initial vertical velocity for the next step.)
Time to travel 56.0 cm: $t = x/v_x$ = (0.560 m)/(5000 m/s) = 1.120×10^{-4} s.
Vertical deflection after leaving the plates:
$\Delta y_2 = v_{0y}t = (0.04160 \text{ kg}\cdot\text{m/C}\cdot\text{s})(q/m)(1.120 \times10^{-4} \text{ s}) = (4.6592 \times10^{-6} \text{ kg}\cdot\text{m/C})(q/m).$
Total vertical deflection:
$d = \Delta y_1 + \Delta y_2$.
1.25 cm = 0.0125 m = $(1.0816 \times10^{-6} \text{ kg}\cdot\text{m/C})(q/m) + (4.6592 \times10^{-6} \text{ kg}\cdot\text{m/C})(q/m)$.
q/m = 2180 C/kg.
EVALUATE: The charge on 1.0 kg is so huge that it could not be dealt with in a laboratory. But this is a tiny object, more likely with a mass in the range of 1.0 μg, so its charge would be (2180 C/kg)(10^{-9} kg) = 2.18×10^{-6} C ≈ 2 μC. That amount of charge could be used in an experiment.

21.79. **IDENTIFY:** Divide the charge distribution into infinitesimal segments of length dx'. Calculate E_x and E_y due to a segment and integrate to find the total field.

SET UP: The charge dQ of a segment of length dx' is $dQ = (Q/a)dx'$. The distance between a segment at x' and a point at x on the x-axis is $x - x'$ since $x > a$.

EXECUTE: **(a)** $dE_x = \dfrac{1}{4\pi\epsilon_0}\dfrac{dQ}{(x-x')^2} = \dfrac{1}{4\pi\epsilon_0}\dfrac{(Q/a)dx'}{(x-x')^2}$. Integrating with respect to x' over the length of the charge distribution gives

$$E_x = \frac{1}{4\pi\epsilon_0}\int_0^a \frac{(Q/a)dx'}{(x-x')^2} = \frac{1}{4\pi\epsilon_0}\frac{Q}{a}\left(\frac{1}{x-a}-\frac{1}{x}\right) = \frac{1}{4\pi\epsilon_0}\frac{Q}{a}\frac{a}{x(x-a)} = \frac{1}{4\pi\epsilon_0}\frac{Q}{x(x-a)}.\ Ey = 0.$$

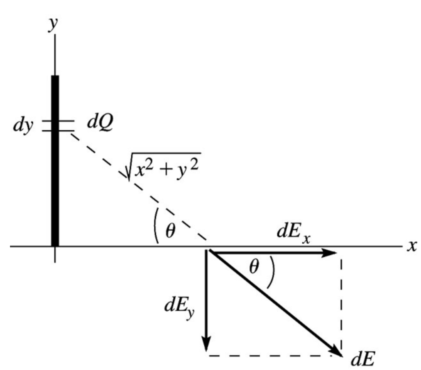
(b) At the location of the charge, $x = r + a$, so $E_x = \dfrac{1}{4\pi\epsilon_0}\dfrac{Q}{(r+a)(r+a-a)} = \dfrac{1}{4\pi\epsilon_0}\dfrac{Q}{r(r+a)}$.

Using $\vec{F} = q\vec{E}$, we have $\vec{F} = q\vec{E} = \dfrac{1}{4\pi\epsilon_0}\dfrac{qQ}{r(r+a)}\hat{\boldsymbol{i}}$.

EVALUATE: **(c)** For $r \gg a$, $r + a \to r$, so the magnitude of the force becomes $F = \dfrac{1}{4\pi\epsilon_0}\dfrac{qQ}{r^2}$. The charge distribution looks like a point charge from far away, so the force takes the form of the force between a pair of point charges.

21.80. **IDENTIFY:** Use $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$ to calculate the electric field due to a small slice of the line of charge and integrate as in Example 21.10. Use $\vec{E} = \dfrac{\vec{F}}{q_0}$ to calculate $\vec{F}$.

SET UP: The electric field due to an infinitesimal segment of the line of charge is sketched in Figure 21.80.



$$\sin\theta = \frac{y}{\sqrt{x^2+y^2}}.$$

$$\cos\theta = \frac{x}{\sqrt{x^2+y^2}}.$$

Figure 21.80

Slice the charge distribution up into small pieces of length dy. The charge dQ in each slice is $dQ = Q(dy/a)$. The electric field this produces at a distance x along the x-axis is dE. Calculate the components of $d\vec{E}$ and then integrate over the charge distribution to find the components of the total field.

EXECUTE: $dE = \dfrac{1}{4\pi\epsilon_0}\left(\dfrac{dQ}{x^2+y^2}\right) = \dfrac{Q}{4\pi\epsilon_0 a}\left(\dfrac{dy}{x^2+y^2}\right)$.

$$dE_x = dE\cos\theta = \frac{Qx}{4\pi\epsilon_0 a}\left(\frac{dy}{(x^2+y^2)^{3/2}}\right).$$

$$dE_y = -dE\sin\theta = -\frac{Q}{4\pi\epsilon_0 a}\left(\frac{ydy}{(x^2+y^2)^{3/2}}\right).$$

$$E_x = \int dE_x = -\frac{Qx}{4\pi\epsilon_0 a}\int_0^a \frac{dy}{(x^2+y^2)^{3/2}} = \frac{Qx}{4\pi\epsilon_0 a}\left[\frac{1}{x^2}\frac{y}{\sqrt{x^2+y^2}}\right]_0^a = \frac{Q}{4\pi\epsilon_0 x}\frac{1}{\sqrt{x^2+a^2}}.$$

$$E_y = \int dEy = -\frac{Q}{4\pi\epsilon_0 a}\int_0^a \frac{ydy}{(x^2+y^2)^{3/2}} = -\frac{Q}{4\pi\epsilon_0 a}\left[-\frac{1}{\sqrt{x^2+y^2}}\right]_0^a = -\frac{Q}{4\pi\epsilon_0 a}\left(\frac{1}{x}-\frac{1}{\sqrt{x^2+a^2}}\right).$$

(b) $\vec{F} = q_0\vec{E}$.

$$F_x = -qE_x = \frac{-qQ}{4\pi\epsilon_0 x}\frac{1}{\sqrt{x^2+a^2}};\ F_y = -qE_y = \frac{qQ}{4\pi\epsilon_0 a}\left(\frac{1}{x}-\frac{1}{\sqrt{x^2+a^2}}\right).$$

(c) For $x \gg a$, $\frac{1}{\sqrt{x^2+a^2}} = \frac{1}{x}\left(1+\frac{a^2}{x^2}\right)^{-1/2} = \frac{1}{x}\left(1-\frac{a^2}{2x^2}\right) = \frac{1}{x}-\frac{a^2}{2x^3}.$

$$F_x \approx -\frac{qQ}{4\pi\epsilon_0 x^2},\ F_y \approx \frac{qQ}{4\pi\epsilon_0 a}\left(\frac{1}{x}-\frac{1}{x}+\frac{a^2}{2x^3}\right) = \frac{qQa}{8\pi\epsilon_0 x^3}.$$

Evaluate: For $x \gg a$, $F_y \ll F_x$ and $F \approx |F_x| = \frac{qQ}{4\pi\epsilon_0 x^2}$ and $\vec{F}$ is in the $-x$-direction. For $x \gg a$ the charge distribution Q acts like a point charge.

21.81. Identify: Apply $E = \frac{\sigma}{2\epsilon_0}[1-(R^2/x^2+1)^{-1/2}]$.

Set Up: $\sigma = Q/A = Q/\pi R^2$. $(1+y^2)^{-1/2} \approx 1-y^2/2$, when $y^2 \ll 1$.

Execute: **(a)** $E = \frac{\sigma}{2\epsilon_0}[1-(R^2/x^2+1)^{-1/2}]$ gives

$$E = \frac{7.00\ \text{pC}/\pi(0.025\ \text{m})^2}{2\epsilon_0}\left[1-\left(\frac{(0.025\ \text{m})^2}{(0.200\ \text{m})^2}+1\right)^{-1/2}\right] = 1.56\ \text{N/C},\ \text{in the } +x\text{-direction.}$$

(b) For $x \gg R$, $E = \frac{\sigma}{2\epsilon_0}[1-(1-R^2/2x^2+\cdots)] \approx \frac{\sigma}{2\epsilon_0}\frac{R^2}{2x^2} = \frac{\sigma\pi R^2}{4\pi\epsilon_0 x^2} = \frac{Q}{4\pi\epsilon_0 x^2}.$

(c) The electric field of (a) is less than that of the point charge (0.90 N/C) since the first correction term to the point charge result is negative.

(d) For $x = 0.200$ m, the percent difference is $\frac{(1.58-1.56)}{1.56} = 0.01 = 1\%$. For $x = 0.100$ m,

$E_{\text{disk}} = 6.00$ N/C and $E_{\text{point}} = 6.30$ N/C, so the percent difference is $\frac{(6.30-6.00)}{6.30} = 0.047 \approx 5\%$.

Evaluate: The field of a disk becomes closer to the field of a point charge as the distance from the disk increases. At $x = 10.0$ cm, $R/x = 25\%$ and the percent difference between the field of the disk and the field of a point charge is 5%.

21.82. Identify: Apply $\sum F_x = 0$ and $\sum F_y = 0$ to the sphere, with x horizontal and y vertical.

Set Up: The free-body diagram for the sphere is given in Figure 21.82. The electric field $\vec{E}$ of the sheet is directed away from the sheet and has magnitude $E = \frac{\sigma}{2\epsilon_0}$.

EXECUTE: $\sum F_y = 0$ gives $T\cos\alpha = mg$ and $T = \dfrac{mg}{\cos\alpha}$. $\sum F_x = 0$ gives $T\sin\alpha = \dfrac{q\sigma}{2\epsilon_0}$ and

$T = \dfrac{q\sigma}{2\epsilon_0 \sin\alpha}$. Combining these two equations we have $\dfrac{mg}{\cos\alpha} = \dfrac{q\sigma}{2\epsilon_0\sin\alpha}$ and $\tan\alpha = \dfrac{q\sigma}{2\epsilon_0 mg}$.

Therefore, $\alpha = \arctan\left(\dfrac{q\sigma}{2\epsilon_0 mg}\right)$.

EVALUATE: The electric field of the sheet, and hence the force it exerts on the sphere, is independent of the distance of the sphere from the sheet.

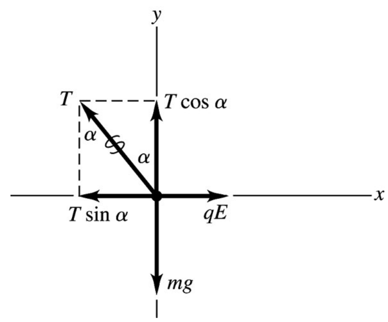


Figure 21.82

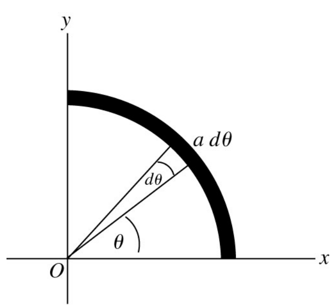
21.83. IDENTIFY: Divide the charge distribution into small segments, use the point charge formula for the electric field due to each small segment and integrate over the charge distribution to find the *x*- and *y*-components of the total field.

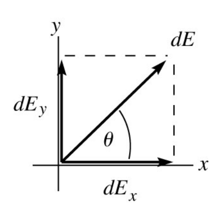
SET UP: Consider the small segment shown in Figure 21.83a.



EXECUTE: A small segment that subtends angle $d\theta$ has length $a\,d\theta$ and contains charge $dQ = \left(\dfrac{a d\theta}{\frac{1}{2}\pi a}\right)Q = \dfrac{2Q}{\pi}d\theta$. ($\frac{1}{2}\pi a$ is the total length of the charge distribution.)

Figure 21.83a

The charge is negative, so the field at the origin is directed toward the small segment. The small segment is located at angle θ as shown in the sketch. The electric field due to dQ is shown in Figure 21.83b, along with its components.



$$dE = \frac{1}{4\pi\epsilon_0}\frac{|dQ|}{a^2}.$$

$$dE = \frac{Q}{2\pi^2\epsilon_0 a^2}d\theta.$$

Figure 21.83b

$dE_x = dE\cos\theta = (Q/2\pi^2 \epsilon_0 a^2)\cos\theta d\theta.$

$E_x = \int dE_x = \dfrac{Q}{2\pi^2 \epsilon_0 a^2}\int_0^{\pi/2}\cos\theta d\theta = \dfrac{Q}{2\pi^2 \epsilon_0 a^2}(\sin\theta\Big|_0^{\pi/2}) = \dfrac{Q}{2\pi^2 \epsilon_0 a^2}.$

$dE_y = dE\sin\theta = (Q/2\pi^2 \epsilon_0 a^2)\sin\theta d\theta.$

$E_y = \int dE_y = \dfrac{Q}{2\pi^2 \epsilon_0 a^2}\int_0^{\pi/2}\sin\theta d\theta = \dfrac{Q}{2\pi^2 \epsilon_0 a^2}(-\cos\theta\Big|_0^{\pi/2}) = \dfrac{Q}{2\pi^2 \epsilon_0 a^2}.$

EVALUATE: Note that $E_x = E_y$, as expected from symmetry.

21.84. IDENTIFY: We must add the electric field components of the positive half and the negative half.

SET UP: From Problem 21.83, the electric field due to the quarter-circle section of positive charge has components $E_x = +\dfrac{Q}{2\pi^2 \epsilon_0 a^2}$, $E_y = -\dfrac{Q}{2\pi^2 \epsilon_0 a^2}$. The field due to the quarter-circle section of negative charge has components $E_x = +\dfrac{Q}{2\pi^2 \epsilon_0 a^2}$, $E_y = +\dfrac{Q}{2\pi^2 \epsilon_0 a^2}$.

EXECUTE: The components of the resultant field are the sum of the *x*- and *y*-components of the fields due to each half of the semicircle. The *y*-components cancel, but the *x*-components add, giving

$E_x = +\dfrac{Q}{\pi^2 \epsilon_0 a^2}$, in the $+x$-direction.

EVALUATE: Even though the net charge on the semicircle is zero, the field it produces is *not* zero because of the way the charge is arranged.

21.85. IDENTIFY: Each wire produces an electric field at *P* due to a finite wire. These fields add by vector addition.

SET UP: Each field has magnitude $\dfrac{1}{4\pi\epsilon_0}\dfrac{Q}{x\sqrt{x^2+a^2}}$. The field due to the negative wire points to the left, while the field due to the positive wire points downward, making the two fields perpendicular to each other and of equal magnitude. The net field is the vector sum of these two, which is $E_{\text{net}} = 2E_1\cos 45° = 2\dfrac{1}{4\pi\epsilon_0}\dfrac{Q}{x\sqrt{x^2+a^2}}\cos 45°$. In part (b), the electrical force on an electron at *P* is *eE*.

EXECUTE: **(a)** The net field is $E_{\text{net}} = 2\dfrac{1}{4\pi\epsilon_0}\dfrac{Q}{x\sqrt{x^2+a^2}}\cos 45°.$

$$E_{\text{net}} = \frac{2(9.00\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(2.50\times10^{-6}\ \text{C})\cos 45°}{(0.600\ \text{m})\sqrt{(0.600\ \text{m})^2+(0.600\ \text{m})^2}} = 6.25\times10^4\ \text{N/C}.$$

The direction is 225° counterclockwise from an axis pointing to the right at point *P*.

(b) $F = eE = (1.60\times10^{-19}\ \text{C})(6.25\times10^4\ \text{N/C}) = 1.00\times10^{-14}\ \text{N}$, opposite to the direction of the electric field, since the electron has negative charge.

EVALUATE: Since the electric fields due to the two wires have equal magnitudes and are perpendicular to each other, we only have to calculate one of them in the solution.

21.86. IDENTIFY: Each sheet produces an electric field that is independent of the distance from the sheet. The net field is the vector sum of the two fields.

SET UP: The formula for each field is $E = \sigma/2\epsilon_0$, and the net field is the vector sum of these, $E_{\text{net}} = \dfrac{\sigma_B}{2\epsilon_0} \pm \dfrac{\sigma_A}{2\epsilon_0} = \dfrac{\sigma_B \pm \sigma_A}{2\epsilon_0}$, where we use the $+$ or $-$ sign depending on whether the fields are in the same or opposite directions and σ_B and σ_A are the magnitudes of the surface charges.

EXECUTE: **(a)** The two fields oppose and the field of *B* is stronger than that of *A*, so

$$E_{\text{net}}=\frac{\sigma_B}{2\epsilon_0}-\frac{\sigma_A}{2\epsilon_0}=\frac{\sigma_B-\sigma_A}{2\epsilon_0}=\frac{11.6\ \mu\text{C/m}^2-8.80\ \mu\text{C/m}^2}{2(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)}=1.58\times10^5\ \text{N/C},\ \text{to the right.}$$

(b) The fields are now in the same direction, so their magnitudes add.

$$E_{\text{net}}=\ (11.6\ \mu\text{C/m}^2+8.80\ \mu\text{C/m}^2)/2\epsilon_0=1.15\times10^6\ \text{N/C},\ \text{to the right.}$$

(c) The fields add but now point to the left, so $E_{\text{net}}=1.15\times10^6$ N/C, to the left.

EVALUATE: We can simplify the calculations by sketching the fields and doing an algebraic solution first.

21.87. **IDENTIFY:** Apply the formula for the electric field of a disk. The hole can be described by adding a disk of charge density $-\sigma$ and radius R_1 to a solid disk of charge density $+\sigma$ and radius R_2.

SET UP: The area of the annulus is $\pi(R_2^2-R_1^2)\sigma$. The electric field of a disk is

$$E=\frac{\sigma}{2\epsilon_0}\left[1-1/\sqrt{(R/x)^2+1}\right].$$

EXECUTE: **(a)** $Q=A\sigma=\pi(R_2^2-R_1^2)\sigma.$

(b) $\vec{\boldsymbol{E}}(x)=\dfrac{\sigma}{2\epsilon_0}\left(\left[1-1/\sqrt{(R_2/x)^2+1}\right]-\left[1-1/\sqrt{(R_1/x)^2+1}\right]\right)\dfrac{|x|}{x}\hat{\boldsymbol{i}}.$

$\vec{\boldsymbol{E}}(x)=\dfrac{\sigma}{2\epsilon_0}\left(1/\sqrt{(R_1/x)^2+1}-1/\sqrt{(R_2/x)^2+1}\right)\dfrac{|x|}{x}\hat{\boldsymbol{i}}.$ The electric field is in the $+x$-direction at points

above

the disk and in the $-x$-direction at points below the disk, and the factor $\dfrac{|x|}{x}\hat{\boldsymbol{i}}$ specifies these directions.

(c) Note that $1/\sqrt{(R_1/x)^2+1}=\dfrac{|x|}{R_1}(1+(x/R_1)^2)^{-1/2}\approx\dfrac{|x|}{R_1}.$ This gives

$\vec{\boldsymbol{E}}(x)=\dfrac{\sigma}{2\epsilon_0}\left(\dfrac{1}{R_1}-\dfrac{1}{R_2}\right)\dfrac{|x|^2}{x}\hat{\boldsymbol{i}}=\dfrac{\sigma}{2\epsilon_0}\left(\dfrac{1}{R_1}-\dfrac{1}{R_2}\right)x\hat{\boldsymbol{i}}.$ Sufficiently close means that $(x/R_1)^2\ll 1.$

(d) $F_x=-qE_x=-\dfrac{q\sigma}{2\epsilon_0}\left(\dfrac{1}{R_1}-\dfrac{1}{R_2}\right)x.$ The force is in the form of Hooke's law: $F_x=-kx,$ with

$$k=\frac{q\sigma}{2\epsilon_0}\left(\frac{1}{R_1}-\frac{1}{R_2}\right).\quad f=\frac{1}{2\pi}\sqrt{\frac{k}{m}}=\frac{1}{2\pi}\sqrt{\frac{q\sigma}{2\epsilon_0 m}\left(\frac{1}{R_1}-\frac{1}{R_2}\right)}.$$

EVALUATE: The frequency is independent of the initial position of the particle, so long as this position is sufficiently close to the center of the annulus for $(x/R_1)^2$ to be small.

21.88. **IDENTIFY:** Apply constant acceleration equations to a drop to find the acceleration. Then use $F=ma$ to find the force and $F=|q|E$ to find $|q|$.

SET UP: Let $D=2.0$ cm be the horizontal distance the drop travels and $d=0.30$ mm be its vertical displacement. Let $+x$ be horizontal and in the direction from the nozzle toward the paper and let $+y$ be vertical, in the direction of the deflection of the drop. $a_x=0$ and call $a_y=a.$

EXECUTE: **(a)** Find the time of flight: $t=D/v=(0.020\ \text{m})/(50\ \text{m/s})=4.00\times10^{-4}$ s. $d=\dfrac{1}{2}at^2.$

$a=\dfrac{2d}{t^2}=\dfrac{2(3.00\times10^{-4}\ \text{m})}{(4.00\times10^{-4}\ \text{s})^2}=3750\ \text{m/s}^2.$ Then $a=F/m=qE/m$ gives

$q=ma/E=\dfrac{(1.4\times10^{-11}\ \text{kg})(3750\ \text{m/s}^2)}{8.00\times10^4\ \text{N/C}}=6.56\times10^{-13}$ C, which rounds to 6.6×10^{-13} s.

(b) Use the equations and calculations above: if $v \rightarrow v/2$, then $t \rightarrow 2t$, so $a \rightarrow a/4$, which means that $q \rightarrow q/4$, so $q = (6.56\times10^{-13}\text{ s})/4 = 1.64\times10^{-13}$ s, which rounds to 1.6×10^{-13} s.

EVALUATE: Since q is positive the vertical deflection is in the direction of the electric field.

21.89 **IDENTIFY:** The net force on the third sphere is the vector sum of the forces due to the other two charges. Coulomb's law gives the forces.

SET UP: $F = k\dfrac{|q_1 q_2|}{r^2}$.

EXECUTE: **(a)** Between the two fixed charges, the electric forces on the third sphere q_3 are in opposite directions and have magnitude 4.50 N in the $+x$-direction. Applying Coulomb's law gives
$4.50\text{ N} = k[q_1(4.00\ \mu\text{C})/(0.200\text{ m})^2 - q_2(4.00\ \mu\text{C})/(0.200\text{ m})^2]$.
Simplifying gives $q_1 - q_2 = 5.00\ \mu$C.
With q_3 at $x = +0.600$ m, the electric forces on q_3 are all in the $+x$-direction and add to 3.50 N. As before, Coulomb's law gives
$3.50\text{ N} = k[q_1(4.00\ \mu\text{C})/(0.600\text{ m})^2 + q_2(4.00\ \mu\text{C})/(0.200\text{ m})^2]$.
Simplifying gives $q_1 + 9q_2 = 35.0\ \mu$C.
Solving the two equations simultaneously gives $q_1 = 8.00\ \mu$C and $q_2 = 3.00\ \mu$C.
(b) Both forces on q_3 are in the $-x$-direction, so their magnitudes add. Factoring out common factors and using the values for q_1 and q_2 we just found, Coulomb's law gives
$F_{\text{net}} = kq_3\,[q_1/(0.200\text{ m})^2 + q_2/(0.600\text{ m})^2]$.
$F_{\text{net}} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\,[(8.00\ \mu\text{C})/(0.200\text{ m})^2 + (3.00\ \mu\text{C})/(0.600\text{ m})^2] = 7.49$ N, and it is in the $-x$-direction.
(c) The forces are in opposite direction and add to zero, so
$0 = kq_1q_3/x^2 - kq_2q_3/(0.400\text{ m} - x)^2$.
$(0.400\text{ m} - x)^2 = (q_2/q_1)x^2$.
Taking square roots of both sides gives
$0.400\text{ m} - x = \pm x\sqrt{q_2/q_1} = \pm 0.6124x$.

Solving for x, we get two values: $x = 0.248$ m and $x = 1.03$ m. The charge q_3 must be between the other two charges for the forces on it to balance. Only the first value is between the two charges, so it is the correct one: $x = 0.248$ m.

EVALUATE: Check the answers in part (a) by substituting these values back into the original equations. $8.00\ \mu\text{C} - 3.00\ \mu\text{C} = 5.00\ \mu$C and $8.00\ \mu\text{C} + 9(3.00\ \mu\text{C}) = 35.0\ \mu$C, so the answers check in both equations. In part (c), the second root, $x = 1.03$ m, has some meaning. The condition we imposed to solve the problem was that the magnitudes of the two forces were equal. This happens at $x = 0.248$ mn, but it also happens at $x = 1.03$ m. However at the second root the forces are both in the $+x$-direction and therefore cannot cancel.

21.90. **IDENTIFY** and **SET UP:** The electric field E_x produced by a uniform ring of charge, for points on an axis perpendicular to the plane of the ring at its center, is $E_x = \dfrac{kQx}{(x^2+a^2)^{3/2}}$, where a is the radius of the ring, x is the distance from its center along the axis, and Q is the total charge on the ring.

EXECUTE: **(a)** Far from the ring, at large values of x, the ring can be considered as a point-charge, so its electric field would be $E = kQ/x^2$. Therefore $Ex^2 = kQ$, which is a constant. From the graph (a) in the problem, we read off that at large distances $Ex^2 = 45\ \text{N}\cdot\text{m}^2/\text{C}$, which is equal to kQ, so we have
$Q = (45\ \text{N}\cdot\text{m}^2/\text{C})/k = 5.0\times10^{-9}\text{ C} = 5.0$ nC.

(b) The electric field along the axis a distance x from the ring is $E_x = \dfrac{kQx}{(x^2+a^2)^{3/2}}$. Very close to the ring, $x^2 << a^2$, so the formula becomes $Ex = kQx/a^3$. Therefore $E/x = kQ/a^3$, which is a constant. From graph (b) in the problem, E/x approaches 700 N/C·m as x approaches zero. So $kQ/a^3 = 700$ N/C·m, which gives

$a = [kQ/(700\ \text{N/C}\cdot\text{m})]^{1/3} = [(45\ \text{N}\cdot\text{m}^2/\text{C})/(700\ \text{N/C}\cdot\text{m})]^{1/3} = 0.40\ \text{m} = 40\ \text{cm}.$

EVALUATE: It is physically reasonable that a ring 40 cm in radius could carry 5.0 nC of charge.

21.91. **IDENTIFY:** An infinite positively charged sheet has a round hole cut in it. A particle with mass m and charge $-q$ is dropped from the center of the hole and falls. The net force on it is the electric force upward and gravity downward.

SET UP and EXECUTE: **(a)** We can think of the sheet with the hole as a combination of an infinite positive sheet and a negative disk of radius R, both having the same magnitude charge density σ, so the net field E_z is $E_z = E_{\text{sheet}} + E_{\text{disk}}$. Calling $+z$ upward, the net field a distance Δ below the center of the hole is $E_z = -\dfrac{\sigma}{2\epsilon_0} + \dfrac{\sigma}{2\epsilon_0}\left[1 - \dfrac{1}{\sqrt{1+(R/\Delta)^2}}\right] = -\dfrac{\sigma}{2\epsilon_0}\left[\dfrac{1}{\sqrt{1+(R/\Delta)^2}}\right]$, and it points downward.

(b) As the particle falls the net electric field *increases* because the field of the negative hole decreases while that of the positive sheet increases. The maximum field occurs very far from the hole, and that field is just due to the sheet, which is $E_z = -\dfrac{\sigma}{2\epsilon_0}$. The maximum mass for which the particle will not fall indefinitely is given by $F_{\text{el}} = m_{\text{max}}g$, so $qE_z = m_{\text{max}}g$, and $\dfrac{q\sigma}{2\epsilon_0} = m_{\text{max}}g$. Thus $m_{\text{max}} = \dfrac{q\sigma}{2g\epsilon_0}$.

(c) We want the work done by the electric field as the particle drops from $z = 0$ to $z = -\Delta$ if $m < m_{\text{max}}$. The force on the particle is upward but its displacement is downward, so the work is negative. Therefore $W_{\text{E}} = -\int qE_z dz = -\int_0^{-\Delta} \dfrac{q\sigma}{2\epsilon_0\sqrt{1+(R/z)^2}}dz = -\dfrac{q\sigma}{2\epsilon_0}\int_0^{-\Delta}\dfrac{zdz}{\sqrt{z^2+R^2}}$. The integration can be done using tables or by letting $u = z^2 + R^2$ and $du = 2zdz$. Either way, the result is

$W_{\text{E}} = -\dfrac{q\sigma}{2\epsilon_0}\sqrt{z^2+R^2}\Big|_0^{-\Delta} = -\dfrac{q\sigma}{2\epsilon_0}\left(\sqrt{\Delta^2+R^2} - R\right).$

(d) Gravity is constant, so $W_{\text{g}} = +mg\Delta$.

(e) We want the depth to which the particle will fall. The work-energy theorem $W_{\text{tot}} = K_2 - K_1$ gives $W_{\text{g}} + W_{\text{E}} = K_2 - K_1$. $K_1 = 0$, so we have $mg\Delta - \dfrac{q\sigma}{2\epsilon_0}\left(\sqrt{\Delta^2+R^2} - R\right) = \dfrac{1}{2}mv^2$. At the maximum depth the particle remains at rest, so solve this result for Δ when $v = 0$ and call the result Δ_{max}. Doing so we have $mg\Delta - \dfrac{q\sigma}{2\epsilon_0}\left(\sqrt{\Delta^2+R^2} - R\right) = 0$. So $\Delta_{\text{max}} = \dfrac{mgq\sigma R}{\epsilon_0\left[(q\sigma/2\epsilon_0)^2 - (mg)^2\right]}$. Finally we express this result in terms of $\alpha = m/m_{\text{max}}$. Using $m_{\text{max}}g = \dfrac{q\sigma}{2\epsilon_0}$ gives $\alpha = \dfrac{m}{\dfrac{q\sigma}{2g\epsilon_0}} = \dfrac{2g\epsilon_0 m}{q\sigma}$. Thus $mg = \dfrac{q\sigma\alpha}{2\epsilon_0}$.

Putting this into our result for Δ_{max} gives $\Delta_{\text{max}} = \dfrac{mgq\sigma R}{\epsilon_0\left[(mg/\alpha)^2 - (mg)^2\right]}$. Substituting $mg = \dfrac{q\sigma\alpha}{2\epsilon_0}$ and simplifying gives $\Delta_{\text{max}} = \dfrac{2R\alpha}{1-\alpha^2}$.

(f) We want to find v as a function of Δ if $\Delta < \Delta_{\text{max}}$. Solve $mg\Delta - \dfrac{q\sigma}{2\epsilon_0}\left(\sqrt{\Delta^2 + R^2} - R\right) = \dfrac{1}{2}mv^2$ for v.

Using $m_{\text{max}}g = \dfrac{q\sigma}{2\epsilon_0}$ gives $mg\Delta - m_{\text{max}}g\left(\sqrt{\Delta^2 + R^2} - R\right) = \dfrac{1}{2}mv^2$. Dividing by m and using

$\alpha = m/m_{\text{max}}$ gives $v^2 = 2g\Delta - \dfrac{2g}{\alpha}\left(\sqrt{\Delta^2 + R^2} - R\right)$, so $v = \sqrt{2g\left(\Delta - \dfrac{\sqrt{\Delta^2 + R^2} - R}{\alpha}\right)}$.

(g) We want m_{max} and Δ_{max}. Using the given quantities, with $\sigma = 1.00\ \text{nC/cm}^2 = 1.00\times10^{-5}\ \text{C/m}^2$, the results from parts (b) and (e) give $m_{\text{max}} = 57.7$ g and $\Delta_{\text{max}} = 10.7$ cm.

EVALUATE: It may seem strange that the electric field gets *stronger* as we get farther from the sheet. But the closer we get to the sheet, the greater the effect of the hole. As we get farther from the sheet the effect of the hole diminishes.

21.92. IDENTIFY: The charges at the ends of the stationary rod exert electric forces on the charges at the ends of the second rod that is free to rotate. These forces produce torques, which cause the second rod to spin about its center.

SET UP: The magnitude of the electric force is $F = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_1q_2|}{r^2}$.

EXECUTE: (a) We want the force $\vec{F}_1$ on the upper right charge of the movable rod due to the charge on the left side of the fixed rod. Fig. 21.92a shows this arrangement and the force $\vec{F}_1$. Use the law of cosines to find the distance r_1. $r_1^2 = (L/2)^2 + (L/2)^2 - 2(L/2)^2\cos(180° - \theta)$. This gives

$r_1^2 = (L^2/2)(1+\cos\theta)$, so $F_1 = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_1q_2|}{r^2} = \dfrac{1}{4\pi\epsilon_0}\dfrac{Q^2}{(L^2/2)(1+\cos\theta)} = \dfrac{2}{4\pi\epsilon_0}\dfrac{Q^2}{L^2(1+\cos\theta)}$. Using Fig. 21.92c, we see that the components of $\vec{F}_1$ are $F_{1x} = F_1\cos\phi = F_1\cos(\theta/2)$ and

$F_{1y} = F_1\sin\phi = F_1\sin(\theta/2)$. Therefore $\vec{F}_1 = \dfrac{Q^2}{2\pi\epsilon_0 L^2(1+\cos\theta)}\left[\cos(\theta/2)\hat{\boldsymbol{i}} + \sin(\theta/2)\hat{\boldsymbol{j}}\right]$.

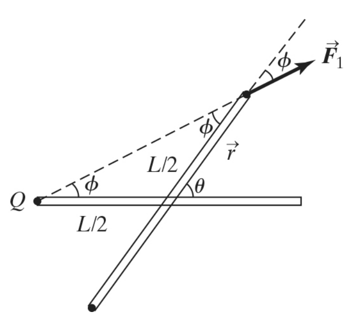


Figure 21.92a

(b) We want the force $\vec{F}_2$ on the upper right charge of the movable rod due to the charge on the right side of the fixed rod. Fig. 21.92b shows this arrangement and for force $\vec{F}_2$. The law of cosines gives r_2:

$r_2^2 = (L/2)^2 + (L/2)^2 - 2(L/2)^2\cos\theta = (L^2/2)(1-\cos\theta)$. Coulomb's law gives $F_2 = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_1q_2|}{r^2}$

$= \dfrac{1}{4\pi\epsilon_0}\dfrac{Q^2}{(L^2/2)(1-\cos\theta)} = \dfrac{2}{4\pi\epsilon_0}\dfrac{Q^2}{L^2(1-\cos\theta)}$. Using Fig. 21.92d, we see that $2\phi + \theta = 180°$, so

$\phi = 180° - \theta/2$. Therefore the components of $\vec{F}_2$ are

$F_{2x} = -F_2 \cos\phi = -F_2 \cos(90° - \theta/2) = -F_2 \sin(\theta/2)$ and

$F_{2y} = F_2 \sin\phi = -F_2 \sin(90° - \theta/2) = F_2 \cos(\theta/2)$. In vector form, the force is

$$\vec{F}_2 = \frac{Q^2}{2\pi\epsilon_0 L^2(1-\cos\theta)}\left[-\sin(\theta/2)\hat{\boldsymbol{i}} + \cos(\theta/2)\hat{\boldsymbol{j}}\right].$$

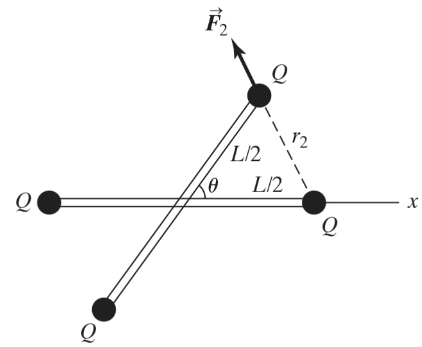

Figure 21.92b

(c) We want the torque due to $\vec{F}_1$. Use $\tau = rF\sin\phi$ for the quantities shown in Fig. 21.92c. $r = L/2$ and extends from the center of the rods to the upper end of the movable rod. From the triangle in the figure, we see that $2\phi + (180° - \theta) = 180°$, so $\phi = \theta/2$. Using $\tau = rF\sin\phi$, we have

$$\tau_1 = \frac{L}{2}\left(\frac{2}{4\pi\epsilon_0}\frac{Q^2}{L^2(1+\cos\theta)}\right)\sin(\theta/2) = \frac{1}{4\pi\epsilon_0}\frac{Q^2\sin(\theta/2)}{L(1+\cos\theta)}, \text{ clockwise.}$$

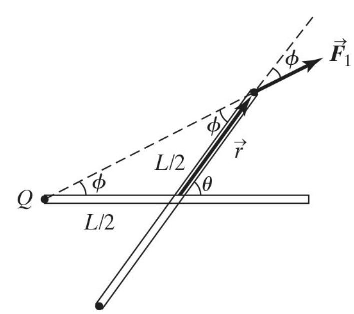

Figure 21.92c

(d) We want the torque due to $\vec{F}_2$. See Fig. 21.92d for the geometry. As in part (c), use $\tau = rF\sin\phi$, where $r = L/2$. From the figure, we see that $2\phi + \theta = 180°$, so $\phi = (180° - \theta)/2 = 90° - \theta/2$. So

$\sin\phi = \cos(\theta/2)$. The torque is $\tau_2 = \dfrac{L}{2}\left(\dfrac{2}{4\pi\epsilon_0}\dfrac{Q^2}{L^2(1-\cos\theta)}\right)\cos(\theta/2) = \dfrac{1}{4\pi\epsilon_0}\dfrac{Q^2\cos(\theta/2)}{L(1-\cos\theta)}$,

counterclockwise.

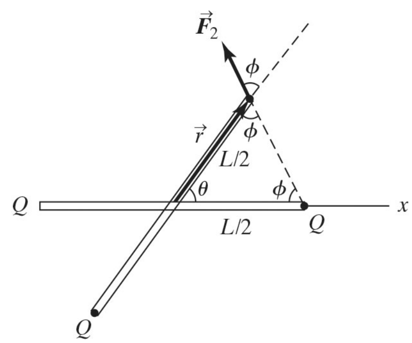

Figure 21.92d

(e) Torque τ_3 is on the lower charge of the movable rod due to the left charge on the fixed rod. This torque is the same as τ_2 and is also counterclockwise, so $\tau_3 = \tau_2$. Torque τ_4 is on the lower charge of the movable rod due to the right charge on the fixed rod. This torque is the same as τ_1 and is also clockwise, so $\tau_4 = \tau_1$. Calling counterclockwise positive, the total torque is

$\tau_{\text{tot}} = -\tau_1 + \tau_2 + \tau_3 - \tau_4 = 2\tau_2 - 2\tau_1 = 2(\tau_2 - \tau_1)$.

$$\tau_{\text{tot}} = 2\left[\frac{1}{4\pi\epsilon_0}\frac{Q^2\cos(\theta/2)}{L(1-\cos\theta)} - \frac{1}{4\pi\epsilon_0}\frac{Q^2\sin(\theta/2)}{L(1+\cos\theta)}\right] = \frac{Q^2}{2\pi\epsilon_0 L}\left[\frac{\cos(\theta/2)}{1-\cos\theta} - \frac{\sin(\theta/2)}{1+\cos\theta}\right].$$

(f) We want the net torque for small angular displacements from the equilibrium position of $\theta = \pi/2$ rad. Letting $\theta = \frac{\pi}{2} - \epsilon$, where $\epsilon \ll 1$ rad, we use $\tau_{\text{net}} = \frac{Q^2}{2\pi\epsilon_0 L}\left[\frac{\cos(\theta/2)}{1-\cos\theta} - \frac{\sin(\theta/2)}{1+\cos\theta}\right]$ with $\theta = \frac{\pi}{2} - \epsilon$ and keep only terms with powers lower than ϵ^2. Using the power series in Appendix B we have the following expansions.

$$\cos(\theta/2) \to \cos\left(\frac{\pi/2-\epsilon}{2}\right) = \cos\left(\frac{\pi}{4} - \frac{\epsilon}{2}\right) = \frac{1}{\sqrt{2}}\cos\frac{\epsilon}{2} + \frac{1}{\sqrt{2}}\sin\frac{\epsilon}{2} \approx \frac{1}{\sqrt{2}}\left(1 - \frac{\epsilon^2}{8}\right) + \frac{\epsilon}{2\sqrt{2}}.$$

$$\sin(\theta/2) \to \sin\left(\frac{\pi/2-\epsilon}{2}\right) = \sin\left(\frac{\pi}{4} - \frac{\epsilon}{2}\right) = \frac{1}{\sqrt{2}}\cos\frac{\epsilon}{2} - \frac{1}{\sqrt{2}}\sin\frac{\epsilon}{2} \approx \frac{1}{\sqrt{2}}\left(1 - \frac{\epsilon^2}{8}\right) - \frac{\epsilon}{2\sqrt{2}}.$$

Both denominators are approximately equal to 1 for small $\mathcal{E}$. Using these results for the torque gives $\tau \approx \frac{Q^2}{2\pi\epsilon_0 L}\left\{\frac{1}{\sqrt{2}}\left(1-\frac{\epsilon^2}{8}\right) + \frac{\epsilon}{2\sqrt{2}} - \left[\frac{1}{\sqrt{2}}\left(1-\frac{\epsilon^2}{8}\right) - \frac{\epsilon}{2\sqrt{2}}\right]\right\}$, which reduces to $\tau = \left(\frac{Q^2}{2\sqrt{2}\pi\epsilon_0 L}\right)\epsilon$.

(g) The torque tends to return the rod to the equilibrium position, so Newton's second law for rotation gives $I\frac{d^2\epsilon}{dt^2} = -\tau$. Using our result from part (f) gives $\frac{d^2\epsilon}{dt^2} = -\left(\frac{Q^2}{2\sqrt{2}\pi\epsilon_0 LI}\right)\epsilon$. From this we see that $\omega = \sqrt{\frac{Q^2}{2\sqrt{2}\pi\epsilon_0 LI}}$, so $f = \frac{1}{2\pi}\sqrt{\frac{Q^2}{2\sqrt{2}\pi\epsilon_0 LI}}$. In this result, I is the moment of inertia of the two small balls at the ends of the bar, which is $I = 2M\left(\frac{L}{2}\right)^2 = \frac{ML^2}{2}$. Using this value for I gives

$$f = \frac{Q}{2\pi\sqrt{\pi\sqrt{2}\epsilon_0 ML^3}}.$$

EVALUATE: According to our result in (f), a large Q gives a high frequency while a large M or L gives a low frequency. These results are physically reasonable.

21.93. **IDENTIFY:** Two parallel rods of length L carry equal positive charge Q and are a distance a apart. We want to find the electric force that each one exerts on the other.

SET UP: We break the rods up into infinitesimal segments and integrate to find the total force that one of them exerts on the other. The force that dq_1 exerts on dq_2 is $dF = \dfrac{1}{4\pi\epsilon_0}\dfrac{dq_1 dq_2}{r_{12}^2}$. Fig. 21.93 shows the charge elements.

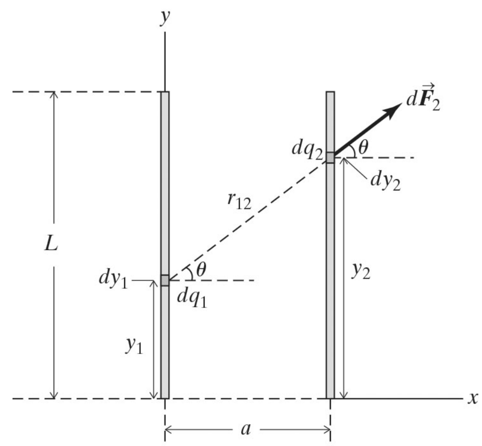

Figure 21.93

EXECUTE: (a) Because both rods have uniform charge distribution, every charge element above the midpoint of rod 1 will have an identical element below the midpoint. So the y components of the force on rod 2 cancel but the x components add.

(b) In light of the answer to part (a), we need only calculate the x components of for force on rod 2. We first find the force that dq_1 exerts on dq_2. Then we integrate over rod 1 to find the *total* force on dq_2 due rod 1. Using the geometry of the figure, we have $dF_{2x} = dF_2\cos\theta = \dfrac{1}{4\pi\epsilon_0}\dfrac{dq_1 dq_2}{r_{12}^2}\cos\theta.$ Using

$dq_1 = \lambda dy_1$, $r_{12}^2 = (y_2 - y_1)^2 + a^2$, and $\cos\theta = \dfrac{a}{r_{12}} = \dfrac{a}{\sqrt{(y_2-y_1)^2+a^2}}$, we have

$dF_{2x} = \left(\dfrac{1}{4\pi\epsilon_0}\displaystyle\int_{y_1=0}^{L}\dfrac{\lambda dy_1\cos\theta}{(y_2-y_1)^2+a^2}\right)dq_2 = \left(\dfrac{\lambda}{4\pi\epsilon_0}\displaystyle\int_{y_1=0}^{L}\dfrac{a\,dy_1}{\left[(y_2-y_1)^2+a^2\right]^{3/2}}\right)dq_2$. The integral can be done by letting $u = y_2 - y_1$, $du = -dy_1$. It is then in the form $\displaystyle\int\dfrac{-du}{(u^2+a^2)^{3/2}} = -\dfrac{1}{a^2}\dfrac{u}{\sqrt{u^2+a^2}}$. Doing this gives us $dF_{2x} = \left(\dfrac{\lambda a}{4\pi\epsilon_0}\right)\left(-\dfrac{1}{a^2}\right)\dfrac{y_2-y_1}{\sqrt{(y_2-y_1)^2+a^2}}\Bigg|_{y_1=0}^{L} dq_2$. Evaluating at the limits and using $dq_2 = \lambda dy_2$ gives $dF_{2x} = \left(-\dfrac{\lambda}{4\pi\epsilon_0\, a}\right)\left[\dfrac{y_2-L}{\sqrt{(y_2-L)^2+a^2}} - \dfrac{y_2}{\sqrt{y_2^2+a^2}}\right]\lambda dy_2$. This result gives us the total x component of the force that rod 1 exerts on dq_2 in rod 2.

(c) We now integrate the result from part (b) over dy_2 to get the total x component of the force F_x on the full length of rod 2. $F_{2x} = \left(-\dfrac{\lambda^2}{4\pi\epsilon_0\, a}\right)\displaystyle\int_0^L\left[\dfrac{y_2-L}{\sqrt{(y_2-L)^2+a^2}} - \dfrac{y_2}{\sqrt{y_2^2+a^2}}\right]dy_2$. We do the integral in two parts. To do the first one, let $u = y_2 - L$, $du = dy_2$, so it becomes $\int \frac{u\,du}{\sqrt{u^2+a^2}} = \sqrt{u^2+a^2}$. Evaluating at the limits, this part of the integral is $a - \sqrt{L^2+a^2}$. The second part of the integral is similar to the first part, and it is equal to $\sqrt{L^2+a^2} - a$. Combining these two results gives $F_{2x} = -\frac{\lambda^2}{4\pi\epsilon_0 a}\left[a - \sqrt{L^2+a^2} - \left(\sqrt{L^2+a^2} - a\right)\right] = \frac{\lambda^2}{2\pi\epsilon_0 a}\left(\sqrt{L^2+a^2} - a\right)$. Using $\lambda = Q/L$ this becomes $F_{2x} = \frac{Q^2}{2\pi\epsilon_0 L^2 a}\left(\sqrt{L^2+a^2} - a\right) = \frac{Q^2}{2\pi\epsilon_0 L^2}\left(\sqrt{(L/a)^2+1} - 1\right)$. The force vector is $\vec{F} = \frac{Q^2}{2\pi\epsilon_0 L^2}\left(\sqrt{(L/a)^2+1} - 1\right)\hat{i}$.

(d) For $a >> L$: Use the result from part (c). $F_{2x} = \frac{Q^2}{2\pi\epsilon_0 L^2}\left(\sqrt{(L/a)^2+1} - 1\right)$. Since $a >> L$, $L/a << 1$, so we can use the approximation $\sqrt{1+x} \approx 1 + x/2$ where $x = (L/a)^2$. Doing so gives $F_{2x} \approx \frac{Q^2}{2\pi\epsilon_0 L^2}\left(1 + \frac{1}{2}(L/a)^2 - 1\right) = \frac{Q^2}{4\pi\epsilon_0 a^2}$, so $\vec{F} \approx \frac{Q^2}{4\pi\epsilon_0 a^2}\hat{i}$. This result is reasonable because the two finite lines behave as point charges if they are far enough away from each other.

(e) $W = \lim_{X\to\infty} \int_X^a F_x dx$. The work we do is the negative of the work done by the electric field. Using F_{2x} from part (c) with x replacing a in the formula, we have $W = -\frac{Q^2}{2\pi\epsilon_0 L^2}\int_X^a \frac{\sqrt{L^2+x^2} - x}{x}dx$.

$W = -\frac{Q^2}{2\pi\epsilon_0 L^2}\int_X^a \left(\frac{\sqrt{L^2+x^2}}{x} - 1\right)dx$. Using tables for the first part of the integral gives

$$W = -\frac{Q^2}{2\pi\epsilon_0 L^2}\left[\sqrt{x^2+L^2} - L\ln\left(\frac{L+\sqrt{x^2+L^2}}{x}\right) - x\right]\Bigg|_X^a$$, which gives

$$W = -\frac{Q^2}{2\pi\epsilon_0 L^2}\left\{\left[\sqrt{a^2+L^2} - L\ln\left(\frac{L+\sqrt{a^2+L^2}}{a}\right) - a\right] - \left[\sqrt{X^2+L^2} - L\ln\left(\frac{L+\sqrt{X^2+L^2}}{X}\right) - X\right]\right\}.$$

Taking the limit as $X \to \infty$ gives $W = \frac{Q^2}{2\pi\epsilon_0 L^2}\left[L\ln\left(\frac{L+\sqrt{a^2+L^2}}{a}\right) + a - \sqrt{a^2+L^2}\right]$.

(f) We want the *relative* speed of the rods when they have moved very far apart, in which case their potential energy is zero. Since the rods have equal masses, they will have equal speeds by conservation of momentum. Therefore $U(x=a) = K(x\to\infty) = K_1 + K_2 = 2K_1 = 2\left(\frac{1}{2}mv^2\right) = mv^2$. We can use the result from part (e). $\frac{Q^2}{2\pi\epsilon_0 L^2}\left[L\ln\left(\frac{L+\sqrt{a^2+L^2}}{a}\right) + a - \sqrt{a^2+L^2}\right] = mv^2$. Solving for v using $Q =$ 10.0 μC, L = 50.0 cm = 0.500 m, m = 500 g = 0.500 kg, a = 10.0 cm = 0.100 m, we get v = 10.735 m/s. This is the speed relative to the earth. The *relative speed* is the speed of one rod relative to the other. Since they are moving away from each other, their *relative* speed is 2(10.735 m/s) = 21.5 m/s.

EVALUATE: Evaluate our result in part (c) if $L \to 0$. For $x << 1$ we can use the approximation $\sqrt{1+x} \approx 1 + x/2$ where $x = (L/a)^2$. Doing so gives $F_{2x} \approx \frac{Q^2}{2\pi\epsilon_0 L^2}\left(1+\frac{1}{2}(L/a)^2 - 1\right) = \frac{Q^2}{4\pi\epsilon_0 a^2}$, so $\vec{F} \approx \frac{Q^2}{4\pi\epsilon_0 a^2}\hat{\boldsymbol{i}}$. This result is reasonable because the two rods behave like point charges if they are extremely short compared to the distance between them, so our result is reasonable. We can also check our result if the rods are extremely long ("infinite"). Using results from the text, we know that in that case $E_1 = \frac{\lambda}{2\pi\epsilon_0 r}$, so the force on rod 2 is $F_2 = E_1 Q_2 = E_1 \lambda L = \left(\frac{\lambda}{2\pi\epsilon_0 a}\right)\lambda L = \frac{\lambda^2 L}{2\pi\epsilon_0 a}$. Therefore the force per unit length on rod 2 is $\frac{F}{L} = \frac{\lambda^2}{2\pi\epsilon_0 a}$. Now look at our result $F = \frac{Q^2}{2\pi\epsilon_0 L^2}\left(\sqrt{(L/a)^2+1} - 1\right)$. $Q = \lambda L$ and for very large L the quantity in parentheses becomes L/a. Therefore the force becomes $F = \frac{(\lambda L)^2}{2\pi\epsilon_0 L^2}(L/a) = \frac{\lambda^2 L}{2\pi\epsilon_0 a}$, so the force per unit length is $\frac{F}{L} = \frac{\lambda^2}{2\pi\epsilon_0 a}$, which is what we just found. Therefore our result checks for very long rods.

21.94. IDENTIFY and SET UP: The electric field exerts a force (and hence a torque) on the charged ball at the end of the rod. This torque is always counterclockwise, so it causes the rod to increase its angular speed as the charged ball passes through the field.

EXECUTE: **(a)** From Fig. 21.94a, $r_x = a\cos\theta$ and $r_y = a\sin\theta$, so $\vec{r} = a\cos\theta\hat{\boldsymbol{i}} + a\sin\theta\hat{\boldsymbol{j}}$.

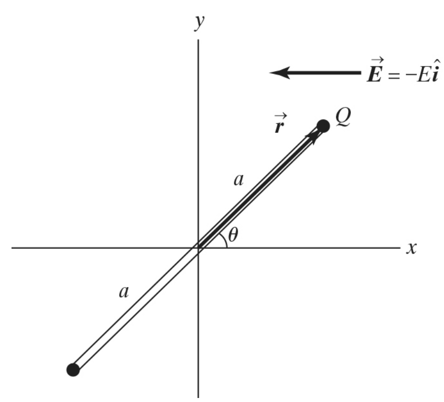

Figure 21.94a

(b) We want the torque on the rod when $0 \le \theta \le \pi$ (see Fig. 21.94b). The magnitude of the torque is $\tau = rF\sin\phi$. From the figure we see that $\phi = \pi - \theta$, so $\sin\phi = \sin(\pi - \theta) = \sin\theta$. $F = QE$ and $r = a$, so $\tau = aQE\sin\theta$. Using $\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{r}} \times \vec{\boldsymbol{F}}$ and the right-hand rule for the vector product, we see that the torque points along the +z-axis, so $\vec{\boldsymbol{\tau}} = aQE\sin\theta\hat{\boldsymbol{k}}$.

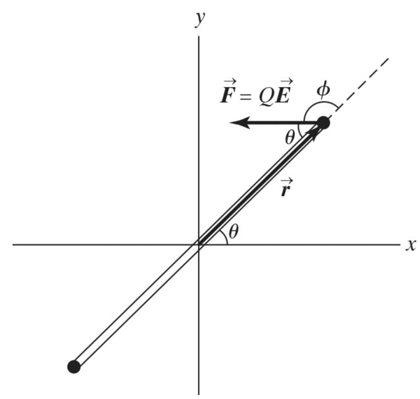

Figure 21.94b

(c) The torque is zero because the electric field is zero.
(d) $I_{\text{balls}} = 2Ma^2$, $I_{\text{rod}} = 0$ since it is very light.
(e) We want to use $\tau = -dU/d\theta$ to find the potential energy $U(\theta)$. Integrating and letting $U_0 = 0$ when $\theta = 0$ gives $U - U_0 = -\int \tau d\theta$.

$\underline{0 \le \theta \le \pi}$: $U - U_0 = U = -\int_0^\theta aQE\sin\theta d\theta = aQE\cos\theta\Big|_0^\theta = aQE(\cos\theta - 1)$.

$\underline{\pi \le \theta \le 2\pi}$: U = constant = $U(\pi) = -2aQE$.

$\underline{2\pi \le \theta \le 3\pi}$: $U - U_0 = -\int_{2\pi}^\theta aQE\sin\theta d\theta = aQE\cos\theta\Big|_{2\pi}^\theta = aQE(\cos\theta - 1)$, which gives $U = aQE(\cos\theta - 1) + (-2aQE) = aQE(\cos\theta - 3)$.

$\underline{3\pi \le \theta \le 4\pi}$: U = constant = $U(3\pi) = -4aQE$.

(f) Calling $\in$ the total energy, we have $\in = \frac{1}{2}I\omega^2 + U(\theta)$. We also know that $\tau = I\alpha = I\frac{d^2\theta}{dt^2} = I\frac{d\omega}{dt}$.

Combining this result with $\tau = -dU/d\theta$ gives $\frac{d\omega}{dt} = -\frac{1}{I}\frac{dU}{d\theta}$. Now look at the energy:

$\frac{d\in}{dt} = I\omega\frac{d\omega}{dt} + \frac{dU}{dt}$. The chain rule gives $\frac{dU}{dt} = \frac{dU}{d\theta}\frac{d\theta}{dt} = \omega\frac{dU}{d\theta}$. Using this and our result for $d\omega/dt$ gives $\frac{d\in}{dt} = I\omega\left(-\frac{1}{I}\frac{dU}{d\theta}\right) + \omega\frac{dU}{d\theta} = -\omega\frac{dU}{d\theta} + \omega\frac{dU}{d\theta} = 0$. Thus the energy is constant and therefore conserved.

(g) We want the angular speed ω at the n^{th} time that Q crosses the $-y$-axis. Doing calculations similar to those in part (e) gives us the following results:
At the first crossing: $\pi \le \theta \le 2\pi$: $U_1 = -2aQE$
At the second crossing: $3\pi \le \theta \le 4\pi$: $U_2 = -4aQE$
At the third crossing: $5\pi \le \theta \le 6\pi$: $U_3 = -6aQE$
At the fourth crossing: $7\pi \le \theta \le 8\pi$: $U_4 = -8aQE$

We can see that the pattern is $U_n = -2naQE$ (n = 1, 2, 3, …). The total energy is $\in = \frac{1}{2}I\omega^2 + U(\theta)$.

Solving for ω gives $\omega = \sqrt{\frac{2(\in - U)}{I}}$. At the n^{th} crossing, we found that $U_n = -2naQE$, so

$\omega_n = \sqrt{\dfrac{2(\epsilon - U_n)}{I}} = \sqrt{\dfrac{2(\epsilon + 2naQE)}{2Ma^2}} = \sqrt{\dfrac{\epsilon + 2naQE}{Ma^2}}$. But $\epsilon = K + U$ and $K_0 = 0$ and $U_0 = 0$, so $\epsilon = 0$.

Therefore $\omega_n = \sqrt{\dfrac{2nQE}{Ma}}$ $(n = 1, 2, 3, \cdots)$.

EVALUATE: The total energy is zero, but that does not mean that the rod stops moving. Remember that the potential energy is negative which cancels out the positive kinetic energy.

21.95. IDENTIFY: Apply Coulomb's law to calculate the forces that q_1 and q_2 exert on q_3, and add these force vectors to get the net force.

SET UP: Like charges repel and unlike charges attract. Let $+x$ be to the right and $+y$ be toward the top of the page.

EXECUTE: **(a)** The four possible force diagrams are sketched in Figure 21.95a.
Only the last picture can result in a net force in the $-x$-direction.

(b) $q_1 = -2.00\ \mu\text{C}, q_3 = +4.00\ \mu\text{C}$, and $q_2 > 0$.

(c) The forces $\vec{F}_1$ and $\vec{F}_2$ and their components are sketched in Figure 21.95b.

$F_y = 0 = -\dfrac{1}{4\pi\epsilon_0}\dfrac{|q_1||q_3|}{(0.0400\text{ m})^2}\sin\theta_1 + \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_2||q_3|}{(0.0300\text{ m})^2}\sin\theta_2$. This gives

$q_2 = \dfrac{9}{16}|q_1|\dfrac{\sin\theta_1}{\sin\theta_2} = \dfrac{9}{16}|q_1|\dfrac{3/5}{4/5} = \dfrac{27}{64}|q_1| = 0.843\ \mu\text{C}.$

(d) $F_x = F_{1x} + F_{2x}$ and $F_y = 0$, so $F = |q_3|\dfrac{1}{4\pi\epsilon_0}\left(\dfrac{|q_1|}{(0.0400\text{ m})^2}\dfrac{4}{5} + \dfrac{|q_2|}{(0.0300\text{ m})^2}\dfrac{3}{5}\right) = 56.2\text{ N}.$

EVALUATE: The net force $\vec{F}$ on q_3 is in the same direction as the resultant electric field at the location of q_3 due to q_1 and q_2.

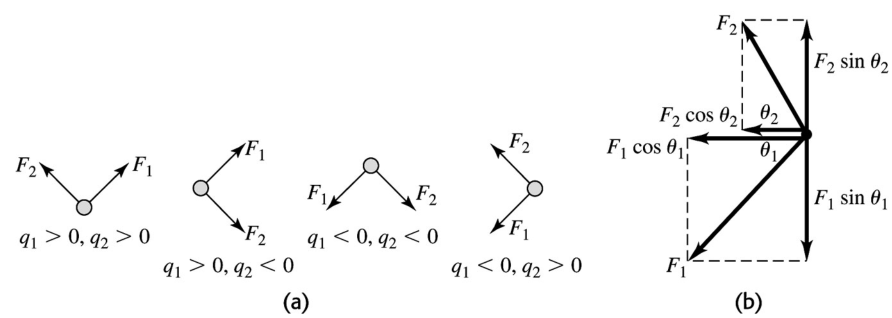

Figure 21.95

21.96. IDENTIFY: Calculate the electric field at *P* due to each charge and add these field vectors to get the net field.

SET UP: The electric field of a point charge is directed away from a positive charge and toward a negative charge. Let $+x$ be to the right and let $+y$ be toward the top of the page.

EXECUTE: **(a)** The four possible diagrams are sketched in Figure 21.96(a).
The first diagram is the only one in which the electric field must point in the negative *y*-direction.

(b) $q_1 = -3.00\ \mu\text{C}$, and $q_2 < 0$.

(c) The electric fields $\vec{E}_1$ and $\vec{E}_2$ and their components are sketched in Figure 21.96(b). $\cos\theta_1 = \dfrac{5}{13}$, $\sin\theta_1 = \dfrac{12}{13}$, $\cos\theta_2 = \dfrac{12}{13}$ and $\sin\theta_2 = \dfrac{5}{13}$. $E_x = 0 = -\dfrac{k|q_1|}{(0.050\text{ m})^2}\dfrac{5}{13} + \dfrac{k|q_2|}{(0.120\text{ m})^2}\dfrac{12}{13}$. This gives

$\dfrac{k|q_2|}{(0.120\text{ m})^2}=\dfrac{k|q_1|}{(0.050\text{ m})^2}\dfrac{5}{12}$. Solving for $|q_2|$ gives $|q_2|=7.2\ \mu\text{C}$, so $q_2=-7.2\ \mu\text{C}$. Then

$E_y=-\dfrac{k|q_1|}{(0.050\text{ m})^2}\dfrac{12}{13}-\dfrac{kq_2}{(0.120\text{ m})^2}\dfrac{5}{13}=-1.17\times10^7\text{ N/C}$. $E=1.17\times10^7\text{ N/C}$.

EVALUATE: With q_1 known, specifying the direction of $\vec{E}$ determines both q_2 and E.

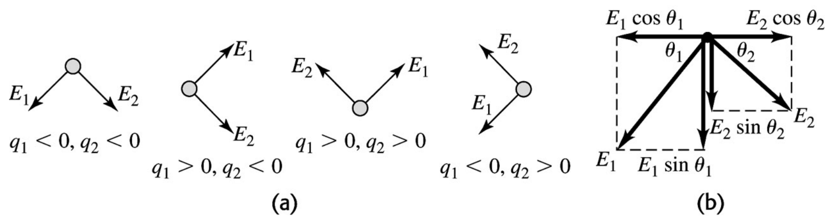

Figure 21.96

21.97. IDENTIFY: To find the electric field due to the second rod, divide that rod into infinitesimal segments of length dx, calculate the field dE due to each segment and integrate over the length of the rod to find the total field due to the rod. Use $d\vec{F}=dq\,\vec{E}$ to find the force the electric field of the second rod exerts on each infinitesimal segment of the first rod.

SET UP: An infinitesimal segment of the second rod is sketched in Figure 21.97. $dQ=(Q/L)dx'$.

EXECUTE: **(a)** $dE=\dfrac{k\,dQ}{(x+a/2+L-x')^2}=\dfrac{kQ}{L}\dfrac{dx'}{(x+a/2+L-x')^2}$.

$$E_x=\int_0^L dE_x=\frac{kQ}{L}\int_0^L\frac{dx'}{(x+a/2+L-x')^2}=\frac{kQ}{L}\left[\frac{1}{x+a/2+L-x'}\right]_0^L=\frac{kQ}{L}\left(\frac{1}{x+a/2}-\frac{1}{x+a/2+L}\right).$$

$$E_x=\frac{2kQ}{L}\left(\frac{1}{2x+a}-\frac{1}{2L+2x+a}\right).$$

(b) Now consider the force that the field of the second rod exerts on an infinitesimal segment dq of the first rod. This force is in the $+x$-direction. $dF=dq\,E$.

$$F=\int E\,dq=\int_{a/2}^{L+a/2}\frac{EQ}{L}\,dx=\frac{2kQ^2}{L^2}\int_{a/2}^{L+a/2}\left(\frac{1}{2x+a}-\frac{1}{2L+2x+a}\right)dx.$$

$$F=\frac{2kQ^2}{L^2}\frac{1}{2}\left(\left[\ln\,(a+2x)\right]_{a/2}^{L+a/2}-\left[\ln(2L+2x+a)\right]_{a/2}^{L+a/2}\right)=\frac{kQ^2}{L^2}\ln\left[\left(\frac{a+2L+a}{2a}\right)\left(\frac{2L+2a}{4L+2a}\right)\right].$$

$$F=\frac{kQ^2}{L^2}\ln\left(\frac{(a+L)^2}{a(a+2L)}\right).$$

(c) For $a\gg L$, $F=\dfrac{kQ^2}{L^2}\ln\left(\dfrac{a^2(1+L/a)^2}{a^2(1+2L/a)}\right)=\dfrac{kQ^2}{L^2}(2\ln\,(1+L/a)-\ln(1+2L/a))$.

For small z, $\ln(1+z)\approx z-\dfrac{z^2}{2}$. Therefore, for $a\gg L$,

$$F\approx\frac{kQ^2}{L^2}\left[2\left(\frac{L}{a}-\frac{L^2}{2a^2}+\cdots\right)-\left(\frac{2L}{a}-\frac{2L^2}{a^2}+\cdots\right)\right]\approx\frac{kQ^2}{a^2}.$$

EVALUATE: The distance between adjacent ends of the rods is a. When $a\gg L$ the distance between the rods is much greater than their lengths and they interact as point charges.

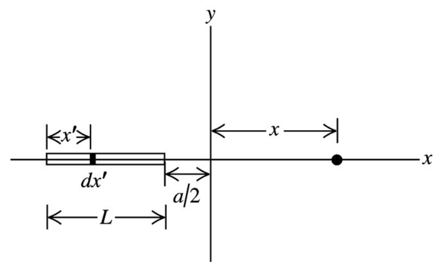

Figure 21.97

21.98. **IDENTIFY** and **SET UP:** The charge of n electrons is ne.
EXECUTE: The charge on the bee is $Q = ne$, so the number of missing electrons is
$n = Q/e = (30 \text{ pC})/e = (30 \times 10^{-12} \text{ C})/(1.60 \times 10^{-19} \text{ C}) = 1.88 \times 10^8 \approx 1.9 \times 10^8$ electrons, which makes choice (a) correct.
EVALUATE: This charge is due to around 190 million electrons.

21.99. **IDENTIFY** and **SET UP:** One charge exerts a force on another charge without being in contact.
EXECUTE: Even though the bee does not touch the stem, the positive charges on the bee attract negative charges (electrons normally) in the stem. This pulls electrons toward the bee, leaving positive charge at the opposite end of the stem, which polarizes it. Thus choice (c) is correct.
EVALUATE: Choice (b) cannot be correct because the bee is positive and would therefore not attract the positive charges in the stem.

21.100. **IDENTIFY** and **SET UP:** Electric field lines begin on positive charges and end on negative charges.
EXECUTE: The flower and bee are both positive, so no field lines can end on either of them. This makes the figure in choice (c) the correct one.
EVALUATE: The net electric field is the vector sum of the field due to the bee and the field due to the flower. Somewhere between the bee and flower the fields cancel, depending on the relative amounts of charge on the bee and flower.

21.101. **IDENTIFY** and **SET UP:** Assume that the charge remains at the end of the stem and that the bees approach to 15 cm from this end of the stem. The electric field is $E = k\dfrac{|q|}{r^2}$.
EXECUTE: Using the numbers given, we have
$E = k\dfrac{|q|}{r^2} = (8.99 \times 10^9 \text{ N} \cdot \text{m}^2/\text{C}^2)(40 \times 10^{-12} \text{ C})/(0.15 \text{ m})^2 = 16 \text{ N/C}$, which is choice (b).
EVALUATE: Even if the charge spread out a bit over the stem, the result would be in the neighborhood of the value we calculated.

22

GAUSS'S LAW

VP22.4.1. **IDENTIFY:** We want to find the electric flux through the surface of a cube.

SET UP: $\Phi_E = \vec{E}\cdot\vec{A} = \vec{E}\cdot\hat{n}A$, $\vec{E} = E_x\hat{i} + E_y\hat{j}$. $\hat{n}$ is the outward normal to the surface. Use $\Phi_E = E_xA_x + E_yA_y + E_zA_z$.

EXECUTE: **(a)** $\hat{n} = -\hat{i}$, so $A_x = -L^2$, $A_y = A_z = 0$. $\Phi_E = E_xA_x + E_yA_y + E_zA_z = E_1(-L^2) = -E_1L^2$.

(b) $\hat{n} = +\hat{i}$, so $\Phi_E = E_1A = E_1L^2$.

(c) $\hat{n} = -\hat{j}$, so $\Phi_E = E_2(-L^2) = -E_2L^2$.

(d) $\hat{n} = +\hat{j}$, so $\Phi_E = E_2A = E_2L^2$.

(e) $E_z = 0$, so $\Phi_E = 0$.

(f) $E_z = 0$, so $\Phi_E = 0$.

(g) $\Phi_E = -E_1L^2 + E_1L^2 - E_2L^2 + E_2L^2 = 0$.

EVALUATE: Every electric field line that enters the cube also goes out of the cube, so the total flux is zero.

VP22.4.2. **IDENTIFY:** This problem involves the electric flux through a hemisphere and Gauss's law.

SET UP: If the spherical surface were *not* but in half, half the flux would go through the upper half and half the flux would go through the lower half. Since the charge q is at the center of the sphere, each of these would be $\frac{1}{2}\left(\frac{q}{\epsilon_0}\right)$ by Gauss's law due to the symmetry of the electric field. Our target variable is the flux.

EXECUTE: **(a)** $\Phi_E = \frac{1}{2}\left(\frac{q}{\epsilon_0}\right) = \frac{1}{2}\left(\frac{8.00\text{ nC}}{\epsilon_0}\right) = +452\text{ N}\cdot\text{m}^2/\text{C}.$

(b) $\Phi_E = \frac{1}{2}\left(\frac{q}{\epsilon_0}\right) = \frac{1}{2}\left(\frac{-4.00\text{ nC}}{\epsilon_0}\right) = -226\text{ N}\cdot\text{m}^2/\text{C}.$

(c) The charge is the same as in part (b), so the answer is the same: $\Phi_E = -226\text{ N}\cdot\text{m}^2/\text{C}$.

EVALUATE: The flux depends only on the charge inside the surface, not on the size of the surface.

VP22.4.3. **IDENTIFY:** This problem involves the electric flux through a cube and Gauss's law.

SET UP: Use $\Phi_E = \dfrac{q}{\epsilon_0}$.

EXECUTE: **(a)** We want the flux. $\Phi_E = \dfrac{q}{\epsilon_0} = \dfrac{+6.00\text{ nC}}{\epsilon_0} = +678\,\text{N}\cdot\text{m}^2/\text{C}$.

(b) The charge is at the center of the cube, so the electric field is symmetric in all directions from the center. Therefore the flux through each of the six faces of the cube is the same.

$\Phi_E = \dfrac{1}{6}(+678\,\text{N}\cdot\text{m}^2/\text{C}) = +113\text{ N}\cdot\text{m}^2/\text{C}$.

EVALUATE: If the charge were inside the cube but not at its center, the answer to part (a) would be the same but the answer to (b) would be different because a different flux would pass through each face of the cube.

VP22.4.4. **IDENTIFY:** This problem involves the electric flux through a sphere and Gauss's law.

SET UP: Use $\Phi_E = \dfrac{q}{\epsilon_0}$. Only charge *within* the sphere contributes to the flux through the surface of the sphere.

EXECUTE: **(a)** q_1 is within the sphere, so $\Phi_E = \dfrac{q_1}{\epsilon_0} = \dfrac{+3.00\text{ nC}}{\epsilon_0} = +339\,\text{N}\cdot\text{m}^2/\text{C}$.

(b) q_2 is also within the sphere, so $q = q_1 + q_2$. $\Phi_E = \dfrac{q_1+q_2}{\epsilon_0} = \dfrac{+3.00\text{ nC} - 8.00\text{ nC}}{\epsilon_0} = -565\,\text{N}\cdot\text{m}^2/\text{C}$.

(c) The distance of q_3 from the origin is $r = \sqrt{(4.00\text{ cm})^2 + (-2.00\text{ cm})^2 + (3.00\text{ cm})^2} = 5.39\text{ cm}$, so q_3 is *not* inside the sphere. Therefore the charge within the sphere is –5.00 nC, as in part (b), so the flux is also the same: $-565\,\text{N}\cdot\text{m}^2/\text{C}$.

EVALUATE: When computing the flux, it doesn't matter *where* the charges are within the sphere, just so they are inside of it.

VP22.10.1. **IDENTIFY:** This problem involves the electric field due to a sphere of charge for points inside and outside the sphere. In one case, the charge is an insulator and in the other case it is a conductor. In each case, the target variable is the magnitude of the electric field.

SET UP and **EXECUTE:** **(a)** Solid insulator. At $r = 4.00$ cm: The point is inside the sphere. From Example 22.9 we know that $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{Qr}{R^3} = \dfrac{1}{4\pi\epsilon_0}\dfrac{Qr}{R^3} = \dfrac{1}{4\pi\epsilon_0}\dfrac{(3.00\text{ nC})(0.0400\text{ m})}{(0.0500\text{ m})^3} = 8630\text{ N/C}$.

At $r = 6.00$ cm: The point is outside the sphere, so the electric field of the sphere is the same as that of a point charge at its center. $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{Q}{r^2} = \dfrac{1}{4\pi\epsilon_0}\dfrac{3.00\text{ nC}}{(0.0600\text{ m})^2} = 7490\text{ N/C}$.

(b) Solid conductor. At $r = 4.00$ cm: All the excess charge of the conductor is on its surface, so $E = 0$ inside the conductor.

At $r = 6.00$ cm: The field is the same as that of a point charge at the center, so $E = 7490$ N/C.

EVALUATE: A uniform sphere of charge behaves like a point charge only for points *outside* the sphere.

VP22.10.2. **IDENTIFY:** We want the electric force on a point charge close to a very long charged wire.

SET UP: $F = qE$ where $E = \dfrac{\lambda}{2\pi\epsilon_0 r}$.

EXECUTE: $F = qE = \dfrac{q\lambda}{2\pi\epsilon_0 r} = \dfrac{(4.00\text{ nC})(3.00\text{ nC/m})}{2\pi\epsilon_0(0.0900\text{ m})} = 2.40\times10^{-6}\text{ N} = 2.40\ \mu\text{N}$. The wire is positive and the point charge is negative, so the wire attracts the point charge.

EVALUATE: Note that the electric field due to the wire is not an inverse square law.

VP22.10.3. **IDENTIFY:** This problem involves the electric fields due to a point charge and an infinite sheet of charge.

SET UP: Sheet: $\sigma/2\epsilon_0$, point charge: $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$. The charge is 8.00 cm from the sheet and $E = 0$ midway between the charge and sheet. The target variable is the surface charge density σ on the sheet.

EXECUTE: At 4.00 cm from the point charge, the fields cancel, so $E_q = E_{\text{sheet}}$. Equate their magnitudes: $\dfrac{\sigma}{2\epsilon_0} = \dfrac{1}{4\pi\epsilon_0}\dfrac{q}{r^2}$. Solve for σ: $\sigma = \dfrac{q}{2\pi r^2} = \dfrac{1.80\text{ nC}}{2\pi(0.0400\text{ m})^2} = 179\text{ nC/m}^2$. The point charge is positive, so its electric field points toward the sheet at the point in question, so the field due to the sheet must point away from the sheet. Therefore the sheet must be positively charged.

EVALUATE: The field due to the sheet is independent of distance from the sheet. So if q were negative, the total field would cancel 4.00 cm from the point charge in a direction away from the sheet.

VP22.10.4. **IDENTIFY:** A point charge is located between two large conducting plates. We know the force on this charge and want to find the surface charge density on each sheet.

SET UP: The field due to the plates is $E = \sigma/\epsilon_0$ and the force on q is $F = qE$.

EXECUTE: $F = qE = q(\sigma/\epsilon_0)$. Solve for σ:

$$\sigma = \frac{\epsilon_0 F}{q} = \frac{\epsilon_0(22.0\ \mu\text{N})}{3.60\text{ nC}} = 5.41\times10^{-8}\text{ C/m}^2 = 54.1\text{ nC/m}^2.$$

EVALUATE: The plates have equal charge densities, so σ is the density on each plate.

VP22.12.1. **IDENTIFY:** A charge is within a cavity inside a copper conductor. We want the charges on the surface of the cavity and the outer surface of the copper block.

SET UP and **EXECUTE:** Do part (b) first. **(b)** Apply Gauss's law using a Gaussian surface that is totally within the copper and encloses the entire cavity. On this Gaussian surface, $E = 0$ inside a conductor, so $q_{\text{inside}} = 0$. Therefore +3.00 nC + $q_{\text{cavity}} = 0$, so $q_{\text{cavity}} = -3.00$ nC.

(a) The excess charge on a conductor is on its surface. The presence of the +3.00 nC charge inside the cavity induces a charge of –3.00 nC on the surface of the cavity, which induces +3.00 nC on the outer surface of the copper block. The net charge on the outer surface is –8.00 nC + 3.00 nC = –5.00 nC.

EVALUATE: It does not matter where the +3.00 nC charge is within the cavity for our answers to hold. If the charge inside the cavity were +8.00 nC, there would be no excess charge on the outer surface of the copper.

VP22.12.2. **IDENTIFY:** A charge is within a cavity inside a silver conductor. We want to find this charge.

SET UP and **EXECUTE:** **(a)** Apply Gauss's law using a Gaussian surface that is totally within the silver and encloses the entire cavity. On this Gaussian surface, $E = 0$ inside a conductor, so $q_{\text{inside}} = 0$. Therefore –2.00 nC + $q_{\text{inside}} = 0$, so $q_{\text{inside}} = +2.00$ nC.

(b) Moving the charge within the cavity would have no effect on the *amount* of charge on the cavity surface or on the outer surface of the silver. We know this because moving the charge would not transfer any charge to (or from) the silver.

EVALUATE: With the point charge at the center of the spherical cavity, the charge would be uniformly distributed over the cavity surface and the outer surface of the silver. This would not be true of the point charge were off center, even though the total amount of charge on each surface would not change.

VP22.12.3. IDENTIFY: We are looking at a charged spherical conducting shell.

SET UP: All the excess charge on a conductor lies on its surface.

EXECUTE: **(a)** All the excess charge is on the outer surface, so $E = 0$ inside the spherical shell.

(b) At the surface of the sphere, it is equivalent to a point charge at its center, so $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$.

Solving for q with $r = R$ gives $q = R^2 E 4\pi\epsilon_0$. Putting in the numbers gives us

$q = (0.90\text{ m})^2(3.0\times10^5\text{ N/C})4\pi\epsilon_0 = 2.7\times10^{-5}\text{ C} = 27\ \mu\text{C}.$

(c) $\sigma = \dfrac{Q}{A} = \dfrac{Q}{4\pi R^2} = \dfrac{R^2 E 4\pi\epsilon_0}{4\pi R^2} = E\epsilon_0 = (3.0\times10^5\text{ N/C})\epsilon_0 = 2.7\,\mu\text{C/m}^2.$

EVALUATE: It takes only 27 μC to create an electric field of 300,000 N/C at the sphere's surface, yet $E = 0$ inside the sphere.

VP22.12.4. IDENTIFY: A charge is within a cavity inside of a conductor.

SET UP and **EXECUTE:** **(a)** Apply Gauss's law using a Gaussian surface that is totally within the conductor and encloses the entire cavity. On this Gaussian surface, $E = 0$ inside a conductor, so $q_{\text{inside}} = 0$. Therefore +4.00 nC + $q_{\text{surface}} = 0$, so $q_{\text{surface}} = -4.00$ nC.

(b) The +4.00 nC induces a charge of –4.00 nC on the cavity surface which induces a charge of +4.00 nC on the outer surface of the sphere. So the total charge on the outer surface is +4.00 nC – 6.00 nC = –2.00 nC.

(c) Inside the cavity, the electric field is due only to the +4.00 nC charge, so

$$E = \frac{1}{4\pi\epsilon_0}\frac{q}{r^2} = \frac{1}{4\pi\epsilon_0}\frac{4.00\text{ nC}}{(0.120\text{ m})^2} = 2.50\times10^3\text{ N/C}.$$

(d) Outside the conductor, the field is due to –2.00 nC on its surface. The magnitude of the field is

$$E = \frac{1}{4\pi\epsilon_0}\frac{|q|}{r^2} = \frac{1}{4\pi\epsilon_0}\frac{2.00\text{ nC}}{(0.330\text{ m})^2} = 1.65\times10^2\text{ N/C}.$$

EVALUATE: The only excess charge on the conductor is –2.00 nC, so outside this conductor all the field is due to this charge.

22.1. IDENTIFY and **SET UP:** $\Phi_E = \int E\cos\phi\, dA$, where ϕ is the angle between the normal to the sheet $\hat{\boldsymbol{n}}$ and the electric field $\vec{\boldsymbol{E}}$.

(a) EXECUTE: In this problem E and $\cos\phi$ are constant over the surface so

$\Phi_E = E\cos\phi\int dA = E\cos\phi A = (14\text{ N/C})(\cos 60°)(0.250\text{ m}^2) = 1.8\text{ N}\cdot\text{m}^2/\text{C}.$

EVALUATE: **(b)** Φ_E is independent of the shape of the sheet as long as ϕ and E are constant at all points on the sheet.

(c) EXECUTE: (i) $\Phi_E = E\cos\phi A.$ Φ_E is largest for $\phi = 0°$, so $\cos\phi = 1$ and $\Phi_E = EA.$

(ii) Φ_E is smallest for $\phi = 90°$, so $\cos\phi = 0$ and $\Phi_E = 0.$

EVALUATE: Φ_E is 0 when the surface is parallel to the field so no electric field lines pass through the surface.

22.2. IDENTIFY: The field is uniform and the surface is flat, so use $\Phi_E = EA\cos\phi.$

SET UP: ϕ is the angle between the normal to the surface and the direction of $\vec{\boldsymbol{E}}$, so $\phi = 70°.$

EXECUTE: $\Phi_E = (90.0\text{ N/C})(0.400\text{ m})(0.600\text{ m})\cos 70° = 7.39\text{ N}\cdot\text{m}^2/\text{C}.$

EVALUATE: If the field were perpendicular to the surface the flux would be $\Phi_E = EA = 21.6\text{ N}\cdot\text{m}^2/\text{C}.$ The flux in this problem is much less than this because only the component of $\vec{\boldsymbol{E}}$ perpendicular to the surface contributes to the flux.

22.3. **IDENTIFY:** The electric flux through an area is defined as the product of the component of the electric field perpendicular to the area times the area.

(a) SET UP: In this case, the electric field is perpendicular to the surface of the sphere, so $\Phi_E = EA = E(4\pi r^2)$.

EXECUTE: Substituting in the numbers gives

$$\Phi_E = (1.25\times10^6\ \text{N/C})4\pi(0.150\ \text{m})^2 = 3.53\times10^5\ \text{N}\cdot\text{m}^2/\text{C}.$$

(b) IDENTIFY: We use the electric field due to a point charge.

SET UP: $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$

EXECUTE: Solving for q and substituting the numbers gives

$$q = 4\pi\epsilon_0 r^2 E = \frac{1}{9.00\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2}(0.150\ \text{m})^2(1.25\times10^6\ \text{N/C}) = 3.13\times10^{-6}\ \text{C}.$$

EVALUATE: The flux would be the same no matter how large the sphere, since the area is proportional to r^2 while the electric field is proportional to $1/r^2$.

22.4. **IDENTIFY:** Use $\Phi_E = \int \vec{E}\cdot d\vec{A} = \int E\cos\phi dA$ to calculate the flux through the surface of the cylinder.

SET UP: The line of charge and the cylinder are sketched in Figure 22.4.

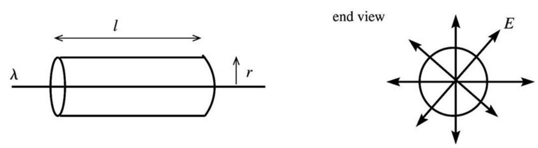

Figure 22.4

EXECUTE: **(a)** The area of the curved part of the cylinder is $A = 2\pi rl$.
The electric field is parallel to the end caps of the cylinder, so $\vec{E}\cdot\vec{A} = 0$ for the ends and the flux through the cylinder end caps is zero.
The electric field is normal to the curved surface of the cylinder and has the same magnitude $E = \lambda/2\pi\epsilon_0 r$ at all points on this surface. Thus $\phi = 0°$ and

$$\Phi_E = EA\cos\phi = EA = (\lambda/2\pi\epsilon_0 r)(2\pi rl) = \frac{\lambda l}{\epsilon_0} = \frac{(3.00\times10^{-6}\ \text{C/m})(0.400\ \text{m})}{8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2} = 1.36\times10^5\ \text{N}\cdot\text{m}^2/\text{C}.$$

(b) In the calculation in part (a) the radius r of the cylinder divided out, so the flux remains the same, $\Phi_E = 1.36\times10^5\ \text{N}\cdot\text{m}^2/\text{C}$.

(c) $\Phi_E = \dfrac{\lambda l}{\epsilon_0} = \dfrac{(3.00\times10^{-6}\ \text{C/m})(0.800\ \text{m})}{8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2} = 2.71\times10^5\ \text{N}\cdot\text{m}^2/\text{C}$, which is twice the flux calculated in parts (a) and (b).

EVALUATE: The flux depends on the number of field lines that pass through the surface of the cylinder.

22.5. **IDENTIFY:** We know the flux through a surface and want to know the magnitude of the electric field causing that flux.

SET UP: $\Phi_E = EA\cos\phi$. ϕ is the angle between the electric field and the normal to the surface, so $\phi = 30.0°$.

EXECUTE: Solve for E: $E = \dfrac{\Phi_E}{A\cos\phi} = \dfrac{4.44\ \text{N}\cdot\text{m}^2/\text{C}}{(6.66\times10^{-4}\ \text{m}^2)(\cos 30.0°)} = 7.70\times10^3\ \text{N/C}.$

EVALUATE: Careful! ϕ is not the angle between the flat surface and the electric field. It is the angle between the normal to the surface and the field.

22.6. **IDENTIFY:** Use $\Phi_E = \vec{E}\cdot\vec{A}$ to calculate the flux for each surface.

SET UP: $\Phi = \vec{E}\cdot\vec{A} = EA\cos\phi$ where $\vec{A} = A\hat{n}$.

EXECUTE: **(a)** $\hat{n}_{S_1} = -\hat{j}$ (left). $\Phi_{S_1} = -(4\times10^3\ \text{N/C})(0.10\ \text{m})^2\cos(90° - 53.1°) = -32\ \text{N}\cdot\text{m}^2/\text{C}.$

$\hat{n}_{S_2} = +\hat{k}$ (top). $\Phi_{S_2} = -(4\times10^3\ \text{N/C})(0.10\ \text{m})^2\cos 90° = 0.$

$\hat{n}_{S_3} = +\hat{j}$ (right). $\Phi_{S_3} = +(4\times10^3\ \text{N/C})(0.10\ \text{m})^2\cos(90° - 53.1°) = +32\ \text{N}\cdot\text{m}^2/\text{C}.$

$\hat{n}_{S_4} = -\hat{k}$ (bottom). $\Phi_{S_4} = (4\times10^3\ \text{N/C})(0.10\ \text{m})^2\cos 90° = 0.$

$\hat{n}_{S_5} = +\hat{i}$ (front). $\Phi_{S_5} = +(4\times10^3\ \text{N/C})(0.10\ \text{m})^2\cos 53.1° = 24\ \text{N}\cdot\text{m}^2/\text{C}.$

$\hat{n}_{S_6} = -\hat{i}$ (back). $\Phi_{S_6} = -(4\times10^3\ \text{N/C})(0.10\ \text{m})^2\cos 53.1° = -24\ \text{N}\cdot\text{m}^2/\text{C}.$

EVALUATE: **(b)** The total flux through the cube must be zero; any flux entering the cube must also leave it, since the field is uniform. Our calculation gives the result; the sum of the fluxes calculated in part (a) is zero.

22.7. **IDENTIFY:** This problem involves Gauss's law.
SET UP: Gauss's law: $\Phi_E = q/\epsilon_0$. $\sigma = Q/A_{\text{sheet}}$ and $q = \sigma A_{\text{enclosed}}$.

EXECUTE: We want the area of the Gaussian surface. $\Phi_E = \dfrac{\sigma A_{\text{enclosed}}}{\epsilon_0} = \dfrac{(Q/A_{\text{sheet}})A_{\text{enclosed}}}{\epsilon_0}$.

$A_{\text{surface}} = \dfrac{\epsilon_0\Phi_E A_{\text{sheet}}}{Q}$. Using $\Phi_E = 5.00\ \text{N}\cdot\text{m}^2/\text{C}$, $A_{\text{sheet}} = 29.2\ \text{cm}^2 = 0.00292\ \text{m}^2$, and $Q = 87.6$ pC, we get $A_{\text{surf}} = 14.8\ \text{cm}^2$.

EVALUATE: The area of the Gaussian surface is less than the area of the sheet, which is reasonable.

22.8. **IDENTIFY:** Apply Gauss's law to each surface.
SET UP: Q_{encl} is the algebraic sum of the charges enclosed by each surface. Flux out of the volume is positive and flux into the enclosed volume is negative.
EXECUTE: **(a)** $\Phi_{S_1} = q_1/\epsilon_0 = (4.00\times10^{-9}\ \text{C})/\epsilon_0 = 452\ \text{N}\cdot\text{m}^2/\text{C}.$

(b) $\Phi_{S_2} = q_2/\epsilon_0 = (-7.80\times10^{-9}\ \text{C})/\epsilon_0 = -881\ \text{N}\cdot\text{m}^2/\text{C}.$

(c) $\Phi_{S_3} = (q_1 + q_2)/\epsilon_0 = ((4.00 - 7.80)\times10^{-9}\ \text{C})/\epsilon_0 = -429\ \text{N}\cdot\text{m}^2/\text{C}.$

(d) $\Phi_{S_4} = (q_1 + q_3)/\epsilon_0 = [(4.00 + 2.40)\times10^{-9}\ \text{C}]/\epsilon_0 = 723\ \text{N}\cdot\text{m}^2/\text{C}.$

(e) $\Phi_{S_5} = (q_1 + q_2 + q_3)/\epsilon_0 = ((4.00 - 7.80 + 2.40)\times10^{-9}\ \text{C})/\epsilon_0 = -158\ \text{N}\cdot\text{m}^2/\text{C}.$

EVALUATE: **(f)** All that matters for Gauss's law is the total amount of charge enclosed by the surface, not its distribution within the surface.

22.9. **IDENTIFY:** Apply the results in Example 22.5 for the field of a spherical shell of charge.

SET UP: Example 22.5 shows that $E = 0$ inside a uniform spherical shell and that $E = k\dfrac{|q|}{r^2}$ outside the shell.

EXECUTE: **(a)** $E = 0$.

(b) $r = 0.060\ \text{m}$ and $E = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{49.0\times10^{-6}\ \text{C}}{(0.060\ \text{m})^2} = 1.22\times10^8\ \text{N/C}$.

(c) $r = 0.110\ \text{m}$ and $E = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{49.0\times10^{-6}\ \text{C}}{(0.110\ \text{m})^2} = 3.64\times10^7\ \text{N/C}$.

EVALUATE: Outside the shell the electric field is the same as if all the charge were concentrated at the center of the shell. But inside the shell the field is not the same as for a point charge at the center of the shell, inside the shell the electric field is zero.

22.10. **IDENTIFY:** Apply Gauss's law to the spherical surface.

SET UP: Q_{encl} is the algebraic sum of the charges enclosed by the sphere.

EXECUTE: **(a)** No charge enclosed so $\Phi_E = 0$.

(b) $\Phi_E = \dfrac{q_2}{\epsilon_0} = \dfrac{-6.00\times10^{-9}\ \text{C}}{8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2} = -678\ \text{N}\cdot\text{m}^2/\text{C}$.

(c) $\Phi_E = \dfrac{q_1+q_2}{\epsilon_0} = \dfrac{(4.00-6.00)\times10^{-9}\ \text{C}}{8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2} = -226\ \text{N}\cdot\text{m}^2/\text{C}$.

EVALUATE: Negative flux corresponds to flux directed into the enclosed volume. The net flux depends only on the net charge enclosed by the surface and is not affected by any charges outside the enclosed volume.

22.11. **IDENTIFY:** Apply Gauss's law to a Gaussian surface that coincides with the cell boundary.

SET UP: $\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$.

EXECUTE: $\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0} = \dfrac{-8.65\times10^{-12}\ \text{C}}{8.854\times10^{-12}\ \text{C}^2/(\text{N}\cdot\text{m}^2)} = -0.977\ \text{N}\cdot\text{m}^2/\text{C}$. Q_{encl} is negative, so the flux is inward.

EVALUATE: If the cell were positive, the field would point outward, so the flux would be positive.

22.12. **IDENTIFY:** Apply the results of Examples 22.9 and 22.10.

SET UP: $E = k\dfrac{|q|}{r^2}$ outside the sphere. A proton has charge $+e$.

EXECUTE: **(a)** $E = k\dfrac{|q|}{r^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{92(1.60\times10^{-19}\ \text{C})}{(7.4\times10^{-15}\ \text{m})^2} = 2.4\times10^{21}\ \text{N/C}$.

(b) For $r = 1.0\times10^{-10}\ \text{m}$, $E = (2.4\times10^{21}\ \text{N/C})\left(\dfrac{7.4\times10^{-15}\ \text{m}}{1.0\times10^{-10}\ \text{m}}\right)^2 = 1.3\times10^{13}\ \text{N/C}$.

(c) $E = 0$, inside a spherical shell.

EVALUATE: The electric field in an atom is very large.

22.13. **IDENTIFY:** Each line lies in the electric field of the other line, and therefore each line experiences a force due to the other line.

SET UP: The field of one line at the location of the other is $E = \dfrac{\lambda}{2\pi\epsilon_0 r}$. For charge $dq = \lambda dx$ on one line, the force on it due to the other line is $dF = Edq$. The total force is $F = \int Edq = E\int dq = Eq$.

EXECUTE: $E = \dfrac{\lambda}{2\pi\epsilon_0 r} = \dfrac{5.20\times10^{-6}\ \text{C/m}}{2\pi(8.854\times10^{-12}\ \text{C}^2/(\text{N}\cdot\text{m}^2))(0.300\ \text{m})} = 3.116\times10^5\ \text{N/C}.$ The force on one line due to the other is $F = Eq,$ where $q = \lambda(0.0500\ \text{m}) = 2.60\times10^{-7}\ \text{C}.$ The net force is

$F = Eq = (3.116\times10^5\ \text{N/C})(2.60\times10^{-7}\ \text{C}) = 0.0810\ \text{N}.$

EVALUATE: Since the electric field at each line due to the other line is uniform, each segment of line experiences the same force, so all we need to use is $F = Eq,$ even though the line is *not* a point charge.

22.14. IDENTIFY: Apply the results of Example 22.5.

SET UP: At a point 0.100 m outside the surface, $r = 0.550$ m.

EXECUTE: **(a)** $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{q}{r^2} = \dfrac{1}{4\pi\epsilon_0}\dfrac{(2.50\times10^{-10}\ \text{C})}{(0.550\ \text{m})^2} = 7.44\ \text{N/C}.$

(b) $E = 0$ inside of a conductor or else free charges would move under the influence of forces, violating our electrostatic assumptions (i.e., that charges aren't moving).

EVALUATE: Outside the sphere its electric field is the same as would be produced by a point charge at its center, with the same charge.

22.15. IDENTIFY: We want the electric field for several charge arrangements.

SET UP and EXECUTE: **(a)** Conducting sphere: Use $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$ for $r > R$. Take rations:

$\dfrac{E_{4R}}{E_{2R}} = \dfrac{(1/4\pi\epsilon_0)Q/(4R)^2}{(1/4\pi\epsilon_0)Q/(2R)^2} = \dfrac{1}{4},$ so $E_{4R} = (1/4)E_{2R} = (1/4)(1400\ \text{N/C}) = 350\ \text{N/C}.$

(b) Conducting cylinder: Use $E = \dfrac{\lambda}{2\pi\epsilon_0 r}$ for $r > R$ and take ratios. $\dfrac{E_{4R}}{E_{2R}} = \dfrac{(\lambda/2\pi\epsilon_0)/(4R)}{(\lambda/2\pi\epsilon_0)/(2R)} = \dfrac{1}{2},$ so

$E_{4R} = (1/2)E_{2R} = (1/2)(1400\ \text{N/C}) = 700\ \text{N/C}.$

(c) Large sheet of charge: $E = \sigma/2\epsilon_0$ which is independent of distance from the sheet, so

$E_{2d} = 1400\ \text{N/C}.$

EVALUATE: For a uniform sphere and point charges $E \propto 1/r^2$, for lines and cylinders $E \propto 1/r$, and for large sheets E is independent of r.

22.16. IDENTIFY: According to the problem, Mars's flux is negative, so its electric field must point toward the center of Mars. Therefore the charge on Mars must be negative. We use Gauss's law to relate the electric flux to the charge causing it.

SET UP: Gauss's law is $\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}.$ The enclosed charge is negative, so the electric flux must also be negative. The flux is $\Phi_E = EA\cos\phi = -EA$ since $\phi = 180°$ and E is the magnitude of the electric field, which is positive.

EXECUTE: **(a)** Solving Gauss's law for q, putting in the numbers, and recalling that q is negative, gives $q = \epsilon_0\Phi_E = (-3.63\times10^{16}\ \text{N}\cdot\text{m}^2/\text{C})(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2) = -3.21\times10^5\ \text{C}.$

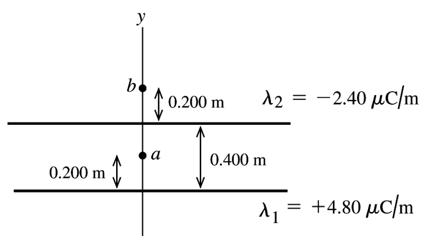
(b) Use the definition of electric flux to find the electric field. The area to use is the surface area of Mars. $E = \dfrac{\Phi_E}{A} = \dfrac{3.63\times10^{16}\ \text{N}\cdot\text{m}^2/\text{C}}{4\pi(3.39\times10^6\ \text{m})^2} = 2.51\times10^2\ \text{N/C}.$

(c) The surface charge density on Mars is therefore $\sigma = \dfrac{q}{A_{\text{Mars}}} = \dfrac{-3.21\times10^5\ \text{C}}{4\pi(3.39\times10^6\ \text{m})^2} = -2.22\times10^{-9}\ \text{C/m}^2.$

22.17. **EVALUATE:** Even though the charge on Mars is very large, it is spread over a large area, giving a small surface charge density.

IDENTIFY: Add the vector electric fields due to each line of charge. $E(r)$ for a line of charge is given by Example 22.6 and is directed toward a negative line of charge and away from a positive line.

SET UP: The two lines of charge are shown in Figure 22.17.



$$E = \frac{1}{2\pi\epsilon_0}\frac{\lambda}{r}.$$

Figure 22.17

EXECUTE: **(a)** At point a, $\vec{E}_1$ and $\vec{E}_2$ are in the $+y$-direction (toward negative charge, away from positive charge).

$E_1 = (1/2\pi\epsilon_0)[(4.80\times10^{-6}\ \text{C/m})/(0.200\ \text{m})] = 4.314\times10^5\ \text{N/C}.$

$E_2 = (1/2\pi\epsilon_0)[(2.40\times10^{-6}\ \text{C/m})/(0.200\ \text{m})] = 2.157\times10^5\ \text{N/C}.$

$E = E_1 + E_2 = 6.47\times10^5\ \text{N/C}$, in the y-direction.

(b) At point b, $\vec{E}_1$ is in the $+y$-direction and $\vec{E}_2$ is in the $-y$-direction.

$E_1 = (1/2\pi\epsilon_0)[(4.80\times10^{-6}\ \text{C/m})/(0.600\ \text{m})] = 1.438\times10^5\ \text{N/C}.$

$E_2 = (1/2\pi\epsilon_0)[(2.40\times10^{-6}\ \text{C/m})/(0.200\ \text{m})] = 2.157\times10^5\ \text{N/C}.$

$E = E_2 - E_1 = 7.2\times10^4\ \text{N/C}$, in the $-y$-direction.

EVALUATE: At point a the two fields are in the same direction and the magnitudes add. At point b the two fields are in opposite directions and the magnitudes subtract.

22.18. **IDENTIFY:** Apply Gauss's law.

SET UP: Draw a cylindrical Gaussian surface with the line of charge as its axis. The cylinder has radius 0.400 m and is 0.0200 m long. The electric field is then 840 N/C at every point on the cylindrical surface and is directed perpendicular to the surface.

EXECUTE: $\oint \vec{E}\cdot d\vec{A} = EA_{\text{cylinder}} = E(2\pi rL) = (840\ \text{N/C})(2\pi)(0.400\ \text{m})(0.0200\ \text{m}) = 42.2\ \text{N}\cdot\text{m}^2/\text{C}.$

The field is parallel to the end caps of the cylinder, so for them $\oint \vec{E}\cdot d\vec{A} = 0.$ From Gauss's law,

$q = \epsilon_0\Phi_E = (8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(42.2\ \text{N}\cdot\text{m}^2/\text{C}) = 3.74\times10^{-10}\ \text{C}.$

EVALUATE: We could have applied the result in Example 22.6 and solved for λ. Then $q = \lambda L.$

22.19. **IDENTIFY:** The electric field inside the conductor is zero, and all of its initial charge lies on its outer surface. The introduction of charge into the cavity induces charge onto the surface of the cavity, which induces an equal but opposite charge on the outer surface of the conductor. The net charge on the outer surface of the conductor is the sum of the positive charge initially there and the additional negative charge due to the introduction of the negative charge into the cavity.

(a) SET UP: First find the initial positive charge on the outer surface of the conductor using $q_i = \sigma A$, where A is the area of its outer surface. Then find the net charge on the surface after the negative charge has been introduced into the cavity. Finally, use the definition of surface charge density.

EXECUTE: The original positive charge on the outer surface is

$$q_i = \sigma A = \sigma(4\pi r^2) = (6.37\times10^{-6}\ \text{C/m}^2)4\pi(0.250\ \text{m})^2 = 5.00\times10^{-6}\ \text{C}.$$

After the introduction of $-0.500\ \mu\text{C}$ into the cavity, the outer charge is now

$$5.00\ \mu\text{C} - 0.500\ \mu\text{C} = 4.50\ \mu\text{C}.$$

The surface charge density is now $\sigma = \dfrac{q}{A} = \dfrac{q}{4\pi r^2} = \dfrac{4.50\times10^{-6}\ \text{C}}{4\pi(0.250\ \text{m})^2} = 5.73\times10^{-6}\ \text{C/m}^2.$

(b) SET UP: Using Gauss's law, the electric field is $E = \dfrac{\Phi_E}{A} = \dfrac{q}{\epsilon_0 A} = \dfrac{q}{\epsilon_0 4\pi r^2}.$

EXECUTE: Substituting numbers gives

$$E = \frac{4.50\times10^{-6}\ \text{C}}{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(4\pi)(0.250\ \text{m})^2} = 6.47\times10^5\ \text{N/C}.$$

(c) SET UP: We use Gauss's law again to find the flux. $\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}.$

EXECUTE: Substituting numbers gives

$$\Phi_E = \frac{-0.500\times10^{-6}\ \text{C}}{8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2} = -5.65\times10^4\ \text{N}\cdot\text{m}^2/\text{C}.$$

EVALUATE: The excess charge on the conductor is still $+5.00\ \mu\text{C}$, as it originally was. The introduction of the $-0.500\ \mu\text{C}$ inside the cavity merely induced equal but opposite charges (for a net of zero) on the surfaces of the conductor.

22.20. IDENTIFY: We want to find the electric field inside and outside an insulating sphere of charge.

SET UP: For $r \le R$: $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{|Q|r}{R^3}$, and for $r \ge R$: $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$.

EXECUTE: $\dfrac{E_{2R}}{E_{R/2}} = \dfrac{(1/4\pi\epsilon_0)Q/(2R)^2}{(1/4\pi\epsilon_0)Q/\left(\dfrac{R/2}{R^3}\right)} = \dfrac{1}{2}$, so E_{2R} = (1/2)(800 N/C) = 400 N/C.

EVALUATE: Inside a sphere of charge the net field is not an inverse square field.

22.21. IDENTIFY: The magnitude of the electric field is constant at any given distance from the center because the charge density is uniform inside the sphere. We can use Gauss's law to relate the field to the charge causing it.

(a) SET UP: Gauss's law tells us that $EA = \dfrac{q}{\epsilon_0}$, and the charge density is given by $\rho = \dfrac{q}{V} = \dfrac{q}{(4/3)\pi R^3}$.

EXECUTE: Solving for q and substituting numbers gives
$q = EA\epsilon_0 = E(4\pi r^2)\epsilon_0 = (1750\ \text{N/C})(4\pi)(0.500\ \text{m})^2(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2) = 4.866\times10^{-8}\ \text{C}$. Using the formula for charge density we get $\rho = \dfrac{q}{V} = \dfrac{q}{(4/3)\pi R^3} = \dfrac{4.866\times10^{-8}\ \text{C}}{(4/3)\pi(0.355\ \text{m})^3} = 2.60\times10^{-7}\ \text{C/m}^3$.

(b) SET UP: Take a Gaussian surface of radius $r = 0.200$ m, concentric with the insulating sphere. The charge enclosed within this surface is $q_{\text{encl}} = \rho V = \rho\left(\dfrac{4}{3}\pi r^3\right)$, and we can treat this charge as a point-charge, using Coulomb's law $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{q_{\text{encl}}}{r^2}$. The charge beyond $r = 0.200$ m makes no contribution to the electric field.

EXECUTE: First find the enclosed charge:

$$q_{\text{encl}} = \rho\left(\frac{4}{3}\pi r^3\right) = (2.60\times10^{-7}\ \text{C/m}^3)\left[\frac{4}{3}\pi(0.200\ \text{m})^3\right] = 8.70\times10^{-9}\ \text{C}$$

Now treat this charge as a point-charge and use Coulomb's law to find the field:

$$E = (9.00\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{8.70\times10^{-9}\ \text{C}}{(0.200\ \text{m})^2} = 1.96\times10^{3}\ \text{N/C}$$

EVALUATE: Outside this sphere, it behaves like a point-charge located at its center. Inside of it, at a distance *r* from the center, the field is due only to the charge between the center and *r*.

22.22. **IDENTIFY:** We apply Gauss's law, taking the Gaussian surface beyond the cavity but inside the solid.

SET UP: Because of the symmetry of the charge, Gauss's law gives us $E_1 = \dfrac{q_{\text{total}}}{\epsilon_0 A}$, where A is the surface area of a sphere of radius $R = 9.50$ cm centered on the point-charge, and q_{total} is the total charge contained within that sphere. This charge is the sum of the $-3.00\ \mu$C point charge at the center of the cavity plus the charge within the solid between $r = 6.50$ cm and $R = 9.50$ cm. The charge within the solid is $q_{\text{solid}} = \rho V = \rho[(4/3)\pi R^3 - (4/3)\pi r^3] = (4\pi/3)\rho(R^3 - r^3)$.

EXECUTE: First find the charge within the solid between $r = 6.50$ cm and $R = 9.50$ cm:

$q_{\text{solid}} = \dfrac{4\pi}{3}(7.35\times10^{-4}\ \text{C/m}^3)[(0.0950\ \text{m})^3 - (0.0650\ \text{m})^3] = 1.794\times10^{-6}\ \text{C}.$

Now find the total charge within the Gaussian surface:

$$q_{\text{total}} = q_{\text{solid}} + q_{\text{point}} = -3.00\ \mu\text{C} + 1.794\ \mu\text{C} = -1.206\ \mu\text{C}.$$

Now find the magnitude of the electric field from Gauss's law:

$$E = \frac{|q|}{\epsilon_0 A} = \frac{|q|}{\epsilon_0 4\pi r^2} = \frac{1}{4\pi\epsilon_0}\frac{|q|}{r^2} = \frac{(8.99\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)(1.206\times10^{-6}\ \text{C})}{(0.0950\ \text{m})^2} = 1.20\times10^{6}\ \text{N/C}.$$

The fact that the charge is negative means that the electric field points radially inward.

EVALUATE: Because of the uniformity of the charge distribution, the charge beyond 9.50 cm does not contribute to the electric field.

22.23. **IDENTIFY:** The charged sheet exerts a force on the electron and therefore does work on it.

SET UP: The electric field is uniform so the force on the electron is constant during the displacement. The electric field due to the sheet is $E = \dfrac{\sigma}{2\epsilon_0}$ and the magnitude of the force the sheet exerts on the electron is $F = qE$. The work the force does on the electron is $W = Fs$. In (b) we can use the work-energy theorem, $W_{\text{tot}} = \Delta K = K_2 - K_1$.

EXECUTE: **(a)** $W = Fs$, where $s = 0.250$ m. $F = Eq$, where

$E = \dfrac{\sigma}{2\epsilon_0} = \dfrac{2.90\times10^{-12}\ \text{C/m}^2}{2(8.854\times10^{-12}\ \text{C}^2/(\text{N}\cdot\text{m}^2))} = 0.1638\ \text{N/C}.$ Therefore the force is

$F = (0.1638\ \text{N/C})(1.602\times10^{-19}\ \text{C}) = 2.624\times10^{-20}\ \text{N}.$ The work this force does is

$W = Fs = 6.56\times10^{-21}\ \text{J}.$

(b) Use the work-energy theorem: $W_{\text{tot}} = \Delta K = K_2 - K_1$. $K_1 = 0$. $K_2 = \frac{1}{2}mv_2^2$. So, $\frac{1}{2}mv_2^2 = W$, which gives $v_2 = \sqrt{\dfrac{2W}{m}} = \sqrt{\dfrac{2(6.559\times10^{-21}\ \text{J})}{9.109\times10^{-31}\ \text{kg}}} = 1.2\times10^{5}\ \text{m/s}.$

EVALUATE: If the field were not constant, we would have to integrate in (a), but we could still use the work-energy theorem in (b).

22.24. IDENTIFY: The charge distribution is uniform, so we can readily apply Gauss's law. Outside a spherically symmetric charge distribution, the electric field is equivalent to that of a point-charge at the center of the sphere.

SET UP: Gauss's law: $\oint \vec{E} \cdot d\vec{A} = \dfrac{Q_{\text{encl}}}{\epsilon_0}$, $E = k\dfrac{|q|}{r^2}$ outside the sphere.

EXECUTE: **(a)** Outside the sphere, $E = k\dfrac{|q|}{r^2}$, so $Q = Er^2/k$, which gives

$Q = (940\text{ N/C})(0.0800\text{ m})^2/(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2) = 6.692\times10^{-10}$ C. The volume charge density is

$\rho = \dfrac{Q}{V} = \dfrac{Q}{\frac{4}{3}\pi R^3} = (6.692\times10^{-10}\text{ C})/(4\pi/3)(0.0400\text{ m})^3 = 2.50\times10^{-6}\text{ C/m}^3$.

(b) Apply Gauss's law: $\oint \vec{E} \cdot d\vec{A} = \dfrac{Q_{\text{encl}}}{\epsilon_0}$, with the Gaussian surface being a sphere of radius $r = 0.0200$ m centered on the sphere of charge. This gives

$E(4\pi r^2) = Q_{\text{encl}}/\epsilon_0$, where $Q_{\text{encl}} = 4/3\ \pi r^3\rho$. Solving for E and simplifying gives

$E = r\rho/3\epsilon_0 = (0.0200\text{ m})(2.50\times10^{-6}\text{ C/m}^3)/[3(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)] = 1880$ N/C.

EVALUATE: Outside the sphere of charge, the electric field obeys an inverse-square law, but inside the field is proportional to the distance from the center of the sphere.

22.25. IDENTIFY: Apply Gauss's law and conservation of charge.

SET UP: Use a Gaussian surface that lies wholly within the conducting material.

EXECUTE: **(a)** Positive charge is attracted to the inner surface of the conductor by the charge in the cavity. Its magnitude is the same as the cavity charge: $q_{\text{inner}} = +6.00$ nC, since $E = 0$ inside a conductor and a Gaussian surface that lies wholly within the conductor must enclose zero net charge.

(b) On the outer surface the charge is a combination of the net charge on the conductor and the charge "left behind" when the +6.00 nC moved to the inner surface:

$$q_{\text{tot}} = q_{\text{inner}} + q_{\text{outer}} \Rightarrow q_{\text{outer}} = q_{\text{tot}} - q_{\text{inner}} = 5.00\text{ nC} - 6.00\text{ nC} = -1.00\text{ nC}.$$

EVALUATE: The electric field outside the conductor is due to the charge on its surface.

EVALUATE: Our result for the field between the plates agrees with the result stated in Example 22.8.

22.26 IDENTIFY: Close to a finite sheet the field is the same as for an infinite sheet. Very far from a finite sheet the field is that of a point charge.

SET UP: For an infinite sheet, $E = \dfrac{\sigma}{2\epsilon_0}$. For a positive point charge, $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$.

EXECUTE: **(a)** At a distance of 0.100 mm from the center, the sheet appears "infinite," so

$$E \approx \frac{\sigma}{2\epsilon_0} = \frac{q}{2\epsilon_0 A} = \frac{4.50\times10^{-9}\text{ C}}{2\epsilon_0(0.800\text{ m})^2} = 397\text{ N/C}.$$

(b) At a distance of 100 m from the center, the sheet looks like a point, so:

$$E \approx \frac{1}{4\pi\epsilon_0}\frac{q}{r^2} = \frac{1}{4\pi\epsilon_0}\frac{(4.50\times10^{-9}\text{ C})}{(100\text{ m})^2} = 4.05\times10^{-3}\text{ N/C}.$$

(c) There would be no difference if the sheet was a conductor. The charge would automatically spread out evenly over both faces, giving it half the charge density on either face as the insulator but the same electric field. Far away, they both look like points with the same charge.

EVALUATE: The sheet can be treated as infinite at points where the distance to the sheet is much less than the distance to the edge of the sheet. The sheet can be treated as a point charge at points for which the distance to the sheet is much greater than the dimensions of the sheet.

22.27. **IDENTIFY:** Apply Gauss's law to a Gaussian surface and calculate E.

(a) SET UP and **EXECUTE:** Consider the charge on a length l of the cylinder. This can be expressed as $q = \lambda l$. But since the surface area is $2\pi Rl$ it can also be expressed as $q = \sigma 2\pi Rl$. These two expressions must be equal, so $\lambda l = \sigma 2\pi Rl$ and $\lambda = 2\pi R\sigma$.

(b) SET UP: Apply Gauss's law to a Gaussian surface that is a cylinder of length l, radius r, and whose axis coincides with the axis of the charge distribution, as shown in Figure 22.27.

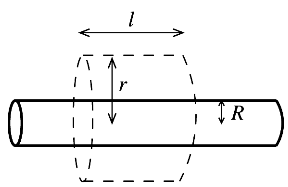


Figure 22.27

EXECUTE:

$Q_{\text{encl}} = \sigma(2\pi Rl)$

$\Phi_E = 2\pi rlE$

$\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$ gives $2\pi rlE = \dfrac{\sigma(2\pi Rl)}{\epsilon_0}$, so $E = \dfrac{\sigma R}{\epsilon_0 r}$.

EVALUATE: **(c)** Example 22.6 shows that the electric field of an infinite line of charge is $E = \lambda/2\pi\epsilon_0 r$. $\sigma = \dfrac{\lambda}{2\pi R}$, so $E = \dfrac{\sigma R}{\epsilon_0 r} = \dfrac{R}{\epsilon_0 r}\left(\dfrac{\lambda}{2\pi R}\right) = \dfrac{\lambda}{2\pi\epsilon_0 r}$, the same as for an infinite line of charge that is along the axis of the cylinder.

22.28. **IDENTIFY:** The net electric field is the vector sum of the fields due to each of the four sheets of charge.

SET UP: The electric field of a large sheet of charge is $E = \sigma/2\epsilon_0$. The field is directed away from a positive sheet and toward a negative sheet.

EXECUTE: **(a)** At A: $E_A = \dfrac{|\sigma_2|}{2\epsilon_0} + \dfrac{|\sigma_3|}{2\epsilon_0} + \dfrac{|\sigma_4|}{2\epsilon_0} - \dfrac{|\sigma_1|}{2\epsilon_0} = \dfrac{|\sigma_2| + |\sigma_3| + |\sigma_4| - |\sigma_1|}{2\epsilon_0}$.

$E_A = \dfrac{1}{2\epsilon_0}(5\ \mu\text{C/m}^2 + 2\ \mu\text{C/m}^2 + 4\ \mu\text{C/m}^2 - 6\ \mu\text{C/m}^2) = 2.82\times10^5$ N/C to the left.

(b) $E_B = \dfrac{|\sigma_1|}{2\epsilon_0} + \dfrac{|\sigma_3|}{2\epsilon_0} + \dfrac{|\sigma_4|}{2\epsilon_0} - \dfrac{|\sigma_2|}{2\epsilon_0} = \dfrac{|\sigma_1| + |\sigma_3| + |\sigma_4| - |\sigma_2|}{2\epsilon_0}$.

$E_B = \dfrac{1}{2\epsilon_0}(6\ \mu\text{C/m}^2 + 2\ \mu\text{C/m}^2 + 4\ \mu\text{C/m}^2 - 5\ \mu\text{C/m}^2) = 3.95\times10^5$ N/C to the left.

(c) $E_C = \dfrac{|\sigma_4|}{2\epsilon_0} + \dfrac{|\sigma_1|}{2\epsilon_0} - \dfrac{|\sigma_2|}{2\epsilon_0} - \dfrac{|\sigma_3|}{2\epsilon_0} = \dfrac{|\sigma_4| + |\sigma_1| - |\sigma_2| - |\sigma_3|}{2\epsilon_0}$.

$E_C = \dfrac{1}{2\epsilon_0}(4\ \mu\text{C/m}^2 + 6\ \mu\text{C/m}^2 - 5\ \mu\text{C/m}^2 - 2\ \mu\text{C/m}^2) = 1.69\times10^5$ N/C to the left.

EVALUATE: The field at C is not zero. The pieces of plastic are not conductors.

22.29. **IDENTIFY:** The uniform electric field of the sheet exerts a constant force on the proton perpendicular to the sheet, and therefore does not change the parallel component of its velocity. Newton's second law allows us to calculate the proton's acceleration perpendicular to the sheet, and uniform-acceleration kinematics allows us to determine its perpendicular velocity component.

SET UP: Let $+x$ be the direction of the initial velocity and let $+y$ be the direction perpendicular to the sheet and pointing away from it. $a_x = 0$ so $v_x = v_{0x} = 9.70\times10^2$ m/s. The electric field due to the sheet is $E = \dfrac{\sigma}{2\epsilon_0}$ and the magnitude of the force the sheet exerts on the proton is $F = eE$.

EXECUTE: $E = \dfrac{\sigma}{2\epsilon_0} = \dfrac{2.34\times10^{-9}\ \text{C/m}^2}{2(8.854\times10^{-12}\ \text{C}^2/(\text{N}\cdot\text{m}^2))} = 132.1\ \text{N/C}.$ Newton's second law gives

$a_y = \dfrac{Eq}{m} = \dfrac{(132.1\ \text{N/C})(1.602\times10^{-19}\ \text{C})}{1.673\times10^{-27}\ \text{kg}} = 1.265\times10^{10}\ \text{m/s}^2.$ Kinematics gives

$v_y = v_{0y} + a_y y = (1.265\times10^{10}\ \text{m/s}^2)(5.00\times10^{-8}\ \text{s}) = 632.7\ \text{m/s}.$ The speed of the proton is the magnitude of its velocity, so $v = \sqrt{v_x^2 + v_y^2} = \sqrt{(9.70\times10^2\ \text{m/s})^2 + (632.7\ \text{m/s})^2} = 1.16\times10^3\ \text{m/s}.$

EVALUATE: We can use the constant-acceleration kinematics equations because the uniform electric field of the sheet exerts a constant force on the proton, giving it a constant acceleration. We could *not* use this approach if the sheet were replaced with a sphere, for example.

22.30. IDENTIFY: The sheet repels the charge electrically, slowing it down and eventually stopping it at its closest approach.

SET UP: Let $+y$ be in the direction toward the sheet. The electric field due to the sheet is $E = \dfrac{\sigma}{2\epsilon_0}$ and the magnitude of the force the sheet exerts on the object is $F = qE.$ Newton's second law, and the constant-acceleration kinematics formulas, apply to the object as it is slowing down.

EXECUTE: $E = \dfrac{\sigma}{2\epsilon_0} = \dfrac{5.90\times10^{-8}\ \text{C/m}^2}{2[8.854\times10^{-12}\ \text{C}^2/(\text{N}\cdot\text{m}^2)]} = 3.332\times10^3\ \text{N/C}.$

$a_y = -\dfrac{F}{m} = -\dfrac{Eq}{m} = -\dfrac{(3.332\times10^3\ \text{N/C})(6.50\times10^{-9}\ \text{C})}{8.20\times10^{-9}\ \text{kg}} = -2.641\times10^3\ \text{m/s}^2.$ Using $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $v_{0y} = \sqrt{-2a_y(y - y_0)} = \sqrt{-2(-2.64\times10^3\ \text{m/s}^2)(0.300\ \text{m})} = 39.8\ \text{m/s}.$

EVALUATE: We can use the constant-acceleration kinematics equations because the uniform electric field of the sheet exerts a constant force on the object, giving it a constant acceleration. We could *not* use this approach if the sheet were replaced with a sphere, for example.

22.31. IDENTIFY: First make a free-body diagram of the sphere. The electric force acts to the left on it since the electric field due to the sheet is horizontal. Since it hangs at rest, the sphere is in equilibrium so the forces on it add to zero, by Newton's first law. Balance horizontal and vertical force components separately.

SET UP: Call T the tension in the thread and E the electric field. Balancing horizontal forces gives $T\sin\theta = qE.$ Balancing vertical forces we get $T\cos\theta = mg.$ Combining these equations gives $\tan\theta = qE/mg,$ which means that $\theta = \arctan(qE/mg).$ The electric field for a sheet of charge is $E = \sigma/2\epsilon_0$.

EXECUTE: Substituting the numbers gives us

$E = \dfrac{\sigma}{2\epsilon_0} = \dfrac{2.50\times10^{-9}\ \text{C/m}^2}{2(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)} = 1.41\times10^2\ \text{N/C}.$ Then

$$\theta = \arctan\left[\frac{(5.00\times10^{-8}\ \text{C})(1.41\times10^2\ \text{N/C})}{(4.00\times10^{-6}\ \text{kg})(9.80\ \text{m/s}^2)}\right] = 10.2°.$$

EVALUATE: Increasing the field, or decreasing the mass of the sphere, would cause the sphere to hang at a larger angle.

22.32. IDENTIFY: Use $\Phi_E = \vec{E}\cdot\vec{A}$ to calculate the flux for each surface. Use $\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$ to calculate the total enclosed charge.

SET UP: $\vec{E} = (-5.00\ \text{N/C}\cdot\text{m})x\hat{\boldsymbol{i}} + (3.00\ \text{N/C}\cdot\text{m})z\hat{\boldsymbol{k}}$. The area of each face is L^2, where $L = 0.300$ m.

EXECUTE: **(a)** $\hat{\boldsymbol{n}}_{S_1} = -\hat{\boldsymbol{j}} \Rightarrow \Phi_1 = \vec{E}\cdot\hat{\boldsymbol{n}}_{S_1}A = 0$.

$\hat{\boldsymbol{n}}_{S_2} = +\hat{\boldsymbol{k}} \Rightarrow \Phi_2 = \vec{E}\cdot\hat{\boldsymbol{n}}_{S_2}A = (3.00\ \text{N/C}\cdot\text{m})(0.300\ \text{m})^2 z = (0.27\ (\text{N/C})\cdot\text{m})z$.

$\Phi_2 = (0.27\ (\text{N/C})\cdot\text{m})(0.300\ \text{m}) = 0.081\ (\text{N/C})\cdot\text{m}^2$.

$\hat{\boldsymbol{n}}_{S_3} = +\hat{\boldsymbol{j}} \Rightarrow \Phi_3 = \vec{E}\cdot\hat{\boldsymbol{n}}_{S_3}A = 0$.

$\hat{\boldsymbol{n}}_{S_4} = -\hat{\boldsymbol{k}} \Rightarrow \Phi_4 = \vec{E}\cdot\hat{\boldsymbol{n}}_{S_4}A = -(0.27\ (\text{N/C})\cdot\text{m})z = 0$ (since $z = 0$).

$\hat{\boldsymbol{n}}_{S_5} = +\hat{\boldsymbol{i}} \Rightarrow \Phi_5 = \vec{E}\cdot\hat{\boldsymbol{n}}_{S_5}A = (-5.00\ \text{N/C}\cdot\text{m})(0.300\ \text{m})^2 x = -(0.45\ (\text{N/C})\cdot\text{m})x$.

$\Phi_5 = -(0.45\ (\text{N/C})\cdot\text{m})(0.300\ \text{m}) = -(0.135\ (\text{N/C})\cdot\text{m}^2)$.

$\hat{\boldsymbol{n}}_{S_6} = -\hat{\boldsymbol{i}} \Rightarrow \Phi_6 = \vec{E}\cdot\hat{\boldsymbol{n}}_{S_6}A = +(0.45\ (\text{N/C})\cdot\text{m})x = 0$ (since $x = 0$).

(b) Total flux: $\Phi = \Phi_2 + \Phi_5 = (0.081 - 0.135)(\text{N/C})\cdot\text{m}^2 = -0.054\ \text{N}\cdot\text{m}^2/\text{C}$. Therefore,

$q = \epsilon_0\Phi = -4.78\times10^{-13}$ C.

EVALUATE: Flux is positive when $\vec{E}$ is directed out of the volume and negative when it is directed into the volume.

22.33. **IDENTIFY:** Use $\Phi_E = \vec{E}\cdot\vec{A}$ to calculate the flux through each surface and use Gauss's law to relate the net flux to the enclosed charge.

SET UP: Flux into the enclosed volume is negative and flux out of the volume is positive.

EXECUTE: **(a)** $\Phi = EA = (125\ \text{N/C})(6.0\ \text{m}^2) = 750\ \text{N}\cdot\text{m}^2/\text{C}$.

(b) Since the field is parallel to the surface, $\Phi = 0$.

(c) Choose the Gaussian surface to equal the volume's surface. Then $750\ \text{N}\cdot\text{m}^2/\text{C} - EA = q/\epsilon_0$ and

$E = \dfrac{1}{6.0\ \text{m}^2}(2.40\times10^{-8}\ \text{C}/\epsilon_0 + 750\ \text{N}\cdot\text{m}^2/\text{C}) = 577\ \text{N/C}$, in the positive x-direction. Since $q < 0$ we must have some net flux flowing *in* so the flux is $-|EA|$ on second face.

EVALUATE: **(d)** $q < 0$ but we have E pointing *away* from face I. This is due to an external field that does not affect the flux but affects the value of E. The electric field is produced by charges both inside and outside the slab.

22.34. **IDENTIFY:** The electric field is perpendicular to the square but varies in magnitude over the surface of the square, so we will need to integrate to find the flux.

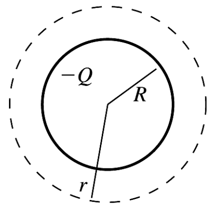
SET UP and **EXECUTE:** $\vec{E} = (964\ \text{N/C}\cdot\text{m})x\hat{\boldsymbol{k}}$. Consider a thin rectangular slice parallel to the y-axis and at coordinate x with width dx. $d\vec{A} = (Ldx)\hat{\boldsymbol{k}}$. $d\Phi_E = \vec{E}\cdot d\vec{A} = (964\ \text{N/C}\cdot\text{m})Lxdx$.

$$\Phi_E = \int_0^L d\Phi_E = (964\ \text{N/C}\cdot\text{m})L\int_0^L xdx = (964\ \text{N/C}\cdot\text{m})L\left(\frac{L^2}{2}\right).$$

$$\Phi_E = \frac{1}{2}(964\ \text{N/C}\cdot\text{m})(0.350\ \text{m})^3 = 20.7\ \text{N}\cdot\text{m}^2/\text{C}.$$

22.35. **IDENTIFY:** Use Gauss's law to find the electric field $\vec{E}$ produced by the shell for $r < R$ and $r > R$ and then use $\vec{F} = q\vec{E}$ to find the force the shell exerts on the point charge.

(a) SET UP: Apply Gauss's law to a spherical Gaussian surface that has radius $r > R$ and that is concentric with the shell, as sketched in Figure 22.35a.



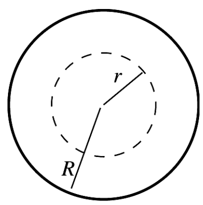
EXECUTE: $\Phi_E = -E(4\pi r^2)$.
$Q_{\text{encl}} = -Q$.

Figure 22.35a

$\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$ gives $-E(4\pi r^2) = \dfrac{-Q}{\epsilon_0}$.

The magnitude of the field is $E = \dfrac{Q}{4\pi\epsilon_0 r^2}$ and it is directed toward the center of the shell. Then $F = qE = \dfrac{qQ}{4\pi\epsilon_0 r^2}$, directed toward the center of the shell. (Since q is positive, $\vec{\boldsymbol{E}}$ and $\vec{\boldsymbol{F}}$ are in the same direction.)

(b) SET UP: Apply Gauss's law to a spherical Gaussian surface that has radius $r < R$ and that is concentric with the shell, as sketched in Figure 22.35b.



EXECUTE: $\Phi_E = E(4\pi r^2)$.
$Q_{\text{encl}} = 0$.

Figure 22.35b

$\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$ gives $E(4\pi r^2) = 0$.

Then $E = 0$ so $F = 0$.

EVALUATE: Outside the shell the electric field and the force it exerts is the same as for a point charge $-Q$ located at the center of the shell. Inside the shell $E = 0$ and there is no force.

EVALUATE: To set up the integral, we take rectangular slices parallel to the *y*-axis (and not the *x*-axis) because the electric field is constant over such a slice. It would not be constant over a slice parallel to the *x*-axis.

22.36. **IDENTIFY:** The α particle feels no force where the net electric field due to the two distributions of charge is zero.

SET UP: The fields can cancel only in the regions *A* and *B* shown in Figure 22.36, because only in these two regions are the two fields in opposite directions.

EXECUTE: $E_{\text{line}} = E_{\text{sheet}}$ gives $\dfrac{\lambda}{2\pi\epsilon_0 r} = \dfrac{\sigma}{2\epsilon_0}$ and $r = \lambda/\pi\sigma = \dfrac{50\ \mu\text{C/m}}{\pi(100\ \mu\text{C/m}^2)} = 0.16\text{ m} = 16\text{ cm}$.

The fields cancel 16 cm from the line in regions *A* and *B*.

EVALUATE: The result is independent of the distance between the line and the sheet. The electric field of an infinite sheet of charge is uniform, independent of the distance from the sheet.

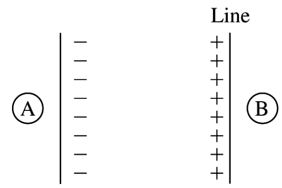


Figure 22.36

22.37. **(a) IDENTIFY:** Apply Gauss's law to a Gaussian cylinder of length l and radius r, where $a < r < b$, and calculate E on the surface of the cylinder.

SET UP: The Gaussian surface is sketched in Figure 22.37a.

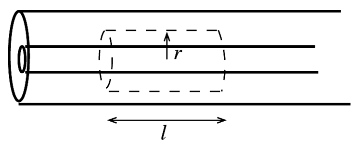

Figure 22.37a

EXECUTE: $\Phi_E = E(2\pi rl)$

$Q_{\text{encl}} = \lambda l$ (the charge on the length l of the inner conductor that is inside the Gaussian surface).

$\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$ gives $E(2\pi rl) = \dfrac{\lambda l}{\epsilon_0}$.

$E = \dfrac{\lambda}{2\pi\epsilon_0 r}$. The enclosed charge is positive so the direction of $\vec{\boldsymbol{E}}$ is radially outward.

(b) IDENTIFY and SET UP: Apply Gauss's law to a Gaussian cylinder of length l and radius r, where $r > c$, as shown in Figure 22.37b.

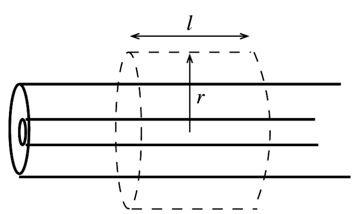

Figure 22.37b

EXECUTE: $\Phi_E = E(2\pi rl)$.

$Q_{\text{encl}} = \lambda l$ (the charge on the length l of the inner conductor that is inside the Gaussian surface; the outer conductor carries no net charge).

$\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$ gives $E(2\pi rl) = \dfrac{\lambda l}{\epsilon_0}$.

$E = \dfrac{\lambda}{2\pi\epsilon_0 r}$. The enclosed charge is positive so the direction of $\vec{\boldsymbol{E}}$ is radially outward.

(c) IDENTIFY and EXECUTE: $E = 0$ within a conductor. Thus $E = 0$ for $r < a$;

$E = \dfrac{\lambda}{2\pi\epsilon_0 r}$ for $a < r < b$; $E = 0$ for $b < r < c$;

$E = \dfrac{\lambda}{2\pi\epsilon_0 r}$ for $r > c$. The graph of E versus r is sketched in Figure 22.37c.

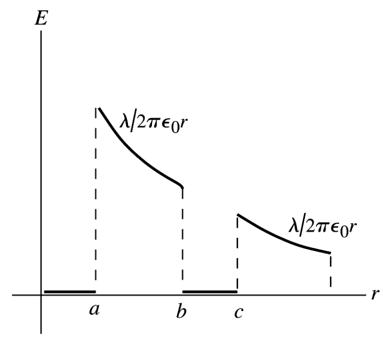

Figure 22.37c

EVALUATE: Inside either conductor $E = 0$. Between the conductors and outside both conductors the electric field is the same as for a line of charge with linear charge density λ lying along the axis of the inner conductor.

(d) IDENTIFY and **SET UP:** <u>inner surface:</u> Apply Gauss's law to a Gaussian cylinder with radius *r*, where $b < r < c$. We know *E* on this surface; calculate Q_{encl}.

EXECUTE: This surface lies within the conductor of the outer cylinder, where $E = 0$, so $\Phi_E = 0$. Thus by Gauss's law $Q_{\text{encl}} = 0$. The surface encloses charge λl on the inner conductor, so it must enclose charge $-\lambda l$ on the inner surface of the outer conductor. The charge per unit length on the inner surface of the outer cylinder is $-\lambda$.

<u>outer surface:</u> The outer cylinder carries no net charge. So if there is charge per unit length $-\lambda$ on its inner surface there must be charge per unit length $+\lambda$ on the outer surface.

EVALUATE: The electric field lines between the conductors originate on the surface charge on the outer surface of the inner conductor and terminate on the surface charges on the inner surface of the outer conductor. These surface charges are equal in magnitude (per unit length) and opposite in sign. The electric field lines outside the outer conductor originate from the surface charge on the outer surface of the outer conductor.

22.38. **IDENTIFY:** Apply Gauss's law.

SET UP: Use a Gaussian surface that is a cylinder of radius *r*, length *l* and that has the line of charge along its axis. The charge on a length *l* of the line of charge or of the tube is $q = \alpha l$.

EXECUTE: **(a)** (i) For $r < a$, Gauss's law gives $E(2\pi r l) = \dfrac{Q_{\text{encl}}}{\epsilon_0} = \dfrac{\alpha l}{\epsilon_0}$ and $E = \dfrac{\alpha}{2\pi \epsilon_0 r}$.

(ii) The electric field is zero because these points are within the conducting material.

(iii) For $r > b$, Gauss's law gives $E(2\pi r l) = \dfrac{Q_{\text{encl}}}{\epsilon_0} = \dfrac{2\alpha l}{\epsilon_0}$ and $E = \dfrac{\alpha}{\pi \epsilon_0 r}$.

The graph of *E* versus *r* is sketched in Figure 22.38.

(b) (i) The Gaussian cylinder with radius *r*, for $a < r < b$, must enclose zero net charge, so the charge per unit length on the inner surface is $-\alpha$. (ii) Since the net charge per length for the tube is $+\alpha$ and there is $-\alpha$ on the inner surface, the charge per unit length on the outer surface must be $+2\alpha$.

EVALUATE: For $r > b$ the electric field is due to the charge on the outer surface of the tube.

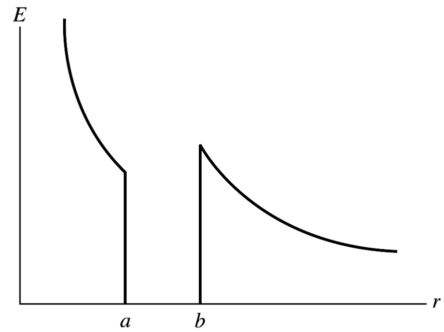

Figure 22.38

22.39. **IDENTIFY:** Apply Gauss's law.

SET UP: Use a Gaussian surface that is a cylinder of radius r and length l, and that is coaxial with the cylindrical charge distributions. The volume of the Gaussian cylinder is $\pi r^2 l$ and the area of its curved surface is $2\pi rl$. The charge on a length l of the charge distribution is $q = \lambda l$, where $\lambda = \rho\pi R^2$.

EXECUTE: **(a)** For $r < R$, $Q_{\text{encl}} = \rho\pi r^2 l$ and Gauss's law gives $E(2\pi rl) = \dfrac{Q_{\text{encl}}}{\epsilon_0} = \dfrac{\rho\pi r^2 l}{\epsilon_0}$ and $E = \dfrac{\rho r}{2\epsilon_0}$, radially outward.

(b) For $r > R$, $Q_{\text{encl}} = \lambda l = \rho\pi R^2 l$ and Gauss's law gives $E(2\pi rl) = \dfrac{Q_{\text{encl}}}{\epsilon_0} = \dfrac{\rho\pi R^2 l}{\epsilon_0}$ and $E = \dfrac{\rho R^2}{2\epsilon_0 r} = \dfrac{\lambda}{2\pi\epsilon_0 r}$, radially outward.

(c) At $r = R$, the electric field for *both* regions is $E = \dfrac{\rho R}{2\epsilon_0}$, so they are consistent.

(d) The graph of E versus r is sketched in Figure 22.39.

EVALUATE: For $r > R$ the field is the same as for a line of charge along the axis of the cylinder.

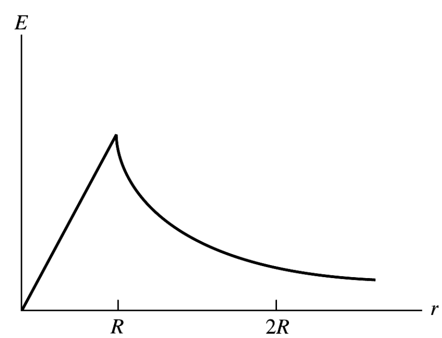

Figure 22.39

22.40. **IDENTIFY:** Apply Gauss's law.

SET UP: Use a Gaussian surface that is a sphere of radius r and that is concentric with the conducting spheres.

EXECUTE: **(a)** For $r < a, E = 0$, since these points are within the conducting material.

For $a < r < b, E = \dfrac{1}{4\pi\epsilon_0}\dfrac{q}{r^2}$, since there is $+q$ inside a radius r.

For $b < r < c, E = 0$, since these points are within the conducting material.

For $r > c, E = \dfrac{1}{4\pi\epsilon_0}\dfrac{q}{r^2}$, since again the total charge enclosed is $+q$.

(b) The graph of E versus r is sketched in Figure 22.40a.
(c) Since the Gaussian sphere of radius r, for $b < r < c$, must enclose zero net charge, the charge on the inner shell surface is $-q$.
(d) Since the hollow sphere has no net charge and has charge $-q$ on its inner surface, the charge on the outer shell surface is $+q$.
(e) The field lines are sketched in Figure 22.40b. Where the field is nonzero, it is radially outward.
EVALUATE: The net charge on the inner solid conducting sphere is on the surface of that sphere. The presence of the hollow sphere does not affect the electric field in the region $r < b$.

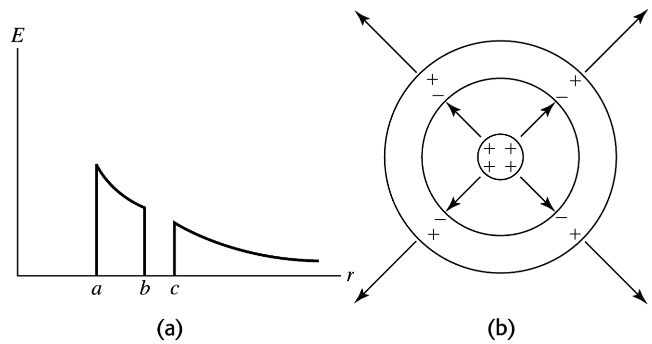

Figure 22.40

22.41. **IDENTIFY:** Apply Gauss's law.
SET UP: Use a Gaussian surface that is a sphere of radius r and that is concentric with the charge distributions.
EXECUTE: **(a)** For $r < R$, $E = 0$, since these points are within the conducting material. For $R < r < 2R$, $E = \frac{1}{4\pi\epsilon_0}\frac{Q}{r^2}$, since the charge enclosed is Q. The field is radially outward. For $r > 2R$, $E = \frac{1}{4\pi\epsilon_0}\frac{2Q}{r^2}$ since the charge enclosed is $2Q$. The field is radially outward.
(b) The graph of E versus r is sketched in Figure 22.41.
EVALUATE: For $r < 2R$ the electric field is unaffected by the presence of the charged shell.

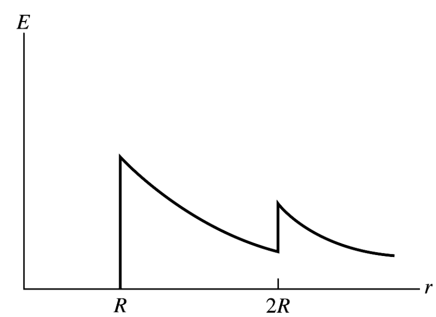

Figure 22.41

22.42. **IDENTIFY:** Apply Gauss's law and conservation of charge.
SET UP: Use a Gaussian surface that is a sphere of radius r and that has the point charge at its center.

EXECUTE: **(a)** For $r < a$, $E = \frac{1}{4\pi\epsilon_0}\frac{Q}{r^2}$, radially outward, since the charge enclosed is Q, the charge of the point charge. For $a < r < b$, $E = 0$ since these points are within the conducting material. For $r > b$, $E = \frac{1}{4\pi\epsilon_0}\frac{2Q}{r^2}$, radially inward, since the total enclosed charge is $-2Q$.

(b) Since a Gaussian surface with radius r, for $a < r < b$, must enclose zero net charge because $E = 0$ inside the conductor, the total charge on the inner surface is $-Q$ and the surface charge density on the inner surface is $\sigma = -\frac{Q}{4\pi a^2}$.

(c) Since the net charge on the shell is $-3Q$ and there is $-Q$ on the inner surface, there must be $-2Q$ on the outer surface. The surface charge density on the outer surface is $\sigma = -\frac{2Q}{4\pi b^2}$.

(d) The field lines and the locations of the charges are sketched in Figure 22.42a.

(e) The graph of E versus r is sketched in Figure 22.42b.

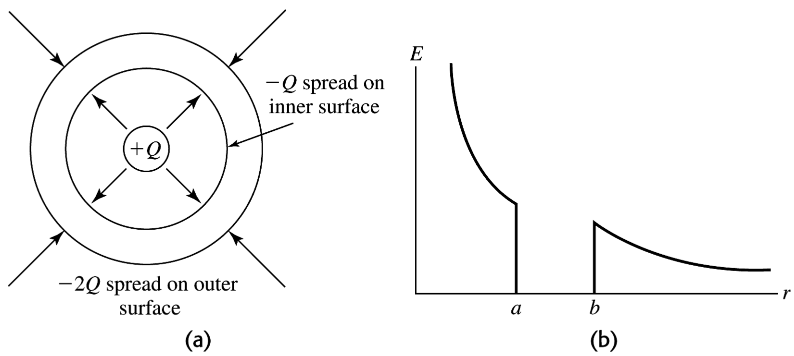

Figure 22.42

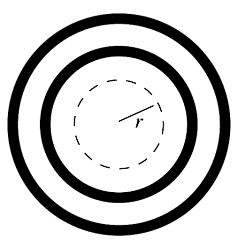
EVALUATE: For $r < a$ the electric field is due solely to the point charge Q. For $r > b$ the electric field is due to the charge $-2Q$ that is on the outer surface of the shell.

22.43. **IDENTIFY:** Apply Gauss's law to a spherical Gaussian surface with radius r. Calculate the electric field at the surface of the Gaussian sphere.

(a) SET UP: (i) $r < a$: The Gaussian surface is sketched in Figure 22.43a.



EXECUTE: $\Phi_E = EA = E(4\pi r^2)$.

$Q_{\text{encl}} = 0$; no charge is enclosed.

$\Phi_E = \frac{Q_{\text{encl}}}{\epsilon_0}$ says

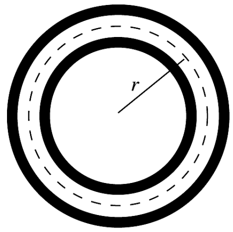
$E(4\pi r^2) = 0$ and $E = 0$.

Figure 22.43a

(ii) $a < r < b$: Points in this region are in the conductor of the small shell, so $E = 0$.

(iii) **SET UP:** $b < r < c$: The Gaussian surface is sketched in Figure 22.43b.

Apply Gauss's law to a spherical Gaussian surface with radius $b < r < c$.



EXECUTE: $\Phi_E = EA = E(4\pi r^2)$.

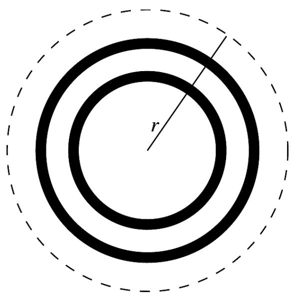
The Gaussian surface encloses all of the small shell and none of the large shell, so $Q_{\text{encl}} = +2q$.

Figure 22.43b

$\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$ gives $E(4\pi r^2) = \dfrac{2q}{\epsilon_0}$ so $E = \dfrac{2q}{4\pi\epsilon_0 r^2}$. Since the enclosed charge is positive the electric field is radially outward.

(iv) $c < r < d$: Points in this region are in the conductor of the large shell, so $E = 0$.

(v) **SET UP:** $r > d$: Apply Gauss's law to a spherical Gaussian surface with radius $r > d$, as shown in Figure 22.43c.



EXECUTE: $\Phi_E = EA = E(4\pi r^2)$.

The Gaussian surface encloses all of the small shell and all of the large shell, so $Q_{\text{encl}} = +2q + 4q = 6q$.

Figure 22.43c

$\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$ gives $E(4\pi r^2) = \dfrac{6q}{\epsilon_0}$.

$E = \dfrac{6q}{4\pi\epsilon_0 r^2}$. Since the enclosed charge is positive the electric field is radially outward.

The graph of E versus r is sketched in Figure 22.43d.

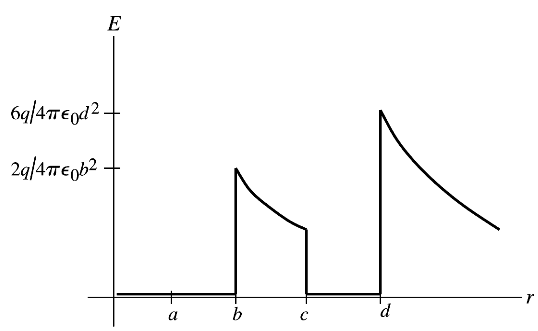


Figure 22.43d

(b) IDENTIFY and **SET UP:** Apply Gauss's law to a sphere that lies outside the surface of the shell for which we want to find the surface charge.

EXECUTE: (i) charge on inner surface of the small shell: Apply Gauss's law to a spherical Gaussian surface with radius $a < r < b$. This surface lies within the conductor of the small shell, where $E = 0$, so $\Phi_E = 0$. Thus by Gauss's law $Q_{\text{encl}} = 0$, so there is zero charge on the inner surface of the small shell.
(ii) charge on outer surface of the small shell: The total charge on the small shell is $+2q$. We found in part (i) that there is zero charge on the inner surface of the shell, so all $+2q$ must reside on the outer surface.
(iii) charge on inner surface of large shell: Apply Gauss's law to a spherical Gaussian surface with radius $c < r < d$. The surface lies within the conductor of the large shell, where $E = 0$, so $\Phi_E = 0$. Thus by Gauss's law $Q_{\text{encl}} = 0$. The surface encloses the $+2q$ on the small shell so there must be charge $-2q$ on the inner surface of the large shell to make the total enclosed charge zero.
(iv) charge on outer surface of large shell: The total charge on the large shell is $+4q$. We showed in part (iii) that the charge on the inner surface is $-2q$, so there must be $+6q$ on the outer surface.
EVALUATE: The electric field lines for $b < r < c$ originate from the surface charge on the outer surface of the inner shell and all terminate on the surface charge on the inner surface of the outer shell. These surface charges have equal magnitude and opposite sign. The electric field lines for $r > d$ originate from the surface charge on the outer surface of the outer sphere.

22.44. IDENTIFY: Apply Gauss's law.
SET UP: Use a Gaussian surface that is a sphere of radius r and that is concentric with the charged shells.
EXECUTE: **(a)** (i) For $r < a, E = 0$, since the charge enclosed is zero. (ii) For $a < r < b, E = 0$, since the points are within the conducting material. (iii) For $b < r < c, E = \frac{1}{4\pi\epsilon_0}\frac{2q}{r^2}$, outward, since the charge enclosed is $+2q$. (iv) For $c < r < d, E = 0$, since the points are within the conducting material. (v) For $r > d, E = 0$, since the net charge enclosed is zero. The graph of E versus r is sketched in Figure 22.44.
(b) (i) small shell inner surface: Since a Gaussian surface with radius r, for $a < r < b$, must enclose zero net charge, the charge on this surface is zero. (ii) small shell outer surface: $+2q$. (iii) large shell inner surface: Since a Gaussian surface with radius r, for $c < r < d$, must enclose zero net charge, the charge on this surface is $-2q$. (iv) large shell outer surface: Since there is $-2q$ on the inner surface and the total charge on this conductor is $-2q$, the charge on this surface is zero.
EVALUATE: The outer shell has no effect on the electric field for $r < c$. For $r > d$ the electric field is due only to the charge on the outer surface of the larger shell.

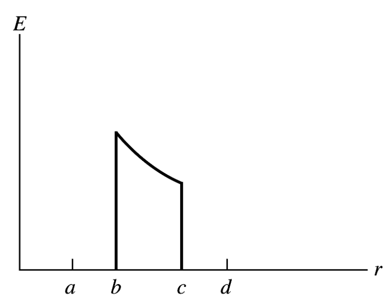

Figure 22.44

22.45. IDENTIFY: We apply Gauss's law in (a) and take a spherical Gaussian surface because of the spherical symmetry of the charge distribution. In (b), the net field is the vector sum of the field due to q and the field due to the sphere.

(a) SET UP: $\rho(r)=\frac{\alpha}{r}$, $dV=4\pi r^2 dr$, and $Q=\int_a^r \rho(r')dV$.

EXECUTE: For a Gaussian sphere of radius r, $Q_{\text{encl}}=\int_a^r \rho(r')dV=4\pi\alpha\int_a^r r'dr'=4\pi\alpha\frac{1}{2}(r^2-a^2)$.

Gauss's law says that $E(4\pi r^2)=\frac{2\pi\alpha(r^2-a^2)}{\epsilon_0}$, which gives $E=\frac{\alpha}{2\epsilon_0}\left(1-\frac{a^2}{r^2}\right)$.

(b) SET UP and EXECUTE: The electric field of the point charge is $E_q=\frac{q}{4\pi\epsilon_0 r^2}$. The total electric field is $E_{\text{total}}=\frac{\alpha}{2\epsilon_0}-\frac{\alpha}{2\epsilon_0}\frac{a^2}{r^2}+\frac{q}{4\pi\epsilon_0 r^2}$. For E_{total} to be constant, $-\frac{\alpha a^2}{2\epsilon_0}+\frac{q}{4\pi\epsilon_0}=0$ and $q=2\pi\alpha a^2$. The constant electric field is $\frac{\alpha}{2\epsilon_0}$.

EVALUATE: The net field is constant, but not zero.

22.46. IDENTIFY: Example 22.9 gives the expression for the electric field both inside and outside a uniformly charged sphere. Use $\vec{F}=-e\vec{E}$ to calculate the force on the electron.

SET UP: The sphere has charge $Q=+e$.

EXECUTE: **(a)** Only at $r=0$ is $E=0$ for the uniformly charged sphere.

(b) At points inside the sphere, $E_r=\frac{er}{4\pi\epsilon_0 R^3}$. The field is radially outward. $F_r=-eE=-\frac{1}{4\pi\epsilon_0}\frac{e^2 r}{R^3}$.

The minus sign denotes that F_r is radially inward. For simple harmonic motion, $F_r=-kr=-m\omega^2 r$, where $\omega=\sqrt{k/m}=2\pi f$. $F_r=-m\omega^2 r=-\frac{1}{4\pi\epsilon_0}\frac{e^2 r}{R^3}$ so $\omega=\sqrt{\frac{1}{4\pi\epsilon_0}\frac{e^2}{mR^3}}$ and $f=\frac{1}{2\pi}\sqrt{\frac{1}{4\pi\epsilon_0}\frac{e^2}{mR^3}}$.

(c) If $f=4.57\times10^{14}\text{ Hz}=\frac{1}{2\pi}\sqrt{\frac{1}{4\pi\epsilon_0}\frac{e^2}{mR^3}}$ then

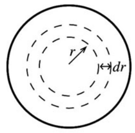
$R=\sqrt[3]{\frac{1}{4\pi\epsilon_0}\frac{(1.60\times10^{-19}\text{ C})^2}{4\pi^2(9.11\times10^{-31}\text{ kg})(4.57\times10^{14}\text{ Hz})^2}}=3.13\times10^{-10}\text{ m}$. The atom radius in this model is the correct order of magnitude.

(d) If $r>R$, $E_r=\frac{e}{4\pi\epsilon_0 r^2}$ and $F_r=-\frac{e^2}{4\pi\epsilon_0 r^2}$. The electron would still oscillate because the force is directed toward the equilibrium position at $r=0$. But the motion would not be simple harmonic, since F_r is proportional to $1/r^2$ and simple harmonic motion requires that the restoring force be proportional to the displacement from equilibrium.

EVALUATE: As long as the initial displacement is less than R the frequency of the motion is independent of the initial displacement.

22.47. (a) IDENTIFY: The charge density varies with r inside the spherical volume. Divide the volume up into thin concentric shells, of radius r and thickness dr. Find the charge dq in each shell and integrate to find the total charge.

SET UP: $\rho(r)=\rho_0(1-r/R)$ for $r\le R$ where $\rho_0=3Q/\pi R^3$. $\rho(r)=0$ for $r\ge R$. The thin shell is sketched in Figure 22.47a.



EXECUTE: The volume of such a shell is $dV = 4\pi r^2 dr$.

The charge contained within the shell is

$$dq = \rho(r)dV = 4\pi r^2 \rho_0 (1 - r/R)dr.$$

Figure 22.47a

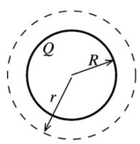
The total charge Q_{tot} in the charge distribution is obtained by integrating dq over all such shells into which the sphere can be subdivided:

$$Q_{\text{tot}} = \int dq = \int_0^R 4\pi r^2 \rho_0 (1 - r/R)dr = 4\pi\rho_0 \int_0^R (r^2 - r^3/R)dr$$

$Q_{\text{tot}} = 4\pi\rho_0 \left[\dfrac{r^3}{3} - \dfrac{r^4}{4R}\right]_0^R = 4\pi\rho_0 \left(\dfrac{R^3}{3} - \dfrac{R^4}{4R}\right) = 4\pi\rho_0 (R^3/12) = 4\pi(3Q/\pi R^3)(R^3/12) = Q,$ as was to be shown.

(b) IDENTIFY: Apply Gauss's law to a spherical surface of radius r, where $r > R$.

SET UP: The Gaussian surface is shown in Figure 22.47b.



EXECUTE: $\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$.

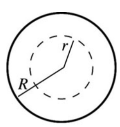
$$E(4\pi r^2) = \frac{Q}{\epsilon_0}.$$

Figure 22.47b

$E = \dfrac{Q}{4\pi \epsilon_0 r^2}$; same as for point charge of charge Q.

(c) IDENTIFY: Apply Gauss's law to a spherical surface of radius r, where $r < R$.

SET UP: The Gaussian surface is shown in Figure 22.47c.



EXECUTE: $\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$.

$$\Phi_E = E(4\pi r^2).$$

Figure 22.47c

To calculate the enclosed charge Q_{encl} use the same technique as in part (a), except integrate dq out to r rather than R. (We want the charge that is inside radius r.)

$$Q_{\text{encl}} = \int_0^r 4\pi r'^2 \rho_0 \left(1 - \frac{r'}{R}\right)dr' = 4\pi\rho_0 \int_0^r \left(r'^2 - \frac{r'^3}{R}\right)dr'.$$

$$Q_{\text{encl}} = 4\pi\rho_0 \left[\frac{r'^3}{3} - \frac{r'^4}{4R}\right]_0^r = 4\pi\rho_0 \left(\frac{r^3}{3} - \frac{r^4}{4R}\right) = 4\pi\rho_0 r^3 \left(\frac{1}{3} - \frac{r}{4R}\right).$$

$\rho_0 = \dfrac{3Q}{\pi R^3}$ so $Q_{\text{encl}} = 12Q\dfrac{r^3}{R^3}\left(\dfrac{1}{3} - \dfrac{r}{4R}\right) = Q\left(\dfrac{r^3}{R^3}\right)\left(4 - 3\dfrac{r}{R}\right).$

Thus Gauss's law gives $E(4\pi r^2) = \dfrac{Q}{\epsilon_0}\left(\dfrac{r^3}{R^3}\right)\left(4 - 3\dfrac{r}{R}\right).$

$E = \dfrac{Qr}{4\pi\varepsilon_0 R^3}\left(4 - \dfrac{3r}{R}\right), r \le R.$

(d) The graph of E versus r is sketched in Figure 22.47d.

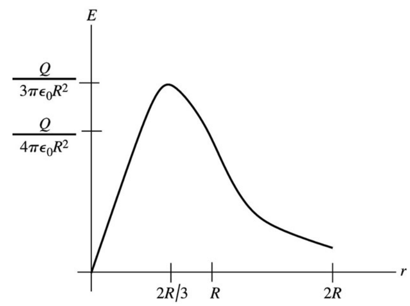


Figure 22.47d

(e) Where the electric field is a maximum, $\dfrac{dE}{dr} = 0.$ Thus

$\dfrac{d}{dr}\left(4r - \dfrac{3r^2}{R}\right) = 0$ so $4 - 6r/R = 0$ and $r = 2R/3.$

At this value of r, $E = \dfrac{Q}{4\pi\epsilon_0 R^3}\left(\dfrac{2R}{3}\right)\left(4 - \dfrac{3}{R}\dfrac{2R}{3}\right) = \dfrac{Q}{3\pi\epsilon_0 R^2}.$

EVALUATE: Our expressions for $E(r)$ for $r < R$ and for $r > R$ agree at $r = R.$ The results of part (e) for the value of r where $E(r)$ is a maximum agrees with the graph in part (d).

22.48. **IDENTIFY:** The method of Example 22.9 shows that the electric field outside the sphere is the same as for a point charge of the same charge located at the center of the sphere.

SET UP: The charge of an electron has magnitude $e = 1.60\times10^{-19}$ C.

EXECUTE: **(a)** $E = k\dfrac{|q|}{r^2}.$ For $r = R = 0.150$ m, $E = 1390$ N/C so

$|q| = \dfrac{Er^2}{k} = \dfrac{(1390 \text{ N/C})(0.150 \text{ m})^2}{8.99\times10^9 \text{ N}\cdot\text{m}^2/\text{C}^2} = 3.479\times10^{-9}$ C. The number of excess electrons is

$\dfrac{3.479\times10^{-9} \text{ C}}{1.60\times10^{-19} \text{ C/electron}} = 2.17\times10^{10}$ electrons.

(b) $r = R + 0.100 \text{ m} = 0.250$ m. $E = k\dfrac{|q|}{r^2} = (8.99\times10^9 \text{ N}\cdot\text{m}^2/\text{C}^2)\dfrac{3.479\times10^{-9} \text{ C}}{(0.250 \text{ m})^2} = 5.00\times10^2$ N/C.

EVALUATE: The magnitude of the electric field decreases according to the square of the distance from the center of the sphere.

22.49. **IDENTIFY:** The charge density inside the cylinder is not uniform but depends on distance from the central axis. We want the electric field both inside and outside the cylinder.

SET UP and EXECUTE: <u>Inside the cylinder ($r \le R$)</u>: For the Gaussian surface, choose a cylinder of length L and radius $r < R$ that is coaxial with the charged cylinder. The electric field is perpendicular to the curved surface and parallel to the ends of this surface. The charge density inside the cylinder depends on r, so we must integrate to get the charge q within the Gaussian surface.

$q = \int \rho dV = \int \alpha\left(1-\frac{r}{R}\right)2\pi rLdr = 2\pi L\alpha r^2\left(\frac{1}{2}-\frac{r}{3R}\right)$. Now apply Gauss's law using the cylindrical Gaussian surface. $E(2\pi rL) = \frac{2\pi L\alpha r^2\left(\frac{1}{2}-\frac{r}{3R}\right)}{\epsilon_0}$. $E = \frac{\alpha r}{\epsilon_0}\left(\frac{1}{2}-\frac{r}{3R}\right)$.

Outside the cylinder ($r \geq R$): Use the same Gaussian surface as above except $r > R$. The enclosed charge is just the charge within the cylinder, not the full Gaussian surface. Use the same formula for q that we found above except use $r = R$. This gives $q = 2\pi L\alpha R^2\left(\frac{1}{2}-\frac{R}{3R}\right) = \pi L\alpha R^2/3$. Now apply Gauss's law.

$E(2\pi rL) = \frac{\pi L\alpha R^2}{3\epsilon_0}$. $E = \frac{\alpha R^2}{6\epsilon_0 r}$.

EVALUATE: Compare E at the surface of the cylinder using the two equations we derived. $E_{\text{inside}} = \frac{\alpha R}{\epsilon_0}\left(\frac{1}{2}-\frac{R}{3R}\right) = \frac{\alpha R}{6\epsilon_0}$. $E_{\text{outside}} = \frac{\alpha R^2}{6\epsilon_0 R} = \frac{\alpha R}{6\epsilon_0}$. Both equations give the same result, as they should.

22.50. **IDENTIFY:** The charge density inside the sphere is not uniform but depends on distance from the center. We want the electric field both inside and outside the sphere. The charge density inside the sphere is $\rho(r) = \rho_0\left(1-\frac{r}{R}\right)$. For Gaussian surfaces, choose a sphere of radius r concentric with the charged sphere.

SET UP and EXECUTE: **(a)** Inside the sphere ($r \leq R$): We need the charge contained within the Gaussian surface. $q = \int \rho dV = \int \rho_0\left(1-\frac{r}{R}\right)4\pi r^2 Ldr = 4\pi\rho_0\left(\frac{r^3}{3}-\frac{r^4}{4R}\right)$. Now use Gauss's law.

$E(4\pi r^2) = \frac{4\pi\rho_0}{\varepsilon_0}\left(\frac{r^3}{3}-\frac{r^4}{4R}\right)$. $E = \frac{\rho_0}{\varepsilon_0}\left(\frac{r}{3}-\frac{r^2}{4R}\right)$.

(b) Outside the sphere ($r \geq R$): For q use the same result as in part (a) except let $r = R$, giving $q = \pi\rho_0 R^3/3$. Now use Gauss's law. $E(4\pi r^2) = \frac{\pi\rho_0 R}{3\epsilon_0}$. $E = \frac{\rho_0 R^3}{12\epsilon_0 r^2}$.

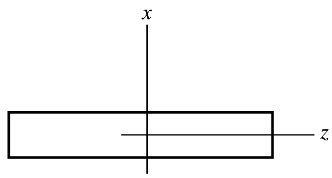
EVALUATE: The electric field should be continuous at the surface of the sphere. Evaluate our results above at $r = R$. $E_{\text{inside}} = \frac{\rho_0}{\epsilon_0}\left(\frac{R}{3}-\frac{R^2}{4R}\right) = \frac{\rho_0 R}{12\epsilon_0}$. $E_{\text{outside}} = \frac{\rho_0 R^3}{12\epsilon_0 R^2} = \frac{\rho_0 R}{12\epsilon_0}$. The field is continuous at the surface.

SET UP and EXECUTE: **(c)** Where is E a maximum? For a maximum, $dE/dr = 0$. Inside the sphere we have $\frac{dE}{dr} = \frac{\rho_0}{\epsilon_0}\left(\frac{1}{3}-\frac{2r}{4R}\right) = 0, r = \frac{2}{3}R$. E decreases after $r = 2R/3$ and is equal to E_{outside} at the surface.

After $r = R$, E_{out} decreases as r increases. So the maximum field occurs at $r = \frac{2}{3}R$.

EVALUATE: For $r > R$, we know that the field should be $E = \frac{Q}{4\pi\epsilon_0 r^2}$, but in part (b) we got $E = \frac{\rho_0 R^3}{12\epsilon_0 r^2}$. But $Q = \pi\rho_0 R^3/3$, so $E = \frac{Q}{4\pi\epsilon_0 r^2} = \frac{\pi\rho_0 R^3/3}{4\pi\epsilon_0 r^2} = \frac{\rho_0 R^3}{12\epsilon_0 r^2}$. Our result agrees with the expected equation.

22.51. **(a) IDENTIFY and SET UP:** Consider the direction of the field for x slightly greater than and slightly less than zero. The slab is sketched in Figure 22.51a.



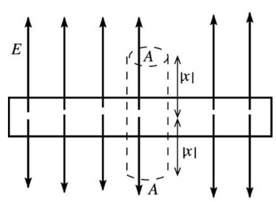
$$\rho(x) = \rho_0 (x/d)^2.$$

Figure 22.51a

EXECUTE: The charge distribution is symmetric about $x = 0$, so by symmetry $E(x) = E(-x)$. But for $x > 0$ the field is in the $+x$-direction and for $x < 0$ the field is in the $-x$-direction. At $x = 0$ the field can't be both in the $+x$- and $-x$-directions so must be zero. That is, $E_x(x) = -E_x(-x)$. At point $x = 0$ this gives $E_x(0) = -E_x(0)$ and this equation is satisfied only for $E_x(0) = 0$.

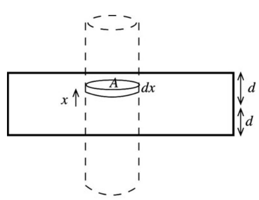
(b) IDENTIFY and SET UP: $\underline{|x| > d}$ (outside the slab).

Apply Gauss's law to a cylindrical Gaussian surface whose axis is perpendicular to the slab and whose end caps have area A and are the same distance $|x| > d$ from $x = 0$, as shown in Figure 22.51b.



EXECUTE: $\Phi_E = 2EA$.

Figure 22.51b



To find Q_{encl} consider a thin disk at coordinate x and with thickness dx, as shown in Figure 22.51c. The charge within this disk is $dq = \rho dV = \rho A dx = (\rho_0 A/d^2)\, x^2 dx$.

Figure 22.51c

The total charge enclosed by the Gaussian cylinder is

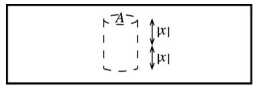
$$Q_{\text{encl}} = 2\int_0^d dq = (2\rho_0 A/d^2)\int_0^d x^2 dx = (2\rho_0 A/d^2)(d^3/3) = \tfrac{2}{3}\rho_0 A d.$$

Then $\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$ gives $2EA = 2\rho_0 A d/3\epsilon_0$. This gives $E = \rho_0 d/3\epsilon_0$.

$\vec{E}$ is directed away from $x = 0$, so $\vec{E} = (\rho_0 d/3\epsilon_0)(x/|x|)\hat{\boldsymbol{i}}$.

(c) IDENTIFY and SET UP: $\underline{|x| < d}$ (inside the slab).

Apply Gauss's law to a cylindrical Gaussian surface whose axis is perpendicular to the slab and whose end caps have area A and are the same distance $|x| < d$ from $x = 0$, as shown in Figure 22.51d.



EXECUTE: $\Phi_E = 2EA.$

Figure 22.51d

Q_{encl} is found as above, but now the integral on dx is only from 0 to x instead of 0 do d.

$$Q_{\text{encl}} = 2\int_0^x dq = (2\rho_0 A/d^2)\int_0^x x^2 dx = (2\rho_0 A/d^2)(x^3/3).$$

Then $\Phi_E = \dfrac{Q_{\text{encl}}}{\epsilon_0}$ gives $2EA = 2\rho_0 Ax^3/3\epsilon_0\, d^2$. This gives $E = \rho_0 x^3/3\epsilon_0\, d^2$.

$\vec{E}$ is directed away from $x = 0$, so $\vec{E} = (\rho_0 x^3/3\epsilon_0\, d^2)\hat{\boldsymbol{i}}$.

EVALUATE: Note that $E = 0$ at $x = 0$ as stated in part (a). Note also that the expressions for $|x| > d$ and $|x| < d$ agree for $x = d$.

22.52. **IDENTIFY:** Apply Gauss's law.

SET UP: Use a Gaussian surface that is a sphere of radius r and that is concentric with the spherical distribution of charge. The volume of a thin spherical shell of radius r and thickness dr is $dV = 4\pi r^2 dr$.

EXECUTE: **(a)** $Q = \int \rho(r)dV = 4\pi\int_0^\infty \rho(r)r^2 dr = 4\pi\rho_0\int_0^R \left(1 - \dfrac{4r}{3R}\right)r^2 dr = 4\pi\rho_0\left[\int_0^R r^2 dr - \dfrac{4}{3R}\int_0^R r^3 dr\right].$

$Q = 4\pi\rho_0\left[\dfrac{R^3}{3} - \dfrac{4}{3R}\dfrac{R^4}{4}\right] = 0.$ The total charge is zero.

(b) For $r \ge R$, $\oint \vec{E}\cdot d\vec{A} = \dfrac{Q_{\text{encl}}}{\epsilon_0} = 0,$ so $E = 0.$

(c) For $r \le R$, $\oint \vec{E}\cdot d\vec{A} = \dfrac{Q_{\text{encl}}}{\epsilon_0} = \dfrac{4\pi}{\epsilon_0}\int_0^r \rho(r')r'^2 dr'.$ $E4\pi r^2 = \dfrac{4\pi\rho_0}{\epsilon_0}\left[\int_0^r r'^2 dr' - \dfrac{4}{3R}\int_0^r r'^3 dr'\right]$ and

$E = \dfrac{\rho_0}{\epsilon_0}\dfrac{1}{r^2}\left[\dfrac{r^3}{3} - \dfrac{r^4}{3R}\right] = \dfrac{\rho_0}{3\epsilon_0}r\left[1 - \dfrac{r}{R}\right].$

(d) The graph of E versus r is sketched in Figure 22.52.

(e) Where E is a maximum, $\dfrac{dE}{dr} = 0.$ This gives $\dfrac{\rho_0}{3\epsilon_0} - \dfrac{2\rho_0 r_{\max}}{3\epsilon_0\, R} = 0$ and $r_{\max} = \dfrac{R}{2}.$ At this r,

$E = \dfrac{\rho_0}{3\epsilon_0}\dfrac{R}{2}\left[1 - \dfrac{1}{2}\right] = \dfrac{\rho_0 R}{12\epsilon_0}.$

EVALUATE: The result in part (b) for $r \le R$ gives $E = 0$ at $r = R$; the field is continuous at the surface of the charge distribution.

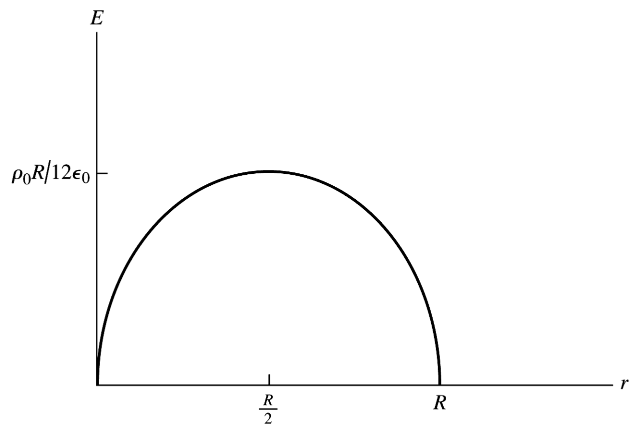


Figure 22.52

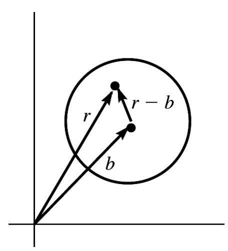
22.53. **(a) IDENTIFY:** Use $\vec{E}(\vec{r})$ from Example (22.9) (inside the sphere) and relate the position vector of a point inside the sphere measured from the origin to that measured from the center of the sphere.

SET UP: For an insulating sphere of uniform charge density ρ and centered at the origin, the electric field inside the sphere is given by $E = Qr'/4\pi\epsilon_0 R^3$ (Example 22.9), where $\vec{r}'$ is the vector from the center of the sphere to the point where E is calculated.

But $\rho = 3Q/4\pi R^3$ so this may be written as $E = \rho r/3\epsilon_0$. And $\vec{E}$ is radially outward, in the direction of $\vec{r}'$, so $\vec{E} = \rho\vec{r}'/3\epsilon_0$.

For a sphere whose center is located by vector $\vec{b}$, a point inside the sphere and located by $\vec{r}$ is located by the vector $\vec{r}' = \vec{r} - \vec{b}$ relative to the center of the sphere, as shown in Figure 22.53.



EXECUTE: Thus $\vec{E} = \dfrac{\rho(\vec{r} - \vec{b})}{3\epsilon_0}$.

Figure 22.53

EVALUATE: When $b = 0$ this reduces to the result of Example 22.9. When $\vec{r} = \vec{b}$, this gives $E = 0$, which is correct since we know that $E = 0$ at the center of the sphere.

(b) IDENTIFY: The charge distribution can be represented as a uniform sphere with charge density ρ and centered at the origin added to a uniform sphere with charge density $-\rho$ and centered at $\vec{r} = \vec{b}$.

SET UP: $\vec{E} = \vec{E}_{\text{uniform}} + \vec{E}_{\text{hole}}$, where $\vec{E}_{\text{uniform}}$ is the field of a uniformly charged sphere with charge density ρ and $\vec{E}_{\text{hole}}$ is the field of a sphere located at the hole and with charge density $-\rho$. (Within the spherical hole the net charge density is $+\rho - \rho = 0$.)

EXECUTE: $\vec{E}_{\text{uniform}} = \dfrac{\rho\vec{r}}{3\epsilon_0}$, where $\vec{r}$ is a vector from the center of the sphere.

$\vec{E}_{\text{hole}} = \dfrac{-\rho(\vec{r} - \vec{b})}{3\epsilon_0}$, at points inside the hole. Then $\vec{E} = \dfrac{\rho\vec{r}}{3\epsilon_0} + \left(\dfrac{-\rho(\vec{r} - \vec{b})}{3\epsilon_0}\right) = \dfrac{\rho\vec{b}}{3\epsilon_0}$.

EVALUATE: $\vec{E}$ is independent of $\vec{r}$ so is uniform inside the hole. The direction of $\vec{E}$ inside the hole is in the direction of the vector $\vec{b}$, the direction from the center of the insulating sphere to the center of the hole.

22.54. **IDENTIFY:** We first find the field of a cylinder off-axis, then the electric field in a hole in a cylinder is the difference between two electric fields: that of a solid cylinder on-axis, and one off-axis, at the location of the hole.

SET UP: Let $\vec{r}$ locate a point within the hole, relative to the axis of the cylinder and let $\vec{r}'$ locate this point relative to the axis of the hole. Let $\vec{b}$ locate the axis of the hole relative to the axis of the cylinder. As shown in Figure 22.54, $\vec{r}' = \vec{r} - \vec{b}$. Problem 22.39 shows that at points within a long insulating cylinder, $\vec{E} = \dfrac{\rho\vec{r}}{2\epsilon_0}$.

EXECUTE: $\vec{E}_{\text{off-axis}} = \dfrac{\rho\vec{r}'}{2\epsilon_0} = \dfrac{\rho(\vec{r}-\vec{b})}{2\epsilon_0}$. $\vec{E}_{\text{hole}} = \vec{E}_{\text{cylinder}} - \vec{E}_{\text{off-axis}} = \dfrac{\rho\vec{r}}{2\epsilon_0} - \dfrac{\rho(\vec{r}-\vec{b})}{2\epsilon_0} = \dfrac{\rho\vec{b}}{2\epsilon_0}$.

Note that $\vec{E}$ is uniform.

EVALUATE: If the hole is coaxial with the cylinder, $b = 0$ and $E_{\text{hole}} = 0$.

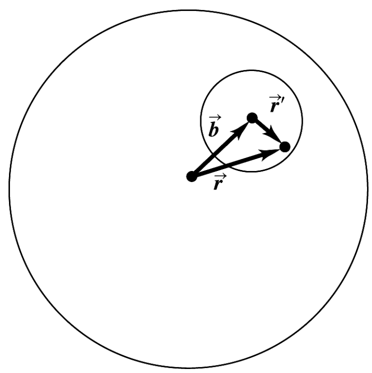


Figure 22.54

22.55. **IDENTIFY** and **SET UP:** For a uniformly charged sphere, $E = k\dfrac{|Q|}{r^2}$, so $Er^2 = k|Q|$ = constant. For a long uniform line of charge, $E = \dfrac{\lambda}{2\pi\epsilon_0 r}$, so $Er = \dfrac{\lambda}{2\pi\epsilon_0}$ = constant.

EXECUTE: **(a)** Figure 22.55a shows the graphs for data set A. We see that the graph of Er versus r is a horizontal line, which means that Er = constant. Therefore data set A is for a uniform straight line of charge.

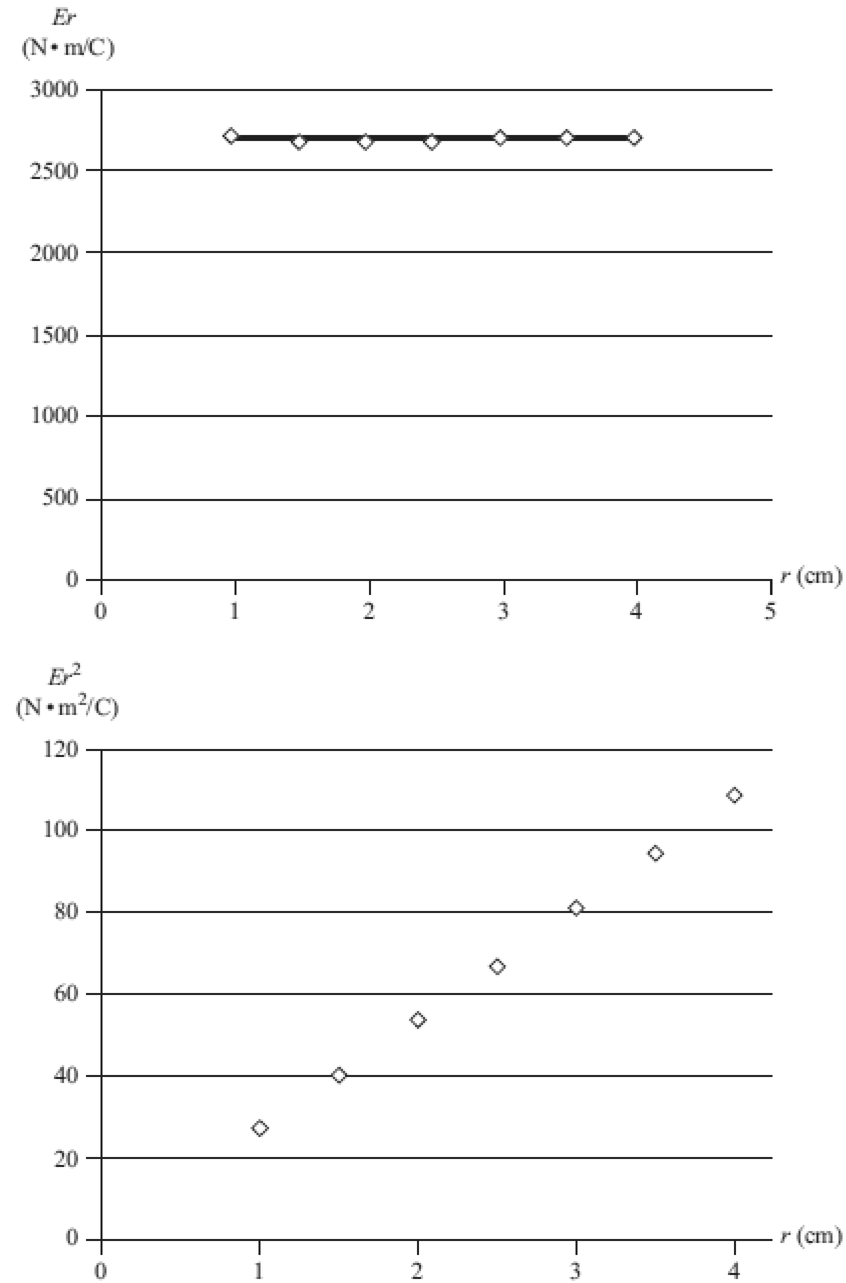

Figure 22.55a

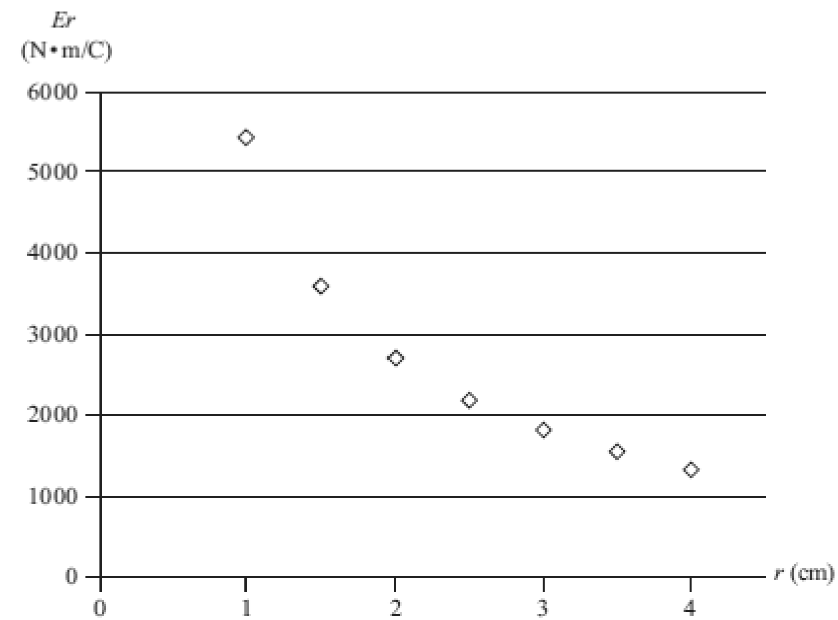
Figure 22.55b shows the graphs for data set B. We see that the graph of Er^2 versus r is a horizontal line, so Er^2 = constant. Thus data set B is for a uniformly charged sphere.



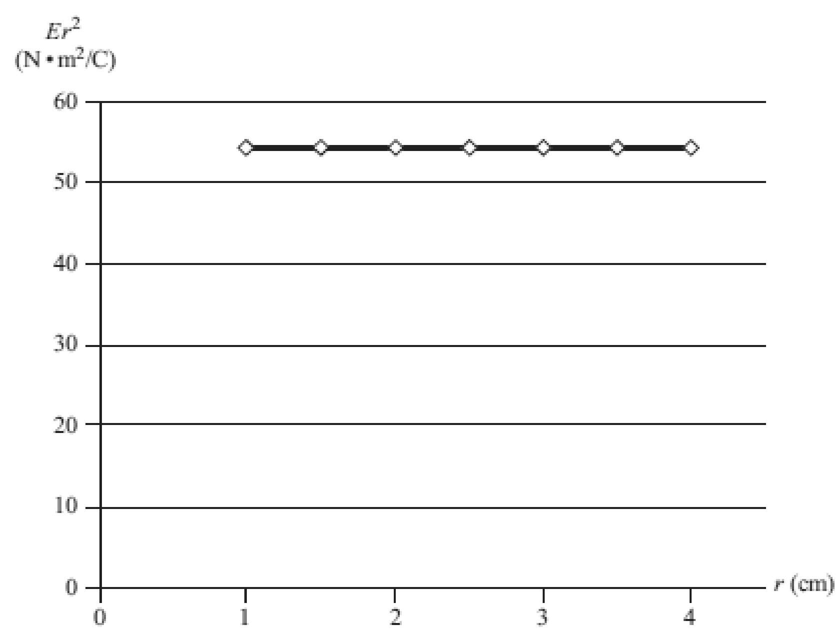


Figure 22.55b

(b) For A: $E = \dfrac{\lambda}{2\pi \epsilon_0 r}$, so $\lambda = 2\pi \epsilon_0 Er$. From our graph in Figure 22.55a, Er = constant = 2690 $\text{N} \cdot \text{m/C}$. Therefore

$\lambda = 2\pi \epsilon_0 Er = 2\pi(8.854 \times 10^{-12}\ \text{C}^2/\text{N} \cdot \text{m}^2)\ (2690\ \text{N} \cdot \text{m/C}) = 1.50 \times 10^{-7}$ C/m = 0.150 μC/m.

For B: $E = k\dfrac{|Q|}{r^2}$, so $kQ = Er^2$ = constant, which means that Q = (constant)/k. From our graph in Figure 22.55b, Er^2 = constant = 54.1 $\text{N} \cdot \text{m}^2/\text{C}$. Therefore

$Q = (54.1\ \text{N} \cdot \text{m}^2/\text{C}) / (8.99 \times 10^9\ \text{N} \cdot \text{m}^2/\text{C}^2) = 6.0175 \times 10^{-9}$ C.

The charge density ρ is $\rho = \dfrac{Q}{V} = \dfrac{Q}{\frac{4}{3}\pi R^3}$ = (6.0175×10^{-9} C)/[(4π/3)(0.00800 m)^3 = 2.81×10^{-3} C/m^3.

EVALUATE: A linear charge density of 0.150 C/m and a volume charge density of 2.81×10^{-3} C/m^3 are both physically reasonable and could be achieved in a normal laboratory.

22.56. **IDENTIFY** and **SET UP:** The electric field inside a uniform sphere of charge does not follow an inverse-square law. Apply Gauss's law, $\oint \vec{E}\cdot d\vec{A} = \dfrac{Q_{\text{encl}}}{\epsilon_0}$, to find the field.

SET UP: Apply $\oint \vec{E}\cdot d\vec{A} = \dfrac{Q_{\text{encl}}}{\epsilon_0}$. As the Gaussian surface, use a sphere of radius r that is centered on the given sphere.

EXECUTE: Gauss's law gives $E(4\pi r^2) = \dfrac{\rho\left(\frac{4}{3}\pi r^3\right)}{\epsilon_0}$, from which we get $E = \dfrac{\rho}{3\epsilon_0} r$. Therefore in a graph of E versus r, the slope is $\dfrac{\rho}{3\epsilon_0}$. From the graph in the problem, the slope is

slope = $\dfrac{(6-3)\times 10^4\ \text{N/C}}{(8-4)\times 10^{-3}\ \text{m}} = 7.5\times 10^6\ \text{N/m}\cdot\text{C}$. Solving for ρ gives

ρ = (slope)($3\epsilon_0$) = $(7.5\times 10^6\ \text{N/m}\cdot\text{C})\,(3)\,(8.854\times 10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)$ = 1.99×10^{-4} C/m^3.

EVALUATE: A sphere of volume 1.0 m^3 would have only 199 μC of charge, which is physically realistic.

22.57. **IDENTIFY** and **SET UP:** Apply Gauss's law, $\oint \vec{E}\cdot d\vec{A} = \dfrac{Q_{\text{encl}}}{\epsilon_0}$. The enclosed charge is $Q_{\text{encl}} = \rho V$, where $V = \dfrac{4}{3}\pi r^3$ for a sphere of radius r. Read the charge densities from the graph in the problem.

EXECUTE: Apply Gauss's law $\oint \vec{E}\cdot d\vec{A} = \dfrac{Q_{\text{encl}}}{\epsilon_0}$. As a Gaussian surface, use a sphere of radius r centered on the given sphere. This gives $E(4\pi r^2) = Q_{\text{encl}}/\epsilon_0$, so $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{Q_{\text{encl}}}{r^2} = k\dfrac{Q_{\text{encl}}}{r^2}$. In each case, we must first use $Q_{\text{encl}} = \rho V$ to calculate Q_{encl} and then use that result to calculate E.

(i) First find Q_{encl}: $Q_{\text{encl}} = \rho V$ = (10.0×10^{-6} C/m^3)(4π/3)(0.00100 m)^3 = 4.19×10^{-14} C.

Now calculate E: $E = k\dfrac{Q_{\text{encl}}}{r^2}$ = (8.99×10^9 N·m^2/C^2)(4.19×10^{-14} C)/(0.00100 m)^2 = 377 N/C.

(ii) Q_{encl} = (10.0×10^{-6} C/m^3)(4π/3)(0.00200 m)^3 + (4.0×10^{-6} C/m^3)(4π/3)[(0.00300 m)^3 – (0.00200 m)^3]
Q_{encl} = 6.534×10^{-13} C.

$E = k\dfrac{Q_{\text{encl}}}{r^2}$ = (8.99×10^9 N·m^2/C^2)(6.534×10^{-13} C)/(0.00300 m)^2 = 653 N/C.

(iii) Q_{encl} = (10.0×10^{-6} C/m^3)(4π/3)(0.00200 m)^3 + (4.0×10^{-6} C/m^3)(4π/3)[(0.00400 m)^3 – (0.00200 m)^3] + (–2.0×10^{-6} C/m^3)(4π/3)[(0.00500 m)^3 – (0.00400 m)^3].
Q_{encl} = 7.624×10^{-13} C.

$E = k\dfrac{Q_{\text{encl}}}{r^2}$ = (8.99×10^9 N·m^2/C^2) (7.624×10^{-13} C)/(0.00500 m)^2 = 274 N/C.

(iv) Q_{encl} = 7.624×10^{-13} C + (–2.0×10^{-6} C/m^3)(4π/3)[(0.00600 m)^3 – (0.00500 m)^3] = 0, so E = 0.

EVALUATE: We found that E = 0 at r = 7.00 mm, but E is also zero at all points beyond r = 6.00 mm because the enclosed charge is zero for any Gaussian surface having a radius r > 6.00 mm.

22.58. **IDENTIFY:** Electrostatic forces affect the behavior of pollen in flowers.

SET UP and EXECUTE: **(a)** Estimate: Diameter of central disk is 1.0 cm.

(b) $q = (75{,}000 \text{ electrons})(1.60\times10^{-19} \text{ C/electron}) = 1.2\times10^{-14} \text{ C}$.

(c) We want the electric field 1.0 cm from the bee. The bee is a sphere, so it is equivalent to a point charge at the edge of the disk. Using $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$ with $q = 1.2\times10^{-14}$ C and $r = 1.0$ cm $= 0.010$ m, we get $E = 0.27$ N/C.

(c) We want the charge on the pollen. The force on the pollen is due to the electric field of the bee, so $F = qE$, which gives $q = F/E = (10 \text{ pN})/(0.27 \text{ N/C}) = 3.7\times10^{-11}$ C.

EVALUATE: The charge on the pollen is very small, but a pollen grain is extremely tiny and needs only a small force to be pulled off the stamen.

22.59. **IDENTIFY:** The charge density inside the cylinder is not uniform but depends on distance from the central axis. It has the form $\rho(r) = \rho_0\left(1-\dfrac{r}{R}\right)$.

SET UP and EXECUTE: **(a)** We want the linear charge density λ of the cylinder. $\lambda = q/L$, so we need to find q in terms of L. $q = \int \rho dV = \int_0^R \rho_0\left(1-\dfrac{r}{R}\right)2\pi rL dr = \dfrac{\pi L\rho_0 R^2}{3}$. Therefore

$$\lambda = \frac{q}{L} = \frac{\pi L\rho_0 R^2/3}{L} = \frac{\pi\rho_0 R^2}{3}.$$

(b) We want the period T of the orbit. Use $\Sigma F = \dfrac{mv^2}{r} = mr\omega^2$ with $F = QE_{\text{cylinder}}$. For a very long cylinder $E = \dfrac{\lambda}{2\pi\epsilon_0 r}$, so $F = QE = \dfrac{Q\lambda}{2\pi\epsilon_0 r}$. Using the λ we found in part (a) gives

$F = \dfrac{Q\left(\pi\rho_0 R^2/3\right)}{2\pi\epsilon_0 r} = \dfrac{Q\rho_0 R^2_{\text{cylinder}}}{6\epsilon_0 R_{\text{orbit}}}$. Using $\Sigma F = mr\omega^2$ gives $\dfrac{Q\rho_0 R^2_{\text{cylinder}}}{6\epsilon_0 R_{\text{orbit}}} = MR_{\text{orbit}}\omega^2$. Solving for ω and using $T = 2\pi/\omega$ gives $T = 2\pi\left(\dfrac{R_{\text{orbit}}}{R_{\text{cylinder}}}\right)\sqrt{\dfrac{6\epsilon_0 M}{Q\rho_0}}$.

EVALUATE: According to our results, if Q is large, T is small. This is reasonable because the force on the particle will be large resulting in fast motion. If M is large, T is small because the particle has more inertia. If R_{orbit} is large, T is large since the particle moves slower at a greater distance. All these results are reasonable.

22.60. **IDENTIFY:** This problem relates the electric flux through an object due to an external electric field and the force exerted on it by that field.

SET UP and EXECUTE: **(a)** Consider a flat charged surface of area A with charge Q in an external electric field of magnitude E. The force perpendicular to this surface is $F_\perp = QE_\perp$. The surface charge density is σ, so $Q = \sigma A$. Therefore $F_\perp = \sigma AE_\perp$. But $AE_\perp = \Phi_E$, so $F_\perp = \sigma\Phi_E$.

(b) We want the mass M for the hemisphere to remain stationary. The electric field due to the sheet is uniform and equal to $\dfrac{\sigma}{2\epsilon_0}$. We can reduce the hemisphere to a flat disk of radius R with charge Q, so $\sigma = Q/\pi R^2$. Using the result from part (a), we have

$F_{\text{el}} = \sigma_{\text{disk}}\Phi_{\text{through disk due to sheet}} = \sigma_{\text{disk}}E_{\text{sheet}}A_{\text{disk}} = \left(\dfrac{Q}{\pi R^2}\right)\left(\dfrac{\sigma}{2\epsilon_0}\right)\left(\pi R^2\right) = \dfrac{Q\sigma}{2\epsilon_0}$. The force of gravity and the electric force must be equal for balance, so $\dfrac{Q\sigma}{2\epsilon_0} = Mg$, giving $M = \dfrac{Q\sigma}{2\epsilon_0 g}$.

(c) We want the acceleration of the hemisphere. The charge density is the same for the sheet and the disk. From (b) we have $F_{\text{el}} = \dfrac{Q\sigma}{2\epsilon_0}$. $Q = \sigma(\pi R^2) = \pi R^2\sigma$. Therefore $F_{\text{el}} = \dfrac{\sigma^2\pi R^2}{2\epsilon_0}$. Using $\sum F_y = ma_y$ gives $a = \dfrac{F_{\text{el}} - Mg}{M} = \dfrac{\sigma^2\pi R^2}{2\epsilon_0 M} - g$. Using the given numbers for σ, R, and M gives $a = 6.17\ \text{m/s}^2$.

EVALUATE: The analysis in (b) and (c) is simplified because the electric field due to a very large sheet is independent of the distance from the sheet and is uniform.

22.61. **IDENTIFY:** A uniformly charged sphere is totally within a hollow cylinder. We want the electric flux through the rounded side of the cylinder and the two flat end caps.

SET UP: The flux through a surface is $\Phi_E = \int E_\perp dA$. The charged sphere is equivalent to a point charge at its center, so $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q|}{r^2}$ where $|q| = Q$.

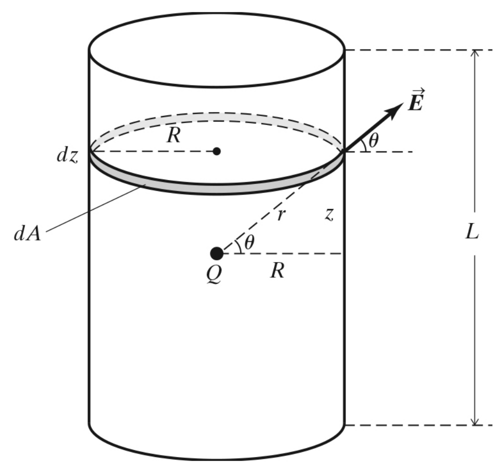

Figure 22.61a

EXECUTE: **(a)** We want the flux through the rounded side of the cylinder. Fig. 22.61a shows the set up of the integral with the central sphere shown as a point charge Q. $dA = 2\pi R dz$, $r^2 = z^2 + R^2$, $E_\perp = E\cos\theta$, and $\cos\theta = \dfrac{R}{r} = \dfrac{R}{\sqrt{z^2+R^2}}$. Calling $1/4\pi\epsilon_0 \equiv k$, we have

$\Phi_E = \int E_\perp dA = 2\int_{z=0}^{L/2} E\cos\theta dA = 2\int_0^{L/2} \dfrac{kQ}{z^2+R^2}\dfrac{R}{\sqrt{z^2+R^2}}2\pi R dz$. Using the integral tables in Appendix B

gives $\Phi_E = (4\pi QkR^2)\left(\dfrac{1}{R^2}\dfrac{z}{\sqrt{z^2+R^2}}\Bigg|_0^{L/2}\right) = \dfrac{2\pi QkL}{\sqrt{(L/2)^2+R^2}} = \dfrac{QL}{2\epsilon_0\sqrt{(L/2)^2+R^2}}$.

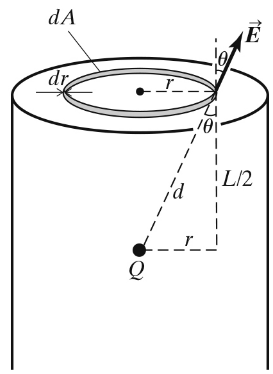

Figure 22.61b

(b) We want the flux through the upper cap. Fig. 22.61b shows the set up of the integral. Using $dA = 2\pi r dr$, $d^2 = r^2 + (L/2)^2$, $E = \dfrac{kQ}{d^2} = \dfrac{kQ}{r^2 + (L/2)^2}$, and $\cos\theta = \dfrac{L/2}{d} = \dfrac{L/2}{\sqrt{r^2 + (L/2)^2}}$, we have

$\Phi_E = \int E\cos\theta dA = \int_0^R \dfrac{kQ}{r^2 + (L/2)^2}\dfrac{L/2}{\sqrt{r^2 + (L/2)^2}} 2\pi r dr$. Using integral tables from Appendix B gives

$\Phi_E = (kQ\pi L)\left(-\dfrac{1}{\sqrt{r^2 + (L/2)^2}}\Bigg|_0^R\right) = kQ\pi L\left(\dfrac{2}{L} - \dfrac{1}{\sqrt{R^2 + (L/2)^2}}\right)$. Using $1/4\pi\epsilon_0 \equiv k$, we get

$\Phi_E = \dfrac{QL}{4\epsilon_0}\left(\dfrac{2}{L} - \dfrac{1}{\sqrt{R^2 + (L/2)^2}}\right)$.

(c) The solution is exactly the same as for part (b) and gives the same answer.

(d) $\Phi_E(\text{total}) = \Phi_{\text{sides}} + 2\Phi_{\text{cap}} = \dfrac{QL}{2\epsilon_0\sqrt{(L/2)^2 + R^2}} + 2\left[\dfrac{QL}{4\epsilon_0}\left(\dfrac{2}{L} - \dfrac{1}{\sqrt{R^2 + (L/2)^2}}\right)\right] = \dfrac{Q}{\epsilon_0}$.

EVALUATE: (e) Gauss's law states that the electric flux through any closed surface is equal to the total charge enclosed divided by epsilon-zero: $\Phi_E = \dfrac{Q}{\epsilon_0}$, which is what we just found. So our result is consistent with Gauss's law.

22.62. IDENTIFY: The charge in a spherical shell of radius r and thickness dr is $dQ = \rho(r)4\pi r^2\,dr$. Apply Gauss's law.

SET UP: Use a Gaussian surface that is a sphere of radius r. Let Q_i be the charge in the region $r \le R/2$ and let Q_0 be the charge in the region where $R/2 \le r \le R$.

EXECUTE: (a) The total charge is $Q = Q_i + Q_0$, where $Q_i = 4\pi\int_0^{R/2}\dfrac{3\alpha r^3}{2R}dr = \dfrac{6\pi\alpha}{R}\dfrac{1}{4}\dfrac{R^4}{16} = \dfrac{3}{32}\pi\alpha R^3$ and

$Q_0 = 4\pi\alpha\int_{R/2}^{R}(1-(r/R)^2)r^2\,dr = 4\pi\alpha R^3\left(\dfrac{7}{24} - \dfrac{31}{160}\right) = \dfrac{47}{120}\pi\alpha R^3$. Therefore,

$Q = \left(\dfrac{3}{32} + \dfrac{47}{120}\right)\pi\alpha R^3 = \dfrac{233}{480}\pi\alpha R^3$ and $\alpha = \dfrac{480Q}{233\pi R^3}$.

(b) For $r \le R/2$, Gauss's law gives $E4\pi r^2 = \dfrac{4\pi}{\epsilon_0}\displaystyle\int_0^r \dfrac{3\alpha r'^3}{2R}dr' = \dfrac{3\pi\alpha r^4}{2\epsilon_0 R}$ and $E = \dfrac{6\alpha r^2}{16\epsilon_0 R} = \dfrac{180Qr^2}{233\pi\epsilon_0 R^4}$.

For $R/2 \le r \le R$, $E4\pi r^2 = \dfrac{Q_i}{\epsilon_0} + \dfrac{4\pi\alpha}{\epsilon_0}\displaystyle\int_{R/2}^r (1-(r'/R)^2)r'^2\, dr' = \dfrac{Q_i}{\epsilon_0} + \dfrac{4\pi\alpha}{\epsilon_0}\left(\dfrac{r^3}{3} - \dfrac{R^3}{24} - \dfrac{r^5}{5R^2} + \dfrac{R^3}{160}\right)$.

$E4\pi r^2 = \dfrac{3}{128}\dfrac{4\pi\alpha R^3}{\epsilon_0} + \dfrac{4\pi\alpha R^3}{\epsilon_0}\left(\dfrac{1}{3}\left(\dfrac{r}{R}\right)^3 - \dfrac{1}{5}\left(\dfrac{r}{R}\right)^5 - \dfrac{17}{480}\right)$ and

$E = \dfrac{480Q}{233\pi\epsilon_0 r^2}\left(\dfrac{1}{3}\left(\dfrac{r}{R}\right)^3 - \dfrac{1}{5}\left(\dfrac{r}{R}\right)^5 - \dfrac{23}{1920}\right)$. For $r \ge R$, $E = \dfrac{Q}{4\pi\epsilon_0 r^2}$, since all the charge is enclosed.

(c) The fraction of Q between $R/2 \le r \le R$ is $\dfrac{Q_0}{Q} = \dfrac{47}{120}\dfrac{480}{233} = 0.807$.

(d) $E = \dfrac{180}{233}\dfrac{Q}{4\pi\epsilon_0 R^2}$ using either of the electric field expressions above, evaluated at $r = R/2$.

EVALUATE: **(e)** The force an electron would feel never is proportional to $-r$ which is necessary for simple harmonic oscillations. It is oscillatory since the force is always attractive, but it has the wrong power of r to be simple harmonic motion.

22.63. **IDENTIFY** and **SET UP:** Treat the sphere as a point-charge, so $E = k\dfrac{|q|}{r^2}$, so $|q| = Er^2/k$.

EXECUTE: $|q| = Er^2/k = (1\times10^6\ \text{N/C})(25\ \text{m})^2/(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2) = 0.0695\ \text{C} \approx 0.07\ \text{C}$. The charge must be negative since the field is intended to repel negative electrons. Choice (a) is correct.

EVALUATE: 0.07 C is quite a large amount of charge, much larger than normally encountered in typical college physics laboratories.

22.64. **IDENTIFY** and **SET UP:** Treat the sphere as a point-charge, so $E = k\dfrac{|q|}{r^2}$. Use the result from the previous problem for the charge on the sphere.

EXECUTE: $E = k\dfrac{|q|}{r^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(0.0695\ \text{C})/(2.5\ \text{m})^2 = 1.0\times10^8\ \text{N/C}$, choice (d).

EVALUATE: The field strength at 2.5 m is 100 times what it is at 25 m. This is reasonable since the field strength obeys an inverse-square law. At 25 m, which is a distance 10 times as far as 2.5 m, the field strength is $[(2.5\ \text{m})/(25\ \text{m})]^2(1\times10^6\ \text{N/C}) = 1\times10^6\ \text{N/C}$, which was given in the previous problem.

22.65. **IDENTIFY** and **SET UP:** Electric field lines point away from positive charges and toward negative charges. For a point-charge, the lines radiated from (or to) the charge. For a uniform sphere of charge, the field lines look the same as those for a point-charge for points outside the sphere.

EXECUTE: The sphere is negative and equivalent to a negative point-charge, so at its surface the field lines are perpendicular to it and pointing inward, which is choice (b).

EVALUATE: The sphere behaves like a point-charge at or above its surface.

22.66. **IDENTIFY** and **SET UP:** All the charge is on the surface of a spherical shell.

EXECUTE: The field inside the sphere comes from any charge that is inside, but there is none. So the field is zero, choice (c).

EVALUATE: This result is true only if the surface of the sphere is uniformly charged.

23

ELECTRIC POTENTIAL

VP23.2.1. **IDENTIFY:** This problem involves the energy of a system consisting of an electron and a lead nucleus.

SET UP: The electric potential energy (relative to infinity) of two point charges is $U = \frac{1}{4\pi\epsilon_0}\frac{q_1q_2}{r}$.

EXECUTE: **(a)** We want the work to move the electron. $W = U_2 - U_1$. Use $U = \frac{1}{4\pi\epsilon_0}\frac{q_1q_2}{r}$:

$$W = \frac{1}{4\pi\epsilon_0}\frac{q_1q_2}{r_2} - \frac{1}{4\pi\epsilon_0}\frac{q_1q_2}{r_1} = \frac{q_1q_2}{4\pi\epsilon_0}\left(\frac{1}{r_2} - \frac{1}{r_1}\right) = \frac{(-e)(82e)}{4\pi\epsilon_0}\left(\frac{1}{5.00\times10^{-10}\ \text{m}} - \frac{1}{1.00\times10^{-10}\ \text{m}}\right).$$

$W = 1.51\times10^{-16}$ J.

(b) We want kinetic energy. Use energy conservation with $K_1 = 0$: $U_1 = U_2 + K_2$. Solving for K_2 gives

$$K_2 = U_1 - U_2 = \frac{q_1q_2}{4\pi\epsilon_0}\left(\frac{1}{r_1} - \frac{1}{r_2}\right) = \frac{(-e)(82e)}{4\pi\epsilon_0}\left(\frac{1}{1.00\times10^{-10}\ \text{m}} - \frac{1}{8.00\times10^{-12}\ \text{m}}\right).\ \ K_2 = 2.17\times10^{-15}\ \text{J}.$$

EVALUATE: As the electron gets closer to the nucleus, its potential energy gets more and more negative, so it is losing potential energy and gaining kinetic energy.

VP23.2.2. **IDENTIFY:** We fire a proton at a nucleus and make use of electric potential energy of point charges.

SET UP: The potential energy is $U = \frac{1}{4\pi\epsilon_0}\frac{q_1q_2}{r}$.

EXECUTE: **(a)** We want the potential energy. Energy conservation gives $K_{-1} = U_2$, where 1 is when the proton is very far from the nucleus and 2 is when it is at its closest point and has stopped moving.

$$U_2 = K_1 = \frac{1}{2}m_\text{p}v^2 = \frac{1}{2}(1.67\times10^{-27}\ \text{kg})(2.50\times10^6\ \text{m/s})^2 = 5.22\times10^{-15}\ \text{J}.$$

(b) Call Q the charge of the nucleus, which is our target variable. $U_2 = \frac{1}{4\pi\epsilon_0}\frac{q_1q_2}{r_2} = \frac{1}{4\pi\epsilon_0}\frac{eQ}{r}$. Solve for Q: $Q = \frac{U_2 r 4\pi\epsilon_0}{e} = \frac{(5.22\times10^{-15}\ \text{J})(5.29\times10^{-13}\ \text{m})(4\pi\epsilon_0)}{1.60\times10^{-19}\ \text{C}} = 1.92\times10^{-18}\ \text{C}.$

EVALUATE: $Q/e = 12$, so this nucleus has 12 protons, which means it must be magnesium (from Appendix D).

VP23.2.3. **IDENTIFY:** This problem involves the potential energy of a system of point charges.

SET UP: Fig. VP22.2.3 shows the three charges in their final arrangement. $U = \frac{1}{4\pi\epsilon_0}\frac{q_1q_2}{r}$.

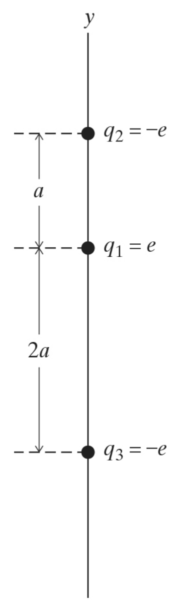

Figure VP23.2.3

EXECUTE: **(a)** The work needed to bring in the charge q_3 is equal to its final potential energy due to the q_1 and q_2. $W = U_{1,3} + U_{2,3} = \frac{1}{4\pi\epsilon_0}\frac{q_1 q_3}{r_{13}} + \frac{1}{4\pi\epsilon_0}\frac{q_2 q_3}{r_{23}} = \frac{-e}{4\pi\epsilon_0}\left(\frac{e}{2a} + \frac{-e}{3a}\right) = -\frac{e^2}{24\pi\epsilon_0 a}$.

(b) $U_{\text{tot}} = U_{1,2} + U_{1,3} + U_{2,3} = \frac{1}{4\pi\epsilon_0}\left(\frac{-e^2}{a} + \frac{-e^2}{3a} + \frac{e^2}{3a}\right) = -\frac{7e^2}{24\pi\epsilon_0 a}$.

EVALUATE: The total potential energy is negative since q_1 attracts q_2 and q_3. Only q_2 and q_3 repel each other.

VP23.2.4. **IDENTIFY:** This problem involves the potential energy of a system of point charges.

SET UP: Fig. VP22.2.4 shows the three charges with q_3 in place. $U = \frac{1}{4\pi\epsilon_0}\frac{q_1 q_2}{r}$.

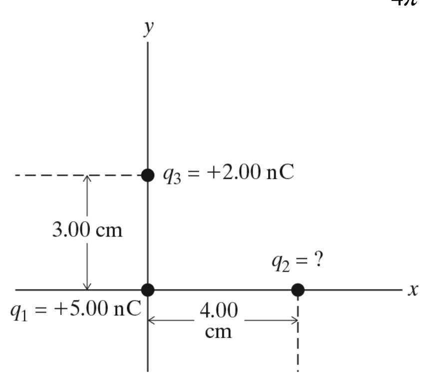

Figure VP23.2.4

EXECUTE: **(a)** We want q_2. The work you do is the potential energy of the q_1-q_2 system.

$W = U_{1,2} = \frac{1}{4\pi\epsilon_0}\frac{q_1 q_2}{r_{12}}$. Solve for q_2: $q_2 = \frac{4\pi\epsilon_0 W r_{12}}{q_1} = \frac{4\pi\epsilon_0 (8.10\times10^{-6}\ \text{J})(0.0400\ \text{m})}{5.00\ \text{nC}} = 7.21$ nC.

(b) The *additional* work is the added potential energy of the system, which is the potential energy of q_3 due to q_1 and q_2. $W = U_{1,3} + U_{2,3} = \frac{1}{4\pi\epsilon_0}\frac{q_1q_3}{r_{13}} + \frac{1}{4\pi\epsilon_0}\frac{q_2q_3}{r_{23}} = \frac{1}{4\pi\epsilon_0}\left(\frac{q_1}{r_{13}} + \frac{q_2}{r_{23}}\right)$. Using the result from part (a) and the given numbers, we get $W = 5.59\times10^{-6}$ J.

EVALUATE: Even though two charges are already present, it takes less work to bring in q_3 than it did to bring in q_2 because $q_3 = (2/7.21)q_2 = 0.277q_2$.

VP23.7.1. **IDENTIFY:** We need to relate the potential to the electric field.

SET UP: Use $V_a - V_b = \int_a^b \vec{E}\cdot d\vec{l}$, $V(0,0,0) = V_0$, $\vec{E} = E_x\hat{i}$, where $E_x = 5.00\times10^2$ V/m. The target variable is the potential difference.

EXECUTE: **(a)** $V_0 - V_P = \int_0^P \vec{E}\cdot d\vec{l} = \int_0^{5.00\text{ cm}} E_x dx = (5.00\times10^2\text{ V/m})(0.0500\text{ m}) = +25.0\text{ V}.$

(b) Since $E_y = E_z = 0$, we have $V_0 - V_P = \int_0^{3.00\text{ cm}} E_x dx = (5.00\times10^2\text{ V/m})(0.0300\text{ m}) = +15.0\text{ V}.$

(c) Since $E_y = E_z = 0$ and $\Delta x = 0$, we have $V_0 - V_P = 0$.

(d) $V_0 - V_P = \int_0^P \vec{E}\cdot d\vec{l} = \int_0^{-5.00\text{ cm}} E_x dx = (5.00\times10^2\text{ V/m})(-0.0500\text{ m}) = -25.0\text{ V}.$

EVALUATE: In parts (a) and (b), $V_P < V_0$, in (c) $V_P = V_0$, and in (d) $V_P > V_0$.

VP23.7.2. **IDENTIFY:** This problem involves the electric potential and electric field of point charges.

SET UP: $V = \frac{1}{4\pi\epsilon_0}\frac{q}{r}$ and $E = \frac{1}{4\pi\epsilon_0}\frac{|q|}{r^2}$. We want the potential. First sketch the arrangement of charges as in Fig. 23.7.2.

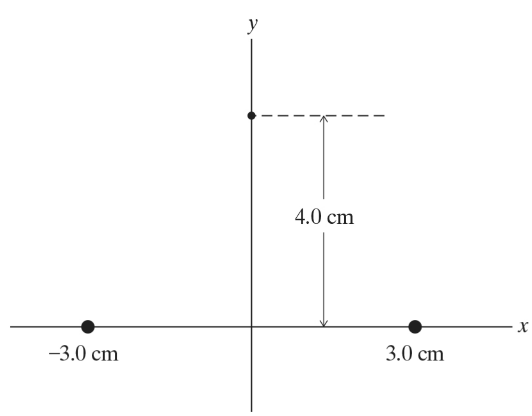

Figure VP23.7.2

EXECUTE: **(a)** The charges are equal and r = 3.0 cm = 0.030 m for each of them. So

$$V = V_1 + V_2 = 2\frac{1}{4\pi\epsilon_0}\frac{q}{r} = \frac{2}{4\pi\epsilon_0}\frac{6.0\text{ nC}}{0.030\text{ m}} = 3600\text{ V} = 3.6\text{ kV}.$$

(b) Use the same procedure as in part (a) with r = 5.0 cm = 0.050 m, giving V = 2200 V = 2.2 kV.

(c) The point we are interested in lies on the x-axis at x = 8.0 cm. So r_1 = 11.0 cm for the left-hand charge and r_2 = 5.0 cm for the right-hand charge. The potential at this point is

$$V = V_1 + V_2 = \frac{q}{4\pi\epsilon_0}\left(\frac{1}{r_1} + \frac{1}{r_2}\right) = \frac{(6.0\text{ nC})}{4\pi\epsilon_0}\left(\frac{1}{0.0500\text{ m}} + \frac{1}{0.110\text{ m}}\right) = 160\text{ V}.$$

(d) The net field can only be zero if the fields due to the two charges have equal magnitudes and are in opposite directions. These conditions are met only at the point (0,0,0), which is the point in part (a).

EVALUATE: Note an important point: In part (d) we saw that if $E = 0$ at a point, it does *not* necessarily follow that $V = 0$ at that point.

VP23.7.3. **IDENTIFY:** This problem involves the potential due to point charges.

SET UP: $V = \dfrac{1}{4\pi\epsilon_0}\dfrac{q}{r}$. Fig. VP23.7.3 shows the charges and the given information.

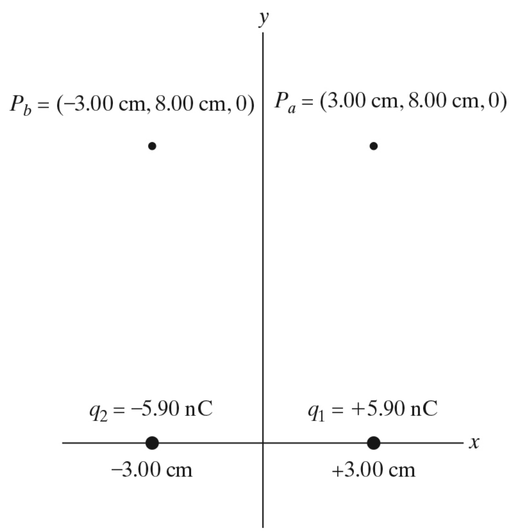

Figure VP23.7.3

EXECUTE: **(a)** We want V_a. $r_2 = \sqrt{(6.00\text{ cm})^2 + (8.00\text{ cm})^2} = 10.0\text{ cm} = 0.100\text{ m}$ and $r_1 = 8.00$ cm = 0.0800 m. $V_a = V_1 + V_2 = \dfrac{1}{4\pi\epsilon_0}\left(\dfrac{q_1}{r_1} + \dfrac{q_2}{r_2}\right) = \dfrac{1}{4\pi\epsilon_0}\left(\dfrac{5.90\text{ nC}}{0.0800\text{ m}} + \dfrac{-5.90\text{ nC}}{0.100\text{ m}}\right) = +133\text{ V}.$

(b) $V_b = V_1 + V_2 = \dfrac{1}{4\pi\epsilon_0}\left(\dfrac{q_1}{r_1} + \dfrac{q_2}{r_2}\right) = \dfrac{1}{4\pi\epsilon_0}\left(\dfrac{5.90\text{ nC}}{0.100\text{ m}} + \dfrac{-5.90\text{ nC}}{0.0800\text{ m}}\right) = -133\text{ V}.$

(c) We want the proton's speed at *a*. The proton starts at *b* and goes to *a*, so it is going from a low to a high potential. Therefore it is losing kinetic energy in the process. So $K_a = K_b - q(V_a - V_b)$. $\dfrac{1}{2}mv_a^2 = \dfrac{1}{2}mv_b^2 - e(V_a - V_b)$. $v_a = \sqrt{v_b^2 - 2e(V_a - V_b)/m}$. Using the given quantities and the results of parts (a) and (b), we get $v_a = 1.98\times10^5$ m/s.

EVALUATE: A positive charge (like a proton) will be accelerated to higher speed by the electric field going from high to low potential (just as a falling object is sped up by the gravitational field as it goes from high potential energy to low potential energy).

VP23.7.4. **IDENTIFY:** We want to get the potential difference by integrating the electric field. We'll need calculus for this.

SET UP: Use $V_a - V_b = -\int_b^a \vec{E} \cdot d\vec{l}$. Call V_0 the potential at the center of the sphere and V_R the potential at the surface when $r = R$. $d\vec{l} = dr\,\hat{r}$ and $\vec{E} = \dfrac{Qr}{4\pi\epsilon_0 R^3}\hat{r}$ inside the sphere.

EXECUTE: **(a)** Using the above quantities gives

$$V_R - V_0 = -\int_0^R \frac{Qr}{4\pi\epsilon_0 R^3}dr = -\left(\frac{Q}{4\pi\epsilon_0 R^3}\right)\frac{r^2}{2}\bigg|_0^R = -\frac{Q}{8\pi\epsilon_0 R}.$$

(b) From part (a), we have $V_R = V_0 - \dfrac{Q}{8\pi\epsilon_0 R}$. This tells us that $V_R < V_0$, so the center is at a higher potential than the surface. Another way to see this is to note that the electric field does work on a positive charge as it goes from the center to the surface because the field points outward. Thus the center is at a higher potential then the surface.

EVOALUATE: Notice that $E = 0$ at the center of the sphere, but the potential is highest there and not zero.

VP23.12.1. **IDENTIFY:** We want to find the work using electric potential.

SET UP: $W = q\Delta V$ and for a point charge $V = \dfrac{1}{4\pi\epsilon_0}\dfrac{q}{r}$.

EXECUTE: **(a)** <u>From $r = 5R$ to $r = 3R$</u>: $W = q_0(V_{3R} - V_{5R}) = q_0\left[\dfrac{q}{4\pi\epsilon_0}\left(\dfrac{1}{3R} - \dfrac{1}{5R}\right)\right] = \dfrac{qq_0}{30\pi\epsilon_0 R}$.

(b) <u>From $r = 2R$ to $r = 7R$</u>: $W = q_0(V_{7R} - V_{2R}) = \dfrac{q_0 q}{4\pi\epsilon_0}\left(\dfrac{1}{3R} - \dfrac{1}{5R}\right) = -\dfrac{5qq_0}{56\pi\epsilon_0 R}$.

(c) <u>From $r = 4R$ to $r = R/2$</u>: Inside the conducting sphere $E = 0$ so no work is done on q_0. So the work required is the work to go from $r = 4R$ to $r = R$, which is

$$W = q_0(V_{4R} - V_R) = \frac{q_0 q}{4\pi\epsilon_0}\left(\frac{1}{4R} - \frac{1}{R}\right) = \frac{3qq_0}{16\pi\epsilon_0 R}.$$

EVALUATE: In parts (a) and (c) the work we do is positive because we must push on q_0 against the electric field. In (b) the work is negative because negative because we must hold back on q_0 since the electric field pulls it in.

VP23.12.2. **IDENTIFY:** This problem involves two oppositely charged parallel plates.

SET UP: The electric field between the plates is uniform everywhere.

EXECUTE: **(a)** We want the potential at 3.0 mm above the lower plate. The electric field is uniform, so $V_{ab} = Ed$. At a distance x above the lower plate, the potential difference over that distance is Ex. Since E is uniform $\dfrac{V_x}{V_{ab}} = \dfrac{Ex}{Ed} = \dfrac{x}{d} = \dfrac{3.00\text{ mm}}{4.50\text{ mm}} = \dfrac{2}{3}$, so $V_x = \dfrac{2}{3}V_{ab} = \dfrac{2}{3}(+24.0\text{ V}) = +16.0\text{ V}$.

(b) $U = qV$, where V is relative to b. So $U = (2.00\text{ nC})(16.0\text{ V}) = 32\text{ nV} = 3.20\times10^{-8}\text{ J}$.

(c) Since it is positive, the particle will move in the direction of the electric field, which is toward the lower plate. Using $U_1 = K_2$ gives $\frac{1}{2}mv^2 = U$, so $v = \sqrt{\frac{2U}{m}} = \sqrt{\frac{2(3.20\times10^{-8}\text{ J})}{5.00\times10^{-9}\text{ kg}}} = 3.58\text{ m/s}$.

EVALUATE: Note in part (c) that the positive particle moved from higher to lower potential.

VP23.12.3. IDENTIFY: We are dealing with the potential of a uniformly charged ring.

SET UP: We know that $U = qV$. Example 23.11 showed that for a ring $V = \frac{1}{4\pi\epsilon_0}\frac{Q}{\sqrt{x^2+a^2}}$. We want the potential energy of the point charge, its kinetic energy, and its speed.

EXECUTE: (a) We want the potential energy of the charge at 8.00 cm from the center of the ring.

$$U_8 = qV = \frac{q}{4\pi\epsilon_0}\frac{Q}{\sqrt{x^2+a^2}} = \frac{(3.00\text{ nC})}{4\pi\epsilon_0}\frac{5.00\text{ nC}}{\sqrt{(0.0800\text{ m})^2+(0.0250\text{ m})^2}} = 1.61\times10^{-6}\text{ J}.$$

(b) At the center of the ring, $x = 0$. Using the above equations gives $U_0 = 5.39\times10^{-6}$ J.

(c) Energy conservation: $K_8 + U_8 = K_0 + U_0 \rightarrow K_0 = K_8 + U_8 - U_0$. From this we get $K_0 = \frac{1}{2}mv_8^2 + U_8 - U_0$. Using the results from parts (a) and (b) as well as the given quantities, we get $K_0 = 3.42\times10^{-6}$ J. Solving $K_0 = \frac{1}{2}mv_8^2$ for v_8 gives $v_8 = \sqrt{\frac{2K_0}{m}}$. Using K_0 and the given quantities gives $v_8 = 41.3$ m/s.

EVALUATE: The point charge loses kinetic energy (and hence speed) because the electric field of the ring does negative work on it as it approaches the center of the ring.

VP23.12.4. IDENTIFY: We want to calculate the potential due to a uniformly charged rod.

SET UP: Break the rod into infinitesimal segments of length dx carrying charge dq. Applying $V = \frac{1}{4\pi\epsilon_0}\frac{q}{r}$ to a typical segment, the potential at the origin is $dV = \frac{1}{4\pi\epsilon_0}\frac{dq}{x}$. Fig. VP23.12.4 shows the arrangement.

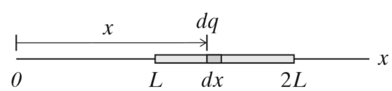

Figure VP23.12.4

EXECUTE: (a) $dq = \lambda dx = (Q/L)dx$.

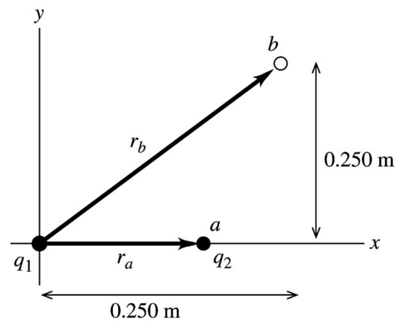
(b) Using Fig. VP23.12.4 and $dV = \frac{1}{4\pi\epsilon_0}\frac{dq}{x}$, and integrating, we have

$$V = \int_0^L \frac{1}{4\pi\epsilon_0}\frac{dq}{x} = \int_0^L \frac{Q/L}{4\pi\epsilon_0}\frac{dx}{x} = \frac{Q}{4\pi\epsilon_0 L}\ln x\Big|_L^{2L} = \frac{Q}{4\pi\epsilon_0 L}\ln 2.$$

EVALUATE: We cannot treat the rod as being equivalent to a point charge at its center. If that were the case, the potential due to the rod at the origin would be $\frac{Q}{4\pi\epsilon_0(3L/2)} = \frac{Q}{6\pi\epsilon_0 L}$, which is *not* what we calculated.

23.1. IDENTIFY: Apply $W_{a\to b} = U_a - U_b$ to calculate the work. The electric potential energy of a pair of point charges is given by $U = \frac{1}{4\pi\epsilon_0}\frac{q_1q_2}{r}$.

SET UP: Let the initial position of q_2 be point a and the final position be point b, as shown in Figure 23.1.



$r_a = 0.150$ m.

$r_b = \sqrt{(0.250\text{ m})^2 + (0.250\text{ m})^2}$.

$r_b = 0.3536$ m.

Figure 23.1

EXECUTE: $W_{a\to b} = U_a - U_b$.

$$U_a = \frac{1}{4\pi\epsilon_0}\frac{q_1 q_2}{r_a} = (8.988\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\frac{(+2.40\times10^{-6}\text{ C})(-4.30\times10^{-6}\text{ C})}{0.150\text{ m}}.$$

$U_a = -0.6184$ J.

$$U_b = \frac{1}{4\pi\epsilon_0}\frac{q_1 q_2}{r_b} = (8.988\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\frac{(+2.40\times10^{-6}\text{ C})(-4.30\times10^{-6}\text{ C})}{0.3536\text{ m}}.$$

$U_b = -0.2623$ J.

$$W_{a\to b} = U_a - U_b = -0.6184\text{ J} - (-0.2623\text{ J}) = -0.356\text{ J}.$$

EVALUATE: The attractive force on q_2 is toward the origin, so it does negative work on q_2 when q_2 moves to larger r.

23.2. **IDENTIFY:** Apply $W_{a\to b} = U_a - U_b$.

SET UP: $U_a = +5.4\times10^{-8}$ J. Solve for U_b.

EXECUTE:

$W_{a\to b} = -1.9\times10^{-8}\text{ J} = U_a - U_b$. $U_b = U_a - W_{a\to b} = +5.4\times10^{-8}\text{ J} - (-1.9\times10^{-8}\text{ J}) = 7.3\times10^{-8}$ J.

EVALUATE: When the electric force does negative work the electrical potential energy increases.

23.3. **IDENTIFY:** The work needed to assemble the nucleus is the sum of the electrical potential energies of the protons in the nucleus, relative to infinity.

SET UP: The total potential energy is the scalar sum of all the individual potential energies, where each potential energy is $U = (1/4\pi\epsilon_0)(qq_0/r)$. Each charge is e and the charges are equidistant from each other, so the total potential energy is $U = \dfrac{1}{4\pi\epsilon_0}\left(\dfrac{e^2}{r} + \dfrac{e^2}{r} + \dfrac{e^2}{r}\right) = \dfrac{3e^2}{4\pi\epsilon_0 r}$.

EXECUTE: Adding the potential energies gives

$$U = \frac{3e^2}{4\pi\epsilon_0 r} = \frac{3(1.60\times10^{-19}\text{ C})^2(9.00\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)}{2.00\times10^{-15}\text{ m}} = 3.46\times10^{-13}\text{ J} = 2.16\text{ MeV}.$$

EVALUATE: This is a small amount of energy on a macroscopic scale, but on the scale of atoms, 2 MeV is quite a lot of energy.

23.4. **IDENTIFY:** The work required is the change in electrical potential energy. The protons gain speed after being released because their potential energy is converted into kinetic energy.

(a) SET UP: Using the potential energy of a pair of point charges relative to infinity, $U = (1/4\pi\epsilon_0)(qq_0/r)$, we have $W = \Delta U = U_2 - U_1 = \dfrac{1}{4\pi\epsilon_0}\left(\dfrac{e^2}{r_2} - \dfrac{e^2}{r_1}\right)$.

EXECUTE: Factoring out the e^2 and substituting numbers gives

$$W = (9.00\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(1.60\times10^{-19}\ \text{C})^2\left(\frac{1}{3.00\times10^{-15}\ \text{m}} - \frac{1}{2.00\times10^{-10}\ \text{m}}\right) = 7.68\times10^{-14}\ \text{J}$$

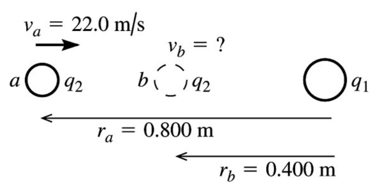
(b) SET UP: The protons have equal momentum, and since they have equal masses, they will have equal speeds and hence equal kinetic energy. $\Delta U = K_1 + K_2 = 2K = 2\left(\dfrac{1}{2}mv^2\right) = mv^2$.

EXECUTE: Solving for v gives $v = \sqrt{\dfrac{\Delta U}{m}} = \sqrt{\dfrac{7.68\times10^{-14}\ \text{J}}{1.67\times10^{-27}\ \text{kg}}} = 6.78\times10^6\ \text{m/s}$.

EVALUATE: The potential energy may seem small (compared to macroscopic energies), but it is enough to give each proton a speed of nearly 7 million m/s.

23.5. **(a) IDENTIFY:** Use conservation of energy: $K_a + U_a + W_{\text{other}} = K_b + U_b$. U for the pair of point charges is given by $U = \dfrac{1}{4\pi\epsilon_0}\dfrac{q_1q_2}{r}$.

SET UP:



Let point a be where q_2 is 0.800 m from q_1 and point b be where q_2 is 0.400 m from q_1, as shown in Figure 23.5a.

Figure 23.5a

EXECUTE: Only the electric force does work, so $W_{\text{other}} = 0$ and $U = \dfrac{1}{4\pi\epsilon_0}\dfrac{q_1q_2}{r}$.

$$K_a = \tfrac{1}{2}mv_a^2 = \tfrac{1}{2}(1.50\times10^{-3}\ \text{kg})(22.0\ \text{m/s})^2 = 0.3630\ \text{J}.$$

$$U_a = \frac{1}{4\pi\epsilon_0}\frac{q_1q_2}{r_a} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(-2.80\times10^{-6}\ \text{C})(-7.80\times10^{-6}\ \text{C})}{0.800\ \text{m}} = +0.2454\ \text{J}.$$

$$K_b = \tfrac{1}{2}mv_b^2.$$

$$U_b = \frac{1}{4\pi\epsilon_0}\frac{q_1q_2}{r_b} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(-2.80\times10^{-6}\ \text{C})(-7.80\times10^{-6}\ \text{C})}{0.400\ \text{m}} = +0.4907\ \text{J}.$$

The conservation of energy equation then gives $K_b = K_a + (U_a - U_b)$.

$$\tfrac{1}{2}mv_b^2 = +0.3630\ \text{J} + (0.2454\ \text{J} - 0.4907\ \text{J}) = 0.1177\ \text{J}.$$

$$v_b = \sqrt{\frac{2(0.1177\ \text{J})}{1.50\times10^{-3}\ \text{kg}}} = 12.5\ \text{m/s}.$$

EVALUATE: The potential energy increases when the two positively charged spheres get closer together, so the kinetic energy and speed decrease.

(b) IDENTIFY: Let point *c* be where q_2 has its speed momentarily reduced to zero. Apply conservation of energy to points *a* and *c*: $K_a + U_a + W_{\text{other}} = K_c + U_c$.

SET UP: Points *a* and *c* are shown in Figure 23.5b.

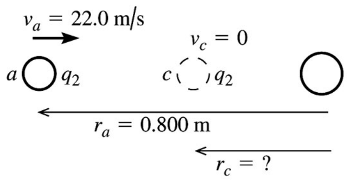


Figure 23.5b

EXECUTE: $K_a = +0.3630$ J (from part (a)).

$U_a = +0.2454$ J (from part (a)).

$K_c = 0$ (at distance of closest approach the speed is zero).

$$U_c = \frac{1}{4\pi\epsilon_0}\frac{q_1 q_2}{r_c}.$$

Thus conservation of energy $K_a + U_a = U_c$ gives $\dfrac{1}{4\pi\epsilon_0}\dfrac{q_1 q_2}{r_c} = +0.3630\text{ J} + 0.2454\text{ J} = 0.6084\text{ J}.$

$$r_c = \frac{1}{4\pi\epsilon_0}\frac{q_1 q_2}{0.6084\text{ J}} = (8.988\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\frac{(-2.80\times10^{-6}\text{ C})(-7.80\times10^{-6}\text{ C})}{+0.6084\text{ J}} = 0.323\text{ m}.$$

EVALUATE: $U \to \infty$ as $r \to 0$ so q_2 will stop no matter what its initial speed is.

23.6. IDENTIFY: The total potential energy is the scalar sum of the individual potential energies of each pair of charges.

SET UP: For a pair of point charges the electrical potential energy is $U = k\dfrac{qq'}{r}$. In the O-H-N combination the O^- is 0.170 nm from the H^+ and 0.280 nm from the N^-. In the N-H-N combination the N^- is 0.190 nm from the H^+ and 0.300 nm from the other N^-. *U* is positive for like charges and negative for unlike charges.

EXECUTE: (a) O-H-N:

$$\text{O}^-\text{- H}^+: U = -(8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\text{ C})^2}{0.170\times10^{-9}\text{ m}} = -1.35\times10^{-18}\text{ J}.$$

$$\text{O}^-\text{-N}^-: U = (8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\text{ C})^2}{0.280\times10^{-9}\text{ m}} = +8.22\times10^{-19}\text{ J}.$$

N-H-N:

$$\text{N}^-\text{- H}^+: U = -(8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\text{ C})^2}{0.190\times10^{-9}\text{ m}} = -1.21\times10^{-18}\text{ J}.$$

$$\text{N}^-\text{-N}^-: U = (8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\text{ C})^2}{0.300\times10^{-9}\text{ m}} = +7.67\times10^{-19}\text{ J}.$$

The total potential energy is

$U_{\text{tot}} = -1.35\times10^{-18}\text{ J} + 8.22\times10^{-19}\text{ J} - 1.21\times10^{-18}\text{ J} + 7.67\times10^{-19}\text{ J} = -9.71\times10^{-19}\text{ J}.$

(b) In the hydrogen atom the electron is 0.0529 nm from the proton.

$$U = -(8.99\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\ \text{C})^2}{0.0529\times10^{-9}\ \text{m}} = -4.35\times10^{-18}\ \text{J}.$$

EVALUATE: The magnitude of the potential energy in the hydrogen atom is about a factor of 4 larger than what it is for the adenine-thymine bond.

23.7. IDENTIFY: Use conservation of energy $U_a + K_a = U_b + K_b$ to find the distance of closest approach r_b. The maximum force is at the distance of closest approach, $F = k\dfrac{|q_1q_2|}{r_b^2}$.

SET UP: $K_b = 0$. Initially the two protons are far apart, so $U_a = 0$. A proton has mass 1.67×10^{-27} kg and charge $q = +e = +1.60\times10^{-19}$ C.

EXECUTE: $K_a = U_b$. $2(\frac{1}{2}mv_a^2) = k\dfrac{q_1q_2}{r_b}$. $mv_a^2 = k\dfrac{e^2}{r_b}$ and

$$r_b = \frac{ke^2}{mv_a^2} = \frac{(8.99\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)(1.60\times10^{-19}\ \text{C})^2}{(1.67\times10^{-27}\ \text{kg})(2.00\times10^{5}\ \text{m/s})^2} = 3.45\times10^{-12}\ \text{m}.$$

$$F = k\frac{e^2}{r_b^2} = (8.99\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\ \text{C})^2}{(3.445\times10^{-12}\ \text{m})^2} = 1.94\times10^{-5}\ \text{N}.$$

EVALUATE: The acceleration $a = F/m$ of each proton produced by this force is extremely large.

23.8. IDENTIFY: Call the three charges 1, 2, and 3. $U = U_{12} + U_{13} + U_{23}$.

SET UP: $U_{12} = U_{23} = U_{13}$ because the charges are equal and each pair of charges has the same separation, 0.400 m.

EXECUTE: $U = \dfrac{3kq^2}{0.400\ \text{m}} = \dfrac{3k(1.2\times10^{-6}\ \text{C})^2}{0.400\ \text{m}} = 0.0971\ \text{J}.$

EVALUATE: When the three charges are brought in from infinity to the corners of the triangle, the repulsive electrical forces between each pair of charges do negative work and electrical potential energy is stored.

23.9. IDENTIFY: The protons repel each other and therefore accelerate away from one another. As they get farther and farther away, their kinetic energy gets greater and greater but their acceleration keeps decreasing. Conservation of energy and Newton's laws apply to these protons.

SET UP: Let *a* be the point when they are 0.750 nm apart and *b* be the point when they are very far apart. A proton has charge $+e$ and mass 1.67×10^{-27} kg. As they move apart the protons have equal kinetic energies and speeds. Their potential energy is $U = ke^2/r$ and $K = \frac{1}{2}mv^2$. $K_a + U_a = K_b + U_b$.

EXECUTE: **(a)** They have maximum speed when they are far apart and all their initial electrical potential energy has been converted to kinetic energy. $K_a + U_a = K_b + U_b$.

$K_a = 0$ and $U_b = 0$, so

$$K_b = U_a = k\frac{e^2}{r_a} = (8.99\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{(1.60\times10^{-19}\ \text{C})^2}{0.750\times10^{-9}\ \text{m}} = 3.07\times10^{-19}\ \text{J}.$$

$K_b = \frac{1}{2}mv_b^2 + \frac{1}{2}mv_b^2$, so $K_b = mv_b^2$ and $v_b = \sqrt{\dfrac{K_b}{m}} = \sqrt{\dfrac{3.07\times10^{-19}\ \text{J}}{1.67\times10^{-27}\ \text{kg}}} = 1.36\times10^{4}\ \text{m/s}.$

(b) Their acceleration is largest when the force between them is largest and this occurs at $r = 0.750$ nm, when they are closest.

$$F = k\frac{e^2}{r^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\left(\frac{1.60\times10^{-19}\ \text{C}}{0.750\times10^{-9}\ \text{m}}\right)^2 = 4.09\times10^{-10}\ \text{N}.$$

$$a = \frac{F}{m} = \frac{4.09\times10^{-10}\ \text{N}}{1.67\times10^{-27}\ \text{kg}} = 2.45\times10^{17}\ \text{m/s}^2.$$

EVALUATE: The acceleration of the protons decreases as they move farther apart, but the force between them is repulsive so they continue to increase their speeds and hence their kinetic energies.

23.10. **IDENTIFY:** The work done on the alpha particle is equal to the difference in its potential energy when it is moved from the midpoint of the square to the midpoint of one of the sides.

SET UP: We apply the formula $W_{a\to b} = U_a - U_b$. In this case, a is the center of the square and b is the midpoint of one of the sides. Therefore $W_{\text{center}\to\text{side}} = U_{\text{center}} - U_{\text{side}}$ is the work done by the Coulomb force. There are 4 electrons, so the potential energy at the center of the square is 4 times the potential energy of a single alpha-electron pair. At the center of the square, the alpha particle is a distance $r_1 = \sqrt{50}$ nm from each electron. At the midpoint of the side, the alpha is a distance $r_2 = 5.00$ nm from the two nearest electrons and a distance $r_3 = \sqrt{125}$ nm from the two most distant electrons. Using the formula for the potential energy (relative to infinity) of two point charges, $U = (1/4\pi\epsilon_0)(qq_0/r)$, the total work done by the Coulomb force is

$$W_{\text{center}\to\text{side}} = U_{\text{center}} - U_{\text{side}} = 4\frac{1}{4\pi\epsilon_0}\frac{q_\alpha q_e}{r_1} - \left(2\frac{1}{4\pi\epsilon_0}\frac{q_\alpha q_e}{r_2} + 2\frac{1}{4\pi\epsilon_0}\frac{q_\alpha q_e}{r_3}\right).$$

Substituting $q_e = -e$ and $q_\alpha = 2e$ and simplifying gives

$$W_{\text{center}\to\text{side}} = -4e^2\frac{1}{4\pi\epsilon_0}\left[\frac{2}{r_1} - \left(\frac{1}{r_2} + \frac{1}{r_3}\right)\right].$$

EXECUTE: Substituting the numerical values into the equation for the work gives

$$W = -4(1.60\times10^{-19}\ \text{C})^2(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\left[\frac{2}{\sqrt{50}\ \text{nm}} - \left(\frac{1}{5.00\ \text{nm}} + \frac{1}{\sqrt{125}\ \text{nm}}\right)\right] = 6.08\times10^{-21}\ \text{J}.$$

EVALUATE: Since the work done by the Coulomb force is positive, the system has more potential energy with the alpha particle at the center of the square than it does with it at the midpoint of a side. To move the alpha particle to the midpoint of a side and leave it there at rest an external force must do -6.08×10^{-21} J of work.

23.11. **IDENTIFY:** We want to find the potential difference by using the electric field.

SET UP and **EXECUTE:** Start with a sketch as shown in Fig. 23.11.

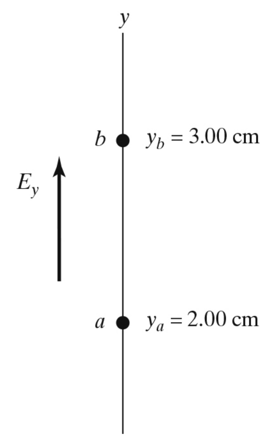

Figure 23.11

$V_a - V_b = \int_a^b E_y dy = \int_a^b (\alpha + \beta / y^2) dy = (\alpha y - \beta / y)\Big|_{y_a}^{y_b}$. Simplifying gives

$V_a - V_b = \alpha(y_b - y_a) + \beta\left(\frac{1}{y_a} - \frac{1}{y_b}\right)$. Using $y_a = 2.00$ cm, $y_b = 3.00$ cm, and the other values gives $V_a - V_b = 89.3$ V. $V_a = V_b + 89.3$ V, so V_a is higher than V_b.

EVALUATE: The electric field points from *a* to *b*, so a positive charge would gain kinetic energy as it was accelerated by the field from *a* to *b*, so the potential at *a* must be higher than at *b*, as we found.

23.12. **IDENTIFY**: Work is done on the object by the electric field, and this changes its kinetic energy, so we can use the work-energy theorem.

SET UP: $W_{A \to B} = \Delta K$ and $W_{A \to B} = q(V_A - V_B)$.

EXECUTE: **(a)** Applying the two equations above gives $W_{A \to B} = q(V_A - V_B) = K_B - 0 = K_B$.

$V_B = V_A - K_B/q = 30.0 \text{ V} - (3.00 \times 10^{-7} \text{ J})/(-6.00 \times 10^{-9} \text{ C}) = 80.0 \text{ V}$.

(b) The negative charge accelerates from *A* to *B*, so the electric field must point from *B* toward *A*. Since the field is uniform, we have $E = \frac{\Delta V}{\Delta x}$ = (50.0 V)/(0.500 m) = 100 V/m.

EVALUATE: A positive charge is accelerated from high to low potential, but a negative charge (as we have here) is accelerated from low to high potential.

23.13. **IDENTIFY** and **SET UP:** Apply conservation of energy to points *A* and *B*.

EXECUTE: $K_A + U_A = K_B + U_B$.

$U = qV$, so $K_A + qV_A = K_B + qV_B$.

$K_B = K_A + q(V_A - V_B) = 0.00250 \text{ J} + (-5.00 \times 10^{-6} \text{ C})(200 \text{ V} - 800 \text{ V}) = 0.00550 \text{ J}$.

$v_B = \sqrt{2K_B/m} = 7.42$ m/s.

EVALUATE: It is faster at *B*; a negative charge gains speed when it moves to higher potential.

23.14. **IDENTIFY**: The work-energy theorem says $W_{a \to b} = K_b - K_a$. $\frac{W_{a \to b}}{q} = V_a - V_b$.

SET UP: Point *a* is the starting point and point *b* is the ending point. Since the field is uniform, $W_{a \to b} = Fs\cos\phi = E|q|s\cos\phi$. The field is to the left so the force on the positive charge is to the left. The particle moves to the left so $\phi = 0°$ and the work $W_{a \to b}$ is positive.

EXECUTE: **(a)** $W_{a\to b} = K_b - K_a = 2.20\times10^{-6}\text{ J} - 0 = 2.20\times10^{-6}\text{ J}.$

(b) $V_a - V_b = \dfrac{W_{a\to b}}{q} = \dfrac{2.20\times10^{-6}\text{ J}}{4.20\times10^{-9}\text{ C}} = 524\text{ V}.$ Point a is at higher potential than point b.

(c) $E|q|s = W_{a\to b}$, so $E = \dfrac{W_{a\to b}}{|q|s} = \dfrac{V_a - V_b}{s} = \dfrac{524\text{ V}}{6.00\times10^{-2}\text{ m}} = 8.73\times10^{3}\text{ V/m}.$

EVALUATE: A positive charge gains kinetic energy when it moves to lower potential; $V_b < V_a$.

23.15. **IDENTIFY**: Apply $W_{a\to b} = q'\int_a^b \vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{l}}$. Use coordinates where $+y$ is upward and $+x$ is to the right. Then $\vec{\boldsymbol{E}} = E\hat{\boldsymbol{j}}$ with $E = 4.00\times10^{4}$ N/C.

SET UP: **(a)** The path is sketched in Figure 23.15a.

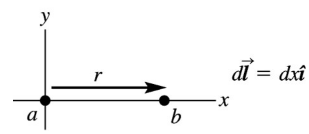

Figure 23.15a

EXECUTE: $\vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{l}} = (E\hat{\boldsymbol{j}})\cdot(dx\hat{\boldsymbol{i}}) = 0$ so $W_{a\to b} = q'\int_a^b \vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{l}} = 0.$

EVALUATE: The electric force on the positive charge is upward (in the direction of the electric field) and does no work for a horizontal displacement of the charge.

(b) SET UP: The path is sketched in Figure 23.15b.

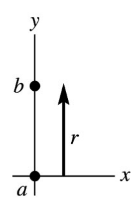

Figure 23.15b

EXECUTE: $\vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{l}} = (E\hat{\boldsymbol{j}})\cdot(dy\hat{\boldsymbol{j}}) = E\,dy.$

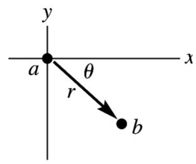
$$W_{a\to b} = q'\int_a^b \vec{\boldsymbol{E}}\cdot d\vec{\boldsymbol{l}} = q'E\int_a^b dy = q'E(y_b - y_a).$$

$y_b - y_a = +0.670$ m; it is positive since the displacement is upward and we have taken $+y$ to be upward.

$$W_{a\to b} = q'E(y_b - y_a) = (+28.0\times10^{-9}\text{ C})(4.00\times10^{4}\text{ N/C})(+0.670\text{ m}) = +7.50\times10^{-4}\text{ J}.$$

EVALUATE: The electric force on the positive charge is upward so it does positive work for an upward displacement of the charge.

(c) SET UP: The path is sketched in Figure 23.15c.



$y_a = 0.$

$y_b = -r\sin\theta = -(2.60\text{ m})\sin 45° = -1.838\text{ m}.$

The vertical component of the 2.60 m displacement is 1.838 m downward.

Figure 23.15c

EXECUTE: $d\vec{l} = dx\hat{i} + dy\hat{j}$ (The displacement has both horizontal and vertical components.)

$\vec{E}\cdot d\vec{l} = (E\hat{j})\cdot(dx\hat{i} + dy\hat{j}) = E\,dy$ (Only the vertical component of the displacement contributes to the work.)

$$W_{a\to b} = q'\int_a^b \vec{E}\cdot d\vec{l} = q'E\int_a^b dy = q'E(y_b - y_a).$$

$$W_{a\to b} = q'E(y_b - y_a) = (+28.0\times10^{-9}\text{ C})(4.00\times10^4\text{ N/C})(-1.838\text{ m}) = -2.06\times10^{-3}\text{ J}.$$

EVALUATE: The electric force on the positive charge is upward so it does negative work for a displacement of the charge that has a downward component.

23.16. IDENTIFY: Apply $K_a + U_a = K_b + U_b$.

SET UP: Let $q_1 = +3.00\text{ nC}$ and $q_2 = +2.00\text{ nC}$. At point *a*, $r_{1a} = r_{2a} = 0.250\text{ m}$. At point *b*, $r_{1b} = 0.100\text{ m}$ and $r_{2b} = 0.400\text{ m}$. The electron has $q = -e$ and $m_e = 9.11\times10^{-31}\text{ kg}$. $K_a = 0$ since the electron is released from rest.

EXECUTE: $-\dfrac{keq_1}{r_{1a}} - \dfrac{keq_2}{r_{2a}} = -\dfrac{keq_1}{r_{1b}} - \dfrac{keq_2}{r_{2b}} + \dfrac{1}{2}m_e v_b^2.$

$$E_a = K_a + U_a = k(-1.60\times10^{-19}\text{ C})\left(\frac{(3.00\times10^{-9}\text{ C})}{0.250\text{ m}} + \frac{(2.00\times10^{-9}\text{ C})}{0.250\text{ m}}\right) = -2.88\times10^{-17}\text{ J}.$$

$$E_b = K_b + U_b = k(-1.60\times10^{-19}\text{ C})\left(\frac{(3.00\times10^{-9}\text{ C})}{0.100\text{ m}} + \frac{(2.00\times10^{-9}\text{ C})}{0.400\text{ m}}\right) + \frac{1}{2}m_e v_b^2 = -5.04\times10^{-17}\text{ J} + \frac{1}{2}m_e v_b^2.$$

Setting $E_a = E_b$ gives $v_b = \sqrt{\dfrac{2}{9.11\times10^{-31}\text{ kg}}(5.04\times10^{-17}\text{ J} - 2.88\times10^{-17}\text{ J})} = 6.89\times10^6\text{ m/s}.$

EVALUATE: $V_a = V_{1a} + V_{2a} = 180\text{ V}$. $V_b = V_{1b} + V_{2b} = 315\text{ V}$. $V_b > V_a$. The negatively charged electron gains kinetic energy when it moves to higher potential.

23.17. IDENTIFY: The potential at any point is the scalar sum of the potentials due to individual charges.

SET UP: $V = kq/r$ and $W_{ab} = q(V_a - V_b)$.

EXECUTE: **(a)** $r_{a1} = r_{a2} = \dfrac{1}{2}\sqrt{(0.0300\text{ m})^2 + (0.0300\text{ m})^2} = 0.0212\text{ m}.$ $V_a = k\left(\dfrac{q_1}{r_{a1}} + \dfrac{q_2}{r_{a2}}\right) = 0.$

(b) $r_{b1} = 0.0424\text{ m}$, $r_{b2} = 0.0300\text{ m}$.

$$V_b = k\left(\frac{q_1}{r_{b1}} + \frac{q_2}{r_{b2}}\right) = (8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\left(\frac{+2.00\times10^{-6}\text{ C}}{0.0424\text{ m}} + \frac{-2.00\times10^{-6}\text{ C}}{0.0300\text{ m}}\right) = -1.75\times10^5\text{ V}.$$

(c) $W_{ab} = q_3(V_a - V_b) = (-5.00\times10^{-6}\text{ C})[0 - (-1.75\times10^5\text{ V})] = -0.875\text{ J}.$

EVALUATE: Since $V_b < V_a$, a positive charge would be pulled by the existing charges from *a* to *b*, so they would do positive work on this charge. But they would repel a negative charge and hence do negative work on it, as we found in part (c).

23.18. **IDENTIFY:** The total potential is the *scalar* sum of the individual potentials, but the net electric field is the *vector* sum of the two fields.

SET UP: The net potential can only be zero if one charge is positive and the other is negative, since it is a scalar. The electric field can only be zero if the two fields point in opposite directions.

EXECUTE: **(a)** (i) Since both charges have the same sign, there are no points for which the potential is zero.

(ii) The two electric fields are in opposite directions only between the two charges, and midway between them the fields have equal magnitudes. So $E = 0$ midway between the charges, but V is never zero.

(b) (i) The two potentials have equal magnitude but opposite sign midway between the charges, so $V = 0$ midway between the charges, but $E \neq 0$ there since the fields point in the same direction.

(ii) Between the two charges, the fields point in the same direction, so E cannot be zero there. In the other two regions, the field due to the nearer charge is always greater than the field due to the more distant charge, so they cannot cancel. Hence E is not zero anywhere.

EVALUATE: It does *not* follow that the electric field is zero where the potential is zero, or that the potential is zero where the electric field is zero.

23.19. **IDENTIFY:** Apply $V = \dfrac{1}{4\pi\varepsilon_0}\sum_i \dfrac{q_i}{r_i}$.

SET UP: The locations of the charges and points A and B are sketched in Figure 23.19.

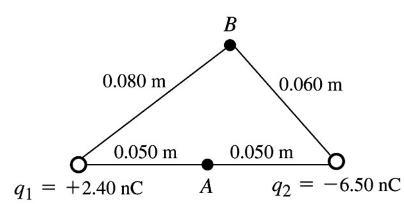


Figure 23.19

EXECUTE: **(a)** $V_A = \dfrac{1}{4\pi\epsilon_0}\left(\dfrac{q_1}{r_{A1}} + \dfrac{q_2}{r_{A2}}\right)$.

$$V_A = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\left(\frac{+2.40\times10^{-9}\ \text{C}}{0.050\ \text{m}} + \frac{-6.50\times10^{-9}\ \text{C}}{0.050\ \text{m}}\right) = -737\ \text{V}.$$

(b) $V_B = \dfrac{1}{4\pi\epsilon_0}\left(\dfrac{q_1}{r_{B1}} + \dfrac{q_2}{r_{B2}}\right)$.

$$V_B = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\left(\frac{+2.40\times10^{-9}\ \text{C}}{0.080\ \text{m}} + \frac{-6.50\times10^{-9}\ \text{C}}{0.060\ \text{m}}\right) = -704\ \text{V}.$$

(c) IDENTIFY and **SET UP:** Use $W_{a\to b} = q(V_a - V_b)$ and the results of parts (a) and (b) to calculate W.

EXECUTE: $W_{B\to A} = q(V_B - V_A) = (2.50\times10^{-9}\ \text{C})\left[-704\ \text{V} - (-737\ \text{V})\right] = +8.2\times10^{-8}\ \text{J}$.

EVALUATE: The electric force does positive work on the positive charge when it moves from higher potential (point B) to lower potential (point A).

23.20. **IDENTIFY** and **SET UP:** Apply conservation of energy: $K_a + U_a = K_b + U_b$. Use $V = U/q_0$ to express U in terms of V.

(a) EXECUTE: $K_1 + qV_1 = K_2 + qV_2$, $q(V_2 - V_1) = K_1 - K_2$; $q = -1.602\times10^{-19}$ C.

$K_1 = \frac{1}{2}m_e v_1^2 = 4.099\times10^{-18}$ J; $K_2 = \frac{1}{2}m_e v_2^2 = 2.915\times10^{-17}$ J. $\Delta V = V_2 - V_1 = \dfrac{K_1 - K_2}{q} = 156$ V.

EVALUATE: The electron gains kinetic energy when it moves to higher potential.

(b) EXECUTE: Now $K_1 = 2.915\times10^{-17}$ J, $K_2 = 0$. $V_2 - V_1 = \dfrac{K_1 - K_2}{q} = -182$ V.

EVALUATE: The electron loses kinetic energy when it moves to lower potential.

23.21. **IDENTIFY:** We want to relate the electric field and potential.
SET UP and **EXECUTE:** (a) $V_B > V_A$. The electric field points from higher to lower potential (from B to A), so E_y is negative.
(b) We want $|E_y|$. $|E_y|(y_B - y_A) = 12.0$ V, so $|E_y| = (12.0\text{ V})/(0.0700\text{ m}) = 171$ V/m.
(c) $V_C - V_B = E_y(y_C - y_B) = (-171\text{ V/m})(0.100\text{ m}) = -17.1$ V.
EVALUATE: The $V_C = V_B - 17.1$ V/m, so $V_B > V_C$.

23.22. **IDENTIFY:** For a point charge, $E = \dfrac{k|q|}{r^2}$ and $V = \dfrac{kq}{r}$.

SET UP: The electric field is directed toward a negative charge and away from a positive charge.

EXECUTE: **(a)** $V > 0$ so $q > 0$. $\dfrac{V}{E} = \dfrac{kq/r}{k|q|/r^2} = \left(\dfrac{kq}{r}\right)\left(\dfrac{r^2}{kq}\right) = r$. $r = \dfrac{4.98\text{ V}}{16.2\text{ V/m}} = 0.307$ m.

(b) $q = \dfrac{rV}{k} = \dfrac{(0.307\text{ m})(4.98\text{ V})}{8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2} = 1.70\times10^{-10}$ C.

(c) $q > 0$, so the electric field is directed away from the charge.

EVALUATE: The ratio of V to E due to a point charge increases as the distance r from the charge increases, because E falls off as $1/r^2$ and V falls off as $1/r$.

23.23. **(a) IDENTIFY** and **EXECUTE:** The direction of $\vec{E}$ is always from high potential to low potential so point b is at higher potential.

(b) IDENTIFY and **SET UP:** Apply $V_b - V_a = -\int_a^b \vec{E}\cdot d\vec{l}$ to relate $V_b - V_a$ to E.

EXECUTE: $V_b - V_a = -\int_a^b \vec{E}\cdot d\vec{l} = \int_a^b E\,dx = E(x_b - x_a)$.

$$E = \frac{V_b - V_a}{x_b - x_a} = \frac{+240\text{ V}}{0.90\text{ m} - 0.60\text{ m}} = 800\text{ V/m}$$

(c) SET UP and **EXECUTE:** $W_{b\to a} = q(V_b - V_a) = (-0.200\times10^{-6}\text{ C})(+240\text{ V}) = -4.80\times10^{-5}$ J.

EVALUATE: The electric force does negative work on a negative charge when the negative charge moves from high potential (point b) to low potential (point a).

23.24. **IDENTIFY:** This problem deals with the potential and energy of point charges.
SET UP and **EXECUTE:** (a) We want $V_A - V_B$. The negative sphere loses kinetic energy as it goes from A to B, so it is gaining potential energy. Thus it has higher potential energy at B than at A. A negative charge is accelerated from low to high potential by the field, so since $U_B > U_A$, it follows that $V_B < V_A$. Thus A has higher potential. Energy conservation gives $U_A + K_A = U_B + K_B$, so
$U_A - U_B = K_B - K_A = q(V_A - V_B)$. Using the given numbers gives $V_A - V_B = +100$ V.

(b) Since $V_A > V_B$, the electric field points from A to B, which is in the $+x$ direction. Thus $E_x \Delta x = \Delta V$.

So $E_x = \dfrac{\Delta V}{\Delta x} = \dfrac{100\text{ V}}{0.400\text{ m}} = +250\text{ V/m}.$

EVALUATE: Careful! Positive charges are accelerated from high to low potential, but negative charges are accelerated from low to high potential.

23.25. **IDENTIFY:** This problem involves the potential energy of point charges.

SET UP and **EXECUTE:** (a) We want the work. $W = -\Delta U = -Q\Delta V = -Q(V_0 - V\infty) = -QV_0$. Using $V = \dfrac{1}{4\pi\epsilon_0}\dfrac{q}{r}$ with $q_1 = q_2 = q$ and $r_1 = r_2 = r$ gives $W = \dfrac{-Qq}{4\pi\epsilon_0}\left(\dfrac{1}{r} + \dfrac{1}{r}\right)$. Using $r = 0.400$ m and the given values gives $W = 0.0539$ J.

(b) We want the speed at the origin. $W = K = \dfrac{1}{2}mv^2$ gives $v = \sqrt{2W/m}$. Using W from part (a) and the given values gives $v = 3.00$ m/s.

EVALUATE: At the origin the force on the sphere is zero, but it does not stop. In fact, its kinetic energy would be converted back to electric potential energy and it would move out to infinity.

23.26. **IDENTIFY:** This problem involves the potential of a small charged sphere.

SET UP and **EXECUTE:** We want the charge on the sphere. We need to relate $V_A - V_B$ to $1/r$ to interpret the graph. $V_A - V_B = \dfrac{1}{4\pi\epsilon_0}\left(\dfrac{q}{r_A} - \dfrac{q}{r}\right)$. The slope should be $-kq$ and the y-intercept $\dfrac{q}{4\pi\epsilon_0 r_A}$.

$q = -4\pi\epsilon_0 \text{ (slope)} = -4\pi\epsilon_0 (-18.0\text{ V}\cdot\text{m}) = +2.00\text{ nC}.$

EVALUATE: Since the y-intercept is $\dfrac{q}{4\pi\epsilon_0 r_A}$, we could use it as a check if we knew its value.

23.27. **IDENTIFY:** The potential at any point is the scalar sum of the potential due to each shell.

SET UP: $V = \dfrac{kq}{R}$ for $r \le R$ and $V = \dfrac{kq}{r}$ for $r > R$.

EXECUTE: **(a)** (i) $r = 0$. This point is inside both shells so

$$V = k\left(\frac{q_1}{R_1} + \frac{q_2}{R_2}\right) = (8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\left(\frac{6.00\times10^{-9}\text{ C}}{0.0300\text{ m}} + \frac{-9.00\times10^{-9}\text{ C}}{0.0500\text{ m}}\right).$$

$$V = +1.798\times10^3\text{ V} + (-1.618\times10^3\text{ V}) = 180\text{ V}.$$

(ii) $r = 4.00$ cm. This point is outside shell 1 and inside shell 2.

$$V = k\left(\frac{q_1}{r} + \frac{q_2}{R_2}\right) = (8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)\left(\frac{6.00\times10^{-9}\text{ C}}{0.0400\text{ m}} + \frac{-9.00\times10^{-9}\text{ C}}{0.0500\text{ m}}\right).$$

$$V = +1.348\times10^3\text{ V} + (-1.618\times10^3\text{ V}) = -270\text{ V}.$$

(iii) $r = 6.00$ cm. This point is outside both shells.

$$V = k\left(\frac{q_1}{r} + \frac{q_2}{r}\right) = \frac{k}{r}(q_1 + q_2) = \frac{8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2}{0.0600\text{ m}}\left[6.00\times10^{-9}\text{ C} + (-9.00\times10^{-9}\text{ C})\right].\ V = -450\text{ V}.$$

(b) At the surface of the inner shell, $r = R_1 = 3.00$ cm. This point is inside the larger shell, so $V_1 = k\left(\dfrac{q_1}{R_1} + \dfrac{q_2}{R_2}\right) = 180$ V. At the surface of the outer shell, $r = R_2 = 5.00$ cm. This point is outside the smaller shell, so

$$V = k\left(\frac{q_1}{r} + \frac{q_2}{R_2}\right) = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\left(\frac{6.00\times10^{-9}\ \text{C}}{0.0500\ \text{m}} + \frac{-9.00\times10^{-9}\ \text{C}}{0.0500\ \text{m}}\right).$$

$V_2 = +1.079\times10^3\ \text{V} + (-1.618\times10^3\ \text{V}) = -539\ \text{V}$. The potential difference is $V_1 - V_2 = 719\ \text{V}$. The inner shell is at higher potential. The potential difference is due entirely to the charge on the inner shell.

EVALUATE: Inside a uniform spherical shell, the electric field is zero so the potential is constant (but *not* necessarily zero).

23.28. **IDENTIFY** and **SET UP:** Outside a solid conducting sphere $V = k\frac{q}{r}$. Inside the sphere the potential is constant because $E = 0$, and it has the same value as at the surface of the sphere.

EXECUTE: **(a)** This is outside the sphere, so $V = \frac{kq}{r} = \frac{k(3.50\times10^{-9}\ \text{C})}{0.480\ \text{m}} = 65.6\ \text{V}$.

(b) This is at the surface of the sphere, so $V = \frac{k(3.50\times10^{-9}\ \text{C})}{0.240\ \text{m}} = 131\ \text{V}$.

(c) This is inside the sphere. The potential has the same value as at the surface, 131 V.

EVALUATE: All points of a conductor are at the same potential.

23.29. **(a) IDENTIFY** and **SET UP:** The electric field on the ring's axis is given by $E_x = \frac{1}{4\pi\epsilon_0}\frac{Qx}{(x^2+a^2)^{3/2}}$.

The magnitude of the force on the electron exerted by this field is given by $F = eE$.

EXECUTE: When the electron is on either side of the center of the ring, the ring exerts an attractive force directed toward the center of the ring. This restoring force produces oscillatory motion of the electron along the axis of the ring, with amplitude 30.0 cm. The force on the electron is *not* of the form $F = -kx$ so the oscillatory motion is not simple harmonic motion.

(b) IDENTIFY: Apply conservation of energy to the motion of the electron.

SET UP: $K_a + U_a = K_b + U_b$ with a at the initial position of the electron and b at the center of the ring.

From Example 23.11, $V = \frac{1}{4\pi\epsilon_0}\frac{Q}{\sqrt{x^2+a^2}}$, where a is the radius of the ring.

EXECUTE: $x_a = 30.0\ \text{cm}, x_b = 0$.

$K_a = 0$ (released from rest), $K_b = \frac{1}{2}mv^2$.

Thus $\frac{1}{2}mv^2 = U_a - U_b$.

And $U = qV = -eV$ so $v = \sqrt{\frac{2e(V_b - V_a)}{m}}$.

$$V_a = \frac{1}{4\pi\epsilon_0}\frac{Q}{\sqrt{x_a^2+a^2}} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{24.0\times10^{-9}\ \text{C}}{\sqrt{(0.300\ \text{m})^2+(0.150\ \text{m})^2}}.$$

$$V_a = 643\ \text{V}.$$

$$V_b = \frac{1}{4\pi\epsilon_0}\frac{Q}{\sqrt{x_b^2+a^2}} = (8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{24.0\times10^{-9}\ \text{C}}{0.150\ \text{m}} = 1438\ \text{V}.$$

$$v = \sqrt{\frac{2e(V_b - V_a)}{m}} = \sqrt{\frac{2(1.602\times10^{-19}\ \text{C})(1438\ \text{V} - 643\ \text{V})}{9.109\times10^{-31}\ \text{kg}}} = 1.67\times10^7\ \text{m/s}.$$

EVALUATE: The positively charged ring attracts the negatively charged electron and accelerates it. The electron has its maximum speed at this point. When the electron moves past the center of the ring the force on it is opposite to its motion and it slows down.

23.30. **IDENTIFY:** For an isolated conducting sphere, all the excess charge is on its outer surface. For points outside the sphere, it behaves like a point-charge at its center, and the electric field is zero inside the sphere.

SET UP: Use V at 1.20 m to find V at the surface. $V = k\dfrac{q}{r}$. We don't know the charge on the sphere, but we know the potential 1.20 m from its center.

EXECUTE: Take the ratio of the potentials: $\dfrac{V_{\text{surface}}}{V_{1.20\text{ m}}} = \dfrac{kq/(0.400\text{ m})}{kq(1.20\text{ m})} = \dfrac{1.20}{0.400} = 3.00,$ so

$V_{\text{surface}} = (3.00)(24.0\text{ V}) = 72.0\text{ V}$.

The electric field is zero inside the sphere, so the potential inside is constant and equal to the potential at the surface. So at the center $V = 72.0$ V.

EVALUATE: An alternative approach would be to use the given information to find the charge on the sphere. Then use that charge to calculate the potential at the surface. The potential is 72.0 V at *all* points inside the sphere, not just at the center. Careful! Just because the electric field inside the sphere is zero, it does not follow that the potential is zero there.

23.31. **IDENTIFY:** If the small sphere is to have its *minimum* speed, it must just stop at 8.00 cm from the surface of the large sphere. In that case, the initial kinetic energy of the small sphere is all converted to electrical potential energy at its point of closest approach.

SET UP: $K_1 + U_1 = K_2 + U_2$. $K_2 = 0$. $U_1 = 0$. Therefore, $K_1 = U_2$. Outside a spherical charge distribution the potential is the same as for a point charge at the location of the center of the sphere, so $U = kqQ/r. K = \frac{1}{2}mv^2$.

EXECUTE: $U_2 = \dfrac{kqQ}{r_2}$, with $r_2 = 12.0\text{ cm} + 8.0\text{ cm} = 0.200\text{ m}$. $\dfrac{1}{2}mv_1^2 = \dfrac{kqQ}{r_2}$.

$$v_1 = \sqrt{\frac{2kqQ}{mr_2}} = \sqrt{\frac{2(8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(3.00\times10^{-6}\text{ C})(5.00\times10^{-6}\text{ C})}{(6.00\times10^{-5}\text{ kg})(0.200\text{ m})}} = 150\text{ m/s}.$$

EVALUATE: If the small sphere had enough initial speed to actually penetrate the surface of the large sphere, we could no longer treat the large sphere as a point charge once the small sphere was inside.

23.32. **IDENTIFY:** For a line of charge, $V_a - V_b = \dfrac{\lambda}{2\pi\epsilon_0}\ln(r_b/r_a)$. Apply conservation of energy to the motion of the proton.

SET UP: Let point a be 18.0 cm from the line and let point b be at the distance of closest approach, where $K_b = 0$.

EXECUTE: **(a)** $K_a = \frac{1}{2}mv^2 = \frac{1}{2}(1.67\times10^{-27}\text{ kg})(3.50\times10^3\text{ m/s})^2 = 1.02\times10^{-20}\text{ J}$.

(b) $K_a + qV_a = K_b + qV_b$. $V_a - V_b = \dfrac{K_b - K_a}{q} = \dfrac{-1.02\times10^{-20}\text{ J}}{1.60\times10^{-19}\text{ C}} = -0.06397\text{ V}$.

$$\ln(r_b/r_a) = \left(\frac{2\pi\epsilon_0}{\lambda}\right)(-0.06397\text{ V}).$$

$$r_b = r_a\exp\left(\frac{2\pi\epsilon_0\,(-0.06397\text{ V})}{\lambda}\right) = (0.180\text{ m})\exp\left(-\frac{2\pi\epsilon_0\,(0.06397\text{ V})}{5.00\times10^{-12}\text{ C/m}}\right) = 0.0883\text{ m} = 8.83\text{ cm}.$$

EVALUATE: The potential increases with decreasing distance from the line of charge. As the positively charged proton approaches the line of charge it gains electrical potential energy and loses kinetic energy.

23.33. IDENTIFY: For points outside the cylinder, its electric field behaves like that of a line of charge. Since a voltmeter reads potential difference, that is what we need to calculate.

SET UP: The potential difference is $\Delta V = \dfrac{\lambda}{2\pi\epsilon_0}\ln(r_b/r_a)$.

EXECUTE: **(a)** Substituting numbers gives

$$\Delta V = \frac{\lambda}{2\pi\epsilon_0}\ln(r_b/r_a) = (8.50\times10^{-6}\text{ C/m})(2\times9.00\times10^{9}\text{ N}\cdot\text{m}^2/\text{C}^2)\ln\left(\frac{10.0\text{ cm}}{6.00\text{ cm}}\right).$$

$$\Delta V = 7.82\times10^{4}\text{ V} = 78{,}200\text{ V} = 78.2\text{ kV}.$$

(b) $E = 0$ inside the cylinder, so the potential is constant there, meaning that the voltmeter reads zero.

EVALUATE: Caution! The fact that the voltmeter reads zero in part (b) does not mean that $V = 0$ inside the cylinder. The electric field is zero, but the potential is constant and equal to the potential at the surface.

23.34. IDENTIFY: The voltmeter reads the potential difference between the two points where the probes are placed. Therefore we must relate the potential difference to the distances of these points from the center of the cylinder. For points outside the cylinder, its electric field behaves like that of a line of charge.

SET UP: Using $\Delta V = \dfrac{\lambda}{2\pi\epsilon_0}\ln(r_b/r_a)$ and solving for r_b, we have $r_b = r_a e^{2\pi\epsilon_0\Delta V/\lambda}$.

EXECUTE: The exponent is $\dfrac{\left(\dfrac{1}{2\times8.99\times10^{9}\text{ N}\cdot\text{m}^2/\text{C}^2}\right)(175\text{ V})}{15.0\times10^{-9}\text{ C/m}} = 0.648$, which gives

$$r_b = (2.50\text{ cm})\,e^{0.648} = 4.78\text{ cm}.$$

The distance above the *surface* is $4.78\text{ cm} - 2.50\text{ cm} = 2.28\text{ cm}$.

EVALUATE: Since a voltmeter measures potential difference, we are actually given ΔV, even though that is not stated explicitly in the problem. We must also be careful when using the formula for the potential difference because each *r* is the distance from the *center* of the cylinder, not from the surface.

23.35. IDENTIFY: The electric field of the line of charge does work on the sphere, increasing its kinetic energy.

SET UP: $K_1 + U_1 = K_2 + U_2$ and $K_1 = 0$. $U = qV$ so $qV_1 = K_2 + qV_2$. $V = \dfrac{\lambda}{2\pi\epsilon_0}\ln\left(\dfrac{r_0}{r}\right)$.

EXECUTE: $V_1 = \dfrac{\lambda}{2\pi\epsilon_0}\ln\left(\dfrac{r_0}{r_1}\right)$. $V_2 = \dfrac{\lambda}{2\pi\epsilon_0}\ln\left(\dfrac{r_0}{r_2}\right)$.

$$K_2 = q(V_1 - V_2) = \frac{q\lambda}{2\pi\epsilon_0}\left(\ln\left(\frac{r_0}{r_1}\right) - \ln\left(\frac{r_0}{r_2}\right)\right) = \frac{\lambda q}{2\pi\epsilon_0}(\ln r_2 - \ln r_1) = \frac{\lambda q}{2\pi\epsilon_0}\ln\left(\frac{r_2}{r_1}\right).$$

$$K_2 = \frac{(3.00\times10^{-6}\text{ C/m})(8.00\times10^{-6}\text{ C})}{2\pi(8.854\times10^{-12}\text{ C}^2/(\text{N}\cdot\text{m}^2)}\ln\left(\frac{4.50}{1.50}\right) = 0.474\text{ J}.$$

EVALUATE: The potential due to the line of charge does *not* go to zero at infinity but is defined to be zero at an arbitrary distance r_0 from the line.

23.36. **IDENTIFY** and **SET UP:** For oppositely charged parallel plates, $E = \sigma/\epsilon_0$ between the plates and the potential difference between the plates is $V = Ed$.

EXECUTE: **(a)** $E = \dfrac{\sigma}{\epsilon_0} = \dfrac{47.0\times10^{-9}\ \text{C/m}^2}{\epsilon_0} = 5310\ \text{N/C}.$

(b) $V = Ed = (5310\ \text{N/C})(0.0220\ \text{m}) = 117\ \text{V}.$

(c) The electric field stays the same if the separation of the plates doubles. The potential difference between the plates doubles.

EVALUATE: The electric field of an infinite sheet of charge is uniform, independent of distance from the sheet. The force on a test charge between the two plates is constant because the electric field is constant. The potential difference is the work per unit charge on a test charge when it moves from one plate to the other. When the distance doubles, the work, which is force times distance, doubles and the potential difference doubles.

23.37. **IDENTIFY** and **SET UP:** Use $\Delta V = Ed$ to relate the electric field between the plates to the potential difference between them and their separation. The magnitude of the force this field exerts on the particle is given by $F = qE$. Use $W_{a\to b} = \int_a^b \vec{F}\cdot d\vec{l}$ to calculate the work.

EXECUTE: **(a)** Using $\Delta V = Ed$ gives $E = \dfrac{V_{ab}}{d} = \dfrac{360\ \text{V}}{0.0450\ \text{m}} = 8000\ \text{V/m}.$

(b) $F = |q|E = (2.40\times10^{-9}\ \text{C})(8000\ \text{V/m}) = +1.92\times10^{-5}\ \text{N}.$

(c) The electric field between the plates is shown in Figure 23.37.

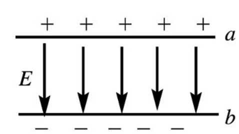

Figure 23.37

The plate with positive charge (plate *a*) is at higher potential. The electric field is directed from high potential toward low potential (or, $\vec{E}$ is from + charge toward − charge), so $\vec{E}$ points from *a* to *b*. Hence the force that $\vec{E}$ exerts on the positive charge is from *a* to *b*, so it does positive work.

$W = \int_a^b \vec{F}\cdot d\vec{l} = Fd$, where *d* is the separation between the plates.

$W = Fd = (1.92\times10^{-5}\ \text{N})(0.0450\ \text{m}) = +8.64\times10^{-7}\ \text{J}.$

(d) $V_a - V_b = +360\ \text{V}$ (plate *a* is at higher potential).

$\Delta U = U_b - U_a = q(V_b - V_a) = (2.40\times10^{-9}\ \text{C})(-360\ \text{V}) = -8.64\times10^{-7}\ \text{J}.$

EVALUATE: We see that $W_{a\to b} = -(U_b - U_a) = U_a - U_b$.

23.38. **IDENTIFY** and **SET UP:** $V_{ab} = Ed$ for parallel plates.

EXECUTE: $d = \dfrac{V_{ab}}{E} = \dfrac{1.5\ \text{V}}{1.0\times10^{-6}\ \text{V/m}} = 1.5\times10^{6}\ \text{m} = 1.5\times10^{3}\ \text{km}.$

EVALUATE: The plates would have to be nearly a thousand miles apart with only a AA battery across them! This is a small field!

23.39. **IDENTIFY:** The potential of a solid conducting sphere is the same at every point inside the sphere because $E = 0$ inside, and this potential has the value $V = q/4\pi\epsilon_0 R$ at the surface. Use the given value of *E* to find *q*.

SET UP: For negative charge the electric field is directed toward the charge.
For points outside this spherical charge distribution the field is the same as if all the charge were concentrated at the center.

EXECUTE: $E = \dfrac{|q|}{4\pi\epsilon_0 r^2}$ and $|q| = 4\pi\epsilon_0 Er^2 = \dfrac{(3800\ \text{N/C})(0.200\ \text{m})^2}{8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2} = 1.69\times10^{-8}\ \text{C}.$

Since the field is directed inward, the charge must be negative. The potential of a point charge, taking ∞ as zero, is $V = \dfrac{q}{4\pi\epsilon_0 r} = \dfrac{(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(-1.69\times10^{-8}\ \text{C})}{0.200\ \text{m}} = -760\ \text{V}$ at the surface of the sphere. Since the charge all resides on the surface of a conductor, the field inside the sphere due to this symmetrical distribution is zero. No work is therefore done in moving a test charge from just inside the surface to the center, and the potential at the center must also be –760 V.

EVALUATE: Inside the sphere the electric field is zero and the potential is constant.

23.40. IDENTIFY: The electric field is zero inside the sphere, so the potential is constant there. Thus the potential at the center must be the same as at the surface, where it is equivalent to that of a point-charge.

SET UP: At the surface, and hence also at the center of the sphere, the potential is that of a point-charge, $V = Q/(4\pi\epsilon_0 R)$.

EXECUTE: **(a)** Solving for Q and substituting the numbers gives

$Q = 4\pi\epsilon_0 RV = (0.125\ \text{m})(3750\ \text{V})/(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2) = 5.21\times10^{-8}\ \text{C} = 52.1\ \text{nC}.$

(b) Since the potential is constant inside the sphere, its value at the surface must be the same as at the center, 3.75 kV.

EVALUATE: The electric field inside the sphere is zero, so the potential is constant but is not zero.

23.41. IDENTIFY and **SET UP:** For a solid metal sphere or for a spherical shell, $V = \dfrac{kq}{r}$ outside the sphere and $V = \dfrac{kq}{R}$ at all points inside the sphere, where R is the radius of the sphere. When the electric field is radial, $E = -\dfrac{\partial V}{\partial r}$.

EXECUTE: **(a)** (i) $r < r_a$: This region is inside both spheres. $V = \dfrac{kq}{r_a} - \dfrac{kq}{r_b} = kq\left(\dfrac{1}{r_a} - \dfrac{1}{r_b}\right).$

(ii) $r_a < r < r_b$: This region is outside the inner shell and inside the outer shell.

$V = \dfrac{kq}{r} - \dfrac{kq}{r_b} = kq\left(\dfrac{1}{r} - \dfrac{1}{r_b}\right).$

(iii) $r > r_b$: This region is outside both spheres and $V = 0$ since outside a sphere the potential is the same as for a point charge. Therefore the potential is the same as for two oppositely charged point charges at the same location. These potentials cancel.

(b) $V_a = \dfrac{1}{4\pi\epsilon_0}\left(\dfrac{q}{r_a} - \dfrac{q}{r_b}\right)$ and $V_b = 0$, so $V_{ab} = \dfrac{1}{4\pi\epsilon_0} q\left(\dfrac{1}{r_a} - \dfrac{1}{r_b}\right).$

(c) Between the spheres $r_a < r < r_b$ and $V = kq\left(\dfrac{1}{r} - \dfrac{1}{r_b}\right).$

$$E_r = -\frac{\partial V}{\partial r} = -\frac{q}{4\pi\epsilon_0}\frac{\partial}{\partial r}\left(\frac{1}{r} - \frac{1}{r_b}\right) = +\frac{1}{4\pi\epsilon_0}\frac{q}{r^2} = \frac{V_{ab}}{\left(\frac{1}{r_a} - \frac{1}{r_b}\right)}\frac{1}{r^2}.$$

(d) Since $E_r = -\frac{\partial V}{\partial r}$, $E = 0$, since V is constant (zero) outside the spheres.

(e) If the outer charge is different, then outside the outer sphere the potential is no longer zero but is $V = \frac{1}{4\pi\epsilon_0}\frac{q}{r} - \frac{1}{4\pi\epsilon_0}\frac{Q}{r} = \frac{1}{4\pi\epsilon_0}\frac{(q-Q)}{r}$. All potentials inside the outer shell are just shifted by an amount $V = \frac{1}{4\pi\epsilon_0}\frac{Q}{r_b}$. Therefore relative potentials within the shells are not affected. Thus (b) and (c) do not change. However, now that the potential does vary outside the spheres, there is an electric field there: $E = -\frac{\partial V}{\partial r} = -\frac{\partial}{\partial r}\left(\frac{kq}{r} + \frac{-kQ}{r}\right) = \frac{kq}{r^2}\left(1 - \frac{Q}{q}\right) = \frac{k}{r^2}(q-Q)$.

EVALUATE: In part (a) the potential is greater than zero for all $r < r_b$.

23.42. **IDENTIFY:** By the definition of electric potential, if a positive charge gains potential along a path, then the potential along that path must have increased. The electric field produced by a very large sheet of charge is uniform and is independent of the distance from the sheet.

(a) SET UP: No matter what the reference point, we must do work on a positive charge to move it away from the negative sheet.

EXECUTE: Since we must do work on the positive charge, it gains potential energy, so the potential increases.

(b) SET UP: Since the electric field is uniform and is equal to $\sigma/2\epsilon_0$, we have $\Delta V = Ed = \frac{\sigma}{2\epsilon_0}d$.

EXECUTE: Solving for d gives

$$d = \frac{2\epsilon_0\,\Delta V}{\sigma} = \frac{2(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(1.00\ \text{V})}{6.00\times10^{-9}\ \text{C/m}^2} = 0.00295\ \text{m} = 2.95\ \text{mm}.$$

EVALUATE: Since the spacing of the equipotential surfaces (d = 2.95 mm) is independent of the distance from the sheet, the equipotential surfaces are planes parallel to the sheet and spaced 2.95 mm apart.

23.43. **IDENTIFY** and **SET UP:** Use $E_x = -\frac{\partial V}{\partial x}$, $E_y = -\frac{\partial V}{\partial y}$, and $E_z = \frac{\partial V}{\partial z}$ to calculate the components of $\vec{E}$.

EXECUTE: $V = Axy - Bx^2 + Cy$.

(a) $E_x = -\frac{\partial V}{\partial x} = -Ay + 2Bx$.

$E_y = -\frac{\partial V}{\partial y} = -Ax - C$.

$E_z = \frac{\partial V}{\partial z} = 0$.

(b) $E = 0$ requires that $E_x = E_y = E_z = 0$.

$E_z = 0$ everywhere.

$E_y = 0$ at $x = -C/A$.

And E_x is also equal to zero for this x, any value of z and $y = 2Bx/A = (2B/A)(-C/A) = -2BC/A^2$.

EVALUATE: V doesn't depend on z so $E_z = 0$ everywhere.

23.44. IDENTIFY: Apply $E_x = -\frac{\partial V}{\partial x}$ and $E_y = -\frac{\partial V}{\partial y}$ to find the components of $\vec{E}$, then use them to find its magnitude and direction. $V(x, y) = Ax^2y - Bxy^2$.

SET UP: $E = \sqrt{E_x^2 + E_y^2}$ and $\tan\theta = E_y/E_x$.

EXECUTE: First find the components of $\vec{E}$: $E_x = -\frac{\partial V}{\partial x} = -\frac{\partial}{\partial x}(Ax^2y - Bxy^2) = -(2Axy - By^2)$.

Now evaluate this result at the point $x = 2.00$ m, $y = 0.400$ m using the given values for A and B.

$E_x = -[2(5.00\ \text{V/m}^3)(2.00\ \text{m})(0.400\ \text{m}) - (8.00\ \text{V/m}^3)(0.400\ \text{m})^2] = -6.72\ \text{V/m}$.

$E_y = -\frac{\partial V}{\partial y} = -\frac{\partial}{\partial y}(Ax^2y - Bxy^2) = -(Ax^2 - 2Bxy)$. At the point (2.00 m, 0.400 m), this is

$E_y = -[(5.00\ \text{V/m}^3)(2.00\ \text{m})^2 - 2(8.00\ \text{V/m}^3)(2.00\ \text{m})(0.400\ \text{m})] = -7.20\ \text{V/m}$.

Now use the components to find the magnitude and direction of $\vec{E}$.

$E = \sqrt{E_x^2 + E_y^2} = \sqrt{(-6.72\ \text{V/m})^2 + (-7.20\ \text{V/m})^2} = 9.85\ \text{V/m}$.

$\tan\theta = E_y/E_x = (-7.20\ \text{V/m})/(-6.72\ \text{V/m})$, which gives $\theta = 47.0°$. Since both components are negative, the vector lies in the third quadrant in the xy-plane and makes an angle of 47.0° + 180.0° = 227.0° with the $+x$-axis.

EVALUATE: V is a scalar but $\vec{E}$ is a vector and has components.

23.45. IDENTIFY: Exercise 23.41 shows that $V = kq\left(\frac{1}{r_a} - \frac{1}{r_b}\right)$ for $r < r_a$, $V = kq\left(\frac{1}{r} - \frac{1}{r_b}\right)$ for $r_a < r < r_b$ and

$V_{ab} = kq\left(\frac{1}{r_a} - \frac{1}{r_b}\right)$.

SET UP: $E = \frac{kq}{r^2}$, radially outward, for $r_a \le r \le r_b$.

EXECUTE: **(a)** $V_{ab} = kq\left(\frac{1}{r_a} - \frac{1}{r_b}\right) = 500\ \text{V}$ gives $q = \dfrac{500\ \text{V}}{k\left(\frac{1}{0.012\ \text{m}} - \frac{1}{0.096\ \text{m}}\right)} = 7.62\times10^{-10}\ \text{C}$

$= 0.762$ nC.

(b) $V_b = 0$ so $V_a = 500$ V. The inner metal sphere is an equipotential with $V = 500$ V. $\frac{1}{r} = \frac{1}{r_a} + \frac{V}{kq}$.

$V = 400$ V at $r = 1.45$ cm, $V = 300$ V at $r = 1.85$ cm, $V = 200$ V at $r = 2.53$ cm, $V = 100$ V at $r = 4.00$ cm, $V = 0$ at $r = 9.60$ cm. The equipotential surfaces are sketched in Figure 23.45.

EVALUATE: **(c)** The equipotential surfaces are concentric spheres and the electric field lines are radial, so the field lines and equipotential surfaces are mutually perpendicular. The equipotentials are closest at smaller r, where the electric field is largest.

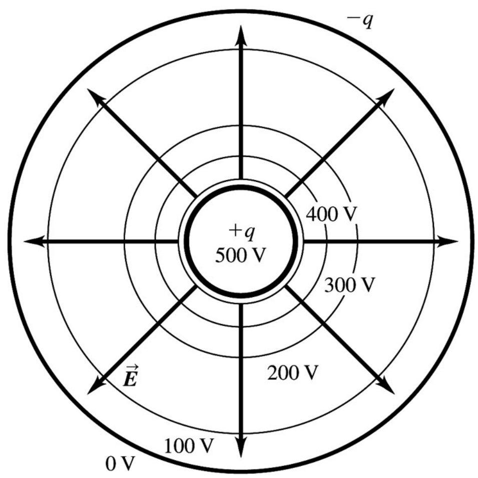

Figure 23.45

23.46. **IDENTIFY:** As the sphere approaches the point charge, the speed of the sphere decreases because it loses kinetic energy, but its acceleration increases because the electric force on it increases. Its mechanical energy is conserved during the motion, and Newton's second law and Coulomb's law both apply.

SET UP: $K_a + U_a = K_b + U_b$, $K = \frac{1}{2}mv^2$, $U = kq_1q_2/r$, $F = kq_1q_2/r^2$, and $F = ma$.

EXECUTE: Find the distance between the two charges when $v_2 = 25.0$ m/s.

$K_a + U_a = K_b + U_b$.

$$K_a = \frac{1}{2}mv_a^2 = \frac{1}{2}(4.00\times10^{-3}\text{ kg})(40.0\text{ m/s})^2 = 3.20\text{ J}.$$

$$K_b = \frac{1}{2}mv_b^2 = \frac{1}{2}(4.00\times10^{-3}\text{ kg})(25.0\text{ m/s})^2 = 1.25\text{ J}.$$

$$U_a = k\frac{q_1q_2}{r_a} = \frac{(8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(5.00\times10^{-6}\text{ C})(2.00\times10^{-6}\text{ C})}{0.0600\text{ m}} = 1.498\text{ J}.$$

$U_b = K_a + U_a - K_b = 3.20\text{ J} + 1.498\text{ J} - 1.25\text{ J} = 3.448\text{ J}$. $U_b = k\dfrac{q_1q_2}{r_b}$ and

$$r_b = \frac{kq_1q_2}{U_b} = \frac{(8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(5.00\times10^{-6}\text{ C})(2.00\times10^{-6}\text{ C})}{3.448\text{ J}} = 0.02607\text{ m}.$$

$$F_b = \frac{kq_1q_2}{r_b^2} = \frac{(8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)(5.00\times10^{-6}\text{ C})(2.00\times10^{-6}\text{ C})}{(0.02607\text{ m})^2} = 132.3\text{ N}.$$

$$a = \frac{F}{m} = \frac{132.3\text{ N}}{4.00\times10^{-3}\text{ kg}} = 3.31\times10^4\text{ m/s}^2.$$

EVALUATE: As the sphere approaches the point charge, its speed decreases but its acceleration keeps increasing because the electric force on it keeps increasing.

23.47. **IDENTIFY:** $U = k\left(\dfrac{q_1q_2}{r_{12}} + \dfrac{q_1q_3}{r_{13}} + \dfrac{q_2q_3}{r_{23}}\right)$.

SET UP: In part (a), $r_{12} = 0.200$ m, $r_{23} = 0.100$ m and $r_{13} = 0.100$ m. In part (b) let particle 3 have coordinate x, so $r_{12} = 0.200$ m, $r_{13} = x$ and $r_{23} = 0.200\text{ m} - x$.

EXECUTE: (a)

$$U = k\left(\frac{(4.00\text{ nC})(-3.00\text{ nC})}{(0.200\text{ m})} + \frac{(4.00\text{ nC})(2.00\text{ nC})}{(0.100\text{ m})} + \frac{(-3.00\text{ nC})(2.00\text{ nC})}{(0.100\text{ m})}\right) = -3.60\times10^{-7}\text{ J}.$$

(b) If $U = 0$, then $0 = k\left(\frac{q_1q_2}{r_{12}} + \frac{q_1q_3}{x} + \frac{q_2q_3}{r_{12}-x}\right)$. Solving for x we find:

$0 = -60 + \frac{8}{x} - \frac{6}{0.2-x} \Rightarrow 60x^2 - 26x + 1.6 = 0 \Rightarrow x = 0.074\text{ m}, 0.360\text{ m}$. Therefore, $x = 0.074\text{ m}$ since it is the only value between the two charges.

EVALUATE: U_{13} is positive and both U_{23} and U_{12} are negative. If $U = 0$, then $|U_{13}| = |U_{23}| + |U_{12}|$. For $x = 0.074\text{ m}$, $U_{13} = +9.7\times10^{-7}\text{ J}$, $U_{23} = -4.3\times10^{-7}\text{ J}$ and $U_{12} = -5.4\times10^{-7}\text{ J}$. It is true that $U = 0$ at this x.

23.48. IDENTIFY: We are dealing with the electric field and potential of point charges.

SET UP: $V = \frac{1}{4\pi\epsilon_0}\frac{q}{r}$ and $E = \frac{1}{4\pi\epsilon_0}\frac{|q|}{r^2}$. Let $\frac{1}{4\pi\epsilon_0}$ be k.

EXECUTE: (a) We want to find where $E = 0$. To cancel, the fields must be in opposite directions and have equal magnitudes. This can happen only for $x > 0.200$ m. Call d the distance between the –4.00 nC charge and the point where $E = 0$. The magnitudes are equal so $\frac{k(8.00\text{ nC})}{(d+0.400\text{ m})^2} = \frac{k(4.00\text{ nC})}{d^2}$. Solving for d gives $d = 1.17$ m.

(b) We want to find where $V = 0$. V can be zero when the potentials have equal magnitude but opposite sign. This occurs only for points closer to the –4.00 nC charge than to the 8.00 nC charge, which is between the charges and for $x > 0.200$ m.

<u>Between the charges</u>: Call x the distance from the –4.00 nC charge. Equating the magnitudes of the potentials gives $\frac{k(8.00\text{ nC})}{0.400\text{ m}-x} = \frac{k(4.00\text{ nC})}{x}$. x =0.067 m.

<u>For $x > 0.200$ m</u>: Call d the distance between the –4.00 nC charge and the point of cancellation. $\frac{k(8.00\text{ nC})}{d+0.400\text{ m}} = \frac{k(4.00\text{ nC})}{d}$. $d = 0.400$ m. $x = 0.400\text{ m} + 0.200\text{ m} = 0.600$ m.

(c) E could be zero only for $x > 0.200$ m, which is at $x = 1.17$ m (as we found), so E is not equal to zero at any of these points.

EVALUATE: This problem is a good illustration of the need to analyze before using any equations. Doing so allows us to decide which regions to consider for E to be zero and for V to be zero before doing any unnecessary calculations.

23.49. IDENTIFY: This problem involves potential difference and electric fields.

SET UP: For a sheet of charge $E_\sigma = \sigma/2\epsilon_0$, and for a line of charge $E_\lambda = \lambda/2\pi\epsilon_0 r$. Make a sketch showing the fields, as in Fig. 23.49. $V_B - V_A$ is due to the two fields. Between the sheet and the line the fields are in opposite directions and on the other side of the line they are in the same direction, as shown in the figure. $V_A - V_B = \Delta V_\sigma + \Delta V_\lambda$.

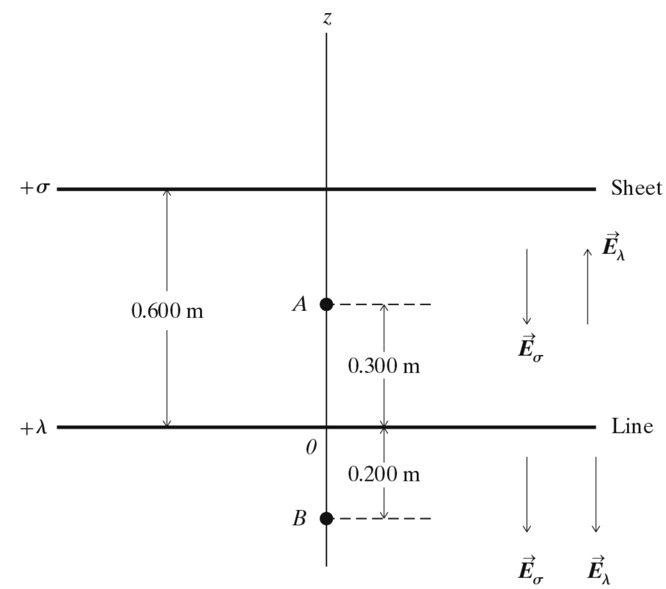

Figure 23.49

EXECUTE: <u>For the sheet</u>: E_σ is uniform, so

$$V_A - V_B = \Delta V_\sigma = E_\sigma \Delta z = \frac{\sigma}{2\epsilon_0}\Delta z = \frac{8.00\mu\text{C/m}^2}{2\epsilon_0}(0.500\text{ m}) = 2.260\times 10^5\text{ V.}$$

<u>For the line</u>: The field due to the line reverses direction as we cross the line. So the potential change in going from 0.200 m to the line is the opposite of the potential change in going from the line to 0.200 m on the other side. Thus the only potential change that does not cancel is in going from 0.300 m to 0.200 m on the upper side of the line. Therefore $\Delta V_\lambda = \int_{0.300\text{ m}}^{0.200\text{ m}} E_z dz = \int_{0.300\text{ m}}^{0.200\text{ m}} \frac{\lambda}{2\pi\epsilon_0 z} dz = \frac{\lambda}{2\pi\epsilon_0}\ln(2/3)$. This gives -3.645×10^4 V.

The total potential difference is $2.26\times 10^5\text{ V} - 3.645\times 10^4\text{ V} = +1.90\times 10^5\text{ V}$.

$V_A = V_B + 1.90\times 10^5$ V, so A is at a higher potential than B.

EVALUATE: It may appear that we skipped over an important point, namely that the potential becomes infinite if the line has no thickness. But any real line has some (but very small) thickness, so the potential difference between 0.200 m above the line can cancel the potential difference below the line without any infinities coming into play.

23.50. **IDENTIFY:** Two forces do work on the sphere as it falls: gravity and the electrical force due to the sheet. The energy of the sphere is conserved.

SET UP: The gravity force is mg, downward. The electric field of the sheet is $E = \frac{\sigma}{2\epsilon_0}$ upward, and the force it exerts on the sphere is $F = qE$. The sphere gains kinetic energy $K = \frac{1}{2}mv^2$ as it falls.

EXECUTE: $mg = 4.90\times10^{-6}$ N. $E = \dfrac{\sigma}{2\epsilon_0} = \dfrac{8.00\times10^{-12}\ \text{C/m}^2}{2(8.854\times10^{-12}\ \text{C}^2/(\text{N}\cdot\text{m}^2))} = 0.4518$ N/C. The electric force is $qE = (7.00\times10^{-6}\ \text{C})(0.4518\ \text{N/C}) = 3.1626\times10^{-6}$ N, upward. The net force is downward, so the sphere moves downward when released. Let $y = 0$ at the sheet. $U_{\text{grav}} = mgy$. For the electric force, $\dfrac{W_{a\to b}}{q} = V_a - V_b$. Let point *a* be at the sheet and let point *b* be a distance *y* above the sheet. Take $V_a = 0$. The force on *q* is qE, upward, so $\dfrac{W_{a\to b}}{q} = Ey$ and $V_b = -Ey$. $U_b = -Eyq$. $K_1 + U_1 = K_2 + U_2$. $K_1 = 0$.

$y_1 = 0.400$ m, $y_2 = 0.100$ m. $K_2 = U_1 - U_2 = mg(y_1 - y_2) - E(y_1 - y_2)q$.

$K_2 = (5.00\times10^{-7}\ \text{kg})(9.80\ \text{m/s}^2)(0.300\ \text{m}) - (0.4518\ \text{N/C})(0.300\ \text{m})(7.00\times10^{-6}\ \text{C})$.

$K_2 = 1.470\times10^{-6}\ \text{J} - 0.94878\times10^{-6}\ \text{J} = 0.52122\times10^{-6}$ J. $K_2 = \dfrac{1}{2}mv_2^2$ so

$$v_2 = \sqrt{\frac{2K_2}{m}} = \sqrt{\frac{2(0.52122\times10^{-6}\ \text{J})}{5.00\times10^{-7}\ \text{kg}}} = 1.44\ \text{m/s}.$$

EVALUATE: Because the weight is greater than the electric force, the sphere will accelerate downward, but if it were light enough the electric force would exceed the weight. In that case it would never get closer to the sheet after being released. We could also solve this problem using Newton's second law and the constant-acceleration kinematics formulas. $a = F/m = (mg - qE)/m$ gives the acceleration. Then we use $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ with $v_{0x} = 0$ to find *v*.

23.51. IDENTIFY and SET UP: Treat the gold nucleus as a point charge so that $V = k\dfrac{q}{r}$. According to conservation of energy we have $K_1 + U_1 = K_2 + U_2$, where $U = qV$.

EXECUTE: Assume that the alpha particle is at rest before it is accelerated and that it momentarily stops when it arrives at its closest approach to the surface of the gold nucleus. Thus we have $K_1 = K_2 = 0$, which implies that $U_1 = U_2$. Since $U = qV$ we conclude that the accelerating voltage must be equal to the voltage at its point of closest approach to the surface of the gold nucleus. Therefore

$$V_a = V_b = k\frac{q}{r} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\frac{79(1.60\times10^{-19}\ \text{C})}{(7.3\times10^{-15}\ \text{m} + 2.0\times10^{-14}\ \text{m})} = 4.2\times10^6\ \text{V}.$$

EVALUATE: Although the alpha particle has kinetic energy as it approaches the gold nucleus this is irrelevant to our solution since energy is conserved for the whole process.

23.52. IDENTIFY: The charged particles repel each other and therefore accelerate away from one another, causing their speeds and kinetic energies to continue to increase. They do not have equal speeds because they have different masses. The mechanical energy and momentum of the system are conserved.

SET UP: The proton has charge $q_\text{p} = +e$ and mass $m_\text{p} = 1.67\times10^{-27}$ kg. The alpha particle has charge $q_\text{a} = +2e$ and mass $m_\text{a} = 4m_\text{p} = 6.68\times10^{-27}$ kg. We can apply both conservation of energy and conservation of linear momentum to the system. $a = \dfrac{F}{m}$, where $F = k\dfrac{|q_1q_2|}{r^2}$.

EXECUTE: *Acceleration:* The maximum force and hence the maximum acceleration occurs just after they are released, when $r = 0.225$ nm. $F = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{(2)(1.60\times10^{-19}\ \text{C})^2}{(0.225\times10^{-9}\ \text{m})^2} = 9.09\times10^{-9}$ N.

$a_{\rm p} = \dfrac{F}{m_{\rm p}} = \dfrac{9.09\times10^{-9}\ \text{N}}{1.67\times10^{-27}\ \text{kg}} = 5.44\times10^{18}\ \text{m/s}^2;\ a_{\rm a} = \dfrac{F}{m_{\rm a}} = \dfrac{9.09\times10^{-9}\ \text{N}}{6.68\times10^{-27}\ \text{kg}} = 1.36\times10^{18}\ \text{m/s}^2$. The acceleration of the proton is larger by a factor of $m_{\rm a}/m_{\rm p}$.

Speed: Conservation of energy says $U_1 + K_1 = U_2 + K_2$. $K_1 = 0$ and $U_2 = 0$, so $K_2 = U_1$.

$U_1 = k\dfrac{q_1 q_2}{r} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{(2)(1.60\times10^{-19}\ \text{C})^2}{0.225\times10^{-9}\ \text{m}} = 2.05\times10^{-18}\ \text{J}$, so the total kinetic energy of the two particles when they are far apart is $K_2 = 2.05\times10^{-18}$ J. Conservation of linear momentum says how this energy is divided between the proton and alpha particle. $p_1 = p_2$. $0 = m_{\rm p}v_{\rm p} - m_{\rm a}v_{\rm a}$ so

$v_{\rm a} = \left(\dfrac{m_{\rm p}}{m_{\rm a}}\right)v_{\rm p}$.

$K_2 = \frac{1}{2}m_{\rm p}v_{\rm p}^2 + \frac{1}{2}m_{\rm a}v_{\rm a}^2 = \frac{1}{2}m_{\rm p}v_{\rm p}^2 + \frac{1}{2}m_{\rm a}\left(\dfrac{m_{\rm p}}{m_{\rm a}}\right)^2 v_{\rm p}^2 = \frac{1}{2}m_{\rm p}v_{\rm p}^2\left(1+\dfrac{m_{\rm p}}{m_{\rm a}}\right)$.

$v_{\rm p} = \sqrt{\dfrac{2K_2}{m_{\rm p}(1+(m_{\rm p}/m_{\rm a}))}} = \sqrt{\dfrac{2(2.05\times10^{-18}\ \text{J})}{(1.67\times10^{-27}\ \text{kg})(1+\frac{1}{4})}} = 4.43\times10^4\ \text{m/s}$.

$v_{\rm a} = \left(\dfrac{m_{\rm p}}{m_{\rm a}}\right)v_{\rm p} = \frac{1}{4}(4.43\times10^4\ \text{m/s}) = 1.11\times10^4\ \text{m/s}$. The maximum acceleration occurs just after they are released. The maximum speed occurs after a long time.

EVALUATE: The proton and alpha particle have equal momenum, but proton has a greater acceleration and more kinetic energy.

23.53. **(a) IDENTIFY:** Apply the work-energy theorem.

SET UP: Points *a* and *b* are shown in Figure 23.53a.

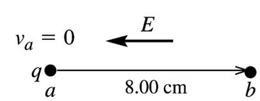

Figure 23.53a

EXECUTE: $W_{\text{tot}} = \Delta K = K_b - K_a = K_b = 4.35\times10^{-5}$ J.

The electric force F_E and the additional force F both do work, so that $W_{\text{tot}} = W_{F_E} + W_F$.

$$W_{F_E} = W_{\text{tot}} - W_F = 4.35\times10^{-5}\ \text{J} - 6.50\times10^{-5}\ \text{J} = -2.15\times10^{-5}\ \text{J}.$$

EVALUATE: The forces on the charged particle are shown in Figure 23.53b.

Figure 23.53b

The electric force is to the left (in the direction of the electric field since the particle has positive charge). The displacement is to the right, so the electric force does negative work. The additional force F is in the direction of the displacement, so it does positive work.

(b) IDENTIFY and **SET UP:** For the work done by the electric force, $W_{a\to b} = q(V_a - V_b)$.

EXECUTE: $V_a - V_b = \dfrac{W_{a\to b}}{q} = \dfrac{-2.15\times10^{-5}\ \text{J}}{7.60\times10^{-9}\ \text{C}} = -2.83\times10^{3}\ \text{V}.$

EVALUATE The starting point (point a) is at 2.83×10^{3} V lower potential than the ending point (point b). We know that $V_b > V_a$ because the electric field always points from high potential toward low potential.

(c) IDENTIFY: Calculate E from $V_a - V_b$ and the separation d between the two points.

SET UP: Since the electric field is uniform and directed opposite to the displacement $W_{a\to b} = -F_E d = -qEd$, where $d = 8.00$ cm is the displacement of the particle.

EXECUTE: $E = -\dfrac{W_{a\to b}}{qd} = -\dfrac{V_a - V_b}{d} = -\dfrac{-2.83\times10^{3}\ \text{V}}{0.0800\ \text{m}} = 3.54\times10^{4}\ \text{V/m}.$

EVALUATE: In part (a), W_{tot} is the total work done by both forces. In parts (b) and (c) $W_{a\to b}$ is the work done just by the electric force.

23.54. IDENTIFY: The net force on q_0 is the vector sum of the forces due to the two charges. Coulomb's law applies.

SET UP: $F = k\dfrac{|q_1 q_2|}{r^2}$, $W_{a\to b} = q(V_a - V_b)$, $V = k\dfrac{q}{r}$.

EXECUTE: **(a)** The magnitude of the force on q_0 due to each of the two charges at opposite corners of the square is $F = k\dfrac{|q_1 q_2|}{r^2}$ = k(5.00 μC)(3.00 μC)/(0.0800 m)^2 = 21.07 N. Adding the two forces vectorially gives the net force F_{net} = (21.07 N) $\sqrt{2}$ = 29.8 N. The direction is from A to B since both charges attract q_0. Figure 23.54 shows this force.

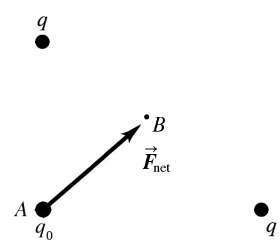

Figure 23.54

(b) At point B the two forces on q_0 are in opposite directions and have equal magnitudes, so they add to zero: $F_{\text{net}} = 0$.

(c) For each charge, $W_{A\to B} = q(V_A - V_B)$, so for both we must double this. Using $V = k\dfrac{q}{r}$ and simplifying we get $W_{A\to B} = 2q(V_A - V_B) = 2kqq_0\left(\dfrac{1}{r_A} - \dfrac{1}{r_B}\right)$. Putting in q_0 = –3.00 μC, q = 5.00 μC, r_A = 0.0800 m, and $r_b = 0.0400\sqrt{2}$ m, we get $W_{A\to B}$ = +1.40 J. The work done on q_0 by the electric field is positive since it this charge moves from A to B in the direction of the force. The charge loses potential energy as it gains kinetic energy. But since q_0 is negative, it moves to a point of higher potential.

EVALUATE: Positive charges accelerate toward lower potential, but negative charges accelerate toward higher potential.

23.55. **IDENTIFY** and **SET UP:** Calculate the components of $\vec{E}$ using $E_x = -\dfrac{\partial V}{\partial x}$, $E_y = -\dfrac{\partial V}{\partial y}$, and $E_z = -\dfrac{\partial V}{\partial z}$, and use $\vec{F} = q\vec{E}$.

EXECUTE: **(a)** $V = Cx^{4/3}$.

$$C = V/x^{4/3} = 240\text{ V}/(13.0\times10^{-3}\text{ m})^{4/3} = 7.85\times10^{4}\text{ V/m}^{4/3}.$$

(b) $E_x(x) = -\dfrac{\partial V}{\partial x} = -\dfrac{4}{3}Cx^{1/3} = -(1.05\times10^{5}\text{ V/m}^{4/3})x^{1/3}$.

The minus sign means that E_x is in the $-x$-direction, which says that $\vec{E}$ points from the positive anode toward the negative cathode.

(c) $\vec{F} = q\vec{E}$ so $F_x = -eE_x = \frac{4}{3}eCx^{1/3}$.

Halfway between the electrodes means $x = 6.50\times10^{-3}$ m.

$$F_x = \tfrac{4}{3}(1.602\times10^{-19}\text{ C})(7.85\times10^{4}\text{ V/m}^{4/3})(6.50\times10^{-3}\text{ m})^{1/3} = 3.13\times10^{-15}\text{ N}.$$

F_x is positive, so the force is directed toward the positive anode.

EVALUATE: V depends only on x, so $E_y = E_z = 0$. $\vec{E}$ is directed from high potential (anode) to low potential (cathode). The electron has negative charge, so the force on it is directed opposite to the electric field.

23.56. **IDENTIFY:** We model the finger as a parallel-plate capacitor.

SET UP and **EXECUTE:** **(a)** Estimate: 2 mm

(b) We want the field E. Assuming a uniform field, $V = Ed$ = (3 MV/m)(2 mm) = 6 kV.

(c) $E = \sigma/\epsilon_0$, so $\sigma = \epsilon_0 E = \epsilon_0$ (3 MV/m) $\approx$ 30 μC/m^2.

(d) Estimate: ½ cm by ½ cm = 0.25 cm^2.

(e) $q = \sigma A$ = (30 μC/m^2)(0.25 cm^2) = 0.02 pC.

(f) $q = ne$, so $n = q/e$ = (0.02 pC)/e = 10^5 electrons.

EVALUATE: A voltage of 6 kV seems dangerous, but only a small amount of charge is involved.

23.57. **IDENTIFY:** $U = \dfrac{kq_1q_2}{r}$.

SET UP: Eight charges means there are $8(8-1)/2 = 28$ pairs. There are 12 pairs of q and $-q$ separated by d, 12 pairs of equal charges separated by $\sqrt{2}d$ and 4 pairs of q and $-q$ separated by $\sqrt{3}d$.

EXECUTE: **(a)** $U = kq^2\left(-\dfrac{12}{d} + \dfrac{12}{\sqrt{2}d} - \dfrac{4}{\sqrt{3}d}\right) = -\dfrac{12kq^2}{d}\left(1 - \dfrac{1}{\sqrt{2}} + \dfrac{1}{3\sqrt{3}}\right) = -1.46q^2/\pi\epsilon_0\, d.$

EVALUATE: **(b)** The fact that the electric potential energy is less than zero means that it is energetically favorable for the crystal ions to be together.

23.58. **IDENTIFY:** We are modeling electrical power lines as conducting cylinders.

SET UP and **EXECUTE:** **(a)** Estimate: About 22 ft ≈ 7.0 m.

(b) We want the linear charge density λ. $\Delta V = \int E_r dr = \displaystyle\int_{0.02\text{ m}}^{7\text{ m}} \frac{\lambda}{2\pi\epsilon_0 r}dr = \frac{\lambda}{2\pi\epsilon_0}\ln(7/0.02).$ Solving for λ using V = 22 kV gives $\lambda \approx$ 210 nC/m which rounds to 200 nC/m.

(c) We want E. $E = \dfrac{\lambda}{2\pi\epsilon_0 r}$. Using λ =210 nC/m and r = 7 m gives $E \approx$ 540 V/m.

EVALUATE: The field in (c) is not very strong compared to many fields in physics labs.

23.59. **IDENTIFY:** Apply $\sum F_x = 0$ and $\sum F_y = 0$ to the sphere. The electric force on the sphere is $F_e = qE$. The potential difference between the plates is $V = Ed$.

SET UP: The free-body diagram for the sphere is given in Figure 23.59.

EXECUTE: $T\cos\theta = mg$ and $T\sin\theta = F_e$ gives

$F_e = mg\tan\theta = (1.50\times10^{-3}\text{ kg})(9.80\text{ m/s}^2)\tan(30°) = 0.0085\text{ N}.$

$F_e = Eq = \dfrac{Vq}{d}$ and $V = \dfrac{Fd}{q} = \dfrac{(0.0085\text{ N})(0.0500\text{ m})}{8.90\times10^{-6}\text{ C}} = 47.8\text{ V}.$

EVALUATE: $E = V/d = 956$ V/m. $E = \sigma/\epsilon_0$ and $\sigma = E\epsilon_0 = 8.46\times10^{-9}\text{ C/m}^2$.

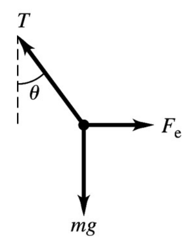

Figure 23.59

23.60. **IDENTIFY:** Outside a uniform spherical shell of charge, the electric field and potential are the same as for a point-charge at the center. Inside the shell, the electric field is zero so the potential is constant and equal to its value at the surface of the shell. The net potential is the scalar sum of the individual potentials.

SET UP: $V = k\dfrac{q}{r}$. Call V_1 the potential due to the inner shell and V_2 the potential due to the outer shell. $V_{net} = V_1 + V_2$.

EXECUTE: **(a)** At $r = 2.50$ cm, we are inside both shells. V_1 is the potential at the surface of the inner shell, so $V_1 = kq_1/R_1$; and V_2 is the potential at the surface of the outer shell, so $V_2 = kq_2/R_2$. The net potential is

$V_{net} = kq_1/R_1 + kq_2/R_2 = k(q_1/R_1 + q_2/R_2)$.

$V_{net} = (8.99\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2)[(3.00\mu\text{C})/(0.0500\text{ m}) + (-5.00\,\mu\text{C})/(0.150\text{ m})] = 2.40\times10^5\text{ V} = 240\text{ kV}.$

(b) At $r = 10.0$ cm, we are outside the inner shell but still inside the outer shell. The inner shell now is equivalent to a point-charge at its center, so the net potential is

$V_{net} = kq_1/r + kq_2/R_2 = k(q_1/r + q_2/R_2)$.

$V_{net} = k[(3.00\,\mu\text{C})/(0.100\text{ m}) + (-5.00\,\mu\text{C})/(0.150\text{ m})] = -30.0$ kV.

(c) At $r = 20.0$ cm, we are outside both shells, so both are equivalent to point-charges at their center. So $V_{net} = kq_1/r + kq_2/r = k(q_1 + q_2)/r = k(-2.00\,\mu\text{C})/(0.200\text{ m}) = -89.9$ kV.

EVALUATE: $E = 0$ inside a spherically symmetric shell, but that does not necessarily mean that $V = 0$ there. It only means that $V_a - V_b = 0$ for any two points in side the shell, so V is constant.

23.61. **(a) IDENTIFY:** The potential at any point is the sum of the potentials due to each of the two charged conductors.

SET UP: For a conducting cylinder with charge per unit length λ the potential outside the cylinder is given by $V = (\lambda/2\pi\epsilon_0)\ln(r_0/r)$ where r is the distance from the cylinder axis and r_0 is the distance from the axis for which we take $V = 0$. Inside the cylinder the potential has the same value as on the cylinder surface. The electric field is the same for a solid conducting cylinder or for a hollow conducting tube so this expression for V applies to both. This problem says to take $r_0 = b$.

EXECUTE: For the hollow tube of radius b and charge per unit length $-\lambda$: outside $V = -(\lambda/2\pi\epsilon_0)\ln(b/r)$; inside $V = 0$ since $V = 0$ at $r = b$.

For the metal cylinder of radius a and charge per unit length λ:
outside $V = (\lambda/2\pi\epsilon_0)\ln(b/r)$, inside $V = (\lambda/2\pi\epsilon_0)\ln(b/a)$, the value at $r = a$.

(i) $r < a$; inside both $V = (\lambda/2\pi\epsilon_0)\ln(b/a)$.

(ii) $a < r < b$; outside cylinder, inside tube $V = (\lambda/2\pi\epsilon_0)\ln(b/r)$.

(iii) $r > b$; outside both the potentials are equal in magnitude and opposite in sign so $V = 0$.

(b) For $r = a$, $V_a = (\lambda/2\pi\epsilon_0)\ln(b/a)$.

For $r = b$, $V_b = 0$.

Thus $V_{ab} = V_a - V_b = (\lambda/2\pi\epsilon_0)\ln(b/a)$.

(c) IDENTIFY and **SET UP:** Use $E_r = -\dfrac{\partial V}{\partial r}$ to calculate E.

EXECUTE: $E = -\dfrac{\partial V}{\partial r} = -\dfrac{\lambda}{2\pi\epsilon_0}\dfrac{\partial}{\partial r}\ln\left(\dfrac{b}{r}\right) = -\dfrac{\lambda}{2\pi\epsilon_0}\left(\dfrac{r}{b}\right)\left(-\dfrac{b}{r^2}\right) = \dfrac{V_{ab}}{\ln(b/a)}\dfrac{1}{r}.$

(**d**) The electric field between the cylinders is due only to the inner cylinder, so V_{ab} is not changed, $V_{ab} = (\lambda/2\pi\epsilon_0)\ln(b/a)$.

EVALUATE: The electric field is not uniform between the cylinders, so $V_{ab} \neq E(b-a)$.

23.62. IDENTIFY: The wire and hollow cylinder form coaxial cylinders. Problem 23.61 gives $E(r) = \dfrac{V_{ab}}{\ln(b/a)}\dfrac{1}{r}$.

SET UP: $a = 145\times10^{-6}$ m, $b = 0.0180$ m.

EXECUTE: $E = \dfrac{V_{ab}}{\ln(b/a)}\dfrac{1}{r}$ and

$V_{ab} = E\ln(b/a)r = (2.00\times10^4 \text{ N/C})(\ln(0.018 \text{ m}/145\times10^{-6} \text{ m}))0.012 \text{ m} = 1157 \text{ V}.$

EVALUATE: The electric field at any r is directly proportional to the potential difference between the wire and the cylinder.

23.63. IDENTIFY and **SET UP:** Use $\vec{F} = q\vec{E}$ to calculate $\vec{F}$ and then $\vec{F} = m\vec{a}$ gives $\vec{a}$. $E = V/d$.

EXECUTE: **(a)** $\vec{F}_E = q\vec{E}$. Since $q = -e$ is negative $\vec{F}_E$ and $\vec{E}$ are in opposite directions; $\vec{E}$ is upward so $\vec{F}_E$ is downward. The magnitude of E is $E = \dfrac{V}{d} = \dfrac{22.0 \text{ V}}{0.0200 \text{ m}} = 1.10\times10^3 \text{ V/m} = 1.10\times10^3 \text{ N/C}$. The magnitude of F_E is $F_E = |q|E = eE = (1.602\times10^{-19} \text{ C})(1.10\times10^3 \text{ N/C}) = 1.76\times10^{-16} \text{ N}$.

(b) Calculate the acceleration of the electron produced by the electric force:

$a = \dfrac{F}{m} = \dfrac{1.76\times10^{-16} \text{ N}}{9.109\times10^{-31} \text{ kg}} = 1.93\times10^{14} \text{ m/s}^2.$

EVALUATE: This acceleration is much larger than $g = 9.80 \text{ m/s}^2$, so the gravity force on the electron can be neglected. $\vec{F}_E$ is downward, so $\vec{a}$ is downward.

(c) IDENTIFY and **SET UP:** The acceleration is constant and downward, so the motion is like that of a projectile. Use the horizontal motion to find the time and then use the time to find the vertical displacement.

EXECUTE: x-component: $v_{0x} = 6.50\times10^6$ m/s; $a_x = 0$; $x - x_0 = 0.060$ m; $t = ?$

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ and the a_x term is zero, so $t = \dfrac{x - x_0}{v_{0x}} = \dfrac{0.060\text{ m}}{6.50\times10^6\text{ m/s}} = 9.231\times10^{-9}$ s.

y-component: $v_{0y} = 0$; $a_y = 1.93\times10^{14}$ m/s^2; $t = 9.231\times10^{-9}$ m/s; $y - y_0 = ?$

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$. $y - y_0 = \frac{1}{2}(1.93\times10^{14}\text{ m/s}^2)(9.231\times10^{-9}\text{ s})^2 = 0.00822\text{ m} = 0.822$ cm.

(d) IDENTIFY and SET UP: The velocity and its components as the electron leaves the plates are sketched in Figure 23.63.

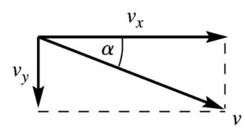

Figure 23.63

EXECUTE:

$v_x = v_{0x} = 6.50\times10^6$ m/s (since $a_x = 0$).

$v_y = v_{0y} + a_y t$.

$v_y = 0 + (1.93\times10^{14}\text{ m/s}^2)(9.231\times10^{-9}\text{ s})$.

$v_y = 1.782\times10^6$ m/s.

$\tan\alpha = \dfrac{v_y}{v_x} = \dfrac{1.782\times10^6\text{ m/s}}{6.50\times10^6\text{ m/s}} = 0.2742$ so $\alpha = 15.3°$.

EVALUATE: The greater the electric field or the smaller the initial speed the greater the downward deflection.

(e) IDENTIFY and SET UP: Consider the motion of the electron after it leaves the region between the plates. Outside the plates there is no electric field, so $a = 0$. (Gravity can still be neglected since the electron is traveling at such high speed and the times are small.) Use the horizontal motion to find the time it takes the electron to travel 0.120 m horizontally to the screen. From this time find the distance downward that the electron travels.

EXECUTE: x-component: $v_{0x} = 6.50\times10^6$ m/s; $a_x = 0$; $x - x_0 = 0.120$ m; $t = ?$

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ and the a_x term is term is zero, so $t = \dfrac{x - x_0}{v_{0x}} = \dfrac{0.120\text{ m}}{6.50\times10^6\text{ m/s}} = 1.846\times10^{-8}$ s.

y-component: $v_{0y} = 1.782\times10^6$ m/s (from part (b)); $a_y = 0$; $t = 1.846\times10^{-8}$ m/s; $y - y_0 = ?$

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = (1.782\times10^6\text{ m/s})(1.846\times10^{-8}\text{ s}) = 0.0329\text{ m} = 3.29$ cm.

EVALUATE: The electron travels downward a distance 0.822 cm while it is between the plates and a distance 3.29 cm while traveling from the edge of the plates to the screen. The total downward deflection is 0.822 cm + 3.29 cm = 4.11 cm. The horizontal distance between the plates is half the horizontal distance the electron travels after it leaves the plates. And the vertical velocity of the electron increases as it travels between the plates, so it makes sense for it to have greater downward displacement during the motion after it leaves the plates.

23.64. IDENTIFY: The charge on the plates and the electric field between them depend on the potential difference across the plates.

SET UP: For two parallel plates, the potential difference between them is $V = Ed = \dfrac{\sigma}{\epsilon_0}d = \dfrac{Qd}{\epsilon_0 A}$.

EXECUTE: **(a)** Solving for Q gives $Q = \epsilon_0 AV/d = \dfrac{(8.85\times10^{-12}\text{ C}^2/\text{N}\cdot\text{m}^2)(0.030\text{ m})^2(25.0\text{ V})}{0.0050\text{ m}}$.

$Q = 3.98\times10^{-11}\text{C} = 39.8$ pC.

(b) $E = V/d = (25.0\text{ V})/(0.0050\text{ m}) = 5.00\times 10^3\text{ V/m}$.

(c) SET UP: Energy conservation gives $\frac{1}{2}mv^2 = eV$.

EXECUTE: Solving for v gives $v = \sqrt{\dfrac{2eV}{m}} = \sqrt{\dfrac{2(1.60\times 10^{-19}\text{C})(25.0\text{ V})}{9.11\times 10^{-31}\text{ kg}}} = 2.96\times 10^6\text{m/s}$.

EVALUATE: Typical voltages in student laboratory work run up to around 25 V, so typical reasonable values for the charge on the plates is about 40 pC and a reasonable value for the electric field is about 5000 V/m, as we found here. The electron speed would be about 3 million m/s.

23.65. **(a) IDENTIFY** and **SET UP:** Problem 23.61 derived that $E = \dfrac{V_{ab}}{\ln(b/a)}\dfrac{1}{r}$, where a is the radius of the inner cylinder (wire) and b is the radius of the outer hollow cylinder. The potential difference between the two cylinders is V_{ab}. Use this expression to calculate E at the specified r.

EXECUTE: Midway between the wire and the cylinder wall is at a radius of $r = (a+b)/2 = (90.0\times 10^{-6}\text{ m} + 0.140\text{ m})/2 = 0.07004\text{ m}$.

$$E = \frac{V_{ab}}{\ln(b/a)}\frac{1}{r} = \frac{50.0\times 10^3\text{ V}}{\ln(0.140\text{ m}/90.0\times 10^{-6}\text{ m})(0.07004\text{ m})} = 9.71\times 10^4\text{ V/m}.$$

(b) IDENTIFY and **SET UP:** The magnitude of the electric force is given by $F = |q|E$. Set this equal to ten times the weight of the particle and solve for $|q|$, the magnitude of the charge on the particle.

EXECUTE: $F_E = 10mg$.

$$|q|E = 10mg \text{ and } |q| = \frac{10mg}{E} = \frac{10(30.0\times 10^{-9}\text{ kg})(9.80\text{ m/s}^2)}{9.71\times 10^4\text{ V/m}} = 3.03\times 10^{-11}\text{ C}.$$

EVALUATE: It requires only this modest net charge for the electric force to be much larger than the weight.

23.66. **(a) IDENTIFY:** Calculate the potential due to each thin ring and integrate over the disk to find the potential. V is a scalar so no components are involved.

SET UP: Consider a thin ring of radius y and width dy. The ring has area $2\pi y\,dy$ so the charge on the ring is $dq = \sigma(2\pi y\,dy)$.

EXECUTE: The result of Example 23.11 then says that the potential due to this thin ring at the point on the axis at a distance x from the ring is

$$dV = \frac{1}{4\pi\epsilon_0}\frac{dq}{\sqrt{x^2+y^2}} = \frac{2\pi\sigma}{4\pi\epsilon_0}\frac{y\,dy}{\sqrt{x^2+y^2}}.$$

$$V = \int dV = \frac{\sigma}{2\epsilon_0}\int_0^R \frac{y\,dy}{\sqrt{x^2+y^2}} = \frac{\sigma}{2\varepsilon_0}\left[\sqrt{x^2+y^2}\right]_0^R = \frac{\sigma}{2\epsilon_0}(\sqrt{x^2+R^2} - x).$$

EVALUATE: For $x \gg R$ this result should reduce to the potential of a point charge with $Q = \sigma\pi R^2$.

$$\sqrt{x^2+R^2} = x(1+R^2/x^2)^{1/2} \approx x(1+R^2/2x^2) \text{ so } \sqrt{x^2+R^2} - x \approx R^2/2x.$$

Then $V \approx \dfrac{\sigma}{2\epsilon_0}\dfrac{R^2}{2x} = \dfrac{\sigma\pi R^2}{4\pi\epsilon_0 x} = \dfrac{Q}{4\pi\epsilon_0 x}$, as expected.

(b) IDENTIFY and **SET UP:** Use $E_x = -\dfrac{\partial V}{\partial x}$ to calculate E_x.

EXECUTE: $E_x = -\dfrac{\partial V}{\partial x} = -\dfrac{\sigma}{2\epsilon_0}\left(\dfrac{x}{\sqrt{x^2+R^2}} - 1\right) = \dfrac{\sigma x}{2\epsilon_0}\left(\dfrac{1}{x} - \dfrac{1}{\sqrt{x^2+R^2}}\right).$

EVALUATE: Our result agrees with the results of Example 21.11.

23.67. **IDENTIFY:** We must integrate to find the total energy because the energy to bring in more charge depends on the charge already present.

SET UP: If ρ is the uniform volume charge density, the charge of a spherical shell of radius r and thickness dr is $dq = \rho 4\pi r^2\, dr$, and $\rho = Q/(4/3\ \pi R^3)$. The charge already present in a sphere of radius r is $q = \rho(4/3\ \pi r^3)$. The energy to bring the charge dq to the surface of the charge q is Vdq, where V is the potential due to q, which is $q/4\pi\epsilon_0\, r$.

EXECUTE: The total energy to assemble the entire sphere of radius R and charge Q is sum (integral) of the tiny increments of energy.

$$U = \int V dq = \int \frac{q}{4\pi\epsilon_0\, r}\, dq = \int_0^R \frac{\rho \frac{4}{3}\pi r^3}{4\pi\epsilon_0\, r}(\rho 4\pi r^2 dr) = \frac{3}{5}\left(\frac{1}{4\pi\epsilon_0}\frac{Q^2}{R}\right)$$

where we have substituted $\rho = Q/(4/3\ \pi R^3)$ and simplified the result.

EVALUATE: For a point charge, $R \to 0$ so $U \to \infty$, which means that a point charge should have infinite self-energy. This suggests that either point charges are impossible, or that our present treatment of physics is not adequate at the extremely small scale, or both.

23.68. **IDENTIFY:** Divide the rod into infinitesimal segments with charge dq. The potential dV due to the segment is $dV = \dfrac{1}{4\pi\epsilon_0}\dfrac{dq}{r}$. Integrate over the rod to find the total potential.

SET UP: $dq = \lambda dl$, with $\lambda = Q/\pi a$ and $dl = a\, d\theta$.

EXECUTE: $dV = \dfrac{1}{4\pi\epsilon_0}\dfrac{dq}{r} = \dfrac{1}{4\pi\epsilon_0}\dfrac{\lambda\, dl}{a} = \dfrac{1}{4\pi\epsilon_0}\dfrac{Q}{\pi a}\dfrac{dl}{a} = \dfrac{1}{4\pi\epsilon_0}\dfrac{Q\, d\theta}{\pi a}.$

$V = \dfrac{1}{4\pi\epsilon_0}\displaystyle\int_0^\pi \dfrac{Q\, d\theta}{\pi a} = \dfrac{1}{4\pi\epsilon_0}\dfrac{Q}{a}.$

EVALUATE: All the charge of the ring is the same distance a from the center of curvature.

23.69. **IDENTIFY** and **SET UP:** The sphere no longer behaves as a point charge because we are inside of it. We know how the electric field varies with distance from the center of the sphere and want to use this to find the potential difference between the center and surface, which requires integration.

$V_a - V_b = \int_a^b \vec{E}\cdot d\vec{l}$. The electric field is radially outward, so $\vec{E}\cdot d\vec{l} = E\, dr$.

EXECUTE: For $r < R$: $E = \dfrac{kQr}{R^3}$. Integrating gives

$V = -\displaystyle\int_\infty^R \vec{E}\cdot d\vec{r}' - \int_R^r \vec{E}\cdot d\vec{r}' = \dfrac{kQ}{R} - \dfrac{kQ}{R^3}\int_R^r r' dr' = \dfrac{kQ}{R} - \dfrac{kQ}{R^3}\dfrac{1}{2}r'^2\Big|_R^r = \dfrac{kQ}{R} + \dfrac{kQ}{2R} - \dfrac{kQr^2}{2R^3} = \dfrac{kQ}{2R}\left[3 - \dfrac{r^2}{R^2}\right]$. At the center of the sphere, $r = 0$ and $V_1 = \dfrac{3kQ}{2R}$. At the surface of the sphere, $r = R$ and $V_2 = \dfrac{kQ}{R}$. The potential difference is $V_1 - V_2 = \dfrac{kQ}{2R} = \dfrac{(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(4.00\times10^{-6}\ \text{C})}{2(0.0500\ \text{m})} = 3.60\times10^5\ \text{V}.$

EVALUATE: To check our answer, we could actually do the integration. We can use the fact that $E = \frac{kQr}{R^3}$ so $V_1 - V_2 = \int_0^R E dr = \frac{kQ}{R^3}\int_0^R r dr = \frac{kQ}{R^3}\left(\frac{R^2}{2}\right) = \frac{kQ}{2R}.$

23.70. IDENTIFY: The potential at the surface of a uniformly charged sphere is $V = \frac{kQ}{R}.$

SET UP: For a sphere, $V = \frac{4}{3}\pi R^3$. When the raindrops merge, the total charge and volume are conserved.

EXECUTE: **(a)** $V = \frac{kQ}{R} = \frac{k(-3.60\times 10^{-12}\text{ C})}{6.50\times 10^{-4}\text{ m}} = -49.8\text{ V}.$

(b) The volume doubles, so the radius increases by the cube root of two: $R_{\text{new}} = \sqrt[3]{2}\,R = 8.19\times 10^{-4}$ m and the new charge is $Q_{\text{new}} = 2Q = -7.20\times 10^{-12}$ C. The new potential is

$V_{\text{new}} = \frac{kQ_{\text{new}}}{R_{\text{new}}} = \frac{k(-7.20\times 10^{-12}\text{ C})}{8.19\times 10^{-4}\text{ m}} = -79.0\text{ V}.$

EVALUATE: The charge doubles but the radius also increases and the potential at the surface increases by only a factor of $\frac{2}{2^{1/3}} = 2^{2/3} \approx 1.6.$

23.71. IDENTIFY: Slice the rod into thin slices and use $V = \frac{1}{4\pi\epsilon_0}\frac{q}{r}$ to calculate the potential due to each slice. Integrate over the length of the rod to find the total potential at each point.

(a) SET UP: An infinitesimal slice of the rod and its distance from point P are shown in Figure 23.71a.

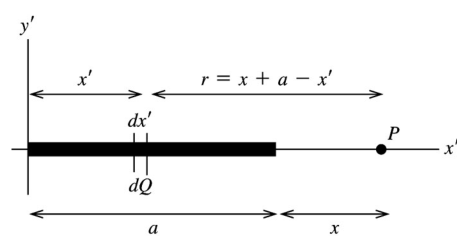

Figure 23.71a

Use coordinates with the origin at the left-hand end of the rod and one axis along the rod. Call the axes x' and y' so as not to confuse them with the distance x given in the problem.

EXECUTE: Slice the charged rod up into thin slices of width dx'. Each slice has charge $dQ = Q(dx'/a)$ and a distance $r = x + a - x'$ from point P. The potential at P due to the small slice dQ is

$$dV = \frac{1}{4\pi\epsilon_0}\left(\frac{dQ}{r}\right) = \frac{1}{4\pi\epsilon_0}\frac{Q}{a}\left(\frac{dx'}{x+a-x'}\right).$$

Compute the total V at P due to the entire rod by integrating dV over the length of the rod ($x' = 0$ to $x' = a$):

$$V = \int dV = \frac{Q}{4\pi\epsilon_0\, a}\int_0^a \frac{dx'}{(x+a-x')} = \frac{Q}{4\pi\epsilon_0\, a}[-\ln(x+a-x')]_0^a = \frac{Q}{4\pi\epsilon_0\, a}\ln\left(\frac{x+a}{x}\right).$$

EVALUATE: As $x \to \infty$, $V \to \dfrac{Q}{4\pi \epsilon_0 a} \ln\left(\dfrac{x}{x}\right) = 0.$

(b) SET UP: An infinitesimal slice of the rod and its distance from point R are shown in Figure 23.71b.

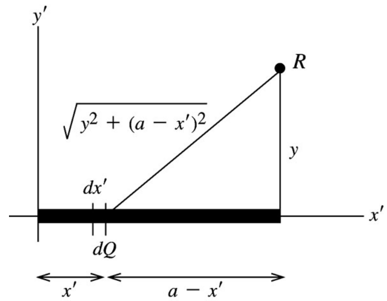

Figure 23.71b

$dQ = (Q/a)dx'$ as in part (a).

Each slice dQ is a distance $r = \sqrt{y^2 + (a - x')^2}$ from point R.

EXECUTE: The potential dV at R due to the small slice dQ is

$$dV = \frac{1}{4\pi \epsilon_0}\left(\frac{dQ}{r}\right) = \frac{1}{4\pi \epsilon_0}\frac{Q}{a}\frac{dx'}{\sqrt{y^2 + (a - x')^2}}.$$

$$V = \int dV = \frac{Q}{4\pi \epsilon_0 a}\int_0^a \frac{dx'}{\sqrt{y^2 + (a - x')^2}}.$$

In the integral make the change of variable $u = a - x'$; $du = -dx'$

$$V = -\frac{Q}{4\pi \epsilon_0 a}\int_a^0 \frac{du}{\sqrt{y^2 + u^2}} = -\frac{Q}{4\pi \epsilon_0 a}\left[\ln\left(u + \sqrt{y^2 + u^2}\right)\right]_a^0.$$

$$V = -\frac{Q}{4\pi \epsilon_0 a}\left[\ln y - \ln(a + \sqrt{y^2 + a^2})\right] = \frac{Q}{4\pi \epsilon_0 a}\left[\ln\left(\frac{a + \sqrt{a^2 + y^2}}{y}\right)\right].$$

(The expression for the integral was found in Appendix B.)

EVALUATE: As $y \to \infty$, $V \to \dfrac{Q}{4\pi \epsilon_0 a} \ln\left(\dfrac{y}{y}\right) = 0.$

(c) SET UP: *part (a):* $V = \dfrac{Q}{4\pi \epsilon_0 a}\ln\left(\dfrac{x + a}{x}\right) = \dfrac{Q}{4\pi \epsilon_0 a}\ln\left(1 + \dfrac{a}{x}\right).$

From Appendix B, $\ln(1 + u) = u - u^2/2\ldots$, so $\ln(1 + a/x) = a/x - a^2/2x^2$ and this becomes a/x when x is large.

EXECUTE: Thus $V \to \dfrac{Q}{4\pi \epsilon_0 a}\left(\dfrac{a}{x}\right) = \dfrac{Q}{4\pi \epsilon_0 x}$. For large x, V becomes the potential of a point charge.

part (b): $V = \dfrac{Q}{4\pi \epsilon_0 a}\left[\ln\left(\dfrac{a + \sqrt{a^2 + y^2}}{y}\right)\right] = \dfrac{Q}{4\pi \epsilon_0 a}\ln\left(\dfrac{a}{y} + \sqrt{1 + \dfrac{a^2}{y^2}}\right).$

From Appendix B, $\sqrt{1 + a^2/y^2} = (1 + a^2/y^2)^{1/2} = 1 + a^2/2y^2 + \ldots$

Thus $a/y+\sqrt{1+a^2/y^2} \to 1+a/y+a^2/2y^2+\ldots \to 1+a/y$. And then using $\ln(1+u)\approx u$ gives

$$V \to \frac{Q}{4\pi\epsilon_0\, a}\ln(1+a/y) \to \frac{Q}{4\pi\epsilon_0\, a}\left(\frac{a}{y}\right)=\frac{Q}{4\pi\epsilon_0\, y}.$$

EVALUATE: For large y, V becomes the potential of a point charge.

23.72. **IDENTIFY:** We are dealing with a charged bar in an external electric field.

SET UP and **EXECUTE:** **(a)** We want V as a function of y. E is constant so $V_y - V_0 = -E_y y$, which gives $V(y) = V_0 - Ey$.

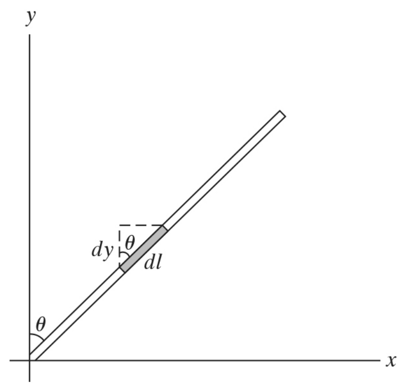

Figure 23.72

(b) We want the potential energy. Refer to Fig. 23.72. $U=\int V dq$. $dq=\lambda dl$ with $\lambda = Q/L$, and

$$dl\cos\theta = dy.\;\; U=\int_0^{L\cos\theta}(V_0-Ey)(Q/L)\frac{dy}{\cos\theta} = \left.\frac{\frac{Q}{L}\left(V_0 y-\frac{Ey^2}{2}\right)}{\cos\theta}\right|_0^{L\cos\theta} = Q\left(V_0-\frac{EL\cos\theta}{2}\right).$$

(c) We want V_0 so $U = 0$ when $\theta = 0°$. $Q\left(V_0-\frac{EL\cos\theta}{2}\right)=0$ gives $V_0 = EL/2$.

(d) We want the angular speed ω at $\theta = 0°$ if the bar is released from rest at $\theta = 90°$. Energy conservation gives $U_0 + K_0 = U_{90} + K_{90}$. We can neglect gravity, so $\frac{1}{2}I\omega^2 = QV_0$. Using the result from (c) and $I = 1/3\, ML^2$ gives $\omega=\sqrt{\frac{3QE}{ML}}$.

(e) We want the frequency f of oscillation. Apply $\sum\tau_z = I\alpha_z$. $-QE\frac{L}{2}\sin\theta=\frac{1}{3}ML^2\frac{d^2\theta}{dt^2}$. This gives $\frac{d^2\theta}{dt^2}=-\left(\frac{3QE}{2ML}\right)\sin\theta\approx-\left(\frac{3QE}{2ML}\right)\theta$ for small amplitude oscillations. $\omega=\sqrt{\frac{3QE}{2ML}}$, so $f=\frac{\omega}{2\pi}=\frac{1}{2\pi}\sqrt{\frac{3QE}{2ML}}$.

EVALUATE: This situation is very similar to an upside-down pendulum.

23.73. **IDENTIFY:** We are modeling forces in the atomic nucleus.

SET UP and **EXECUTE:** **(a)** We want the potential energy U. $U = U_{\text{spring}} + U_{\text{electric}}$, so
$U = \frac{1}{2}kd^2 + \frac{1}{4\pi\epsilon_0}\frac{e^2}{d}$.

(b) We want the equilibrium separation d_0. When U is a minimum, $dU/dd = 0$. Taking the derivative of the energy in (a) gives $kd - \frac{1}{4\pi\epsilon_0}\frac{e^2}{d^2} = 0$. Solve for $d = d_0$: $d_0 = \left(\frac{e^2}{4\pi\epsilon_0 k}\right)^{1/3}$.

(c) We want k. Solve the result of (b) for k and use d_0 = 1.00 fm = 1.00×10^{-15} m, giving $k = 2.30\times10^{17}$ N/m.

(d) We want the stored energy. $U_0 = \frac{1}{2}kd_0^2 + \frac{1}{4\pi\epsilon_0}\frac{e^2}{d_0}$. Using d_0 and k from above gives

$U_0 = 3.45\times10^{-13}$ J = 2.16 MeV.

(e) We want the speed v. $U_0 = \frac{1}{2}mv^2 + \frac{1}{2}mv^2 = mv^2$, so $v = \sqrt{U_0/m}$ = 1.44×10^7 m/s.

EVALUATE: $v/c = 1.44/3.0 = 0.048$, so $v \approx 5\%$ of the speed of light.

23.74. **IDENTIFY** and **SET UP:** For points outside of them, the spheres behave as though all the charge were concentrated at their centers. The charge initially on sphere 1 spreads between the two spheres such as to bring them to the same potential.

EXECUTE: **(a)** $E_1 = \frac{1}{4\pi\epsilon_0}\frac{Q_1}{R_1^2}$, $V_1 = \frac{1}{4\pi\epsilon_0}\frac{Q_1}{R_1} = R_1E_1$.

(b) Two conditions must be met:

1) Let q_1 and q_2 be the final charges of each sphere. Then $q_1 + q_2 = Q_1$ (charge conservation).

2) Let V_1 and V_2 be the final potentials of each sphere. All points of a conductor are at the same potential, so $V_1 = V_2$.

$V_1 = V_2$ requires that $\frac{1}{4\pi\epsilon_0}\frac{q_1}{R_1} = \frac{1}{4\pi\epsilon_0}\frac{q_2}{R_2}$ and then $q_1/R_1 = q_2/R_2$.

$$q_1R_2 = q_2R_1 = (Q_1 - q_1)R_1.$$

This gives $q_1 = (R_1/[R_1 + R_2])Q_1$ and $q_2 = Q_1 - q_1 = Q_1(1 - R_1/[R_1 + R_2]) = Q_1(R_2/[R_1 + R_2])$.

(c) $V_1 = \frac{1}{4\pi\epsilon_0}\frac{q_1}{R_1} = \frac{Q_1}{4\pi\epsilon_0(R_1 + R_2)}$ and $V_2 = \frac{1}{4\pi\epsilon_0}\frac{q_2}{R_2} = \frac{Q_1}{4\pi\epsilon_0(R_1 + R_2)}$, which equals V_1 as it should.

(d) $E_1 = \frac{V_1}{R_1} = \frac{Q_1}{4\pi\epsilon_0 R_1(R_1 + R_2)}$. $E_2 = \frac{V_2}{R_2} = \frac{Q_1}{4\pi\epsilon_0 R_2(R_1 + R_2)}$.

EVALUATE: Part (a) says $q_2 = q_1(R_2/R_1)$. The sphere with the larger radius needs more charge to produce the same potential at its surface. When $R_1 = R_2$, $q_1 = q_2 = Q_1/2$. The sphere with the larger radius has the smaller electric field at its surface.

23.75. **IDENTIFY:** Apply conservation of energy, $K_a + U_a = K_b + U_b$.

SET UP: Assume the particles initially are far apart, so $U_a = 0$. The alpha particle has zero speed at the distance of closest approach, so $K_b = 0$. $1\text{ eV} = 1.60\times10^{-19}$ J. The alpha particle has charge $+2e$ and the lead nucleus has charge $+82e$.

EXECUTE: Set the alpha particle's kinetic energy equal to its potential energy: $K_a = U_b$ gives

$$9.50\text{ MeV} = \frac{k(2e)(82e)}{r} \text{ and } r = \frac{k(164)(1.60\times10^{-19}\text{ C})^2}{(9.50\times10^6\text{ eV})(1.60\times10^{-19}\text{ J/eV})} = 2.48\times10^{-14}\text{ m}.$$

EVALUATE: The calculation assumes that at the distance of closest approach the alpha particle is outside the radius of the lead nucleus.

23.76. **IDENTIFY** and **SET UP:** Apply $\vec{E} = -\left(\frac{\partial V}{\partial x}\hat{\boldsymbol{i}} + \frac{\partial V}{\partial y}\hat{\boldsymbol{j}} + \frac{\partial V}{\partial z}\hat{\boldsymbol{k}}\right)$. $\frac{W_{a\to b}}{q_0} = V_a - V_b$ and $V_a - V_b = \int_a^b \vec{E}\cdot d\vec{l}$.

EXECUTE: **(a)** $\vec{E} = -\frac{\partial V}{\partial x}\hat{\boldsymbol{i}} - \frac{\partial V}{\partial y}\hat{\boldsymbol{j}} - \frac{\partial V}{\partial z}\hat{\boldsymbol{k}} = -2Ax\hat{\boldsymbol{i}} + 6Ay\hat{\boldsymbol{j}} - 2Az\hat{\boldsymbol{k}}.$

(b) A charge is moved in along the z-axis. The work done is given by

$W = q\int_{z_0}^{0} \vec{E}\cdot\hat{\boldsymbol{k}}dz = q\int_{z_0}^{0}(-2Az)dz = +(Aq)z_0^2$. Therefore,

$$A = \frac{W_{a\to b}}{qz_0^2} = \frac{6.00\times10^{-5}\text{ J}}{(1.5\times10^{-6}\text{ C})(0.250\text{ m})^2} = 640\text{ V/m}^2.$$

(c) $\vec{E}(0,0,0.250) = -2(640\text{ V/m}^2)(0.250\text{ m})\hat{\boldsymbol{k}} = -(320\text{ V/m})\hat{\boldsymbol{k}}.$

(d) In every plane parallel to the xz-plane, y is constant, so $V(x,y,z) = Ax^2 + Az^2 - C$, where $C = 3Ay^2$. $x^2 + z^2 = \frac{V+C}{A} = R^2$, which is the equation for a circle since R is constant as long as we have constant potential on those planes.

(e) $V = 1280$ V and $y = 2.00$ m, so $x^2 + z^2 = \frac{1280\text{ V} + 3(640\text{ V/m}^2)(2.00\text{ m})^2}{640\text{ V/m}^2} = 14.0\text{ m}^2$ and the radius of the circle is 3.74 m.

EVALUATE: In any plane parallel to the xz-plane, $\vec{E}$ projected onto the plane is radial and hence perpendicular to the equipotential circles.

23.77. **IDENTIFY** and **SET UP:** We know that the potential is of the mathematical form $V(x,y,z) = Ax^l + By^m + Cz^n + D$. We also know that $E_x = -\frac{\partial V}{\partial x}$, $E_y = -\frac{\partial V}{\partial y}$, and $E_z = -\frac{\partial V}{\partial z}$. Various measurements are given in the table with the problem in the text.

EXECUTE: **(a)** First get A, B, C, and D using data from the table in the problem.

$V(0, 0, 0) = 10.0\text{ V} = 0 + 0 + 0 + D$, so $D = 10.0$ V.

$V(1.00, 0, 0) = A(1.00\text{ m})^l + 0 + 0 + 10.0\text{ V} = 4.00$ V, so $A = -6.0\text{ V}\cdot\text{m}^{-l}$.

$V(0, 1.00, 0) = B(1.00\text{ m})^m + 10.0\text{ V} = 6.0$ V, so $B = -4.0\text{ V}\cdot\text{m}^{-m}$.

$V(0, 0, 1.00\text{ m}) = C(1.00\text{ m})^n + 10.0\text{ V} = 8.0$ V, so $C = -2.0\text{ V}\cdot\text{m}^{-n}$.

Now get l, m, and n.

$E_x = -\frac{\partial V}{\partial x} = -lAx^{l-1}$, and from the table we know that $E_x(1.00, 0, 0) = 12.0$ V/m. Therefore

$-l(-6.0\text{ V}\cdot\text{m}^{-l})(1.00\text{ m})^{l-1} = 12.0$ V/m.

$l(6.0\text{ V}\cdot\text{m}^{-1}) = 12.0$ V/m.

$l = 2.0$.

$E_y = -\frac{\partial V}{\partial y} = -mBy^{m-1}$.

$E_y(0, 1.00, 0) = -m(-4.0\text{ V}\cdot\text{m}^{-m})(1.00\text{ m})^{m-1} = 12.0$ V/m.

$m = 3.0$.

$E_z = -\frac{\partial V}{\partial z} = -nCz^{n-1}$.

$E_z(0, 0, 1.00) = -n(-2.0\ \text{V}\cdot\text{m}^{-n})(1.00\ \text{m})^{n-1} = 12.0\ \text{V/m}$.
$n = 6.0$.
Now that we have l, m, and n, we see the units of A, B, and C, so
$A = -6.0\ \text{V/m}^2$.
$B = -4.0\ \text{V/m}^3$.
$C = -2.0\ \text{V/m}^6$.
Therefore the equation for $V(x,y,z)$ is
$V = (-6.0\ \text{V/m}^2)x^2 + (-4.0\ \text{V/m}^3)y^3 + (-2.0\ \text{V/m}^6)z^6 + 10.0\ \text{V}$.
(b) At (0, 0, 0): $V = 0$ and $E = 0$ (from the table with the problem).
At (0.50 m, 0.50 m, 0.50 m):
$V = (-6.0\ \text{V/m}^2)(0.50\ \text{m})^2 + (-4.0\ \text{V/m}^3)(0.50\ \text{m})^3 + (-2.0\ \text{V/m}^6)(0.50\ \text{m})^6 + 10.0\ \text{V} = 8.0\ \text{V}$.

$$E_x = -\frac{\partial V}{\partial x} = -(-12.0\ \text{V/m}^2)x = (12.0\ \text{V/m}^2)(0.50\ \text{m}) = 6.0\ \text{V/m}.$$

$$E_y = -\frac{\partial V}{\partial y} = -3(-4.0\ \text{V/m}^3)y^2 = (12\ \text{V/m}^3)(0.50\ \text{m})^2 = 3.0\ \text{V/m}.$$

$$E_z = -\frac{\partial V}{\partial z} = -(-12.0\ \text{V/m}^6)z^5 = (12.0\ \text{V/m}^6)(0.50\ \text{m})^5 = 0.375\ \text{V/m}.$$

$$E = \sqrt{E_x^2 + E_y^2 + E_z^2} = \sqrt{(6.0\ \text{V/m})^2 + (3.0\ \text{V/m})^2 + (0.375\ \text{V/m})^2} = 6.7\ \text{V/m}.$$

At (1.00 m, 1.00 m, 1.00 m):
Follow the same procedure as above. The results are $V = -2.0$ V, $E = 21$ V/m.
EVALUATE: We know that l, m, and n must be greater that 1 because the components of the electric field are all zero at (0, 0, 0).

23.78. IDENTIFY and SET UP: Energy is conserved and the potential energy is $U = k\frac{q_1 q_2}{r}$. $K_1 + U_1 = K_2 + U_2$.

EXECUTE: **(a)** Energy conservation gives $K_1 + 0 = K_2 + U_2$.

$$\frac{1}{2}mv_0^2 = \frac{1}{2}mv^2 + k\frac{qQ}{x} \quad\rightarrow\quad v^2 = v_0^2 - \frac{2kqQ}{m}\cdot\frac{1}{x}.$$

On a graph of v_2 versus $1/x$, the graph of this equation will be a straight line with y-intercept equal to v_0^2 and slope equal to $-\frac{2kqQ}{m}$.

(b) With the given equation of the line in the problem, we have $v^2 = 400\ \text{m}^2/\text{s}^2 - (15.75\ \text{m}^3/\text{s}^2)\frac{1}{x}$. As x gets very large, $1/x$ approaches zero, so $v_0 = \sqrt{400\,\text{m}^2/\text{s}^2} = 20$ m/s.

(c) The slope is $-\frac{2kqQ}{m} = -15.75\ \text{m}^3/\text{s}^2$, which gives

$$Q = -m(\text{slope})/2kq = -(4.00\times10^{-4}\ \text{kg})(-15.75\ \text{m}^3/\text{s}^2)/[2k(5.00\times10^{-8}\ \text{C})] = +7.01\times10^{-6}\ \text{C} = +7.01\ \mu\text{C}.$$

(d) The particle is closest when its speed is zero, so

$v^2 = 400\ \text{m}^2/\text{s}^2 - (15.75\ \text{m}^3/\text{s}^2)\frac{1}{x} = 0$, which gives $x = 3.94\times10^{-2}\ \text{m} = 3.94\ \text{cm}$.

EVALUATE: From the graph in the problem, we see that v^2 decreases as $1/x$ increases, so v^2 decreases as x decreases. This means that the positively charged particle is slowing down as it gets closer to the sphere, so the sphere is repelling it. Therefore the sphere must be positively charged, as we found.

23.79. IDENTIFY: When the oil drop is at rest, the upward force $|q|E$ from the electric field equals the downward weight of the drop. When the drop is falling at its terminal speed, the upward viscous force equals the downward weight of the drop.

SET UP: The volume of the drop is related to its radius r by $V = \frac{4}{3}\pi r^3$.

EXECUTE: **(a)** $F_g = mg = \frac{4\pi r^3}{3}\rho g$. $F_e = |q|E = |q|V_{AB}/d$. $F_e = F_g$ gives $|q| = \frac{4\pi}{3}\frac{\rho r^3 gd}{V_{AB}}$.

(b) $\frac{4\pi r^3}{3}\rho g = 6\pi\eta r v_t$ gives $r = \sqrt{\frac{9\eta v_t}{2\rho g}}$. Using this result to replace r in the expression in part (a) gives

$$|q| = \frac{4\pi}{3}\frac{\rho g d}{V_{AB}}\left[\sqrt{\frac{9\eta v_t}{2\rho g}}\right]^3 = 18\pi\frac{d}{V_{AB}}\sqrt{\frac{\eta^3 v_t^3}{2\rho g}}.$$

(c) We use the values for V_{AB} and v_t given in the table in the problem and the formula

$|q| = 18\pi\frac{d}{V_{AB}}\sqrt{\frac{\eta^3 v_t^3}{2\rho g}}$ from (c). For example, for drop 1 we get

$|q| = 18\pi\frac{1.00\times10^{-3}\text{ m}}{9.16\text{ V}}\sqrt{\frac{(1.81\times10^{-5}\text{ N}\cdot\text{s/m}^2)^3(2.54\times10^{-5}\text{ m/s})^3}{2(824\text{ kg/m}^3)(9.80\text{ m/s}^2)}} = 4.79\times10^{-19}\text{ C}$. Similar calculations for the remaining drops gives the following results:

Drop 1: 4.79×10^{-19} C
Drop 2: 1.59×10^{-19} C
Drop 3: 8.09×10^{-19} C
Drop 4: 3.23×10^{-19} C

(d) Use $n = q/e_2$ to find the number of excess electrons on each drop. Since all quantities have a power of 10^{-19} C, this factor will cancel, so all we need to do is divide the coefficients of 10^{-19} C. This gives

Drop 1: $n = q_1/q_2 = 4.79/1.59 = 3$ excess electrons
Drop 2: $n = q_2/q_2 = 1$ excess electron
Drop 3: $n = q_3/q_2 = 8.09/1.59 = 5$ excess electrons
Drop 4: $n = q_4/q_2 = 3.23/1.59 = 2$ excess electrons

(e) Using $q = -ne$ gives $e = -q/n$. All the charges are negative, so e will come out positive. Thus we get

Drop 1: $e_1 = q_1/n_1 = (4.79\times10^{-19}\text{ C})/3 = 1.60\times10^{-19}$ C
Drop 2: $e_2 = q_2/n_2 = (1.59\times10^{-19}\text{ C})/1 = 1.59\times10^{-19}$ C
Drop 3: $e_3 = q_3/n_3 = (8.09\times10^{-19}\text{ C})/5 = 1.62\times10^{-19}$ C
Drop 4: $e_4 = q_4/n_4 = (3.23\times10^{-19}\text{ C})/2 = 1.61\times10^{-19}$ C

The average is

$e_{av} = (e_1 + e_2 + e_3 + e_4)/4 = [(1.60 + 1.59 + 1.62 + 1.61)\times10^{-19}\text{ C}]/4 = 1.61\times10^{-19}$ C.

EVALUATE: The result $e = 1.61\times10^{-19}$ C is very close to the well-established value of 1.60×10^{-19} C.

23.80. **IDENTIFY:** We want the potential due to an annulus. For this we need to use calculus.

SET UP: Fig. 23.80 shows the mathematical set up. $V = \int\frac{1}{4\pi\epsilon_0}\frac{dq}{D}$, where $D = \sqrt{z^2 + r^2}$, $dq = \sigma dA$, and $dA = 2\pi r dr$.

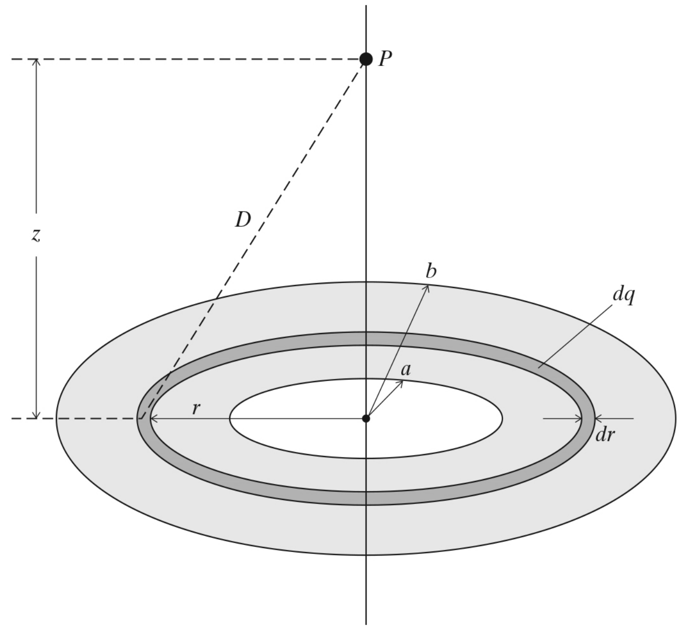

Figure 23.80

EXECUTE: **(a)** $V = \int \frac{1}{4\pi \epsilon_0} \frac{dq}{D} = \int_a^b \frac{\sigma 2\pi r dr}{4\pi \epsilon_0 \sqrt{z^2 + r^2}} = \frac{\sigma}{4\epsilon_0} \int_a^b \frac{2rdr}{\sqrt{z^2+r^2}}$. To integrate, let $u = z^2 + r^2$ so $du = 2rdr$. The integral is then of the form $\int \frac{du}{u^{1/2}} = 2u^{1/2}$, which gives $V = \frac{\sigma}{4\epsilon_0}\left(2\sqrt{z^2+r^2}\right)\Big|_a^b$.

$V = \frac{\sigma}{2\epsilon_0}\left(\sqrt{z^2+b^2} - \sqrt{z^2+a^2}\right)$.

(b) We want E_z. Use $E_z = -dV/dz$ for the result from (a), giving $\vec{E} = \frac{\sigma z}{2\epsilon_0}\left(\frac{1}{\sqrt{z^2+a^2}} - \frac{1}{\sqrt{z^2+b^2}}\right)\hat{k}$.

(c) Let $a \to 0$: $E_z \to \frac{\sigma z}{2\epsilon_0}\left(\frac{1}{z} - \frac{1}{\sqrt{z^2+b^2}}\right)$.

Let $b \to \infty$: The second term approaches zero, so $E_z \to \frac{\sigma z}{2\epsilon_0}\left(\frac{1}{z}\right) = \frac{\sigma}{2\epsilon_0}$, which is the field for an infinite sheet of charge.

(d) We want the potential at the origin. At the origin, $z = 0$, so $V(0) = \frac{\sigma}{2\epsilon_0}(b-a)$.

$\sigma = \frac{Q}{A} = \frac{Q}{\pi b^2 - \pi a^2} = \frac{Q}{\pi(b^2-a^2)}$, so $V(0) = \frac{Q}{2\pi\epsilon_0 (b^2-a^2)}(b-a) = \frac{Q}{2\pi\epsilon_0 (b+a)}$.

Using $a = 5.00$ cm, $b = 10.0$ cm, and $Q = 1.00\ \mu$C gives $V(0) = 120$ kV.

(e) We want the speed v. Energy conservation gives $qV = \frac{1}{2}mv^2$, so $v = \sqrt{2qV/m}$. Using $V = 120$ kV and $m = 0.00100$ kg gives $v = 15.5$ m/s.

EVALUATE: The electric field is *not* an inverse square in *z* and the potential is *not* an inverse *z*.

23.81. IDENTIFY: We are dealing with a heart cell that is modeled as a cylindrical shell of charge.

SET UP: $E = \dfrac{\lambda}{2\pi \epsilon_0 r}$.

EXECUTE: **(a)** We want the charge Q. Using $E = \dfrac{\lambda}{2\pi \epsilon_0 r}$ with $\lambda = Q/L$, we have

$\Delta V = \int E_r dr = \int \dfrac{\lambda}{2\pi \epsilon_0} dr = \int_a^b \dfrac{Q/L}{2\pi \epsilon_0 r} dr = \dfrac{Q/L}{2\pi \epsilon_0} \ln(b/a)$. Solving for Q and using $\Delta V = 90.0$ mV, a = 9.0 μm, b = 10.0 μm, and L = 100 μm gives $Q = 4.75 \times 10^{-15}$ C.

(b) We want the electric field just inside the membrane at $r = a = 9.0$ μm. Using $E = \dfrac{Q/L}{2\pi \epsilon_0 a}$ gives E = 94.9 kV/m.

(c) We want to find out how much charged moved across the cell wall. The potential went from -90.0 mV to +20.0 mV, so $\Delta V = 110$ mV. Using information from (a) gives $Q = \dfrac{(2\pi \epsilon_0)(\Delta V)L}{\ln(b/a)}$.

With $\Delta V = 110$ mV and the given numbers, we get $Q = 5.81 \times 10^{-15}$ C.

(d) We want to know how many Na^+ ions crossed the boundary. $N = \dfrac{5.81 \times 10^{-15} \text{ C}}{1.60 \times 10^{-19} \text{ C/ion}} = 36{,}300.$

EVALUATE: Note how small the charges, fields, and potentials are in cellular electrical processes. By contrast the electric field of the proton in a hydrogen atom at the location of the electron is approximately 6×10^{11} V/m.

23.82. IDENTIFY: Consider the potential due to an infinitesimal slice of the cylinder and integrate over the length of the cylinder to find the total potential. The electric field is along the axis of the tube and is given by $E = -\dfrac{\partial V}{\partial x}$.

SET UP: Use the expression from Example 23.11 for the potential due to each infinitesimal slice. Let the slice be at coordinate z along the x-axis, relative to the center of the tube.

EXECUTE: **(a)** For an infinitesimal slice of the finite cylinder, we have the potential

$dV = \dfrac{k\,dQ}{\sqrt{(x-z)^2 + R^2}} = \dfrac{kQ}{L}\dfrac{dz}{\sqrt{(x-z)^2 + R^2}}$. Integrating gives

$V = \dfrac{kQ}{L}\int_{-L/2}^{L/2} \dfrac{dz}{\sqrt{(x-z)^2 + R^2}} = \dfrac{kQ}{L}\int_{-L/2-x}^{L/2-x} \dfrac{du}{\sqrt{u^2 + R^2}}$ where $u = x - z$. Therefore,

$V = \dfrac{kQ}{L}\ln\left[\dfrac{\sqrt{(L/2-x)^2 + R^2} + (L/2-x)}{\sqrt{(L/2+x)^2 + R^2} - L/2 - x}\right]$ on the cylinder axis.

(b) For $L << R$, $V \approx \dfrac{kQ}{L}\ln\left[\dfrac{\sqrt{(L/2-x)^2 + R^2} + L/2 - x}{\sqrt{(L/2+x)^2 + R^2} - L/2 - x}\right] \approx \dfrac{kQ}{L}\ln\left[\dfrac{\sqrt{x^2 - xL + R^2} + L/2 - x}{\sqrt{x^2 + xL + R^2} - L/2 - x}\right]$.

$$V \approx \frac{kQ}{L}\ln\left[\frac{\sqrt{1 - xL/(R^2 + x^2)} + (L/2 - x)/\sqrt{R^2 + x^2}}{\sqrt{1 + xL/(R^2 + x^2)} + (-L/2 - x)/\sqrt{R^2 + x^2}}\right] = \frac{kQ}{L}\ln\left[\frac{1 - xL/2(R^2 + x^2) + (L/2 - x)/\sqrt{R^2 + x^2}}{1 + xL/2(R^2 + x^2) + (-L/2 - x)/\sqrt{R^2 + x^2}}\right].$$

$$V \approx \frac{kQ}{L}\ln\left[\frac{1 + L/2\sqrt{R^2 + x^2}}{1 - L/2\sqrt{R^2 + x^2}}\right] = \frac{kQ}{L}\left(\ln\left[1 + \frac{L}{2\sqrt{R^2 + x^2}}\right] - \ln\left[1 - \frac{L}{2\sqrt{R^2 + x^2}}\right]\right).$$

$V \approx \frac{kQ}{L}\frac{2L}{2\sqrt{x^2+R^2}} = \frac{kQ}{\sqrt{x^2+R^2}}$, which is the same as for a ring.

(c) $E_x = -\frac{\partial V}{\partial x} = \frac{2kQ\left(\sqrt{(L-2x)^2+4R^2}-\sqrt{(L+2x)^2+4R^2}\right)}{\sqrt{(L-2x)^2+4R^2}\sqrt{(L+2x)^2+4R^2}}.$

EVALUATE: For $L << R$ the expression for E_x reduces to that for a ring of charge, $E_x = \frac{kQx}{(x^2+a^2)^{3/2}}$, as shown in Example 23.14.

23.83. **IDENTIFY:** Angular momentum and energy must be conserved.

SET UP: At the distance of closest approach the speed is not zero. $E = K + U$. $q_1 = 2e$, $q_2 = 82e$.

EXECUTE: $mv_1 b = mv_2 r_2$. $E_1 = E_2$ gives $E_1 = \frac{1}{2}mv_2{}^2 + \frac{kq_1q_2}{r_2}$. $E_1 = 11\text{ MeV} = 1.76\times10^{-12}$ J. r_2 is the distance of closest approach. Substituting in for $v_2 = v_1\left(\frac{b}{r_2}\right)$ we find $E_1 = E_1\frac{b^2}{r_2{}^2} + \frac{kq_1q_2}{r_2}$.

$(E_1)r_2^2 - (kq_1q_2)r_2 - E_1 b^2 = 0$. For $b = 10^{-12}$ m, $r_2 = 1.01\times10^{-12}$ m. For $b = 10^{-13}$ m, $r_2 = 1.11\times10^{-13}$ m. And for $b = 10^{-14}$ m, $r_2 = 2.54\times10^{-14}$ m.

EVALUATE: As b decreases the collision is closer to being head-on and the distance of closest approach decreases.

23.84. **IDENTIFY** and **SET UP:** The He ions are first accelerated toward the center and then accelerated away from the center, but always in the same direction. During the first acceleration, their charge is $-e$, and during the second acceleration it is $+2e$. The work-energy theorem gives $\Delta K = q\Delta V$. Call V the voltage at the center.

EXECUTE: **(a)** Toward the center: $\Delta K = q\Delta V = eV$.

Away from the center: $\Delta K = q\Delta V = 2eV$.

The ions gain 3.0 MeV of kinetic energy, so $eV + 2eV = 3.0$ MeV.

$3eV = 3.0$ MeV.

$V = +1.0$ MV, since the e cancels. This is choice (d).

EVALUATE: The negative He^- ions are accelerating to higher potential, and the positive He^{++} ions are accelerating toward lower potential.

23.85. **IDENTIFY** and **SET UP:** Conservation of energy gives $K = U_{\text{electric}} = k\frac{q_1q_2}{r}$.

EXECUTE: Solve for Q: $Q = rK/kq = (10\times10^{-15}\text{ m})(3.0\text{ MeV})/(2ek) = 1.67\times10^{-18}$ C. In terms of e, this is $Q = (1.67\times10^{-18}\text{ C})/(1.60\times10^{-19}\text{ C}) = 10.4e \approx 11e$, so choice (b) is best.

EVALUATE: If $Q = 11e$, the atom is sodium (Na), which has an atomic mass of 23, compared to 4 for He. So it is reasonable to assume that the nucleus does not move appreciably, since it is about 6 times more massive than the He.

23.86. **IDENTIFY** and **SET UP:** The potential changes by 6.0 MV over a distance of 12 m. $E_{\text{av}} = \frac{\Delta V}{\Delta x}$.

EXECUTE: $E_{\text{av}} = \frac{\Delta V}{\Delta x} = (6.0\text{ MV})/(12\text{ m}) = 0.50\times10^6\text{ V/m} = 500{,}000\text{ V/m}$, which is choice (c).

EVALUATE: The actual variation of the field may be somewhat complicated, but the average value gives a good idea of a typical electric field in such apparatus.

24

CAPACITANCE AND DIELECTRICS

VP24.4.1. **IDENTIFY:** We are dealing with a parallel-plate capacitor.

SET UP and **EXECUTE:** **(a)** We want the capacitance. $C = \dfrac{\epsilon_0 A}{d} = \dfrac{\epsilon_0 (2.75\text{ m}^2)}{0.00350\text{ m}} = 6.95\text{ nF}.$

(b) We want the potential difference between the plates. $V = Ed = (\sigma/\epsilon_0)d$. Using the given values gives $V = 5.54$ kV.

EVALUATE: $E = \sigma/\epsilon_0 = 1.58$ MV/m between the plates, so we get a large potential difference of over 5000 V.

VP24.4.2. **IDENTIFY:** We are dealing with a parallel-plate capacitor.

SET UP and **EXECUTE:** **(a)** We want the plate spacing. Solving $C = \dfrac{\epsilon_0 A}{d}$ for d gives $d = \dfrac{\epsilon_0 A}{C}$. Using the given numbers we get $d = 4.80$ mm.

(b) We want the charge on the plates and the potential difference between them when $V = 3.00$ kV. $Q = CV = (8.30\text{ nF})(3.00\text{ kV}) = 24.9\ \mu\text{C}$. $E = V/d = (3.00\text{ kV})/(4.80\text{ mm}) = 625$ kV/m.

EVALUATE: Use $E = \sigma/\epsilon_0 = \dfrac{Q/A}{\epsilon_0}$, which gives the same answer as in (b).

VP24.4.3. **IDENTIFY** and **SET UP:** We have a spherical capacitor. $C = 4\pi\epsilon_0\left(\dfrac{r_a r_b}{r_b - r_a}\right)$.

EXECUTE: **(a)** We want the outer radius of the inner shell, which is r_a. Solve $C = 4\pi\epsilon_0\left(\dfrac{r_a r_b}{r_b - r_a}\right)$ for r_a giving $r_a = \dfrac{r_b C}{C + 4\pi\epsilon_0 r_b}$. The given numbers yield $r_a = 8.33$ cm.

(b) We want the charge when $V = 355$ V. $Q = CV = (125\text{ pF})(355\text{ V}) = 44.4$ nC.

(c) We want the surface charge density at both surfaces. $\sigma = \dfrac{Q}{A} = \dfrac{Q}{4\pi r^2}$.

Outer surface: $\sigma_b = \dfrac{Q}{4\pi r_b^2} = \dfrac{-44.4\text{ nC}}{4\pi(0.0900\text{ m})^2} = -4.36\times10^{-7}\text{ C/m}^2.$

Inner surface: $\sigma_a = \dfrac{Q}{4\pi r_a^2} = \dfrac{+44.4\text{ nC}}{4\pi(0.0833\text{ m})^2} = +5.09\times10^{-7}\text{ C/m}^2.$

EVALUATE: The inner and outer surfaces carry the same magnitude charge, but the inner surface has a smaller area so its charge density should be greater than that of the outer surface. This agrees with our result.

VP24.4.4. **IDENTIFY** and **SET UP:** We have a cylindrical capacitor. From Example 24.4, $C/L = \dfrac{2\pi\epsilon_0}{\ln(r_b/r_a)}$.

EXECUTE: **(a)** We want r_b/r_a. Solving $C/L = \dfrac{2\pi\epsilon_0}{\ln(r_b/r_a)}$ for r_b/r_a and putting in the given numbers we have $\ln(r_b/r_a) = \dfrac{2\pi\epsilon_0}{C/L} = 0.80524$. $r_b/r_a = e^{0.80524} = 2.24$.

(b) We want the potential difference. $C = \dfrac{Q}{V}$, so $C/L = \dfrac{Q/L}{V}$, giving

$V = \dfrac{Q/L}{C/L} = \dfrac{8.62\text{ nC/m}}{69.0\text{ pF/m}} = 125\text{ V}$. The inner conductor is positive, so the electric field between the cylinders does work on a positive charge in going from a to b, so the inner conductor is at a higher potential then the outer one.

EVALUATE: A kilometer of this cylinder would have a capacitance of only 69 nF.

VP24.9.1. **IDENTIFY:** We have capacitors in series and parallel.

SET UP: In series: $1/C_{\text{eq}} = 1/C_1 + 1/C_2 + \cdots$, in parallel: $C_{\text{eq}} = C_1 + C_2 + \text{L}$. We want the equivalent capacitance.

EXECUTE: **(a)** $1/C_{\text{eq}} = 1/(1.00\ \mu\text{F}) + 1/(2.50\ \mu\text{F}) + 1/(5.00\ \mu\text{F})$. $C_{\text{eq}} = 0.625\ \mu\text{F}$.

(b) $C_{\text{eq}} = 1.00\ \mu\text{F} + 2.50\ \mu\text{F} + 5.00\ \mu\text{F} = 8.50\ \mu\text{F}$.

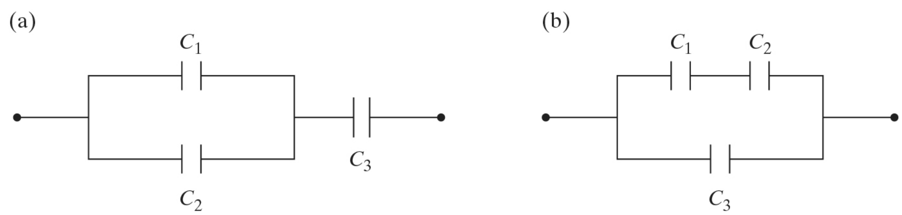

Figure VP24.9.1

(c) Figure VP24.9.1(a) shows the combination. The parallel combination is given by $C_{\text{p}} = 1.00\ \mu\text{F} + 2.50\ \mu\text{F} = 3.50\ \mu\text{F}$. The series combination is given by $1/C_S = 1/(3.50\ \mu\text{F}) + 1/(5.00\ \mu\text{F})$. This gives $C_S = 2.06\ \mu\text{F}$.

(d) Fig. VP24.9.1(b) shows the combination. For the series combination, $1/C_S = 1/(1.00\ \mu\text{F}) + 1/(2.50\ \mu\text{F})$. $C_S = 0.715\ \mu\text{F}$. The equivalent capacitance is $C_{\text{eq}} = 0.714\ \mu\text{F} + 5.00\ \mu\text{F} = 5.71\ \mu\text{F}$.

EVALUATE: Notice that for capacitors in series, the equivalent capacitance is less than the smallest capacitance, but when they are in parallel the equivalent capacitance is larger than the largest capacitance.

VP24.9.2. **IDENTIFY:** We are dealing with the energy stored in capacitors in combination.

SET UP: $U = \dfrac{Q^2}{2C} = \dfrac{1}{2}CV^2$. We want to find the stored energy.

EXECUTE: **(a)** $U_1 = \dfrac{Q^2}{2C_1} =$ 0.0675 J using the given numbers. Similarly $U_2 = 0.0169$ J. We see that C_1 stores more energy than C_2.

(b) $U_1 = \dfrac{1}{2}C_1V^2 = 0.0117$ J using the given numbers. Similarly $U_2 = 0.0469$ J. C_2 has more energy than C_1.

EVALUATE: Note that a larger capacitor does *not necessarily* store more energy than a small capacitor. It depends on how they are connected.

VP24.9.3. **IDENTIFY:** We are dealing with the energy stored in capacitors in combination.

SET UP: $U = \dfrac{Q^2}{2C} = \dfrac{1}{2}CV^2$. $1/C_{eq} = 1/C_1 + 1/C_2 = \dfrac{C_1 + C_2}{C_1 C_2}$. We want the stored energy.

EXECUTE: **(a)** Series: $U_S = \dfrac{1}{2}CV^2 = \dfrac{1}{2}\left(\dfrac{C_1C_2}{C_1 + C_2}\right)V^2$ = 0.0115 J using the given numbers.

Parallel: $U_p = \dfrac{1}{2}(C_1 + C_2)V^2 =$ 0.0578 J using the given numbers. The parallel combination stores more energy than the series combination.

(b) Series: $U_S = \dfrac{Q^2}{2C_{eq}} = \dfrac{Q^2}{2}\left(\dfrac{1}{C_1} + \dfrac{1}{C_2}\right) = 0.0733$ J using the given numbers.

Parallel: $U_p = \dfrac{Q^2}{2C_{eq}} = \dfrac{Q^2}{2(C_1 + C_2)} = 0.0145$ J using the given numbers. The series combination stores more energy.

EVALUATE: In part (a) the parallel combination stored more energy, but in (b) the series store more. The result depends on how the capacitors are connected in the circuit.

VP24.9.4. **IDENTIFY:** This problem involves a parallel-plate capacitor.

SET UP and **EXECUTE:** **(a)** We want the surface charge density on the plates. Using $\sigma = Q/A$ and the given numbers, we get σ = 5.10 μC/m^2.f

(b) We want the electric field. $E = \sigma/\epsilon_0$ = 576 kV/m.

(c) We want the energy density. $u = \dfrac{1}{2}\epsilon_0 E^2$ = 1.47 J/m^3 using the result from (b).

(d) We want the total energy. $U = u$(volume) $= uAd$ = (1.47 J/m^3)(2.45 m^2)(0.00140 m) = 5.04 mJ.

EVALUATE: As a check, use $U = \dfrac{Q^2}{2C}$ and $C = \epsilon_0 A/d$ to get $U = \dfrac{Q^2 d}{2\epsilon_0 A}$ = 5.04 mJ, which agrees with our result in (d).

VP24.11.1. **IDENTIFY:** We are dealing with a capacitor containing dielectric.

SET UP and **EXECUTE:** **(a)** We want C without dielectric. $C = \dfrac{\epsilon_0 A}{d}$ = 1.36 nF using the given numbers.

(b) We want the charge. $Q = CV$ = (1.36 nF)(4.00 kV) = 5.43 μC.

(c) We want the dielectric constant. $V = V_0/K$, so $K = V_0/V$ = (4.00 kV)/(2.50 kV) = 1.60.

(d) We want the capacitance. $C = KC_0$ = (1.60)(1.36 nF) = 2.17 nF.

(e) We want the induced charge. $Q_{\neg i} = Q(1 - 1/K)$ = (5.43 μC)(1 – 1/1.60) = 2.04 μC.

EVALUATE: The dielectric increases the capacitance. The presence of the induced charge decreases the potential difference between the plates. This charge produces and electric field opposite to the original field.

VP24.11.2. **IDENTIFY:** We are dealing with a capacitor containing dielectric.

SET UP and **EXECUTE:** **(a)** We want the capacitance. $C = \epsilon_0 A/d$ = 2.36 nF using the given numbers.

(b) We want the charge. $Q = swCV$ = (2.36 nF)(3.50 kV) = 8.26 μC.

(c) We want C with the dielectric. $C = KC_0$ = (2.50)(2.36 nF) = 5.90 nF.

(d) We want the charge. $Q = CV$ = (5.90 nF)(3.50 kV) = 20.7 μC.

(e) We want the induced charge. With the battery connected, V remains the same, so $E = V/d$ also remains the same. Thus there must be more charge on the plates than for an empty capacitor to make up for the electric field due to the induced charge of the dielectric. Using $E = \sigma/\epsilon_0$ gives

$\dfrac{\sigma_{plates}}{\epsilon_0} = \dfrac{\sigma_0}{\epsilon_0} + \dfrac{|\sigma_{induced}|}{\epsilon_0}$. Which gives $|Q_{induced}| = Q_{plates} - Q_0$ = 20.7 μC – 8.26 μC = 12.4 μC.

EVALUATE: If the battery were not left connected while the dielectric was inserted, V would *not* remain constant but the charge Q on the plates would stay constant as in problem VP24.11.1.

VP24.11.3. **IDENTIFY:** We are dealing with the energy stored in a capacitor with dielectric.

SET UP and **EXECUTE:** We want the energy stored before and after the dielectric is inserted.

(a) $U_0 = \frac{1}{2}CV_0^2 = 17.6$ J using the given numbers.

(b) $K = V_0/V$ and $C = KC_0$, so $U = \frac{1}{2}CV^2 = \frac{1}{2}(KC_0)V^2 = \frac{1}{2}\left(\frac{V_0}{V}C_0\right)V^2 = \frac{1}{2}C_0V_0V$. Using $C_0 = 4.50\ \mu$F, $V_0 = 2.80$ kV, and $V = 1.20$ kV gives $U = 7.56$ J.

EVALUATE: The dielectric increased the capacitance but decreased the stored energy because V decreased.

VP24.11.4. **IDENTIFY:** We are dealing with the energy stored in a capacitor with dielectric.

SET UP and **EXECUTE:** We want the energy stored before and after the dielectric is inserted.

(a) $U_0 = \frac{1}{2}CV_0^2 = 6.30$ J using the given numbers.

(b) $U = \frac{1}{2}CV^2 = \frac{1}{2}(KC_0)V^2 = K\left(\frac{1}{2}C_0V^2\right) = KU_0 = (2.85)(6.30\text{ J}) = 18.0$ J.

EVALUATE: With the battery connected as the dielectric is inserted, V stays the same and C increases, so U increases by a factor of K.

24.1. **IDENTIFY:** The capacitance depends on the geometry (area and plate separation) of the plates.

SET UP: For a parallel-plate capacitor, $V_{ab} = Ed$, $E = \frac{Q}{\epsilon_0 A}$, and $C = \frac{Q}{V_{ab}}$.

EXECUTE: **(a)** $V_{ab} = Ed = (4.00\times10^6\text{ V/m})(2.50\times10^{-3}\text{ m}) = 1.00\times10^4$ V.

(b) Solving for the area gives

$$A = \frac{Q}{E\epsilon_0} = \frac{80.0\times10^{-9}\text{ C}}{(4.00\times10^6\text{ V/m})[8.854\times10^{-12}\text{ C}^2/(\text{N}\cdot\text{m}^2)]} = 2.26\times10^{-3}\text{ m}^2 = 22.6\text{ cm}^2.$$

(c) $C = \frac{Q}{V_{ab}} = \frac{80.0\times10^{-9}\text{ C}}{1.00\times10^4\text{ V}} = 8.00\times10^{-12}\text{ F} = 8.00$ pF.

EVALUATE: The capacitance is reasonable for laboratory capacitors, but the area is rather large.

24.2. **IDENTIFY** and **SET UP:** $C = \frac{\epsilon_0 A}{d}$, $C = \frac{Q}{V}$ and $V = Ed$.

EXECUTE: **(a)** $C = \epsilon_0 \frac{A}{d} = \epsilon_0 \frac{0.000982\text{ m}^2}{0.00328\text{ m}} = 2.65$ pF.

(b) $V = \frac{Q}{C} = \frac{4.35\times10^{-8}\text{ C}}{2.65\times10^{-12}\text{ F}} = 16.4$ kV.

(c) $E = \frac{V}{d} = \frac{16.4\times10^3\text{ V}}{0.00328\text{ m}} = 5.00\times10^6$ V/m.

EVALUATE: The electric field is uniform between the plates, at points that aren't close to the edges.

24.3. **IDENTIFY** and **SET UP:** It is a parallel-plate air capacitor, so we can apply the equations of Section 24.1.

EXECUTE: **(a)** $C = \dfrac{Q}{V_{ab}}$ so $V_{ab} = \dfrac{Q}{C} = \dfrac{0.148\times10^{-6}\text{ C}}{245\times10^{-12}\text{ F}} = 604\text{ V}.$

(b) $C = \dfrac{\epsilon_0 A}{d}$ so $A = \dfrac{Cd}{\epsilon_0} = \dfrac{(245\times10^{-12}\text{ F})(0.328\times10^{-3}\text{ m})}{8.854\times10^{-12}\text{ C}^2/\text{N}\cdot\text{m}^2} = 9.08\times10^{-3}\text{ m}^2 = 90.8\text{ cm}^2.$

(c) $V_{ab} = Ed$ so $E = \dfrac{V_{ab}}{d} = \dfrac{604\text{ V}}{0.328\times10^{-3}\text{ m}} = 1.84\times10^6\text{ V/m}.$

(d) $E = \dfrac{\sigma}{\epsilon_0}$ so $\sigma = E\epsilon_0 = (1.84\times10^6\text{ V/m})(8.854\times10^{-12}\text{ C}^2/\text{N}\cdot\text{m}^2) = 1.63\times10^{-5}\text{ C/m}^2.$

EVALUATE: We could also calculate σ directly as Q/A. $\sigma = \dfrac{Q}{A} = \dfrac{0.148\times10^{-6}\text{ C}}{9.08\times10^{-3}\text{ m}^2} = 1.63\times10^{-5}\text{ C/m}^2,$ which checks.

24.4. **IDENTIFY:** $C = \dfrac{Q}{V_{ab}}$. $C = \dfrac{\epsilon_0 A}{d}$.

SET UP: When the capacitor is connected to the battery, enough charge flows onto the plates to make $V_{ab} = 12.0\text{ V}$.

EXECUTE: **(a)** 12.0 V.

(b) (i) When d is doubled, C is halved. $V_{ab} = \dfrac{Q}{C}$ and Q is constant, so V doubles. $V = 24.0\text{ V}$.

(ii) When r is doubled, A increases by a factor of 4. V decreases by a factor of 4 and $V = 3.0\text{ V}$.

EVALUATE: The electric field between the plates is $E = \dfrac{\sigma}{\epsilon_0} = \dfrac{Q}{\epsilon_0 A}$. $V_{ab} = Ed$. When d is doubled E is unchanged and V doubles. When A is increased by a factor of 4, E decreases by a factor of 4 so V decreases by a factor of 4.

24.5. **IDENTIFY:** $C = \dfrac{Q}{V_{ab}}$. $C = \dfrac{\epsilon_0 A}{d}$.

SET UP: When the capacitor is connected to the battery, $V_{ab} = 12.0\text{ V}$.

EXECUTE: **(a)** $Q = CV_{ab} = (10.0\times10^{-6}\text{ F})(12.0\text{ V}) = 1.20\times10^{-4}\text{ C} = 120\ \mu\text{C}.$

(b) When d is doubled C is halved, so Q is halved. $Q = 60\ \mu\text{C}$.

(c) If r is doubled, A increases by a factor of 4. C increases by a factor of 4 and Q increases by a factor of 4. $Q = 480\ \mu\text{C}$.

EVALUATE: When the plates are moved apart, less charge on the plates is required to produce the same potential difference. With the separation of the plates constant, the electric field must remain constant to produce the same potential difference. The electric field depends on the surface charge density, σ. To produce the same σ, more charge is required when the area increases.

24.6. **IDENTIFY:** $C = \dfrac{Q}{V_{ab}}$. $V_{ab} = Ed$. $C = \dfrac{\epsilon_0 A}{d}$.

SET UP: We want $E = 1.00\times10^4\text{ N/C}$ when $V = 100\text{ V}$.

EXECUTE: **(a)** $d = \dfrac{V_{ab}}{E} = \dfrac{1.00\times10^2 \text{ V}}{1.00\times10^4 \text{ N/C}} = 1.00\times10^{-2} \text{ m} = 1.00 \text{ cm}.$

$A = \dfrac{Cd}{\epsilon_0} = \dfrac{(5.00\times10^{-12} \text{ F})(1.00\times10^{-2} \text{ m})}{8.854\times10^{-12} \text{ C}^2/(\text{N}\cdot\text{m}^2)} = 5.65\times10^{-3} \text{ m}^2.$ $A = \pi r^2$ so

$r = \sqrt{\dfrac{A}{\pi}} = 4.24\times10^{-2} \text{ m} = 4.24 \text{ cm}.$

(b) $Q = CV_{ab} = (5.00\times10^{-12} \text{ F})(1.00\times10^2 \text{ V}) = 5.00\times10^{-10} \text{ C} = 500 \text{ pC}.$

EVALUATE: $C = \dfrac{\epsilon_0 A}{d}$. We could have a larger d, along with a larger A, and still achieve the required C without exceeding the maximum allowed E.

24.7. **IDENTIFY:** The energy stored in a capacitor depends on its capacitance, which in turn depends on its geometry.

SET UP: $C = Q/V$ for any capacitor, and $C = \dfrac{\epsilon_0 A}{d}$ for a parallel-plate capacitor.

EXECUTE: **(a)** $C = \dfrac{Q}{V} = \dfrac{2.40\times10^{-10} \text{ C}}{42.0 \text{ V}} = 5.714\times10^{-12} \text{ F}.$ Using $C = \dfrac{\epsilon_0 A}{d}$ gives

$d = \dfrac{\epsilon_0 A}{C} = \dfrac{[8.854\times10^{-12} \text{ C}^2/(\text{N}\cdot\text{m}^2)](6.80\times10^{-4} \text{ m}^2)}{5.714\times10^{-12} \text{ F}} = 1.05 \text{ mm}.$

(b) $d = 2.10\times10^{-3}$ m. $C = \dfrac{\epsilon_0 A}{d} = \dfrac{5.714\times10^{-12} \text{ F}}{2} = 2.857\times10^{-12} \text{ F}.$ $V = \dfrac{Q}{C}$, so

$V = 2(42.0 \text{ V}) = 84.0 \text{ V}.$

EVALUATE: Doubling the plate separation halves the capacitance, so twice the potential difference is required to keep the same charge on the plates.

24.8. **IDENTIFY:** Capacitance depends on the geometry of the object.

(a) SET UP: The capacitance of a cylindrical capacitor is $C = \dfrac{2\pi\epsilon_0 L}{\ln(r_b/r_a)}$. Solving for r_b gives

$r_b = r_a e^{2\pi\epsilon_0 L/C}$.

EXECUTE: Substituting in the numbers for the exponent gives

$$\frac{2\pi(8.85\times10^{-12} \text{ C}^2/\text{N}\cdot\text{m}^2)(0.120 \text{ m})}{3.67\times10^{-11} \text{ F}} = 0.182.$$

Now use this value to calculate r_b: $r_b = r_a e^{0.182} = (0.250 \text{ cm})e^{0.182} = 0.300 \text{ cm}.$

(b) SET UP: For any capacitor, $C = Q/V$ and $\lambda = Q/L$. Combining these equations and substituting the numbers gives $\lambda = Q/L = CV/L$.

EXECUTE: Numerically we get

$$\lambda = \frac{CV}{L} = \frac{(3.67\times10^{-11} \text{ F})(125 \text{ V})}{0.120 \text{ m}} = 3.82\times10^{-8} \text{ C/m} = 38.2 \text{ nC/m}.$$

EVALUATE: The distance between the surfaces of the two cylinders would be only 0.050 cm, which is just 0.50 mm. These cylinders would have to be carefully constructed.

24.9. **IDENTIFY:** Apply the results of Example 24.4. $C = Q/V$.

SET UP: $r_a = 0.50$ mm, $r_b = 5.00$ mm.

EXECUTE: **(a)** $C = \dfrac{L 2\pi\epsilon_0}{\ln(r_b/r_a)} = \dfrac{(0.180 \text{ m})2\pi\epsilon_0}{\ln(5.00/0.50)} = 4.35\times10^{-12} \text{ F}.$

(b) $V = Q/C = (10.0\times10^{-12}\text{ C})/(4.35\times10^{-12}\text{ F}) = 2.30\text{ V}.$

EVALUATE: $\dfrac{C}{L} = 24.2\text{ pF}.$ This value is similar to those in Example 24.4. The capacitance is determined entirely by the dimensions of the cylinders.

24.10. **IDENTIFY** and **SET UP:** Use $\dfrac{C}{L} = \dfrac{2\pi\epsilon_0}{\ln(r_b/r_a)}$ which was derived in Example 24.4. Then use $Q = CV$ to calculate Q.

EXECUTE: **(a)** Using $\dfrac{C}{L} = \dfrac{2\pi\epsilon_0}{\ln(r_b/r_a)}$ gives

$$\frac{C}{L} = \frac{2\pi(8.854\times10^{-12}\text{ C}^2/\text{N}\cdot\text{m}^2)}{\ln[(3.5\text{ mm})/(2.2\text{ mm})]} = 1.2\times10^{-10}\text{ F/m} = 120\text{ pF/m}.$$

(b) $C = (1.20\times10^{-10}\text{ F/m})(2.8\text{ m}) = 3.355\times10^{-10}\text{ F}.$

$Q = CV = (3.355\times10^{-10}\text{ F})(350\times10^{-3}\text{ V}) = 1.2\times10^{-10}\text{ C} = 120\text{ pC}.$

The conductor at higher potential has the positive charge, so there is +120 pC on the inner conductor and −120 pC on the outer conductor.

EVALUATE: C depends only on the dimensions of the capacitor. Q and V are proportional.

24.11. **IDENTIFY:** We can use the definition of capacitance to find the capacitance of the capacitor, and then relate the capacitance to geometry to find the inner radius.

(a) SET UP: By the definition of capacitance, $C = Q/V$.

EXECUTE: $C = \dfrac{Q}{V} = \dfrac{3.30\times10^{-9}\text{ C}}{2.20\times10^{2}\text{ V}} = 1.50\times10^{-11}\text{ F} = 15.0\text{ pF}.$

(b) SET UP: The capacitance of a spherical capacitor is $C = 4\pi\epsilon_0\dfrac{r_a r_b}{r_b - r_a}.$

EXECUTE: Solve for r_a and evaluate using $C = 15.0\text{ pF}$ and $r_b = 4.00\text{ cm},$ giving $r_a = 3.09\text{ cm}.$

(c) SET UP: We can treat the inner sphere as a point charge located at its center and use Coulomb's law, $E = \dfrac{1}{4\pi\epsilon_0}\dfrac{q}{r^2}.$

EXECUTE: $E = \dfrac{(8.99\times10^{9}\text{ N}\cdot\text{m}^2/\text{C}^2)(3.30\times10^{-9}\text{ C})}{(0.0309\text{ m})^2} = 3.12\times10^{4}\text{ N/C}.$

EVALUATE: Outside the capacitor, the electric field is zero because the charges on the spheres are equal in magnitude but opposite in sign.

24.12. **IDENTIFY:** Apply the results of Example 24.3. $C = Q/V$.

SET UP: $r_a = 15.0\text{ cm}.$ Solve for r_b.

EXECUTE: **(a)** For two concentric spherical shells, the capacitance is $C = \dfrac{1}{k}\left(\dfrac{r_a r_b}{r_b - r_a}\right).$

$kCr_b - kCr_a = r_a r_b$ and $r_b = \dfrac{kCr_a}{kC - r_a} = \dfrac{k(116\times10^{-12}\text{ F})(0.150\text{ m})}{k(116\times10^{-12}\text{ F}) - 0.150\text{ m}} = 0.175\text{ m} = 17.5\text{ cm}.$

(b) $V = 220\text{ V}$ and $Q = CV = (116\times10^{-12}\text{ F})(220\text{ V}) = 2.55\times10^{-8}\text{ C} = 25.5\text{ nC}.$

EVALUATE: A parallel-plate capacitor with $A = 4\pi r_a r_b = 0.33\text{ m}^2$ and $d = r_b - r_a = 2.5\times10^{-2}\text{ m}$ has $C = \dfrac{\epsilon_0 A}{d} = 117\text{ pF},$ in excellent agreement with the value of C for the spherical capacitor.

24.13. **IDENTIFY:** This problem involves dielectrics and capacitors in series.
SET UP: First sketch the circuit as in Fig. 24.13. The graph plots V_2 versus V, so we need to find a relationship between these quantities so we can interpret the slope. We want to find C_1.

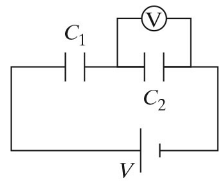

Figure 24.13

EXECUTE: For capacitors in series $Q_1 = Q_2 = Q = C_{eq}V$. $V_2 = Q/C_2 = C_{eq}V/C_2$. $C_{eq} = \dfrac{C_1C_2}{C_1+C_2}$, so $V_2 = \left(\dfrac{C_1C_2}{C_1+C_2}\right)\dfrac{V}{C_2} = \left(\dfrac{C_1}{C_1+C_2}\right)V$. Therefore the slope of the graph is $\dfrac{C_1}{C_1+C_2}$ = slope, which gives $C_1 = \dfrac{C_2(\text{slope})}{1-\text{slope}} = \dfrac{(3.00\,\mu\text{F})(0.650)}{1-0.650} = 5.57\ \mu\text{F}$.

EVALUATE: This seems an odd way to measure C_1, but potentials are easy to measure using simple voltmeters, so these measurements could easily be made.

24.14. **IDENTIFY:** Simplify the network by replacing series and parallel combinations of capacitors by their equivalents.

SET UP: For capacitors in series the voltages add and the charges are the same; $\dfrac{1}{C_{eq}} = \dfrac{1}{C_1} + \dfrac{1}{C_2} + \ldots$ For capacitors in parallel the voltages are the same and the charges add; $C_{eq} = C_1 + C_2 + \ldots$ $C = \dfrac{Q}{V}$.

EXECUTE: **(a)** The equivalent capacitance of the $5.0\ \mu\text{F}$ and $8.0\ \mu\text{F}$ capacitors in parallel is $13.0\ \mu\text{F}$. When these two capacitors are replaced by their equivalent we get the network sketched in Figure 24.14. The equivalent capacitance of these three capacitors in series is $3.47\ \mu\text{F}$.

(b) $Q_{tot} = C_{tot}V = (3.47\ \mu\text{F})(50.0\ \text{V}) = 174\ \mu\text{C}$.

(c) Q_{tot} is the same as Q for each of the capacitors in the series combination shown in Figure 24.22, so Q for each of the capacitors is $174\ \mu\text{C}$.

EVALUATE: The voltages across each capacitor in Figure 24.14 are $V_{10} = \dfrac{Q_{tot}}{C_{10}} = 17.4\ \text{V}$, $V_{13} = \dfrac{Q_{tot}}{C_{13}} = 13.4\ \text{V}$, and $V_9 = \dfrac{Q_{tot}}{C_9} = 19.3\ \text{V}$. $V_{10} + V_{13} + V_9 = 17.4\ \text{V} + 13.4\ \text{V} + 19.3\ \text{V} = 50.1\ \text{V}$. The sum of the voltages equals the applied voltage, apart from a small difference due to rounding.

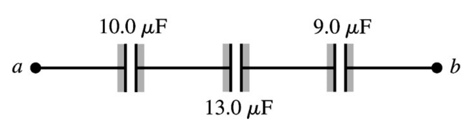

Figure 24.14

24.15. **IDENTIFY:** For capacitors in series the voltage across the combination equals the sum of the voltages in the individual capacitors. For capacitors in parallel the voltage across the combination is the same as the voltage across each individual capacitor.
SET UP and EXECUTE: **(a)** Connect the capacitors in series so their voltages will add.

(b) $V = V_1 + V_2 + V_3 + \ldots = NV_1,$ where N is the number of capacitors in the series combination, since the capacitors are identical. $N = \dfrac{V}{V_1} = \dfrac{500\text{ V}}{0.10\text{ V}} = 5000.$

EVALUATE: It requires many small cells to produce a large voltage surge.

24.16. **IDENTIFY:** The capacitors between b and c are in parallel. This combination is in series with the 15 pF capacitor.

SET UP: Let $C_1 = 15\text{ pF},\; C_2 = 9.0\text{ pF}$ and $C_3 = 11\text{ pF}.$

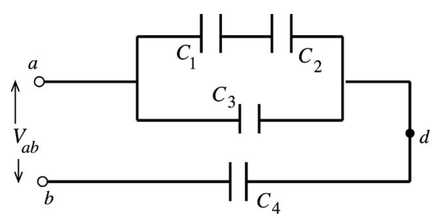
EXECUTE: **(a)** For capacitors in parallel, $C_{\text{eq}} = C_1 + C_2 + \ldots$ so $C_{23} = C_2 + C_3 = 20\text{ pF}.$

(b) $C_1 = 15\text{ pF}$ is in series with $C_{23} = 20\text{ pF}.$ For capacitors in series, $\dfrac{1}{C_{\text{eq}}} = \dfrac{1}{C_1} + \dfrac{1}{C_2} + \ldots$ so $\dfrac{1}{C_{123}} = \dfrac{1}{C_1} + \dfrac{1}{C_{23}}$ and $C_{123} = \dfrac{C_1 C_{23}}{C_1 + C_{23}} = \dfrac{(15\text{ pF})(20\text{ pF})}{15\text{ pF} + 20\text{ pF}} = 8.6\text{ pF}.$

EVALUATE: For capacitors in parallel the equivalent capacitance is larger than any of the individual capacitors. For capacitors in series the equivalent capacitance is smaller than any of the individual capacitors.

24.17. **IDENTIFY:** Replace series and parallel combinations of capacitors by their equivalents. In each equivalent network apply the rules for Q and V for capacitors in series and parallel; start with the simplest network and work back to the original circuit.

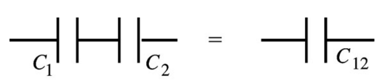
SET UP: Do parts (a) and (b) together. The capacitor network is drawn in Figure 24.17a.



$C_1 = C_2 = C_3 = C_4 = 4.00\;\mu\text{F}.$
$V_{ab} = 28.0\text{ V}.$

Figure 24.17a

EXECUTE: Simplify the circuit by replacing the capacitor combinations by their equivalents: C_1 and C_2 are in series and are equivalent to C_{12} (Figure 24.17b).

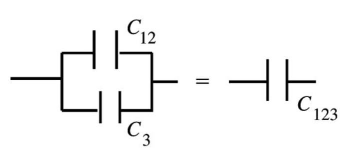


$$\frac{1}{C_{12}} = \frac{1}{C_1} + \frac{1}{C_2}.$$

Figure 24.17b

$$C_{12} = \frac{C_1 C_2}{C_1 + C_2} = \frac{(4.00\times 10^{-6}\text{ F})(4.00\times 10^{-6}\text{ F})}{4.00\times 10^{-6}\text{ F} + 4.00\times 10^{-6}\text{ F}} = 2.00\times 10^{-6}\text{ F}.$$

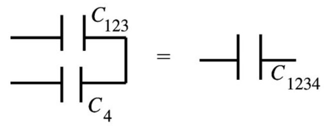
C_{12} and C_3 are in parallel and are equivalent to C_{123} (Figure 24.17c).



$C_{123} = C_{12} + C_3.$
$C_{123} = 2.00\times 10^{-6}\text{ F} + 4.00\times 10^{-6}\text{ F}.$
$C_{123} = 6.00\times 10^{-6}\text{ F}.$

Figure 24.17c

C_{123} and C_4 are in series and are equivalent to C_{1234} (Figure 24.17d).

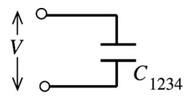


$$\frac{1}{C_{1234}}=\frac{1}{C_{123}}+\frac{1}{C_4}.$$

Figure 24.17d

$$C_{1234}=\frac{C_{123}C_4}{C_{123}+C_4}=\frac{(6.00\times10^{-6}\text{ F})(4.00\times10^{-6}\text{ F})}{6.00\times10^{-6}\text{ F}+4.00\times10^{-6}\text{ F}}=2.40\times10^{-6}\text{ F}.$$

The circuit is equivalent to the circuit shown in Figure 24.17e.

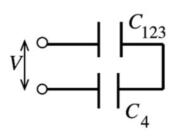


$V_{1234}=V=28.0\text{ V}.$

$Q_{1234}=C_{1234}V=(2.40\times10^{-6}\text{ F})(28.0\text{ V})=67.2\ \mu\text{C}.$

Figure 24.17e

Now build back up the original circuit, step by step. C_{1234} represents C_{123} and C_4 in series (Figure 24.17f).



$Q_{123}=Q_4=Q_{1234}=67.2\ \mu\text{C}$

(charge same for capacitors in series).

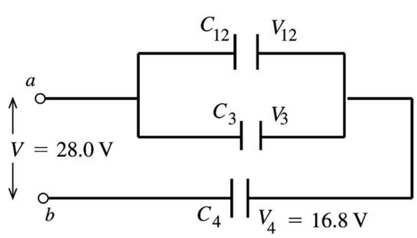
Figure 24.17f

Then $V_{123}=\dfrac{Q_{123}}{C_{123}}=\dfrac{67.2\ \mu\text{C}}{6.00\ \mu\text{F}}=11.2\text{ V}$.

$$V_4=\frac{Q_4}{C_4}=\frac{67.2\ \mu\text{C}}{4.00\ \mu\text{F}}=16.8\text{ V}.$$

Note that $V_4+V_{123}=16.8\text{ V}+11.2\text{ V}=28.0\text{ V}$, as it should.

Next consider the circuit as written in Figure 24.17g.



$V_3=V_{12}=28.0\text{ V}-V_4.$

$V_3=11.2\text{ V}.$

$Q_3=C_3V_3=(4.00\ \mu\text{F})(11.2\text{ V}).$

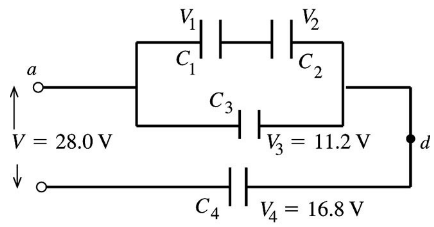
$Q_3=44.8\ \mu\text{C}.$

$Q_{12}=C_{12}V_{12}=(2.00\ \mu\text{F})(11.2\text{ V}).$

$Q_{12}=22.4\ \mu\text{C}.$

Figure 24.17g

Finally, consider the original circuit, as shown in Figure 24.17h.



$Q_1 = Q_2 = Q_{12} = 22.4\ \mu\text{C}$

(charge same for capacitors in series).

$$V_1 = \frac{Q_1}{C_1} = \frac{22.4\ \mu\text{C}}{4.00\ \mu\text{F}} = 5.6\ \text{V}.$$

$$V_2 = \frac{Q_2}{C_2} = \frac{22.4\ \mu\text{C}}{4.00\ \mu\text{F}} = 5.6\ \text{V}.$$

Figure 24.17h

Note that $V_1 + V_2 = 11.2$ V, which equals V_3 as it should.

Summary: $Q_1 = 22.4\ \mu\text{C},\ V_1 = 5.6\ \text{V}.$

$Q_2 = 22.4\ \mu\text{C},\ V_2 = 5.6\ \text{V}.$

$Q_3 = 44.8\ \mu\text{C},\ V_3 = 11.2\ \text{V}.$

$Q_4 = 67.2\ \mu\text{C},\ V_4 = 16.8\ \text{V}.$

(c) $V_{ad} = V_3 = 11.2$ V.

EVALUATE: $V_1 + V_2 + V_4 = V$, or $V_3 + V_4 = V$. $Q_1 = Q_2, Q_1 + Q_3 = Q_4$ and $Q_4 = Q_{1234}$.

24.18. **IDENTIFY:** The two capacitors are in series. The equivalent capacitance is given by $\dfrac{1}{C_{\text{eq}}} = \dfrac{1}{C_1} + \dfrac{1}{C_2}$.

SET UP: For capacitors in series the charges are the same and the potentials add to give the potential across the network.

EXECUTE: **(a)** $\dfrac{1}{C_{\text{eq}}} = \dfrac{1}{C_1} + \dfrac{1}{C_2} = \dfrac{1}{(3.00\times10^{-6}\ \text{F})} + \dfrac{1}{(5.00\times10^{-6}\ \text{F})}$, so $C_{\text{eq}} = 1.875\times10^{-6}$ F. Then

$Q = VC_{\text{eq}} = (64.0\ \text{V})(1.875\times10^{-6}\ \text{F}) = 1.20\times10^{-4}\ \text{C} = 120\ \mu\text{C}$. Each capacitor has a charge of $1.20\times10^{-4}\ \text{C} = 120\ \mu\text{C}$.

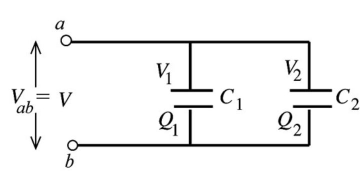
(b) $V_1 = Q/C_1 = (1.20\times10^{-4}\ \text{C})/(3.0\times10^{-6}\ \text{F}) = 40.0\ \text{V}.$

$V_2 = Q/C_2 = (1.20\times10^{-4}\ \text{C})/(5.0\times10^{-6}\ \text{F}) = 24.0\ \text{V}.$

EVALUATE: $V_1 + V_2 = 64.0$ V, which is equal to the applied potential V_{ab}. The capacitor with the smaller *C* has the larger *V*.

24.19. **IDENTIFY:** The two capacitors are in parallel so the voltage is the same on each, and equal to the applied voltage V_{ab}.

SET UP: Do parts (a) and (b) together. The network is sketched in Figure 24.19.



EXECUTE: $V_1 = V_2 = V$.

$V_1 = 52.0$ V.

$V_2 = 52.0$ V.

Figure 24.19

$C = Q/V$ so $Q = CV$.

$Q_1 = C_1V_1 = (3.00\ \mu\text{F})(52.0\ \text{V}) = 156\ \mu\text{C}$. $Q_2 = C_2V_2 = (5.00\ \mu\text{F})(52.0\ \text{V}) = 260\ \mu\text{C}$.

EVALUATE: To produce the same potential difference, the capacitor with the larger C has the larger Q.

24.20. IDENTIFY: For capacitors in parallel the voltages are the same and the charges add. For capacitors in series, the charges are the same and the voltages add. $C = Q/V$.

SET UP: C_1 and C_2 are in parallel and C_3 is in series with the parallel combination of C_1 and C_2.

EXECUTE: **(a)** C_1 and C_2 are in parallel and so have the same potential across them:

$V_1 = V_2 = \dfrac{Q_2}{C_2} = \dfrac{30.0\times10^{-6}\ \text{C}}{3.00\times10^{-6}\ \text{F}} = 10.0\ \text{V}$. Therefore, $Q_1 = V_1C_1 = (10.0\ \text{V})(6.00\times10^{-6}\ \text{F}) = 60.0\times10^{-6}\ \text{C}$.

Since C_3 is in series with the parallel combination of C_1 and C_2, its charge must be equal to their combined charge: $Q_3 = 30.0\times10^{-6}\ \text{C} + 60.0\times10^{-6}\ \text{C} = 90.0\times10^{-6}\ \text{C}$.

(b) The total capacitance is found from $\dfrac{1}{C_\text{eq}} = \dfrac{1}{C_{12}} + \dfrac{1}{C_3} = \dfrac{1}{9.00\times10^{-6}\ \text{F}} + \dfrac{1}{5.00\times10^{-6}\ \text{F}}$ and

$C_\text{eq} = 3.21\ \mu\text{F}$. $V_{ab} = \dfrac{Q_\text{tot}}{C_\text{eq}} = \dfrac{90.0\times10^{-6}\ \text{C}}{3.21\times10^{-6}\ \text{F}} = 28.0\ \text{V}$.

EVALUATE: $V_3 = \dfrac{Q_3}{C_3} = \dfrac{90.0\times10^{-6}\ \text{C}}{5.00\times10^{-6}\ \text{F}} = 18.0\ \text{V}$. $V_{ab} = V_1 + V_3 = 10.0\ \text{V} + 18.0\ \text{V} = 28.0\ \text{V}$, as we just found.

24.21. IDENTIFY: Three of the capacitors are in series, and this combination is in parallel with the other two capacitors.

SET UP: For capacitors in series the voltages add and the charges are the same; $\dfrac{1}{C_\text{eq}} = \dfrac{1}{C_1} + \dfrac{1}{C_2} + \ldots$. For capacitors in parallel the voltages are the same and the charges add; $C_\text{eq} = C_1 + C_2 + \ldots$. $C = \dfrac{Q}{V}$.

EXECUTE: **(a)** The equivalent capacitance of the 18.0 nF, 30.0 nF and 10.0 nF capacitors in series is 5.29 nF. When these capacitors are replaced by their equivalent we get the network sketched in Figure 24.21. The equivalent capacitance of these three capacitors in parallel is 19.3 nF, and this is the equivalent capacitance of the original network.

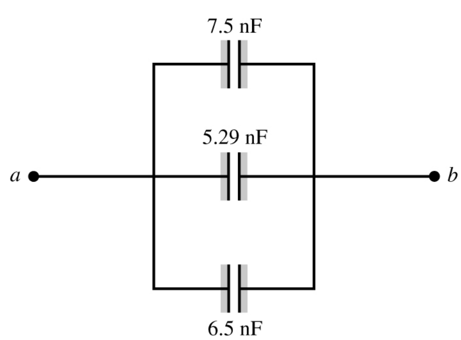


Figure 24.21

(b) $Q_{\text{tot}} = C_{\text{eq}}V = (19.3 \text{ nF})(25 \text{ V}) = 482 \text{ nC}.$

(c) The potential across each capacitor in the parallel network of Figure 24.21 is 25 V. $Q_{6.5} = C_{6.5}V_{6.5} = (6.5 \text{ nF})(25 \text{ V}) = 162 \text{ nC}.$

(d) 25 V.

EVALUATE: As with most circuits, we must go through a series of steps to simplify it as we solve for the unknowns.

24.22. IDENTIFY: Apply $u = \frac{1}{2}\epsilon_0 E^2$.

SET UP: Example 24.3 shows that $E = \dfrac{Q}{4\pi\epsilon_0 r^2}$ between the conducting shells and that $\dfrac{Q}{4\pi\epsilon_0} = \left(\dfrac{r_a r_b}{r_b - r_a}\right)V_{ab}.$

EXECUTE: $E = \left(\dfrac{r_a r_b}{r_b - r_a}\right)\dfrac{V_{ab}}{r^2} = \left(\dfrac{(0.125 \text{ m})(0.148 \text{ m})}{0.148 \text{ m} - 0.125 \text{ m}}\right)\dfrac{120 \text{ V}}{r^2} = \dfrac{96.5 \text{ V}\cdot\text{m}}{r^2}.$

(a) For $r = 0.126$ m, $E = 6.08\times10^3$ V/m. $u = \frac{1}{2}\epsilon_0 E^2 = 1.64\times10^{-4} \text{ J/m}^3.$

(b) For $r = 0.147$ m, $E = 4.47\times10^3$ V/m. $u = \frac{1}{2}\epsilon_0 E^2 = 8.85\times10^{-5} \text{ J/m}^3.$

EVALUATE: **(c)** No, the results of parts (a) and (b) show that the energy density is not uniform in the region between the plates. *E* decreases as *r* increases, so *u* decreases also.

24.23. IDENTIFY and **SET UP:** The energy density is given by $u = \frac{1}{2}\epsilon_0 E^2$. Use $V = Ed$ to solve for *E*.

EXECUTE: Calculate *E*: $E = \dfrac{V}{d} = \dfrac{400 \text{ V}}{5.00\times10^{-3} \text{ m}} = 8.00\times10^4 \text{ V/m}.$

Then $u = \frac{1}{2}\epsilon_0 E^2 = \frac{1}{2}(8.854\times10^{-12} \text{ C}^2/\text{N}\cdot\text{m}^2)(8.00\times10^4 \text{ V/m})^2 = 0.0283 \text{ J/m}^3.$

EVALUATE: *E* is smaller than the value in Example 24.8 by about a factor of 6 so *u* is smaller by about a factor of $6^2 = 36$.

24.24. IDENTIFY: Apply $C = Q/V$. $C = \dfrac{\epsilon_0 A}{d}$. The work done to double the separation equals the change in the stored energy.

SET UP: $U = \dfrac{1}{2}CV^2 = \dfrac{Q^2}{2C}.$

EXECUTE: **(a)** $V = Q/C = (3.90 \,\mu\text{C})/(920\times10^{-12} \text{ F}) = 4240 \text{ V} = 4.24 \text{ kV}.$

(b) $C = \dfrac{\epsilon_0 A}{d}$ says that since the charge is kept constant while the separation doubles, that means that the capacitance halves and the voltage doubles to 8480 V = 8.48 kV.

(c) $U_i = \dfrac{Q^2}{2C} = \dfrac{(3.90\times10^{-6} \text{ C})^2}{2(920\times10^{-12} \text{ F})} = 8.27\times10^{-3} \text{ J} = 8.27 \text{ mJ}.$ If the separation is doubled while *Q* stays the same, the capacitance halves, and the energy stored doubles to $2U_i$. The amount of work done to move the plates equals the difference in energy stored in the capacitor, so $\Delta U = U_f - U_i = 2U_i - U_i = U_i = 8.27 \text{ mJ}.$

EVALUATE: The oppositely charged plates attract each other so positive work must be done by an external force to pull them farther apart.

24.25. IDENTIFY: $C = \dfrac{Q}{V_{ab}}$. $C = \dfrac{\epsilon_0 A}{d}$. $V_{ab} = Ed$. The stored energy is $\frac{1}{2}QV$.

SET UP: $d = 1.50\times10^{-3}$ m. $1\,\mu\text{C} = 10^{-6}$ C

EXECUTE: **(a)** $C = \dfrac{0.0180\times10^{-6}\ \text{C}}{200\ \text{V}} = 9.00\times10^{-11}\ \text{F} = 90.0\ \text{pF}.$

(b) $C = \dfrac{\epsilon_0 A}{d}$ so $A = \dfrac{Cd}{\epsilon_0} = \dfrac{(9.00\times10^{-11}\ \text{F})(1.50\times10^{-3}\ \text{m})}{8.854\times10^{-12}\ \text{C}^2/(\text{N}\cdot\text{m}^2)} = 0.0152\ \text{m}^2.$

(c) $V = Ed = (3.0\times10^6\ \text{V/m})(1.50\times10^{-3}\ \text{m}) = 4.5\times10^3\ \text{V} = 4.5\ \text{kV}.$

(d) Energy $= \frac{1}{2}QV = \frac{1}{2}(0.0180\times10^{-6}\ \text{C})(200\ \text{V}) = 1.80\times10^{-6}\ \text{J} = 1.80\ \mu\text{J}.$

EVALUATE: We could also calculate the stored energy as $\dfrac{Q^2}{2C} = \dfrac{(0.0180\times10^{-6}\ \text{C})^2}{2(9.00\times10^{-11}\ \text{F})} = 1.80\ \mu\text{J}.$

24.26. IDENTIFY: $C = \dfrac{\epsilon_0 A}{d}$. The stored energy can be expressed either as $\dfrac{Q^2}{2C}$ or as $\dfrac{CV^2}{2}$, whichever is more convenient for the calculation.

SET UP: Since d is halved, C doubles.

EXECUTE: **(a)** If the separation distance is halved while the charge is kept fixed, then the capacitance increases and the stored energy, which was 8.38 J, decreases since $U = Q^2/2C$. Therefore the new energy is 4.19 J.

(b) If the voltage is kept fixed while the separation is decreased by one half, then the doubling of the capacitance leads to a doubling of the stored energy to 16.8 J, using $U = CV^2/2$, when V is held constant throughout.

EVALUATE: When the capacitor is disconnected, the stored energy decreases because of the positive work done by the attractive force between the plates. When the capacitor remains connected to the battery, $Q = CV$ tells us that the charge on the plates increases. The increased stored energy comes from the battery when it puts more charge onto the plates.

24.27. IDENTIFY: Use the rules for series and for parallel capacitors to express the voltage for each capacitor in terms of the applied voltage. Express U, Q, and E in terms of the capacitor voltage.

SET UP: Let the applied voltage be V. Let each capacitor have capacitance C. $U = \frac{1}{2}CV^2$ for a single capacitor with voltage V.

EXECUTE: **(a)** Series: The voltage across each capacitor is $V/2$. The total energy stored is $U_\text{s} = 2(\frac{1}{2}C(V/2)^2) = \frac{1}{4}CV^2$.

Parallel: The voltage across each capacitor is V. The total energy stored is

$U_\text{p} = 2(\frac{1}{2}CV^2) = CV^2 \quad \rightarrow \quad U_\text{p} = 4U_\text{s}$.

(b) $Q = CV$ for a single capacitor with voltage V. $Q_\text{s} = 2[C(V/2)] = CV$; $Q_\text{p} = 2(CV) = 2CV$; $Q_\text{p} = 2Q_\text{s}$.

(c) $E = V/d$ for a capacitor with voltage V. $E_\text{s} = V/2d$; $E_\text{p} = V/d$; $E_\text{p} = 2E_\text{s}$.

EVALUATE: The parallel combination stores more energy and more charge since the voltage for each capacitor is larger for parallel. More energy stored and larger voltage for parallel means larger electric field in the parallel case.

24.28. IDENTIFY: The two capacitors are in series. $\frac{1}{C_{\text{eq}}} = \frac{1}{C_1} + \frac{1}{C_2} + \ldots$, $C = \frac{Q}{V}$, and $U = \frac{1}{2}CV^2$.

SET UP: For capacitors in series the voltages add and the charges are the same.

EXECUTE: **(a)** $\frac{1}{C_{\text{eq}}} = \frac{1}{C_1} + \frac{1}{C_2}$ so $C_{\text{eq}} = \frac{C_1C_2}{C_1 + C_2} = \frac{(150\text{ nF})(120\text{ nF})}{150\text{ nF} + 120\text{ nF}} = 66.7\text{ nF}$.

$Q = CV = (66.7\text{ nF})(48\text{ V}) = 3.2\times10^{-6}\text{ C} = 3.2\ \mu\text{C}$.

(b) $Q = 3.2\ \mu\text{C}$ for each capacitor.

(c) $U = \frac{1}{2}C_{\text{eq}}V^2 = \frac{1}{2}(66.7\times10^{-9}\text{ F})(48\text{ V})^2 = 77\ \mu\text{J}$.

(d) We know C and Q for each capacitor so rewrite U in terms of these quantities.

$U = \frac{1}{2}CV^2 = \frac{1}{2}C(Q/C)^2 = Q^2/2C$.

150 nF: $U = \frac{(3.2\times10^{-6}\text{ C})^2}{2(150\times10^{-9}\text{ F})} = 34\ \mu\text{J}$.

120 nF: $U = \frac{(3.2\times10^{-6}\text{ C})^2}{2(120\times10^{-9}\text{ F})} = 43\ \mu\text{J}$.

Note that $34\ \mu\text{J} + 43\ \mu\text{J} = 77\ \mu\text{J}$, the total stored energy calculated in part (c).

(e) 150 nF: $V = \frac{Q}{C} = \frac{3.2\times10^{-6}\text{ C}}{150\times10^{-9}\text{ F}} = 21\text{ V}$.

120 nF: $V = \frac{Q}{C} = \frac{3.2\times10^{-6}\text{ C}}{120\times10^{-9}\text{ F}} = 27\text{ V}$.

Note that these two voltages sum to 48 V, the voltage applied across the network.

EVALUATE: Since Q is the same, the capacitor with smaller C stores more energy $\left(U = Q^2/2C\right)$ and has a larger voltage $(V = Q/C)$.

24.29. IDENTIFY: The two capacitors are in parallel. $C_{\text{eq}} = C_1 + C_2$. $C = \frac{Q}{V}$. $U = \frac{1}{2}CV^2$.

SET UP: For capacitors in parallel, the voltages are the same and the charges add.

EXECUTE: **(a)** $C_{\text{eq}} = C_1 + C_2 = 35\text{ nF} + 75\text{ nF} = 110\text{ nF}$. $Q_{\text{tot}} = C_{\text{eq}}V = (110\times10^{-9}\text{ F})(220\text{ V}) = 24.2\ \mu\text{C}$

(b) $V = 220\text{ V}$ for each capacitor.

35 nF: $Q_{35} = C_{35}V = (35\times10^{-9}\text{ F})(220\text{ V}) = 7.7\ \mu\text{C}$; 75 nF:

$Q_{75} = C_{75}V = (75\times10^{-9}\text{ F})(220\text{ V}) = 16.5\ \mu\text{C}$. Note that $Q_{35} + Q_{75} = Q_{\text{tot}}$.

(c) $U_{\text{tot}} = \frac{1}{2}C_{\text{eq}}V^2 = \frac{1}{2}(110\times10^{-9}\text{ F})(220\text{ V})^2 = 2.66\text{ mJ}$.

(d) 35 nF: $U_{35} = \frac{1}{2}C_{35}V^2 = \frac{1}{2}(35\times10^{-9}\text{ F})(220\text{ V})^2 = 0.85\text{ mJ}$;

75 nF: $U_{75} = \frac{1}{2}C_{75}V^2 = \frac{1}{2}(75\times10^{-9}\text{ F})(220\text{ V})^2 = 1.81\text{ mJ}$. Since V is the same the capacitor with larger C stores more energy.

(e) 220 V for each capacitor.

EVALUATE: The capacitor with the larger C has the larger Q.

24.30. **IDENTIFY:** This problem involves dielectrics and capacitors in parallel.

SET UP: First sketch the circuit as in Fig. 24.30. $C_{eq} = C_1 + C_2$, $C = KC_0$, and $Q = CV$. We want the charge in both cases.

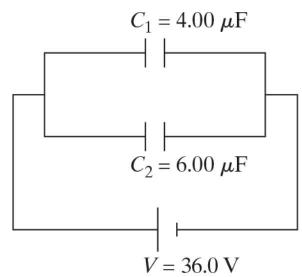

Figure 24.30

EXECUTE: **(a)** $Q = C_{eq}V = (C_1 + C_2)V = (10.0\ \mu F)(36.0\ V) = 360\ \mu C$.

(b) C_1 is now $KC_0 = (5.00)(4.00\ \mu F) = 20.0\ \mu F$. $Q = C_{eq}V = (26.0\ \mu F)(36.0\ V) = 936\ \mu C$.

EVALUATE: The total charge increases due to the insertion of the dielectric. The dielectric increases the equivalent capacitance which increases the stored charge.

24.31. **IDENTIFY:** $C = KC_0$. $U = \frac{1}{2}CV^2$.

SET UP: $C_0 = 12.5\ \mu F$ is the value of the capacitance without the dielectric present.

EXECUTE: **(a)** With the dielectric, $C = (3.75)(12.5\ \mu F) = 46.9\ \mu F$.

Before: $U = \frac{1}{2}C_0V^2 = \frac{1}{2}(12.5\times10^{-6}\ F)(24.0\ V)^2 = 3.60\ mJ$.

After: $U = \frac{1}{2}CV^2 = \frac{1}{2}(46.9\times10^{-6}\ F)(24.0\ V)^2 = 13.5\ mJ$.

(b) $\Delta U = 13.5\ mJ - 3.6\ mJ = 9.9\ mJ$. The energy increased.

EVALUATE: The power supply must put additional charge on the plates to maintain the same potential difference when the dielectric is inserted. $U = \frac{1}{2}QV$, so the stored energy increases.

24.32. **IDENTIFY:** $V = Ed$ and $C = Q/V$. With the dielectric present, $C = KC_0$.

SET UP: $V = Ed$ holds both with and without the dielectric.

EXECUTE: **(a)** $V = Ed = (3.00\times10^4\ V/m)(1.50\times10^{-3}\ m) = 45.0\ V$.

$Q = C_0V = (8.00\times10^{-12}\ F)(45.0\ V) = 3.60\times10^{-10}\ C = 360\ pC$.

(b) With the dielectric, $C = KC_0 = (2.70)(8.00\ pF) = 21.6\ pF$. V is still 45.0 V, so

$Q = CV = (21.6\times10^{-12}\ F)(45.0\ V) = 9.72\times10^{-10}\ C = 972\ pC$.

EVALUATE: The presence of the dielectric increases the amount of charge that can be stored for a given potential difference and electric field between the plates. Q increases by a factor of K.

24.33. **IDENTIFY** and **SET UP:** Q is constant so we can apply Eq. (24.14). The charge density on each surface of the dielectric is given by $\sigma_i = \sigma(1 - 1/K)$.

EXECUTE: $E = \dfrac{E_0}{K}$ so $K = \dfrac{E_0}{E} = \dfrac{3.20\times10^5\ V/m}{2.50\times10^5\ V/m} = 1.28$.

(a) $\sigma_i = \sigma(1 - 1/K)$.

$\sigma = \epsilon_0 E_0 = (8.854\times10^{-12}\ C^2/N\cdot m^2)(3.20\times10^5\ N/C) = 2.833\times10^{-6}\ C/m^2$.

$\sigma_i = (2.833\times10^{-6}\ C/m^2)(1 - 1/1.28) = 6.20\times10^{-7}\ C/m^2$.

(b) As calculated above, $K = 1.28$.

EVALUATE: The surface charges on the dielectric produce an electric field that partially cancels the electric field produced by the charges on the capacitor plates.

24.34. **IDENTIFY:** We are dealing with the energy in a capacitor with dielectric.

SET UP: $1/C_{eq} = 1/C_1 + 1/C_2$. $U = \frac{1}{2}CV^2$. In this case, $C_1 = C_2 = C$. We want the ratio of U/U_0.

EXECUTE: Without dielectric: $1/C_{eq} = 1/C + 1/C = 2/C$, so $C_{eq} = C/2$.

$$U = \frac{1}{2}C_{eq}V^2 = \frac{1}{2}\left(\frac{C}{2}\right)V^2 = \frac{CV^2}{4}.$$

With dielectric: $1/C_{eq} = 1/KC + 1/C = KC/(1 + K)$. $U = \frac{1}{2}C_{eq}V^2 = \frac{1}{2}\left(\frac{KC}{1+K}\right)V^2 = \frac{CV^2}{4}$.

$$\frac{U}{U_0} = \frac{\frac{1}{2}\left(\frac{KC}{1+K}\right)V^2}{\frac{CV^2}{4}} = \frac{2K}{1+K}.$$

EVALUATE: $\frac{U}{U_0} = \frac{2K}{1+K}$. $K \geq 1$, so the smallest this ratio can be is 1 and the largest it can be is 2.

Therefore $U \geq U_0$, so the dielectric *increases* the stored energy.

24.35. **IDENTIFY:** This problem involves capacitors in series, with and without dielectric.
SET UP: $1/C_{eq} = 1/C_1 + 1/C_2$. $C = KC_0$. $Q = CV$. The charge is the same on capacitors in series. We want the charge on C_1 (the capacitor with dielectric).
EXECUTE: Without dielectric: $1/C_{eq} = 1/C + 1/C = 2/C$, so $C_{eq} = C/2$. $Q_0 = C_{eq}V = CV/2$.
With dielectric: $1/C_{eq} = 1/KC + 1/C$, so $C_{eq} = CK/(1 + K)$. $Q = CV_{eq} = \left(\frac{CK}{1+K}\right)V$. $Q_0 = CV/2$, so $V = 2Q_0/C$, which gives $Q = \left(\frac{CK}{1+K}\right)\left(\frac{2Q_0}{C}\right) = \frac{2KQ_0}{1+K}$.
EVALUATE: $K \geq 1$, so $Q_{min} = Q_0$ and $Q_{max} = 2Q_0$. Therefore Q *increases*.

24.36. **IDENTIFY:** We are dealing with a capacitors in series and in parallel with dielectric.
SET UP: $E = V/d$, series: $1/C_{eq} = 1/C_1 + 1/C_2$, parallel: $C_{eq} = C_1 + C_2$. $Q = CV$. We want the ratio E_2/E_{02}.

EXECUTE: **(a)** Without dielectric: $1/C_{eq} = 1/(3.00\ \mu\text{F}) + 1/(6.00\ \mu\text{F})$. $C_{eq} = 2.00\ \mu\text{F}$. For the combination $Q = C_{eq}V = (2.00\ \mu\text{F})V$, which is the same charge on each capacitor. For C_2, $V_2 = Q_2/C_2 = Q/C_2 = \frac{(2.00\mu\text{F})V}{6.00\mu\text{F}} = \frac{V}{3}$. $E_{02} = V_2/d = V/3d$.

With dielectric: $C_1 = KC_0 = (4)(3.00\ \mu\text{F}) = 12.0\ \mu\text{F}$. $1/C_{eq} = 1/(12.0\ \mu\text{F}) + 1/(6.00\ \mu\text{F})$, which gives $C_{eq} = 4.00\ \mu\text{F}$. $Q = C_{eq}V = (4.00\ \mu\text{F})V$. For C_2, $V_2 = Q/C_2 = \frac{(4.00\mu\text{F})V}{6.00\mu\text{F}} = \frac{2V}{3}$. $E_2 = \frac{V_2}{d} = \frac{2V/3}{d}$.

$$\frac{E_2}{E_{02}} = \frac{2V/3d}{V/3d} = 2.00.$$ The field in C_2 has *increased*.

(b) Without dielectric: V is the same for both capacitors, so $E_{02} = V/d$.
With dielectric: V is unchanged, so $E_2 = V/d$. $E_2/E_{02} = 1$. The dielectric in C_1 does not affect the electric field in C_2.
EVALUATE: When the capacitors were in series, the capacitor in one affected the field in the other one. But when they were in parallel, the dielectric had no effect on the other capacitor.

24.37. **IDENTIFY and SET UP:** For a parallel-plate capacitor with a dielectric we can use the equation $C = K\varepsilon_0 A/d$. Minimum A means smallest possible d. d is limited by the requirement that E be less than 1.60×10^7 V/m when V is as large as 5500 V.

EXECUTE: $V = Ed$ so $d = \dfrac{V}{E} = \dfrac{5500 \text{ V}}{1.60\times10^7 \text{ V/m}} = 3.44\times10^{-4}$ m.

Then $A = \dfrac{Cd}{K\epsilon_0} = \dfrac{(1.25\times10^{-9} \text{ F})(3.44\times10^{-4} \text{ m})}{(3.60)(8.854\times10^{-12} \text{ C}^2/\text{N}\cdot\text{m}^2)} = 0.0135 \text{ m}^2.$

EVALUATE: The relation $V = Ed$ applies with or without a dielectric present. A would have to be larger if there were no dielectric.

24.38. **IDENTIFY:** We can model the cell wall as a large sheet carrying equal but opposite charges, which makes it equivalent to a parallel-plate capacitor.

SET UP: With air between the layers, $E_0 = \dfrac{Q}{\epsilon_0 A} = \dfrac{\sigma}{\epsilon_0}$ and $V_0 = E_0 d$. The energy density in the electric field is $u = \frac{1}{2}\epsilon_0 E^2$. The volume of a shell of thickness t and average radius R is $4\pi R^2 t$. The volume of a solid sphere of radius R is $\frac{4}{3}\pi R^3$. With the dielectric present, $E = \dfrac{E_0}{K}$ and $V = \dfrac{V_0}{K}$.

EXECUTE: **(a)** $E_0 = \dfrac{\sigma}{\epsilon_0} = \dfrac{0.50\times10^{-3} \text{ C/m}^2}{8.854\times10^{-12} \text{ C}^2/(\text{N}\cdot\text{m}^2)} = 5.6\times10^7$ V/m.

(b) $V_0 = E_0 d = (5.6\times10^7 \text{ V/m})(5.0\times10^{-9} \text{ m}) = 0.28$ V. The outer wall of the cell is at higher potential, since it has positive charge.

(c) For the cell, $V_{\text{cell}} = \frac{4}{3}\pi R^3$, which gives $R = \left(\dfrac{3V_{\text{cell}}}{4\pi}\right)^{1/3} = \left(\dfrac{3(10^{-16} \text{ m}^3)}{4\pi}\right)^{1/3} = 2.9\times10^{-6}$ m. The volume of the cell wall is $V_{\text{wall}} = 4\pi R^2 t = 4\pi(2.9\times10^{-6} \text{ m})^2(5.0\times10^{-9} \text{ m}) = 5.3\times10^{-19} \text{ m}^3$. The energy density in the cell wall is $u_0 = \frac{1}{2}\epsilon_0 E_0^2 = \frac{1}{2}[8.854\times10^{-12} \text{ C}^2/(\text{N}\cdot\text{m}^2)](5.6\times10^7 \text{ V/m})^2 = 1.39\times10^4 \text{ J/m}^3$. The total electric-field energy in the cell wall is $(1.39\times10^4 \text{ J/m}^3)(5.3\times10^{-19} \text{ m}^3) = 7\times10^{-15}$ J.

(d) $E = \dfrac{E_0}{K} = \dfrac{5.6\times10^7 \text{ V/m}}{5.4} = 1.0\times10^7$ V/m and $V = \dfrac{V_0}{K} = \dfrac{0.28 \text{ V}}{5.4} = 0.052$ V.

EVALUATE: To a first approximation, many biological structures can be modeled as basic circuit elements.

24.39. **IDENTIFY:** $C = Q/V$. $C = KC_0$. $V = Ed$.

SET UP: Table 24.1 gives $K = 3.1$ for mylar.

EXECUTE: **(a)** $\Delta Q = Q - Q_0 = (K-1)Q_0 = (K-1)C_0V_0 = (2.1)(2.5\times10^{-7} \text{ F})(12 \text{ V}) = 6.3\times10^{-6}$ C.

(b) $\sigma_{\text{i}} = \sigma(1-1/K)$ so $Q_{\text{i}} = Q(1-1/K) = (9.3\times10^{-6} \text{ C})(1-1/3.1) = 6.3\times10^{-6}$ C.

(c) The addition of the mylar doesn't affect the electric field since the induced charge cancels the additional charge drawn to the plates.

EVALUATE: $E = V/d$ and V is constant so E doesn't change when the dielectric is inserted.

24.40. **IDENTIFY and SET UP:** The energy density is due to the electric field in the dielectric. $u = \frac{1}{2}\epsilon E^2$, where $\epsilon = K\epsilon_0$. $V = Ed$. In this case, $E = 0.800E_{\text{m}}$.

EXECUTE: **(a)** Using $u = \frac{1}{2}\epsilon E^2$ with $\epsilon = K\epsilon_0$, we have

$u = (1/2)(2.6)(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)[(0.800)(2.0\times10^7\ \text{V/m})]^2 = 2945\ \text{J/m}^3$, which rounds to 2900 J/m^3.

(b) First get the plate separation d: $V = Ed$ gives

$d = V/E = (500\ V)/[(0.800)(2.0\times10^7\ \text{V/m})] = 3.125\times10^{-5}\ \text{m}$.

The stored energy is $U = u\times\text{volume} = uAd$, so

$A = U/ud = (0.200\times10^{-3}\ \text{J})/[(2945\ \text{J/m}^3)(3.125\times10^{-5}\text{m})] = 2.2\times10^{-3}\ \text{m}^2 = 22\ \text{cm}^2$.

EVALUATE: If this capacitor has square plates, their dimensions would be $x = (22\ \text{cm}^2)^{1/2} = 4.7$ cm on each side. This is considerably larger than ordinary laboratory capacitors used in circuits.

24.41. **(a) IDENTIFY** and **SET UP:** Since the capacitor remains connected to the power supply the potential difference doesn't change when the dielectric is inserted. Use $U = \frac{1}{2}CV^2$ to calculate V and combine it with $K = C/C_0$ to obtain a relation between the stored energies and the dielectric constant and use this to calculate K.

EXECUTE: Before the dielectric is inserted $U_0 = \frac{1}{2}C_0V^2$ so $V = \sqrt{\dfrac{2U_0}{C_0}} = \sqrt{\dfrac{2(1.85\times10^{-5}\ \text{J})}{360\times10^{-9}\ \text{F}}} = 10.1\ \text{V}$.

(b) $K = C/C_0$.

$U_0 = \frac{1}{2}C_0V^2$, $U = \frac{1}{2}CV^2$ so $C/C_0 = U/U_0$.

$$K = \frac{U}{U_0} = \frac{1.85\times10^{-5}\ \text{J} + 2.32\times10^{-5}\ \text{J}}{1.85\times10^{-5}\ \text{J}} = 2.25.$$

EVALUATE: K increases the capacitance and then from $U = \frac{1}{2}CV^2$, with V constant an increase in C gives an increase in U.

24.42. **IDENTIFY:** $C = KC_0$. $C = Q/V$. $V = Ed$.

SET UP: Since the capacitor remains connected to the battery the potential between the plates of the capacitor doesn't change.

EXECUTE: **(a)** The capacitance changes by a factor of K when the dielectric is inserted. Since V is unchanged (the battery is still connected), $\dfrac{C_{\text{after}}}{C_{\text{before}}} = \dfrac{Q_{\text{after}}}{Q_{\text{before}}} = \dfrac{45.0\ \text{pC}}{25.0\ \text{pC}} = K = 1.80$.

(b) The area of the plates is $\pi r^2 = \pi(0.0300\ \text{m})^2 = 2.827\times10^{-3}\ \text{m}^2$ and the separation between them is thus $d = \dfrac{\epsilon_0 A}{C} = \dfrac{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(2.827\times10^{-3}\ \text{m}^2)}{12.5\times10^{-12}\ \text{F}} = 2.00\times10^{-3}\ \text{m}$. Before the dielectric is inserted, $C = \dfrac{\epsilon_0 A}{d} = \dfrac{Q}{V}$ and $V = \dfrac{Qd}{\epsilon_0 A} = \dfrac{(25.0\times10^{-12}\ \text{C})(2.00\times10^{-3}\ \text{m})}{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(2.827\times10^{-3}\ \text{m}^2)} = 2.00\ \text{V}$. The battery remains connected, so the potential difference is unchanged after the dielectric is inserted.

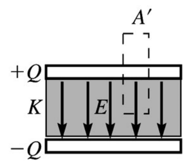
(c) Before the dielectric is inserted, $E = \dfrac{Q}{\epsilon_0 A} = \dfrac{25.0\times10^{-12}\ \text{C}}{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(2.827\times10^{-3}\ \text{m}^2)} = 1000\ \text{N/C}$.

Again, since the voltage is unchanged after the dielectric is inserted, the electric field is also unchanged.

EVALUATE: $E = \dfrac{V}{d} = \dfrac{2.00\ \text{V}}{2.00\times10^{-3}\ \text{m}} = 1000\ \text{N/C}$, whether or not the dielectric is present. This agrees with the result in part (c). The electric field has this value at any point between the plates. We need d to calculate E because V is the potential difference between points separated by distance d.

24.43. IDENTIFY: Apply $\oint K\vec{E}\cdot d\vec{A} = \frac{Q_{\text{encl-free}}}{\epsilon_0}$ to calculate E. $V = Ed$ and $C = Q/V$ apply whether there is a dielectric between the plates or not.

(a) SET UP: Apply $\oint K\vec{E}\cdot d\vec{A} = \frac{Q_{\text{encl-free}}}{\epsilon_0}$ to the dashed surface in Figure 24.43.



EXECUTE: $\oint K\vec{E}\cdot d\vec{A} = \frac{Q_{\text{encl-free}}}{\epsilon_0}$.

$\oint K\vec{E}\cdot d\vec{A} = KEA'$.

since $E = 0$ outside the plates

$Q_{\text{encl-free}} = \sigma A' = (Q/A)A'$.

Figure 24.43

Thus $KEA' = \frac{(Q/A)A'}{\epsilon_0}$ and $E = \frac{Q}{\epsilon_0 AK}$.

SET UP and EXECUTE: **(b)** $V = Ed = \frac{Qd}{\epsilon_0 AK}$.

(c) $C = \frac{Q}{V} = \frac{Q}{Qd/\epsilon_0 AK} = K\frac{\epsilon_0 A}{d} = KC_0$.

EVALUATE: Our result shows that $K = C/C_0$, which is Eq. (24.12).

24.44. IDENTIFY: Gauss's law in dielectrics has the same form as in vacuum except that the electric field is multiplied by a factor of K and the charge enclosed by the Gaussian surface is the free charge. The capacitance of an object depends on its geometry.

(a) SET UP: The capacitance of a parallel-plate capacitor is $C = K\epsilon_0 A/d$ and the charge on its plates is $Q = CV$.

EXECUTE: First find the capacitance:

$$C = \frac{K\epsilon_0 A}{d} = \frac{(2.1)(8.85\times 10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(0.0225\ \text{m}^2)}{1.00\times 10^{-3}\ \text{m}} = 4.18\times 10^{-10}\ \text{F}.$$

Now find the charge on the plates: $Q = CV = (4.18\times 10^{-10}\ \text{F})(12.0\ \text{V}) = 5.02\times 10^{-9}\ \text{C}$.

(b) SET UP: Gauss's law within the dielectric gives $KEA = Q_{\text{free}}/\epsilon_0$.

EXECUTE: Solving for E gives

$$E = \frac{Q_{\text{free}}}{KA\epsilon_0} = \frac{5.02\times 10^{-9}\ \text{C}}{(2.1)(0.0225\ \text{m}^2)(8.85\times 10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)} = 1.20\times 10^4\ \text{N/C}.$$

(c) SET UP: Without the Teflon and the voltage source, the charge is unchanged but the potential increases, so $C = \epsilon_0 A/d$ and Gauss's law now gives $EA = Q/\epsilon_0$.

EXECUTE: First find the capacitance:

$$C = \frac{\epsilon_0 A}{d} = \frac{(8.85\times 10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(0.0225\ \text{m}^2)}{1.00\times 10^{-3}\ \text{m}} = 1.99\times 10^{-10}\ \text{F}.$$

The potential difference is $V = \frac{Q}{C} = \frac{5.02\times 10^{-9}\ \text{C}}{1.99\times 10^{-10}\ \text{F}} = 25.2\ \text{V}$. From Gauss's law, the electric field is

$$E = \frac{Q}{\epsilon_0 A} = \frac{5.02\times 10^{-9}\ \text{C}}{(8.85\times 10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(0.0225\ \text{m}^2)} = 2.52\times 10^4\ \text{N/C}.$$

Evaluate: The dielectric reduces the electric field inside the capacitor because the electric field due to the dipoles of the dielectric is opposite to the external field due to the free charge on the plates.

24.45. **Identify:** $P = E/t$, where E is the total light energy output. The energy stored in the capacitor is $U = \frac{1}{2}CV^2$.

Set Up: $E = 0.95U$.

Execute: **(a)** The power output is 2.70×10^5 W, and 95% of the original energy is converted, so $E = Pt = (2.70\times10^5 \text{ W})(1.48\times10^{-3} \text{ s}) = 400 \text{ J}$. $U = \dfrac{400 \text{ J}}{0.95} = 421 \text{ J}$.

(b) $U = \frac{1}{2}CV^2$ so $C = \dfrac{2U}{V^2} = \dfrac{2(421 \text{ J})}{(125 \text{ V})^2} = 0.054 \text{ F}$.

Evaluate: For a given V, the stored energy increases linearly with C.

24.46. **Identify** and **Set Up:** $C = \dfrac{\epsilon_0 A}{d}$. $C = Q/V$. $V = Ed$. $U = \frac{1}{2}CV^2$. With the battery disconnected, Q is constant. When the separation d is doubled, C is halved.

Execute: **(a)** $C = \dfrac{\epsilon_0 A}{d} = \dfrac{\epsilon_0 (0.12 \text{ m})^2}{3.7\times10^{-3} \text{ m}} = 3.446\times10^{-11} \text{ F}$, which rounds to 34 pF.

(b) $Q = CV = (3.446\times10^{-11} \text{ F})(12 \text{ V}) = 4.135\times10^{-10} \text{ C}$, which rounds to 410 pC.

(c) $E = V/d = (12 \text{ V})/(3.7\times10^{-3} \text{ m}) = 3200 \text{ V/m}$.

(d) $U = \frac{1}{2}CV^2 = \frac{1}{2}(3.446\times10^{-11} \text{ F})(12 \text{ V})^2 = 2.48\times10^{-9} \text{ J}$, which rounds to 2.5 nJ.

(e) If the battery is disconnected, so the charge remains constant, and the plates are pulled farther apart to 0.0074 m, then the calculations above can be carried out just as before, and we find:

(a) $C = 1.7\times10^{-11} \text{ F} = 17 \text{ pF}$.

(b) $Q = 4.1\times10^{-10} \text{ C} = 410 \text{ pC}$.

(c) $E = 3200 \text{ V/m}$.

(d) $U = \dfrac{Q^2}{2C} = \dfrac{(4.1\times10^{-10} \text{ C})^2}{2(1.7\times10^{-11} \text{ F})} = 5.0\times10^{-9} \text{ J} = 5.0 \text{ nJ}$.

Evaluate: Q is unchanged. $E = \dfrac{Q}{\epsilon_0 A}$ so E is therefore unchanged. U doubles because C is halved with Q unchanged. The additional stored energy comes from the work done by the force that pulled the plates apart.

24.47. **Identify:** $C = \dfrac{\epsilon_0 A}{d}$.

Set Up: $A = 4.2\times10^{-5} \text{ m}^2$. The original separation between the plates is $d = 0.700\times10^{-3}$ m. d' is the separation between the plates at the new value of C.

Execute: $C_0 = \dfrac{A\epsilon_0}{d} = \dfrac{(4.20\times10^{-5} \text{ m}^2)\epsilon_0}{7.00\times10^{-4} \text{ m}} = 5.31\times10^{-13} \text{ F}$. The new value of C is $C = C_0 + 0.25 \text{ pF} = 7.81\times10^{-13} \text{ F}$. But $C = \dfrac{A\epsilon_0}{d'}$, so $d' = \dfrac{A\epsilon_0}{C} = \dfrac{(4.20\times10^{-5} \text{ m}^2)\epsilon_0}{7.81\times10^{-13} \text{ F}} = 4.76\times10^{-4} \text{m}$.

Therefore the key must be depressed by a distance of $7.00\times10^{-4} \text{ m} - 4.76\times10^{-4} \text{ m} = 0.224 \text{ mm}$.

Evaluate: When the key is depressed, d decreases and C increases.

24.48. **Identify:** $C = KC_0 = K\epsilon_0 \dfrac{A}{d}$. $V = Ed$ for a parallel plate capacitor; this equation applies whether or not a dielectric is present.

SET UP: $A = 1.0 \text{ cm}^2 = 1.0\times10^{-4} \text{ m}^2$.

EXECUTE: **(a)** $C = (10)\dfrac{(8.85\times10^{-12} \text{ F/m})(1.0\times10^{-4} \text{ m}^2)}{7.5\times10^{-9} \text{ m}} = 1.18\,\mu\text{F per cm}^2$.

(b) $E = \dfrac{V}{d} = \dfrac{85 \text{ mV}}{7.5\times10^{-9} \text{ m}} = 1.13\times10^{7} \text{ V/m}$.

EVALUATE: The dielectric material increases the capacitance. If the dielectric were not present, the same charge density on the faces of the membrane would produce a larger potential difference across the membrane.

24.49. **IDENTIFY:** Some of the charge from the original capacitor flows onto the uncharged capacitor until the potential differences across the two capacitors are the same.

SET UP: $C = \dfrac{Q}{V_{ab}}$. Let $C_1 = 20.0\,\mu\text{F}$ and $C_2 = 10.0\,\mu\text{F}$. The energy stored in a capacitor is $\frac{1}{2}QV_{ab} = \frac{1}{2}CV_{ab}^2 = \dfrac{Q^2}{2C}$.

EXECUTE: **(a)** The initial charge on the $20.0\,\mu\text{F}$ capacitor is

$Q = C_1(800 \text{ V}) = (20.0\times10^{-6} \text{ F})(800 \text{ V}) = 0.0160 \text{ C}$.

(b) In the final circuit, charge Q is distributed between the two capacitors and $Q_1 + Q_2 = Q$. The final circuit contains only the two capacitors, so the voltage across each is the same, $V_1 = V_2$. $V = \dfrac{Q}{C}$ so $V_1 = V_2$ gives $\dfrac{Q_1}{C_1} = \dfrac{Q_2}{C_2}$. $Q_1 = \dfrac{C_1}{C_2}Q_2 = 2Q_2$. Using this in $Q_1 + Q_2 = 0.0160 \text{ C}$ gives $3Q_2 = 0.0160 \text{ C}$ and $Q_2 = 5.33\times10^{-3} \text{ C}$. $Q = 2Q_2 = 1.066\times10^{-2} \text{ C}$. $V_1 = \dfrac{Q_1}{C_1} = \dfrac{1.066\times10^{-2} \text{ C}}{20.0\times10^{-6} \text{ F}} = 533 \text{ V}$. $V_2 = \dfrac{Q_2}{C_2} = \dfrac{5.33\times10^{23} \text{ C}}{10.0\times10^{26} \text{ F}} = 533 \text{ V}$. The potential differences across the capacitors are the same, as they should be.

(c) $\text{Energy} = \frac{1}{2}C_1V^2 + \frac{1}{2}C_2V^2 = \frac{1}{2}(C_1 + C_2)V^2$ gives

$\text{Energy} = \frac{1}{2}(20.0\times10^{-6} \text{ F} + 10.0\times10^{-6} \text{ F})(533 \text{ V})^2 = 4.26 \text{ J}$.

(d) The $20.0\,\mu\text{F}$ capacitor initially has $\text{energy} = \frac{1}{2}C_1V^2 = \frac{1}{2}(20.0\times10^{-6} \text{ F})(800 \text{ V})^2 = 6.40 \text{ J}$. The decrease in stored energy that occurs when the capacitors are connected is $6.40 \text{ J} - 4.26 \text{ J} = 2.14 \text{ J}$.

EVALUATE: The decrease in stored energy is because of conversion of electrical energy to other forms during the motion of the charge when it becomes distributed between the two capacitors. Thermal energy is generated by the current in the wires and energy is emitted in electromagnetic waves.

24.50. **IDENTIFY:** We model a car as a spherical capacitor.

SET UP: $C = 4\pi\epsilon_0 \dfrac{r_a r_b}{r_b - r_a}$.

EXECUTE: **(a)** Using $C = 4\pi\epsilon_0 \dfrac{r_a r_b}{r_b - r_a}$ and let $r_b \to \infty$. $C \to 4\pi\epsilon_0 \dfrac{r_a r_b}{r_b} = 4\pi\epsilon_0\, r_a$.

Using a charged sphere, $C = Q/V = \dfrac{Q}{\dfrac{1}{4\pi\epsilon_0}\dfrac{Q}{r_a}} = 4\pi\epsilon_0\, r_a$. Our results agree.

(b) Estimate: Care is about 4 paces long $\approx$ 4.0 m long, so $r \approx 2.0$ m.

(c) $C = 4\pi\epsilon_0\, r_a = 4\pi\epsilon_0\,(2.0 \text{ m})$ □ 220 pF.

(d) $Q = CV = (220 \text{ pF})(100 \text{ MV}) = 22 \text{ mC}$.

EVALUATE: This is quite a large charge, which why lightning strikes can be fatal!

24.51. **IDENTIFY:** Simplify the network by replacing series and parallel combinations by their equivalent. The stored energy in a capacitor is $U = \frac{1}{2}CV^2$.

SET UP: For capacitors in series the voltages add and the charges are the same; $\dfrac{1}{C_{eq}} = \dfrac{1}{C_1} + \dfrac{1}{C_2} + \ldots$ For capacitors in parallel the voltages are the same and the charges add; $C_{eq} = C_1 + C_2 + \ldots$ $C = \dfrac{Q}{V}$.

$U = \frac{1}{2}CV^2$.

EXECUTE: **(a)** Find C_{eq} for the network by replacing each series or parallel combination by its equivalent. The successive simplified circuits are shown in Figure 24.51.

$U_{tot} = \frac{1}{2}C_{eq}V^2 = \frac{1}{2}(2.19\times10^{-6}\text{ F})(12.0\text{ V})^2 = 1.58\times10^{-4}\text{ J} = 158\ \mu\text{J}$.

(b) From Figure 24.51c, $Q_{tot} = C_{eq}V = (2.19\times10^{-6}\text{ F})(12.0\text{ V}) = 2.63\times10^{-5}\text{ C}$. From Figure 24.51b,

$Q_{4.8} = 2.63\times10^{-5}\text{ C}$. $V_{4.8} = \dfrac{Q_{4.8}}{C_{4.8}} = \dfrac{2.63\times10^{-5}\text{ C}}{4.80\times10^{-6}\text{ F}} = 5.48\text{ V}$.

$U_{4.8} = \frac{1}{2}CV^2 = \frac{1}{2}(4.80\times10^{-6}\text{ F})(5.48\text{ V})^2 = 7.21\times10^{-5}\text{ J} = 72.1\ \mu\text{J}$.

This one capacitor stores nearly half the total stored energy.

EVALUATE: $U = \dfrac{Q^2}{2C}$. For capacitors in series the capacitor with the smallest C stores the greatest amount of energy.

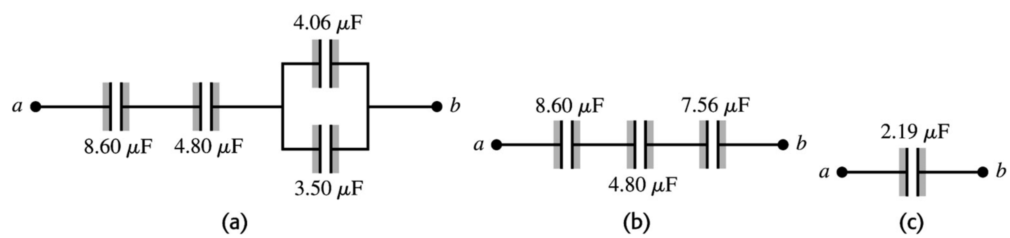


Figure 24.51

24.52. **IDENTIFY** and **SET UP:** The charge Q is the same on capacitors in series, and the potential V is the same for capacitors in parallel. C_1 is in series with C_2, and that combination is in parallel with C_3. The C_1-C_2-C_3 combination is in series with C_4. $V = Q/C$.

EXECUTE: **(a)** Since C_1 and C_2 are in series, and that combination is in parallel with C_3, the potential difference across the C_1-C_2 combination is the same as the potential difference across C_3, which is 40.0 V. Also, $Q_1 = Q_2 = Q$.

$V_1 + V_2 = 40.0$ V.

$Q/C_1 + Q/C_2 = 40.0$ V.

$Q/(6.00\ \mu\text{F}) + Q/(3.00\ \mu\text{F}) = 40.0$ V.

$Q = 80.0\ \mu\text{C}$.

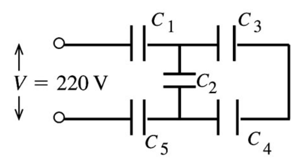
Therefore

$V_1 = Q/C_1 = (80.0\ \mu\text{C})/(6.00\ \mu\text{F}) = 13.3$ V.

$V_2 = Q/C_2 = (80.0\ \mu\text{C})/(3.00\ \mu\text{F}) = 26.7$ V.

(b) First get the charge Q_4 on C_4. We know that $Q_1 = Q_2 = Q = 80.0\ \mu\text{C}$. We also have
$Q_3 = C_3V_3 = (4.00\ \mu\text{F})(40.0\ \text{V}) = 160\ \mu\text{C}$.
$Q_4 = Q + Q_3 = 80.0\ \mu\text{C} + 160\ \mu\text{C} = 240\ \mu\text{C}$.
$V_4 = Q_4/C_4 = (240\ \mu\text{C})/(8.00\ \mu\text{F}) = 30.0\ \text{V}$.
(c) $V_{ab} = V_3 + V_4 = 40.0\ \text{V} + 30.0\ \text{V} = 70.0\ \text{V}$.
EVALUATE: C_3 and C_4 are *not* in parallel, so $V_3 \neq V_4$.

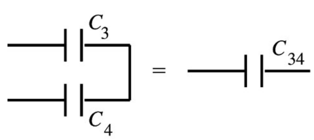
24.53. **(a) IDENTIFY:** Replace series and parallel combinations of capacitors by their equivalents.
SET UP: The network is sketched in Figure 24.53a.



$C_1 = C_5 = 8.4\ \mu\text{F}$.
$C_2 = C_3 = C_4 = 4.2\ \mu\text{F}$.

Figure 24.53a

EXECUTE: Simplify the circuit by replacing the capacitor combinations by their equivalents:
C_3 and C_4 are in series and can be replaced by C_{34} (Figure 24.53b):

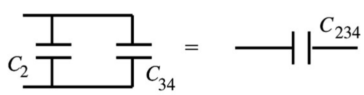


$$\frac{1}{C_{34}} = \frac{1}{C_3} + \frac{1}{C_4}.$$
$$\frac{1}{C_{34}} = \frac{C_3 + C_4}{C_3C_4}.$$

Figure 24.53b

$$C_{34} = \frac{C_3C_4}{C_3 + C_4} = \frac{(4.2\ \mu\text{F})(4.2\ \mu\text{F})}{4.2\ \mu\text{F} + 4.2\ \mu\text{F}} = 2.1\ \mu\text{F}.$$

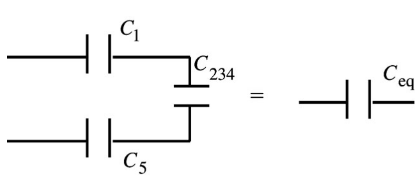
C_2 and C_{34} are in parallel and can be replaced by their equivalent (Figure 24.53c):



$C_{234} = C_2 + C_{34}$.
$C_{234} = 4.2\ \mu\text{F} + 2.1\ \mu\text{F}$.
$C_{234} = 6.3\ \mu\text{F}$.

Figure 24.53c

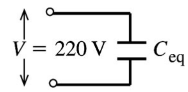
C_1, C_5, and C_{234} are in series and can be replaced by C_{eq} (Figure 24.53d):



$$\frac{1}{C_{\text{eq}}} = \frac{1}{C_1} + \frac{1}{C_5} + \frac{1}{C_{234}}.$$
$$\frac{1}{C_{\text{eq}}} = \frac{2}{8.4\ \mu\text{F}} + \frac{1}{6.3\ \mu\text{F}}.$$
$$C_{\text{eq}} = 2.5\ \mu\text{F}.$$

Figure 24.53d

EVALUATE: For capacitors in series the equivalent capacitor is smaller than any of those in series. For capacitors in parallel the equivalent capacitance is larger than any of those in parallel.
(b) IDENTIFY and **SET UP:** In each equivalent network apply the rules for Q and V for capacitors in series and parallel; start with the simplest network and work back to the original circuit.
EXECUTE: The equivalent circuit is drawn in Figure 24.53e.



$Q_{eq} = C_{eq}V.$
$Q_{eq} = (2.5\ \mu\text{F})(220\ \text{V}) = 550\ \mu\text{C}.$

Figure 24.53e

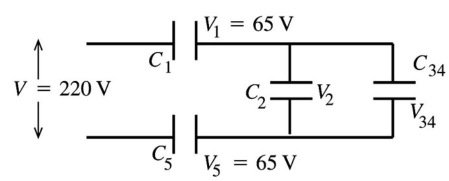
$Q_1 = Q_5 = Q_{234} = 550\ \mu\text{C}$ (capacitors in series have same charge).

$$V_1 = \frac{Q_1}{C_1} = \frac{550\ \mu\text{C}}{8.4\ \mu\text{F}} = 65\ \text{V}.$$

$$V_5 = \frac{Q_5}{C_5} = \frac{550\ \mu\text{C}}{8.4\ \mu\text{F}} = 65\ \text{V}.$$

$$V_{234} = \frac{Q_{234}}{C_{234}} = \frac{550\ \mu\text{C}}{6.3\ \mu\text{F}} = 87\ \text{V}.$$

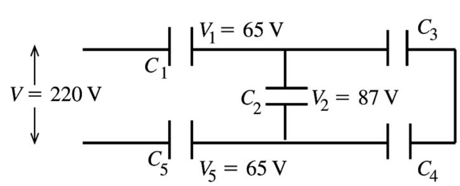
Now draw the network as in Figure 24.53f.



$V_2 = V_{34} = V_{234} = 87\ \text{V}$
capacitors in parallel have the same potential.

Figure 24.53f

$Q_2 = C_2V_2 = (4.2\ \mu\text{F})(87\ \text{V}) = 370\ \mu\text{C}.$
$Q_{34} = C_{34}V_{34} = (2.1\ \mu\text{F})(87\ \text{V}) = 180\ \mu\text{C}.$
Finally, consider the original circuit (Figure 24.53g).



$Q_3 = Q_4 = Q_{34} = 180\ \mu\text{C}$
capacitors in series have the same charge.

Figure 24.53g

$$V_3 = \frac{Q_3}{C_3} = \frac{180\ \mu\text{C}}{4.2\ \mu\text{F}} = 43\ \text{V}.$$

$$V_4 = \frac{Q_4}{C_4} = \frac{180\ \mu\text{C}}{4.2\ \mu\text{F}} = 43\ \text{V}.$$

Summary: $Q_1 = 550\ \mu\text{C},\ V_1 = 65\ \text{V}.$
$Q_2 = 370\ \mu\text{C},\ V_2 = 87\ \text{V}.$
$Q_3 = 180\ \mu\text{C},\ V_3 = 43\ \text{V}.$
$Q_4 = 180\ \mu\text{C},\ V_4 = 43\ \text{V}.$

$Q_5 = 550\ \mu\text{C},\ V_5 = 65\ \text{V}.$

EVALUATE: $V_3 + V_4 = V_2$ and $V_1 + V_2 + V_5 = 220\ \text{V}$ (apart from some small rounding error)

$Q_1 = Q_2 + Q_3$ and $Q_5 = Q_2 + Q_4$.

24.54. **IDENTIFY** and **SET UP:** We want to estimate the excess charge rubbed onto our head and the resulting voltage when we comb our hair. Treat the head as a sphere and model it as a spherical capacitor.

EXECUTE: **(a)** Estimate: $L \approx 15$ cm = 0.15 m long.

(b) m = (65 μg/cm)(15 cm) ≈ 975 μg.

(c) Estimate: N = 25 hairs.

(d) The electric force $F = \dfrac{1}{4\pi\epsilon_0}\dfrac{|q_1 q_2|}{r^2}$ is the force between the charges at both ends of a hair. $q_1 = q_2 = Q/N$, $r = L$, and the force is twice the weight of the hair, which is $2mg$. Therefore $2mg = \dfrac{1}{4\pi\epsilon_0}\dfrac{(Q/N)^2}{L^2}$. Solve for Q: $Q = \sqrt{(2mg)(4\pi\epsilon_0)L^2 N}$. Using m = 975 μg, L = 0.15 m, and N = 25 gives Q = 0.35 μC. The total charge on your head is $2Q$, so Q_{head} = 0.70 μC.

(e) Estimate: Diameter ≈ 22 cm, so $R \approx 11$ cm. $C = 4\pi\epsilon_0 R = 4\pi\epsilon_0$ (0.11 m) = 12 pF.

(f) $V = Q/C$ = (0.35 μC)/(12 pF) = 29 kV.

EVALUATE: This is a large potential but it is not dangerous because of the small amount of charge.

24.55. **IDENTIFY:** Capacitors in series carry the same charge, while capacitors in parallel have the same potential difference across them.

SET UP: $V_{ab} = 150\ \text{V},\ Q_1 = 150\ \mu\text{C},\ Q_3 = 450\ \mu\text{C}$, and $V = Q/C$.

EXECUTE: $C_1 = 3.00\ \mu\text{F}$ so $V_1 = \dfrac{Q_1}{C_1} = \dfrac{150\ \mu\text{C}}{3.00\ \mu\text{F}} = 50.0\ \text{V}$ and $V_1 = V_2 = 50.0\ \text{V}$. $V_1 + V_3 = V_{ab}$ so $V_3 = 100\ \text{V}$. $C_3 = \dfrac{Q_3}{V_3} = \dfrac{450\ \mu\text{C}}{100\ \text{V}} = 4.50\ \mu\text{F}$. $Q_1 + Q_2 = Q_3$ so $Q_2 = Q_3 - Q_1 = 450\ \mu\text{C} - 150\ \mu\text{C} = 300\ \mu\text{C}$ and $C_2 = \dfrac{Q_2}{V_2} = \dfrac{300\ \mu\text{C}}{50.0\ \text{V}} = 6.00\ \mu\text{F}$.

EVALUATE: Capacitors in parallel only carry the same charge if they have the same capacitance.

24.56. **IDENTIFY:** Apply the rules for combining capacitors in series and in parallel.

SET UP: With the switch open, each pair of $3.00\ \mu\text{F}$ and $6.00\ \mu\text{F}$ capacitors are in series with each other and each pair is in parallel with the other pair. When the switch is closed, each pair of $3.00\ \mu\text{F}$ and $6.00\ \mu\text{F}$ capacitors are in parallel with each other and the two pairs are in series.

EXECUTE: **(a)** With the switch open $C_{\text{eq}} = \left(\left(\dfrac{1}{3\ \mu\text{F}} + \dfrac{1}{6\ \mu\text{F}}\right)^{-1} + \left(\dfrac{1}{3\ \mu\text{F}} + \dfrac{1}{6\ \mu\text{F}}\right)^{-1}\right) = 4.00\ \mu\text{F}.$

$Q_{\text{total}} = C_{\text{eq}}V = (4.00\ \mu\text{F})(210\ \text{V}) = 8.40\times10^{-4}\ \text{C}$. By symmetry, each capacitor carries $4.20\times10^{-4}\ \text{C}$. The voltages are then calculated via $V = Q/C$. This gives $V_{ad} = Q/C_3 = 140\ \text{V}$ and $V_{ac} = Q/C_6 = 70\ \text{V}$. $V_{cd} = V_{ad} - V_{ac} = 70\ \text{V}$.

(b) When the switch is closed, the points c and d must be at the same potential, so the equivalent capacitance is $C_{\text{eq}} = \left(\dfrac{1}{(3.00 + 6.00)\ \mu\text{F}} + \dfrac{1}{(3.00 + 6.00)\ \mu\text{F}}\right)^{-1} = 4.5\ \mu\text{F}.$

$Q_{\text{total}} = C_{\text{eq}}V = (4.50\ \mu\text{F})(210\ \text{V}) = 9.5\times10^{-4}\ \text{C}$, and each capacitor has the same potential difference of 105 V (again, by symmetry).

(c) Consider the $C_3 = 3.00\ \mu\text{F}$ and $C_6 = 6.00\ \mu\text{F}$ capacitors in the upper branch of the network. The only way for the net charge Q_{net} on the negative plate of C_3 and the positive plate of C_6 to change is by charge to flow through the switch. With the switch open all four capacitors have the same charge and $Q_{\text{net}} = 0$. With the switch closed the charge on C_3 is $Q_3 = (3.00\ \mu\text{F})(105\ \text{V}) = 315\ \mu\text{C}$ and the charge on C_6 is $Q_6 = (6.00\ \mu\text{F})(105\ \text{V}) = 630\ \mu\text{C}$ and $Q_{\text{net}} = Q_2 - Q_1 = 315\ \mu\text{C}$. Therefore, the change in Q_{net} is $315\ \mu\text{C}$ and this is the amount of charge that flowed through the switch when it was closed.

EVALUATE: When the switch is closed the charge must redistribute to make points *c* and *d* be at the same potential.

24.57. **(a) IDENTIFY:** Replace the three capacitors in series by their equivalent. The charge on the equivalent capacitor equals the charge on each of the original capacitors.

SET UP: The three capacitors can be replaced by their equivalent as shown in Figure 24.57a.

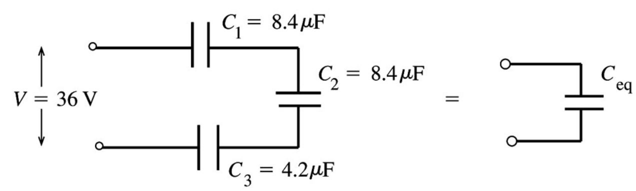


Figure 24.57a

EXECUTE: $C_3 = C_1/2$ so $\dfrac{1}{C_{\text{eq}}} = \dfrac{1}{C_1} + \dfrac{1}{C_2} + \dfrac{1}{C_3} = \dfrac{4}{8.4\ \mu\text{F}}$ and $C_{\text{eq}} = 8.4\ \mu\text{F}/4 = 2.1\ \mu\text{F}$.

$Q = C_{\text{eq}}V = (2.1\ \mu\text{F})(36\ \text{V}) = 76\ \mu\text{C}$.

The three capacitors are in series so they each have the same charge: $Q_1 = Q_2 = Q_3 = 76\ \mu\text{C}$.

EVALUATE: The equivalent capacitance for capacitors in series is smaller than each of the original capacitors.

(b) IDENTIFY and **SET UP:** Use $U = \frac{1}{2}QV$. We know each Q and we know that $V_1 + V_2 + V_3 = 36\ \text{V}$.

EXECUTE: $U = \frac{1}{2}Q_1V_1 + \frac{1}{2}Q_2V_2 + \frac{1}{2}Q_3V_3$.

But $Q_1 = Q_2 = Q_3 = Q$ so $U = \frac{1}{2}Q(V_1 + V_2 + V_3)$.

But also $V_1 + V_2 + V_3 = V = 36\ \text{V}$, so $U = \frac{1}{2}QV = \frac{1}{2}(76\ \mu\text{C})(36\ \text{V}) = 1.4\times10^{-3}\ \text{J}$.

EVALUATE: We could also use $U = Q^2/2C$ and calculate U for each capacitor.

(c) IDENTIFY: The charges on the plates redistribute to make the potentials across each capacitor the same.

SET UP: The capacitors before and after they are connected are sketched in Figure 24.57b.

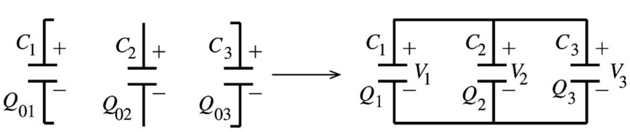

Figure 24.57b

EXECUTE: The total positive charge that is available to be distributed on the upper plates of the three capacitors is $Q_0 = Q_{01} + Q_{02} + Q_{03} = 3(76\ \mu\text{C}) = 228\ \mu\text{C}$. Thus $Q_1 + Q_2 + Q_3 = 228\ \mu\text{C}$. After the circuit is completed the charge distributes to make $V_1 = V_2 = V_3$. $V = Q/C$ and $V_1 = V_2$ so $Q_1/C_1 = Q_2/C_2$ and then $C_1 = C_2$ says $Q_1 = Q_2$. $V_1 = V_3$ says $Q_1/C_1 = Q_3/C_3$ and $Q_1 = Q_3(C_1/C_3) = Q_3(8.4\ \mu\text{F} / 4.2\ \mu\text{F}) = 2Q_3$.

Using $Q_2 = Q_1$ and $Q_1 = 2Q_3$ in the above equation gives $2Q_3 + 2Q_3 + Q_3 = 228\ \mu\text{C}$.

$5Q_3 = 228\ \mu\text{C}$ and $Q_3 = 45.6\ \mu\text{C}$, $Q_1 = Q_2 = 91.2\ \mu\text{C}$

Then $V_1 = \dfrac{Q_1}{C_1} = \dfrac{91.2\ \mu\text{C}}{8.4\ \mu\text{F}} = 11\ \text{V}$, $V_2 = \dfrac{Q_2}{C_2} = \dfrac{91.2\ \mu\text{C}}{8.4\ \mu\text{F}} = 11\ \text{V}$, and $V_3 = \dfrac{Q_3}{C_3} = \dfrac{45.6\ \mu\text{C}}{4.2\ \mu\text{F}} = 11\ \text{V}$.

The voltage across each capacitor in the parallel combination is 11 V.

(d) $U = \tfrac{1}{2}Q_1V_1 + \tfrac{1}{2}Q_2V_2 + \tfrac{1}{2}Q_3V_3$.

But $V_1 = V_2 = V_3$ so $U = \tfrac{1}{2}V_1(Q_1 + Q_2 + Q_3) = \tfrac{1}{2}(11\ \text{V})(228\ \mu\text{C}) = 1.3\times10^{-3}\ \text{J}$.

EVALUATE: This is less than the original energy of 1.4×10^{-3} J. The stored energy has decreased, as in Example 24.7.

24.58. IDENTIFY: $C = \dfrac{\epsilon_0 A}{d}$. $C = \dfrac{Q}{V}$. $V = Ed$. $U = \tfrac{1}{2}QV$.

SET UP: $d = 3.0\times10^3$ m. $A = \pi r^2$, with $r = 1.0\times10^3$ m.

EXECUTE: **(a)** $C = \dfrac{\epsilon_0 A}{d} = \dfrac{(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)\pi(1.0\times10^3\ \text{m})^2}{3.0\times10^3\ \text{m}} = 9.3\times10^{-9}\ \text{F}$.

(b) $V = \dfrac{Q}{C} = \dfrac{20\ \text{C}}{9.3\times10^{-9}\ \text{F}} = 2.2\times10^9\ \text{V}$.

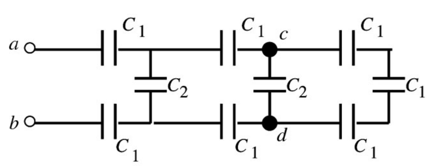
(c) $E = \dfrac{V}{d} = \dfrac{2.2\times10^9\ \text{V}}{3.0\times10^3\ \text{m}} = 7.3\times10^5\ \text{V/m}$.

(d) $U = \tfrac{1}{2}QV = \tfrac{1}{2}(20\ \text{C})(2.2\times10^9\ \text{V}) = 2.2\times10^{10}\ \text{J}$.

EVALUATE: Thunderclouds involve very large potential differences and large amounts of stored energy.

24.59. IDENTIFY: Replace series and parallel combinations of capacitors by their equivalents. In each equivalent network apply the rules for Q and V for capacitors in series and parallel; start with the simplest network and work back to the original circuit.

(a) SET UP: The network is sketched in Figure 24.59a.

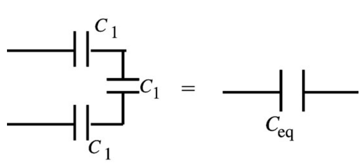


$C_1 = 6.9\ \mu\text{F}$.

$C_2 = 4.6\ \mu\text{F}$.

Figure 24.59a

EXECUTE: Simplify the network by replacing the capacitor combinations by their equivalents. Make the replacement shown in Figure 24.59b.

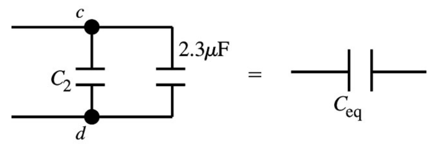


$\dfrac{1}{C_{eq}} = \dfrac{3}{C_1}$.

$C_{eq} = \dfrac{C_1}{3} = \dfrac{6.9\ \mu\text{F}}{3} = 2.3\ \mu\text{F}$.

Figure 24.59b

Next make the replacement shown in Figure 24.59c.

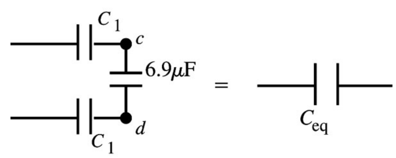


$C_{eq} = 2.3\ \mu\text{F} + C_2.$

$C_{eq} = 2.3\ \mu\text{F} + 4.6\ \mu\text{F} = 6.9\ \mu\text{F}.$

Figure 24.59c

Make the replacement shown in Figure 24.59d.

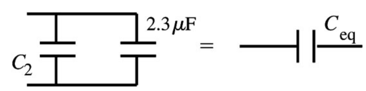


$$\frac{1}{C_{eq}} = \frac{2}{C_1} + \frac{1}{6.9\ \mu\text{F}} = \frac{3}{6.9\ \mu\text{F}}.$$

$C_{eq} = 2.3\ \mu\text{F}.$

Figure 24.59d

Make the replacement shown in Figure 24.59e.

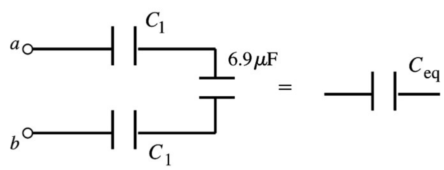


$C_{eq} = C_2 + 2.3\ \mu\text{F} = 4.6\ \mu\text{F} + 2.3\ \mu\text{F}.$

$C_{eq} = 6.9\ \mu\text{F}.$

Figure 24.59e

Make the replacement shown in Figure 24.59f.

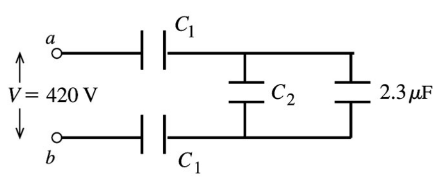


$$\frac{1}{C_{eq}} = \frac{2}{C_1} + \frac{1}{6.9\ \mu\text{F}} = \frac{3}{6.9\ \mu\text{F}}.$$

$C_{eq} = 2.3\ \mu\text{F}.$

Figure 24.59f

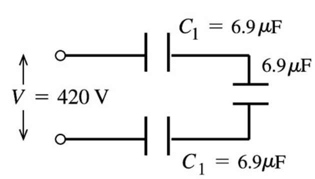
(b) SET UP and **EXECUTE**: Consider the network as drawn in Figure 24.59g.



From part (a) $2.3\ \mu\text{F}$ is the equivalent capacitance of the rest of the network.

Figure 24.59g

The equivalent network is shown in Figure 24.59h.

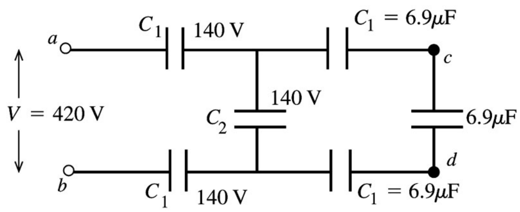


The capacitors are in series, so all three capacitors have the same Q.

Figure 24.59h

But here all three have the same C, so by $V = Q/C$ all three must have the same V. The three voltages must add to 420 V, so each capacitor has $V = 140$ V. The $6.9\ \mu\text{F}$ to the right is the equivalent of C_2 and the $2.3\ \mu\text{F}$ capacitor in parallel, so $V_2 = 140$ V. (Capacitors in parallel have the same potential difference.) Hence $Q_1 = C_1V_1 = (6.9\ \mu\text{F})(140\ \text{V}) = 9.7\times10^{-4}$ C and
$Q_2 = C_2V_2 = (4.6\ \mu\text{F})(140\ \text{V}) = 6.4\times10^{-4}$ C.

(c) From the potentials deduced in part (b) we have the situation shown in Figure 24.59i.



From part (a) $6.9\ \mu\text{F}$ is the equivalent capacitance of the rest of the network.

Figure 24.59i

The three right-most capacitors are in series and therefore have the same charge. But their capacitances are also equal, so by $V = Q/C$ they each have the same potential difference. Their potentials must sum to 140 V, so the potential across each is 47 V and $V_{cd} = 47$ V.

EVALUATE: In each capacitor network the rules for combining V for capacitors in series and parallel are obeyed. Note that $V_{cd} < V$, in fact $V - 2(140\ \text{V}) - 2(47\ \text{V}) = V_{cd}$.

24.60. **IDENTIFY:** This situation is analogous to having two capacitors C_1 in series, each with separation $\frac{1}{2}(d-a)$.

SET UP: For capacitors in series, $\dfrac{1}{C_{\text{eq}}} = \dfrac{1}{C_1} + \dfrac{1}{C_2}$.

EXECUTE: **(a)** $C = \left(\dfrac{1}{C_1} + \dfrac{1}{C_1}\right)^{-1} = \frac{1}{2}C_1 = \frac{1}{2}\dfrac{\epsilon_0 A}{(d-a)/2} = \dfrac{\epsilon_0 A}{d-a}$.

(b) $C = \dfrac{\epsilon_0 A}{d-a} = \dfrac{\epsilon_0 A}{d}\dfrac{d}{d-a} = C_0\dfrac{d}{d-a}$.

EVALUATE: **(c)** As $a \to 0$, $C \to C_0$. The metal slab has no effect if it is very thin. And as $a \to d$, $C \to \infty$. $V = Q/C$. $V = Ey$ is the potential difference between two points separated by a distance y parallel to a uniform electric field. When the distance is very small, it takes a very large field and hence a large Q on the plates for a given potential difference. Since $Q = CV$ this corresponds to a very large C.

24.61. **IDENTIFY:** Capacitors in series carry the same charge, but capacitors in parallel have the same potential difference across them.

SET UP: $V_{ab} = 48.0$ V. $C = Q/V$ and $U = \dfrac{1}{2}CV^2$. For capacitors in parallel, $C = C_1 + C_2$, and for capacitors in series, $1/C = 1/C_1 + 1/C_2$.

EXECUTE: Using $U = \dfrac{1}{2}CV^2$ gives $C = \dfrac{2U}{V^2} = \dfrac{2(2.90\times10^{-3}\ \text{J})}{(48.0\ \text{V})^2} = 2.517\times10^{-6}$ F, which is the equivalent capacitance of the network. The equivalent capacitance for C_1 and C_2 in series is $C_{12} = \dfrac{1}{2}(4.00\ \mu\text{F}) = 2.00\ \mu\text{F}$. If C_{123} is the equivalent capacitance for C_{12} and C_3 in parallel, then

$\dfrac{1}{C_{123}}+\dfrac{1}{C_4}=\dfrac{1}{C}$. Solving for C_{123} gives

$\dfrac{1}{C_{123}}=\dfrac{1}{C}-\dfrac{1}{C_4}=\dfrac{1}{2.517\times10^{-6}\text{ F}}-\dfrac{1}{8.00\times10^{-6}\text{ F}}=2.722\times10^5\text{ F}^{-1}$, so $C_{123}=3.673\times10^{-6}$ F.

$C_{12}+C_3=C_{123}$. $C_3=C_{123}-C_{12}=3.673\ \mu\text{F}-2.00\ \mu\text{F}=1.67\ \mu\text{F}$.

EVALUATE: As with most circuits, it is necessary to solve them in a series of steps rather than using a single step.

24.62. **IDENTIFY:** The electric field energy density is $u=\frac{1}{2}\epsilon_0 E^2$. $U=\dfrac{Q^2}{2C}$.

SET UP: For this charge distribution, $E=0$ for $r<r_a$, $E=\dfrac{\lambda}{2\pi\epsilon_0 r}$ for $r_a<r<r_b$ and $E=0$ for $r>r_b$.

Example 24.4 shows that $\dfrac{C}{L}=\dfrac{2\pi\epsilon_0}{\ln(r_b/r_a)}$ for a cylindrical capacitor.

EXECUTE: **(a)** $u=\frac{1}{2}\epsilon_0 E^2=\frac{1}{2}\epsilon_0\left(\dfrac{\lambda}{2\pi\epsilon_0 r}\right)^2=\dfrac{\lambda^2}{8\pi^2\epsilon_0 r^2}$.

(b) $U=\int u\,dV=2\pi L\int ur\,dr=\dfrac{L\lambda^2}{4\pi\epsilon_0}\int_{r_a}^{r_b}\dfrac{dr}{r}$ and $\dfrac{U}{L}=\dfrac{\lambda^2}{4\pi\epsilon_0}\ln(r_b/r_a)$.

(c) $U=\dfrac{Q^2}{2C}=\dfrac{Q^2}{4\pi\epsilon_0 L}\ln(r_b/r_a)=\dfrac{\lambda^2 L}{4\pi\epsilon_0}\ln(r_b/r_a)$. This agrees with the result of part (b).

EVALUATE: We could have used the results of part (b) and $U=\dfrac{Q^2}{2C}$ to calculate C/L and would obtain the same result as in Example 24.4.

24.63. **IDENTIFY:** We are dealing with a parallel-plate capacitor.
SET UP: $E=E_0/K$ with dielectric, where $E_0=\sigma/\epsilon_0$.

EXECUTE: **(a)** We want the compressive force applied to the dielectric. $F_{\text{on }+Q}=QE_{-Q}=$ $Q\left(\dfrac{\sigma}{2\epsilon_0 K}\right)=Q\left(\dfrac{Q/A}{2\epsilon_0 K}\right)=\dfrac{Q^2}{2A\epsilon_0 K}$, and the force on $-Q$ is the same.

(b) We want the squeezing coefficient s. $d=d_0-sQ^2$, so $\Delta d=d_0-d=sQ^2$. Young's modulus is $Y=\dfrac{F_\perp}{A}\dfrac{\ell_0}{\Delta\ell}$. Applied here, $\Delta\ell=\Delta d=sQ^2$ and $\ell_0=d_0$. Solving for s: $s=\dfrac{F_\perp d_0}{AQ^2Y}$. Using F from part (a) gives $s=\left(\dfrac{Q^2}{2A\epsilon_0 K}\right)\dfrac{d_0}{AQ^2Y}=\dfrac{d_0}{2A^2\epsilon_0 YK}$.

(c) Using A = 1.00 cm^2, d_0 = 0.400 mm, K = 3.00, and Y = 0.0100 GPa gives $s=7.53\times10^7$ m/C^2.

(d) We want the applied voltage. $V=Ed=\dfrac{E_0}{K}\left(d_0-sQ^2\right)=\dfrac{\sigma/\epsilon_0}{K}\left(d_0-sQ^2\right)=\dfrac{Q}{A\epsilon_0 K}\left(d_0-sQ^2\right)$.

Using Q = 0.700 μC and the other given numbers, we get V = 95.7 kV.
(e) We want the voltage if we double the charge. The same calculation but using Q = 1.40 μC leads to V = 133 kV.
EVALUATE: Doubling the charge did not double the potential.

24.64. **IDENTIFY:** The capacitor is equivalent to two capacitors in parallel, as shown in Figure 24.64.

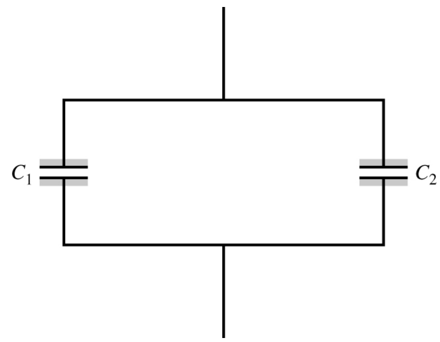


Figure 24.64

SET UP: Each of these two capacitors have plates that are 12.0 cm by 6.0 cm. For a parallel-plate capacitor with dielectric filling the volume between the plates, $C = K\epsilon_0 \dfrac{A}{d}$. For two capacitors in parallel, $C = C_1 + C_2$. The energy stored in a capacitor is $U = \tfrac{1}{2}CV^2$.

EXECUTE: **(a)** $C = C_1 + C_2$.

$$C_2 = \epsilon_0 \frac{A}{d} = \frac{(8.854\times10^{-12}\ \text{F/m})(0.120\ \text{m})(0.060\ \text{m})}{4.50\times10^{-3}\ \text{m}} = 1.42\times10^{-11}\ \text{F}.$$

$C_1 = KC_2 = (3.40)(1.42\times10^{-11}\ \text{F}) = 4.83\times10^{-11}\ \text{F}$. $C = C_1 + C_2 = 6.25\times10^{-11}\ \text{F} = 62.5\ \text{pF}$.

(b) $U = \tfrac{1}{2}CV^2 = \tfrac{1}{2}(6.25\times10^{-11}\ \text{F})(18.0\ \text{V})^2 = 1.01\times10^{-8}\ \text{J}$.

(c) Now $C_1 = C_2$ and $C = 2(1.42\times10^{-11}\ \text{F}) = 2.84\times10^{-11}\ \text{F}$.

$U = \tfrac{1}{2}CV^2 = \tfrac{1}{2}(2.84\times10^{-11}\ \text{F})(18.0\ \text{V})^2 = 4.60\times10^{-9}\ \text{J}$.

EVALUATE: The plexiglass increases the capacitance and that increases the energy stored for the same voltage across the capacitor.

24.65. **IDENTIFY:** We are looking at the force between oppositely charged parallel plates.

SET UP: The plates are oppositely charged so they attract. The tension in the cable is equal to the force with which the plates attract each other.

EXECUTE: **(a)** We want the tension in the cable. The force on the upper plate is $F_{\text{upper}} = QE_{\text{lower}}$. The field between the plates is σ/ϵ_0, half of which is due to each plate, so $E_{\text{lower}} = \sigma/2\epsilon_0$. Using $\sigma = Q/A$ we get $F_{\text{electric}} = \dfrac{Q^2}{2\epsilon_0 A}$. For a parallel-plate capacitor with plates a distance z apart, $C = \epsilon_0 A/z$, where $A = \pi r^2$. $Q = CV = \dfrac{\epsilon_0 A}{z}V$, so $F_{\text{electric}} = \left(\dfrac{\epsilon_0 AV}{z}\right)\dfrac{1}{2\epsilon_0 A} = \dfrac{\pi\epsilon_0 r^2V^2}{2z^2}$, which is the tension in the cable.

(b) We want the work. $\displaystyle\int_d^{2d} F\,dz = \int_d^{2d} \frac{\pi\epsilon_0 r^2V^2}{2z^2}dz = \frac{\pi\epsilon_0 r^2V^2}{2}\left(-\frac{1}{z}\right)\Bigg|_d^{2d} = \frac{\pi\epsilon_0 r^2V^2}{4d}$.

(c) We want the initial energy stored in the electric field of the capacitor.

$$U_1 = \frac{1}{2}CV^2 = \frac{1}{2}\left(\frac{\epsilon_0 A}{d}\right)V^2 = \frac{\pi\epsilon_0 r^2V^2}{2d}.$$

(d) We want the energy stored in the electric field of the capacitor after raising the plate.

$U_1 = \frac{1}{2}CV^2 = \frac{1}{2}\left(\frac{\epsilon_0 A}{2d}\right)V^2 = \frac{\pi\epsilon_0 r^2V^2}{4d}.$

EVALUATE: **(e)** Subtract the two energies, giving $\Delta U = -\frac{\pi\epsilon_0 r^2V^2}{4d}$. The work done in separating the plates is equal to the *magnitude* of the energy change in the plates. This does *not* mean that the work done is *equal* to the change in the energy stored in the plates. The work done on the plates is positive but the plates *lose* energy. The plates are connected to the battery, so the potential difference across them remains constant as they are separated. Therefore change is forced off of the plates through the battery, which does work on the battery. We have neglected gravity because it was much weaker than the electric force.

24.66. **IDENTIFY:** The system is equivalent to two capacitors in parallel. One of the capacitors has plate separation *d*, plate area $w(L-h)$ and air between the plates. The other has the same plate separation *d*, plate area *wh* and dielectric constant *K*.

SET UP: Define K_{eff} by $C_{\text{eq}} = \frac{K_{\text{eff}}\epsilon_0 A}{d}$, where $A = wL$. For two capacitors in parallel, $C_{\text{eq}} = C_1 + C_2$.

EXECUTE: **(a)** The capacitors are in parallel, so $C = \frac{\epsilon_0 w(L-h)}{d} + \frac{K\epsilon_0 wh}{d} = \frac{\epsilon_0 wL}{d}\left(1 + \frac{Kh}{L} - \frac{h}{L}\right)$.

This gives $K_{\text{eff}} = \left(1 + \frac{Kh}{L} - \frac{h}{L}\right)$.

(b) For gasoline, with $K = 1.95$: $\frac{1}{4}$ full: $K_{\text{eff}}\left(h = \frac{L}{4}\right) = 1.24$; $\frac{1}{2}$ full: $K_{\text{eff}}\left(h = \frac{L}{2}\right) = 1.48$; $\frac{3}{4}$ full: $K_{\text{eff}}\left(h = \frac{3L}{4}\right) = 1.71$.

(c) For methanol, with $K = 33$: $\frac{1}{4}$ full: $K_{\text{eff}}\left(h = \frac{L}{4}\right) = 9$; $\frac{1}{2}$ full: $K_{\text{eff}}\left(h = \frac{L}{2}\right) = 17$; $\frac{3}{4}$ full: $K_{\text{eff}}\left(h = \frac{3L}{4}\right) = 25$.

(d) This kind of fuel tank sensor will work best for methanol since it has the greater range of K_{eff} values.

EVALUATE: When $h = 0$, $K_{\text{eff}} = 1$. When $h = L$, $K_{\text{eff}} = K$.

24.67. **IDENTIFY** and **SET UP:** For two capacitors in series, $\frac{1}{C_1} + \frac{1}{C_2} = \frac{1}{C_{\text{eq}}}$, which gives $C_{\text{eq}} = \frac{C_1C_2}{C_1 + C_2}$. For two capacitors in parallel, $C_{\text{eq}} = C_1 + C_2$. $C = Q/V$. The stored energy can be written as $U = \frac{1}{2}CV^2$ or $U = \frac{Q^2}{2C}$.

EXECUTE: **(a)** When connected in series, the stored energy is 0.0400 J, so

a = $\frac{1}{2}\left(\frac{C_1C_2}{C_1 + C_2}\right)V^2 = \frac{1}{2}\left(\frac{C_1C_2}{C_1 + C_2}\right)(200.0 \text{ V})^2 = 0.0400$ J, which gives

$\frac{C_1C_2}{C_1 + C_2} = 2.00\ \mu\text{F}.$

When connected in parallel, the stored energy is 0.180 J, so

$U = \frac{1}{2}CV^2 = \frac{1}{2}(C_1 + C_2)V^2 = \frac{1}{2}(C_1 + C_2)(200.0 \text{ V})^2 = 0.180$ J.

$C_1 + C_2 = 9.00\ \mu$F.

Solving the two equations for C_1 and C_2 gives $C_1 = 6.00\ \mu$F and $C_2 = 3.00\ \mu$F.

(b) When the capacitors are in series, both have the same charge. The stored energy is $U = \dfrac{Q^2}{2C}$, so the capacitor with the *smaller* capacitance stores more energy, which is C_2.
(c) When the capacitors are in parallel, the potential across them is the same. The stored energy is $U = \frac{1}{2}CV^2$, so the capacitor with the *larger* capacitance stores the most energy, which is C_1.

EVALUATE: When the two capacitors are connected in parallel, they can store considerably more energy than when in series.

24.68. **IDENTIFY** and **SET UP:** The presence of the dielectric affects the charge and energy in the capacitor for a given potential difference. $V = Ed$, $Q = CV$, $K = C/C_0$, $U = \frac{1}{2}CV^2$. We use the values for K and E_{m} from Table 24.2. In this case, $E = 0.500E_{\text{m}}$ and $d = 2.50$ mm $= 0.00250$ m.

EXECUTE: **(a)** Using $U = \frac{1}{2}CV^2$, $C = KC_0$, $V = Ed$, and $E = 0.500E_{\text{m}}$, the stored energy is

$$U = \tfrac{1}{2}CV^2 = \tfrac{1}{2}KC_0(Ed)^2 = \tfrac{1}{2}KC_0(0.500E_{\text{m}}d)^2.$$

For polycarbonate, $K = 2.8$ and $E_{\text{m}} = 3\times10^7$ V/m. Therefore the stored energy is

$U = (1/2)[(2.8)(6.00\times10^{-12}\text{ F})][(0.500)(3\times10^7\text{ V/m})(0.00250\text{ m})]^2 = 1.18\times10^{-2}\text{ J}$, which rounds to 12 mJ. Using similar calculations for the other materials, the results for U are:
12 mJ (polycarbonate)
56 mJ (polyester)
51 mJ (polypropylene)
4.9 mJ (polystyrene)
2.2 mJ (pyrex)
(b) $Q = CV = KC_0(Ed) = KC_0(0.500E_{\text{m}})d$.
For polycarbonate we have

$Q = (2.8)(6.00\times10^{-12}\text{ F})(0.500)(3\times10^7\text{ V/m})(0.00250\text{ m}) = 6.3\times10^{-7}\text{ C} = 0.63\ \mu\text{C}$.

Similar calculations for the other materials yield:
0.63 μC (polycarbonate)
1.5 μC (polyester)
1.2 μC (polypropylene)
0.39 μC (polystyrene)
0.35 μC (pyrex)
(c) $V = Ed = 0.500E_{\text{m}}d$. For polycarbonate this gives

$V = (0.500)(3\times10^7\text{ V/m})(0.00250\text{ m}) = 3.8\times10^4\text{ V} = 38\text{ kV}$.

Similar calculations for the other materials yield:
38 kV (polycarbonate)
75 kV (polyester)
88 kV (polypropylene)
25 kV (polystyrene)
13 kV (pyrex)

EVALUATE: **(d)** Polyester is best for maximum energy storage and maximum charge, but polypropylene is best for maximum voltage. No single material is best for all three categories. As so often occurs, the choice of materials is a trade-off.

24.69. **IDENTIFY** and **SET UP:** For a parallel-plate capacitor, $C = \dfrac{\epsilon_0 A}{d}$. The stored energy can be expressed as $U = \tfrac{1}{2}CV^2$ or $U = \dfrac{Q^2}{2C}$.

EXECUTE: **(a)** If the battery remains connected, V remains constant, so it is useful to write the energy in terms of V and C:

$$U = \tfrac{1}{2}CV^2 = \tfrac{1}{2}\left(\frac{\epsilon_0 A}{d}\right)V^2 = \frac{\epsilon_0 AV^2}{2}\cdot\frac{1}{d}.$$

If the battery is disconnected, Q remains constant, so it is useful to write the energy in terms of Q and C:

$$U = \frac{Q^2}{2C} = \frac{Q^2}{2\left(\dfrac{\epsilon_0 A}{d}\right)} = \left(\frac{Q^2}{2\epsilon_0 A}\right)d.$$

The graph shows a linear relationship between U and $1/d$, so it must represent the case where the battery remains connected to the capacitor.

(b) In a graph of U versus $1/d$ for the equation $U = \dfrac{\epsilon_0 AV^2}{2}\cdot\dfrac{1}{d}$, the slope should be equal to $\dfrac{\epsilon_0 AV^2}{2}$.

Choosing points on the graph in the problem, the slope is $\dfrac{(73-18)\times 10^{-9}\ \text{J}}{20.0\ \text{cm}^{-1} - 5.0\ \text{cm}^{-1}} = 3.67\times 10^{-11}\ \text{J}\cdot\text{m}.$

Solving for A gives

$A = 2(\text{slope})/\epsilon_0 V^2 = 2(3.67\times 10^{-11}\ \text{J}\cdot\text{m})/(8.854\times 10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(24.0\ \text{V})^2] = 0.014\ \text{m}^2 = 144\ \text{cm}^2.$

(c) <u>With the battery connected</u>: $U = \dfrac{\epsilon_0 AV^2}{2}\cdot\dfrac{1}{d}$, so as we increase d from 0.0500 cm to 0.400 cm, the energy *decreases* since V remains constant.

<u>With the battery disconnected</u>: $U = \left(\dfrac{Q^2}{2\epsilon_0 A}\right)d$, so as we increase d, the energy *increases* since Q does not change. Therefore there is more energy stored with the battery *disconnected* as d is increased.

EVALUATE: If this capacitor were square, its plates would be $12\ \text{cm}\times 12\ \text{cm}$. This is a reasonable size for a piece of apparatus for use in a laboratory and could easily be manufactured.

24.70. **IDENTIFY:** Two coaxial conducting shells with dielectric in the space between them form a cylindrical capacitor. We assume that there are no appreciable effects due to the part of the dielectric that is not within the region between the cylinders.

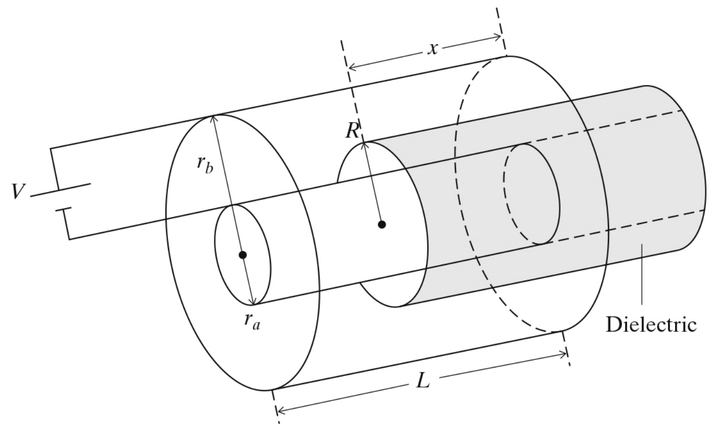

Figure 24.70a

SET UP: Refer to Fig. 24.70a. We can think of this combination as two capacitors in parallel. One capacitor is the section without dielectric and the other is the section with dielectric. They are in parallel because they share the same positive side and the same negative side. The section containing dielectric can be viewed as two cylindrical capacitors of length x in series, as shown in Fig. 24.70b. If R is the radius of the dielectric section, that part has an inner radius r_a and outer radius R. The part without dielectric has inner radius R and outer radius r_b. For a cylindrical capacitor of length ℓ with inner radius r_a and outer radius r_b, $C = \dfrac{2\pi \epsilon_0 \ell}{\ln(r_b / r_a)}$. We want the capacitance of this device.

EXECUTE: (a) The section containing no dielectric: Use $C = \dfrac{2\pi \epsilon_0 \ell}{\ln(r_b / r_a)}$ with $\ell = L - x$. Call this capacitance C_1 so $C_1 = \dfrac{2\pi \epsilon_0 (L-x)}{\ln(r_b / r_a)}$.

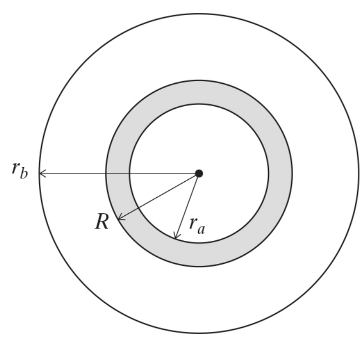

Figure 24.70b

The section partially filled with dielectric: Refer to Fig. 24.70b. Call the inner part (radii r_a and R) C_{aR}. Applying $C = \dfrac{2\pi \epsilon_0 \ell}{\ln(r_b / r_a)}$ with $\ell = x$ and allowing for the dielectric, we have $C_{aR} = \dfrac{K 2\pi \epsilon_0 x}{\ln(R / r_a)}$. Call the outer part (radii R and r_b) C_{Rb}. Applying the same formula gives $C_{Rb} = \dfrac{2\pi \epsilon_0 x}{\ln(r_b / R)}$. Call C_2 the equivalent capacitance of C_{aR} and C_{Rb}. Since they are in series, their equivalent capacitance is given by $\dfrac{1}{C_2} = \dfrac{1}{C_{aR}} + \dfrac{1}{C_{Rb}} = \dfrac{\ln(R / r_a)}{K 2\pi \epsilon_0 x} + \dfrac{\ln(r_b / R)}{2\pi \epsilon_0 x}$. This gives $C_2 = \dfrac{2\pi \epsilon_0 x}{\dfrac{\ln(R / r_a)}{K} + \ln(r_b / R)}$. Since C_1 and C_2 are in

series, the equivalent capacitance of this device is $C = C_1 + C_2$, which gives
$$C = \frac{2\pi\epsilon_0 (L-x)}{\ln(r_b/r_a)} + \frac{2\pi\epsilon_0 x}{\dfrac{\ln(R/r_a)}{K} + \ln(r_b/R)}.$$

(b) We want the equivalent capacitance when $x = 0$. Using our result from part (a) gives
$C = \dfrac{2\pi\epsilon_0 (L-x)}{\ln(r_b/r_a)}$. We recognize this as an ordinary air-filled cylindrical capacitor of length $L-x$.

Using $L = 10.0$ cm, $r_a = 1.00$ cm, $r_b = 4.00$ cm, and $K = 3.21$, we get $C = 4.01$ pF.

(c) We want C when $x = L$. Using the result from (a) with $K = 3.21$ gives $C = 8.83$ pF.

(d) We want x. First find C. $C = Q/V = (6.00\text{ nC})/(1.00\text{ kV}) = 6.00$ pF. Use our result from (a) and solve for x: $C = \dfrac{2\pi\epsilon_0 (L-x)}{\ln(r_b/r_a)} + \dfrac{2\pi\epsilon_0 x}{\dfrac{\ln(R/r_a)}{K} + \ln(r_b/R)} = 6.00$ pF. The result is $x = 4.12$ cm.

EVALUATE: A device like this one could be used to make a variable capacitor that one could easily vary as desired simply by sliding the dielectric in and out.

24.71. IDENTIFY: This problem involves a capacitor with dielectric inside.

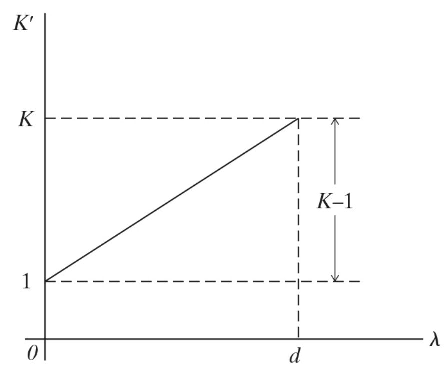

Figure 24.71a

SET UP: The dielectric constant K' is not uniform within the capacitor. We first need to find an equation for K'. At the first plate, the $K' = 1$, at the second plate $K' = K$, and it varies linearly. Call x the distance of any point from the first plate. Using this information, sketch the graph of K' versus x, as shown in Fig. 24.71a. Using the slope-intercept form, we see that the slope of this line is $(K-1)/d$ and the x-intercept is 1. The equation is $K' = \left(\dfrac{K-1}{d}\right)x + 1$.

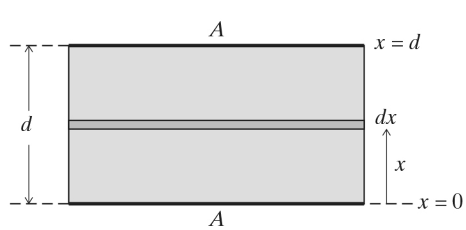

Figure 24.71b

EXECUTE: (a) We want to find the capacitance of this device. Since K' depends only on the distance x from the first plate, break the dielectric into thin slabs of area A and thickness dx as shown in Fig.

24.71b. Using the equation $C=\frac{\epsilon_0 AK}{d}$, the capacitance of a single slab is $dC=\frac{\epsilon_0 AK}{dx}$. These slabs are all in series with each other, so we apply the equation $1/C_{eq} = 1/C_1 + 1/C_2 + \ldots$ But in this case each capacitance to be added is infinitesimal, so we must integrate to get the sum. Doing so gives $\frac{1}{C}=\int\frac{1}{dC}=\int_0^d\frac{dx}{K'\epsilon_0 A}=\frac{1}{\epsilon_0 A}\int_0^d\frac{dx}{1+(K-1)x/d}=\frac{d}{\epsilon_0 A(K-1)}\ln\left[1+(K-1)x/d\right]\Big|_0^d$. Evaluating at the two limits and rearranging gives $C=\frac{\epsilon_0 A(K-1)}{d\ln K}$.

(b) We want to find C when $K = 1$. Putting $K = 1$ into our result gives $\frac{0}{0}$, which is indeterminate. So to evaluate the limit, we need to use L'Hopital's rule, which gives
$C=\lim_{K\to 1}\left[\frac{\epsilon_0 A(K-1)}{d\ln K}\right]=\lim_{K\to 1}\left[\frac{\epsilon_0 A}{d}\frac{d(K-1)/dK}{d(\ln K)/dK}\right]=\left(\frac{\epsilon_0 A}{d}\right)\left(\frac{1}{1/K}\right)=\frac{K\epsilon_0 A}{d}$. We recognize this result as the capacitance of a parallel-plate capacitor filled with uniform material having dielectric constant K.

EVALUATE: It would be plausible to construct a capacitor like this by filling the gap between the plates with thin layers of material have a progressively larger value of K.

24.72. **IDENTIFY:** The system can be considered to be two capacitors in parallel, one with plate area $L(L-x)$ and air between the plates and one with area Lx and dielectric filling the space between the plates.

SET UP: $C=\frac{K\epsilon_0 A}{d}$ for a parallel-plate capacitor with plate area A.

EXECUTE: **(a)** $C=\frac{\epsilon_0}{D}\left[(L-x)L+xKL\right]=\frac{\epsilon_0 L}{D}\left[L+(K-1)x\right]$.

(b) $dU=\frac{1}{2}(dC)V^2$, where $C=C_0+\frac{\epsilon_0 L}{D}(-dx+dxK)$, with $C_0=\frac{\epsilon_0 L}{D}\left[L+(K-1)x\right]$. This gives
$dU=\frac{1}{2}\left(\frac{\epsilon_0 Ldx}{D}(K-1)\right)V^2=\frac{(K-1)\epsilon_0 V^2 L}{2D}dx.$

(c) If the charge is kept constant on the plates, then $Q=\frac{\epsilon_0 LV}{D}\left[L+(K-1)x\right]$ and
$U=\frac{1}{2}CV^2=\frac{1}{2}C_0V^2\left(\frac{C}{C_0}\right)$. $U\approx\frac{C_0V^2}{2}\left(1-\frac{\epsilon_0 L}{DC_0}(K-1)dx\right)$ and $\Delta U=U-U_0=-\frac{(K-1)\epsilon_0 V^2 L}{2D}dx.$

(d) Since $dU=-Fdx=-\frac{(K-1)\epsilon_0 V^2 L}{2D}dx$, the force is in the opposite direction to the motion dx, meaning that the slab feels a force pushing it out.

EVALUATE: **(e)** When the plates are connected to the battery, the plates plus slab are not an isolated system. In addition to the work done on the slab by the charges on the plates, energy is also transferred between the battery and the plates. Comparing the results for dU in part (c) to $dU=-Fdx$ gives
$F=\frac{(K-1)\epsilon_0 V^2 L}{2D}.$

24.73. **IDENTIFY** and **SET UP:** The potential difference is V = 30 mV – (–70 mV) = 100 mV, and $Q = CV$.
EXECUTE: $Q = CV$ gives $Q/\text{cm}^2 = (C/\text{cm}^2)V = (1\ \mu\text{F/cm}^2)(100\ \text{mV})(1\ \text{mol}/10^5\ \text{C}) = 10^{-12}\ \text{mol/cm}^2$, which is choice (c).
EVALUATE: This charge produces a potential difference of 100 mV = 0.1 V, which is certainly measurable using ordinary laboratory meters.

24.74. **IDENTIFY** and **SET UP:** The change in concentration of Na^+ ions is equal to the added charge divided by the volume of the spherical egg. The original concentration of ions is given as 30 mmol/L. We use the answer from Problem 24.73 to get the added charge.

EXECUTE: The added charge is (10^{-12} mol/cm^2)(surface area of egg) = (10^{-12} mol/cm^2)($4\pi R^2$), and the original volume of the egg is $(4\pi/3)R^3$. Therefore the change in concentration is

$$(10^{-12}\ \text{mol/cm}^2)(4\pi R^2)/\left[(4\pi/3)R^3\right] = 3(10^{-12}\ \text{mol/cm}^2)/R = 3(10^{-12}\ \text{mol/cm}^2)/(100\times10^{-4}\,\text{cm}) =$$

$$3\times10^{10}\ \text{mol/cm}^3 = 3\times10^{-5}\ \text{mmol/L}.$$

The fractional change in the concentrations is $(3\times10^{-5}\ \text{mmol/L})/(30\ \text{mmol/L}) = 10^{-5}$, which is 1 part in 10^5. Therefore choice (b) is correct.

EVALUATE: As a percent, this change is 10^{-3}% = 0.001%, which is quite small yet certainly important for the organism.

24.75. **IDENTIFY** and **SET UP:** The calcium Ca^{2+} ions carry twice the charge of the Na^+ ions.

EXECUTE: The charge to produce the given voltage change would be the same as with Na^+, so we would need only half as many Ca^{2+} ions to accomplish this. Thus choice (a) is correct.

EVALUATE: Ca^{+2} ions are nearly twice as heavy as Na^+ ions, so they may not move as readily as the sodium ions.

24.76. **IDENTIFY** and **SET UP:** The energy is needed to change the potential from 30 mV to –70 mV. $U = \frac{1}{2}CV^2$. The capacitance is (1 μF/cm^2)(surface area of egg).

EXECUTE: For a spherical egg, the surface area is $4\pi R^2$, so the capacitance is

$$C = (1\ \mu\text{F/cm}^2)(4\pi R^2) = (1\ \mu\text{F/cm}^2)(4\pi)(100\times10^{-4}\ \text{cm})^2 = 1.26\times10^{-9}\ \text{F}.$$

The change in stored energy is

$$\Delta U = \tfrac{1}{2}CV_2^2 - \tfrac{1}{2}CV_1^2 = \tfrac{1}{2}C(V_2^2 - V_1^2).$$

$\Delta U = (1/2)(1.26\times10^{-9}\ \text{F})[(-70\times10^{-3}\ \text{V})^2 - (30\times10^{-3}\ \text{V})^2] = 2.5\times10^{-12}\ \text{J} = 2.5\ \text{pJ} \approx 3\ \text{pJ}$, which makes choice (d) the correct one.

EVALUATE: The actual energy required would probably be greater than 2.5 pJ, depending on the process by which the charging is accomplished, but our value is the minimum energy needed.

25

Current, Resistance, and Electromotive Force

VP25.3.1. **Identify:** We are looking at resistivity, resistance, and the electric field in a wire.

Set Up: $R = \dfrac{\rho L}{A}$, $V = EL$, $V = RI$.

Execute: **(a)** We want the electric field. $E = V/L = (1.45\text{ V})/(35.0\text{ m}) = 0.0414\text{ V/m}$.

(b) The resistance is the target variable. $R = V/I = (1.45\text{ V})/(1.20\text{ A}) = 1.21\ \Omega$.

(c) We want the cross-sectional area of the wire. Solve $R = \dfrac{\rho L}{A}$ for A, giving $A = \dfrac{\rho L}{R}$. Using the given numbers we get $A = 7.97\times10^{-7}\ \text{m}^2$.

Evaluate: Copper has a resistivity of 1.72×10^{-8} ž·m, so if this wire were made of copper, its resistance would be $[(1.72)/(2.75)](1.21\ \Omega) = 0.756\ \Omega$, which is roughly 60% that of the aluminum wire.

VP25.3.2. **Identify:** We are looking at resistivity and the resistance of a wire.

Set Up: $R = \dfrac{\rho L}{A}$, $V = EL$, $V = RI$.

Execute: **(a)** We want the resistance. Combine $V = EL$ and $V = RI$ to get $R = EL/I = 0.596\ \Omega$ using the given values.

(b) Resistivity is the target variable. Solve $R = \dfrac{\rho L}{A}$ for ρ, giving $\rho = \dfrac{RA}{L} = 2.44\times10^{-8}$ ž·m using the given or calculated values for R, A, and L.

Evaluate: According to Table 25.1, this resistivity is the same as that of gold. These wires must be really special!

VP25.3.3. **Identify:** We want to compare the electrical characteristics of two wires.

Set Up: Wire 1: radius r and length L. Wire 2: radius $2r$, length $2L$. The potential difference is the same across both wires.

Execute: **(a)** We want R_2/R_1. Use $R = \dfrac{\rho L}{A}$ and take the ratio of the resistances, which gives

$$\frac{R_2}{R_1} = \frac{\rho L_2 / A_2}{\rho L_1 / A_1} = \frac{L_2}{L_1}\frac{A_1}{A_2} = \frac{L_2}{L_1}\left(\frac{r_1}{r_2}\right)^2 = \frac{2L}{L}\left(\frac{r}{2r}\right)^2 = \frac{1}{2}.$$

(b) We want I_2/I_1. Use $I = V/R$ and take the ratio. $\dfrac{I_2}{I_1} = \dfrac{V/R_2}{V/R_1} = \dfrac{R_1}{R_2} = 2.$

(c) We want J_2/J_1. Use $J = I/A$ and take the ratio. $\dfrac{J_2}{J_1} = \dfrac{I_2/(\pi r_2^2)}{I_1/(\pi r_1^2)} = \dfrac{I_2}{I_1}\left(\dfrac{r_1}{r_2}\right)^2 = 2\left(\dfrac{r}{2r}\right)^2 = \dfrac{1}{2}.$

(d) We want E_2/E_1. Use $E = V/L$ and take the ratio. $\frac{E_2}{E_1} = \frac{V/L_2}{V/L_1} = \frac{L_1}{L_2} = \frac{L}{2L} = \frac{1}{2}$.

EVALUATE: As should now be clear, the *geometry* of a wire affects its electrical characteristics.

VP25.3.4. **IDENTIFY:** We are investigating the effect of temperatures on the resistance of a wire.

SET UP: $\rho(T) = \rho_0[1+\alpha(T-T_0)]$ so $R(T) = R_0[1+\alpha(T-T_0)]$. $V = RI$.

EXECUTE: **(a)** We want to find R at 20.0°C and 80.0°C.

At 20.0°C: $R = V/I$ = (1.50 V)/(2.40 A) = 0.625 Ω.

At 80.0°C: $R = V/I$ = (1.50 V)/(2.00 A) = 0.750 Ω.

(b) The target variable is α. Call T_0 = 20.0°C and T = 80.0°C and use $R(T) = R_0[1+\alpha(T-T_0)]$.

0.750 Ω = (0.625 Ω)$[1+\alpha(80.0°\text{C} - 20.0°\text{C})]$. α = 0.00333 (C°)$^{-1}$.

EVALUATE: As we see, resistance can vary considerably as the temperature changes.

VP25.5.1. **IDENTIFY:** We are dealing with internal resistance of a battery in a circuit.

SET UP and EXECUTE: **(a)** We want the current. $I = \frac{\mathcal{E}}{R} = \frac{9.00\text{ V}}{15.3\ \Omega + 1.10\ \Omega} = 0.549\text{ A}$.

(b) We want V across the resistor. $V = RI$ = (15.3 Ω)(0.549 A) = 8.40 V.

(c) We want the terminal voltage. $\mathcal{E}_{\text{terminal}} = \mathcal{E} - rI =$ 9.00 V – (1.10 Ω)(0.549 A) = 8.40 V.

EVALUATE: The terminal voltage (8.40 V) is less than the internal emf (9.00 V) because there is a potential drop across the internal resistance.

VP25.5.2. **IDENTIFY:** We are dealing with internal resistance of a battery in a circuit.

SET UP and EXECUTE: **(a)** We want the potential difference across the resistor.

$V = RI$ = (25.0 Ω)(0.480 A) = 12.0 V.

(b) We want the internal resistance. $\mathcal{E} = (R+r)I \quad \rightarrow \quad r = \frac{\mathcal{E}}{I} - R = \frac{12.6\text{ V}}{0.480\text{ A}} - 25.0\ \Omega = 1.3\ \Omega$.

EVALUATE: An internal resistance of 1.3 Ω is large enough to affect a circuit containing only small resistors.

VP25.5.3. **IDENTIFY:** We are dealing with internal resistance of a battery in a circuit.

SET UP and EXECUTE: **(a)** We want the current. $I = \frac{\mathcal{E}_{\text{terminal}}}{R}$ = (1.30 V)/(20.0 Ω) = 0.0650 A.

(b) We want the internal resistance. $\mathcal{E} - \mathcal{E}_{\text{terminal}} = rI$. 1.50 V – 1.30 V = (0.0650 A)r. r = 3.1 Ω.

EVALUATE: An internal resistance of 3.1 Ω is large enough to considerably affect a circuit containing only small resistors.

VP25.5.4. **IDENTIFY:** We are dealing with internal resistance of a battery in a circuit.

SET UP and EXECUTE: **(a)** We want the resistance. $\mathcal{E} = rI + RI$ so $R = \frac{\mathcal{E} - rI}{I}$. This gives

$$R = \frac{1.50\text{ V} - (0.160\ \Omega)(2.00\text{ A})}{2.00\text{ A}} = 0.590\ \Omega.$$

(b) We want the internal resistance. $\mathcal{E}_{\text{terminal}} = \mathcal{E} - rI$ = 1.50 V – (0.160 Ω)(2.00 A) = 1.18 V.

EVALUATE: A resistance smaller than 0.590 Ω would draw a current greater than 2.00 A which would run down the battery.

VP25.9.1. **IDENTIFY:** We are dealing with internal resistance of a battery in a circuit.

SET UP and EXECUTE: **(a)** We want the current. $\mathcal{E} = rI + RI$. $I = \frac{\mathcal{E}}{R+r} = \frac{24.0\text{ V}}{18.0\ \Omega + 1.30\ \Omega} = 1.24\text{ A}$.

(b) We want the rate of energy conversion in the battery, which is the power. $P = I\mathcal{E}$ which gives P = (1.24 A)(24.0 V) = 29.8 W.
(c) We want the rate of energy dissipation in the battery. This takes place in the internal resistance. $P_{\text{int}} = I^2 r$ = (1.24 A)^2(1.30 Ω) = 2.01 W.
(d) We want the net power output of the battery. $P_{\text{net}} = P - P_{\text{int}}$ = 29.8 W – 2.01 W = 27.8 W.
(e) We want the power in the 18.0 ohm resistor. $P_{18} = I^2 R$ = (1.24 A)^2(18.0 Ω) = 27.8 W.
EVALUATE: Note that the net power output of the battery is equal to the power dissipated in the 18.0 ohm resistor. This result is consistent with the conservation of energy.

VP25.9.2. **IDENTIFY:** We are dealing with internal resistance of a battery in a circuit.
SET UP and **EXECUTE:** **(a)** We want the current. Solve $P = I^2 R$ for I. $I = \sqrt{P/R}$ = 0.738 W using the given values.
(b) We want the net power output of the battery. This is the power dissipated in the resistor, which is given as P = 6.54 W.
(c) Target variable is the terminal voltage. $\mathcal{E}_{\text{terminal}} = RI$ = (0.738 A)(12.0 Ω) = 8.86 V.
(d) Target variable is the internal resistance. $\mathcal{E} = (R + r)I. r = \dfrac{\mathcal{E}}{I} - R.$ Using the numbers gives

$$r = \frac{9.00\text{ V}}{0.738\text{ A}} - 12.0\ \Omega = 0.191\ \Omega,\ \text{which rounds to } 0.2\ \Omega.$$

EVALUATE: The battery gives 6.54 W of power to the 12.0 Ω resistor, but the internal resistance dissipates energy at a rate of $I^2 r$ = (0.738 A)^2(0.191 Ω) = 0.10 W. This power is small compared to the power in the 12.0 Ω resistor.

VP25.9.3. **IDENTIFY:** We are dealing with internal resistance of a battery in a circuit.
SET UP and **EXECUTE:** **(a)** We want the terminal voltage. $\mathcal{E}_{\text{terminal}} = RI$ = (16.0 Ω)(0.720 A) = 11.5 V.
(b) We want the internal resistance. $\mathcal{E} = (R + r)I. r = \dfrac{\mathcal{E}}{I} - R.$ $r = \dfrac{12.0\text{ V}}{0.720\text{ A}} - 16.0\ \Omega = 0.667\ \Omega,$ which rounds to 0.7 Ω.
(c) The target variable is the power in the resistor. $P = I^2 R$ = (0.720 A)^2(16.0 Ω) = 8.29 W.
(d) We want the power generated in the battery. $P = I\mathcal{E} =$ (0.720 A)(12.0 V) = 8.64 W.
(e) We want the rate of energy dissipation within the battery. This power is due to the internal resistance, so $P = I^2 r$ = (0.720 A)^2(0.667 Ω) = 0.346 W, which rounds to 0.3 W.
EVALUATE: The internal resistance is much smaller than the external resistance so most of the power is dissipated in the external resistor.

VP25.9.4. **IDENTIFY:** We are dealing with internal resistance of a battery in a circuit.
SET UP and **EXECUTE:** **(a)** We want I_2/I_1.

<u>First circuit</u>: $\mathcal{E} = (R_1 + r)I_1. I_1 = \dfrac{\mathcal{E}}{R_1 + r} = \dfrac{\mathcal{E}}{R + r}.$

<u>Second circuit</u>: $\mathcal{E} = (R_2 + r)I_2. I_2 = \dfrac{\mathcal{E}}{R_2 + r} = \dfrac{\mathcal{E}}{2R + r}.$

$$\frac{I_2}{I_1} = \frac{\dfrac{\mathcal{E}}{2R + r}}{\dfrac{\mathcal{E}}{R + r}} = \frac{R + r}{2R + r}.$$

(b) We want P_2/P_1.

<u>First circuit</u>: $P_1 = I_1^2 R_1 = \left(\dfrac{\mathcal{E}}{R + r}\right)^2 R.$

<u>Second circuit</u>: $P_2 = I_2^2 R_2 = \left(\dfrac{\mathcal{E}}{2R + r}\right)^2 2R.$

$$\frac{P_2}{P_1}=\frac{\left(\frac{\mathcal{E}}{2R+r}\right)^2 2R}{\left(\frac{\mathcal{E}}{R+r}\right)^2 R}=2\left(\frac{R+r}{2R+r}\right)^2.$$

(c) We want to compare the currents and the power dissipation. $\frac{I_2}{I_1}=\frac{R+r}{2R+r}$. Since $2R+r>R+r$, $\frac{R+r}{2R+r}<1$, so the current is greater in R_1. $\frac{P_2}{P_1}=2\left(\frac{R+r}{2R+r}\right)^2$. Since $R>r$, $0<r\le R$. If $r=R$, $\frac{P_2}{P_1}=2\left(\frac{2R}{3R}\right)^2=\frac{8}{9}$, so $P_1>P_2$. If $r=0$, $\frac{P_2}{P_1}=2\left(\frac{R}{2R}\right)^2=\frac{1}{2}$, so $P_1>P_2$. In all cases, $P_1>P_2$, so the power dissipation is greatest in R_1.

EVALUATE: Our result tells us that increase the resistance decreases the current (which is reasonable) and decreases the power dissipation (which is also reasonable).

25.1. IDENTIFY and SET UP: The lightning is a current that lasts for a brief time. $I=\frac{\Delta Q}{\Delta t}$.

EXECUTE: $\Delta Q=I\Delta t=(25{,}000\text{ A})(40\times10^{-6}\text{ s})=1.0\text{ C}$.

EVALUATE: Even though it lasts for only 40 μs, the lightning carries a huge amount of charge since it is an enormous current.

25.2. IDENTIFY: $I=Q/t$. Use $I=n|q|v_\text{d}A$ to calculate the drift velocity v_d.

SET UP: $n=5.8\times10^{28}\text{ m}^{-3}$. $|q|=1.60\times10^{-19}\text{ C}$.

EXECUTE: **(a)** $I=\frac{Q}{t}=\frac{420\text{ C}}{80(60\text{ s})}=8.75\times10^{-2}\text{ A}$.

(b) $I=n|q|v_\text{d}A$. This gives $v_\text{d}=\frac{I}{n|q|A}=\frac{8.75\times10^{-2}\text{ A}}{(5.8\times10^{28})(1.60\times10^{-19}\text{ C})(\pi(1.3\times10^{-3}\text{ m})^2)}=1.78\times10^{-6}\text{ m/s}$.

EVALUATE: v_d is smaller than in Example 25.1, because I is smaller in this problem.

25.3. IDENTIFY: $I=Q/t$. $J=I/A$. $J=n|q|v_\text{d}$.

SET UP: $A=(\pi/4)D^2$, with $D=2.05\times10^{-3}$ m. The charge of an electron has magnitude $+e=1.60\times10^{-19}$ C.

EXECUTE: **(a)** $Q=It=(5.00\text{ A})(1.00\text{ s})=5.00\text{ C}$. The number of electrons is $\frac{Q}{e}=3.12\times10^{19}$.

(b) $J=\frac{I}{(\pi/4)D^2}=\frac{5.00\text{ A}}{(\pi/4)(2.05\times10^{-3}\text{ m})^2}=1.51\times10^6\text{ A/m}^2$.

(c) $v_\text{d}=\frac{J}{n|q|}=\frac{1.51\times10^6\text{ A/m}^2}{(8.5\times10^{28}\text{ m}^{-3})(1.60\times10^{-19}\text{ C})}=1.11\times10^{-4}\text{ m/s}=0.111\text{ mm/s}$.

EVALUATE: **(d)** If I is the same, $J=I/A$ would decrease and v_d would decrease. The number of electrons passing through the light bulb in 1.00 s would not change.

25.4. (a) IDENTIFY: By definition, $J=I/A$ and radius is one-half the diameter.

SET UP: Solve for the current: $I=JA=J\pi(D/2)^2$

EXECUTE: $I = (3.20\times10^6\ \text{A/m}^2)(\pi)[(0.00102\ \text{m})/2]^2 = 2.61\ \text{A}.$

EVALUATE: This is a realistic current.

(b) IDENTIFY: The current density is $J = n|q|v_\text{d}$.

SET UP: Solve for the drift velocity: $v_\text{d} = J/n|q|$

EXECUTE: We use the value of *n* for copper, giving

$v_\text{d} = (3.20\times10^6\ \text{A/m}^2)/[(8.5\times10^{28}/\text{m}^3)(1.60\times10^{-19}\ \text{C})] = 2.4\times10^{-4}\ \text{m/s} = 0.24\ \text{mm/s}.$

EVALUATE: This is a typical drift velocity for ordinary currents and wires.

25.5. **IDENTIFY:** This problem is about the drift speed in a current-carrying wire.

SET UP: $\rho = E/J$ and $J = nqv_\text{d}$.

EXECUTE: **(a)** The drift velocity is the target variable. Combine $\rho = E/J$ and $J = nqv_\text{d}$. $J = E/\rho$ = nqv_d gives $v_\text{d} = \dfrac{E}{nq\rho} = \dfrac{E}{ne\rho}$. Using the given numbers gives v_d = 0.26 mm/s.

(b) We want the potential difference. $V = Ed$ = (0.0600 N/C)(0.200 m) = 0.0120 N/C.

EVALUATE: Note how small v_d, *E*, and *V* are for metals.

25.6. **IDENTIFY:** The resistance depends on the length, cross-sectional area, and material of the wires.

SET UP: $R = \dfrac{\rho L}{A}$, $A = \pi r^2 = d^2/4$. The resistivities come from Table 25.1.

EXECUTE: **(a)** Combining $R = \dfrac{\rho L}{A}$ and $A = \pi d^2/4$, gives $R = \dfrac{\rho L}{\frac{\pi}{4}d^2} = \dfrac{4\rho L}{\pi d^2}$. Solving for *L* gives

$L = \dfrac{R\pi d^2}{4\rho}$. Using this formula gives the length of each type of metal.

<u>Gold</u>: $L = \dfrac{(1.00\ \Omega)\pi(1.00\times10^{-3}\ \text{m})^2}{4(2.44\times10^{-8}\ \Omega\cdot\text{m})} = 32.2\ \text{m}.$

<u>Copper</u>: Using $\rho = 1.72\times10^{-8}\ \Omega\cdot\text{m}$ we get L = 45.7 m.

<u>Aluminum</u>: Using $\rho = 2.75\times10^{-8}\ \Omega\cdot\text{m}$, we get L = 28.6 m.

(b) The mass of the gold is the product of its mass density and its volume, so

$m = (density)(\pi d^2/4)L = (1.93\times10^4\ \text{kg/m}^3)\pi(1.00\times10^{-3}\ \text{m})^2(32.2\ \text{m})/4 = 0.488\ \text{kg} = 488\ g.$

If gold is currently worth \$40 per gram, the cost of the gold wire would be (\$40/g)(488 g) = \$19,500. At this price, you wouldn't want to wire your house with gold wires!

EVALUATE: The resistivities of the three metals are all fairly close to each other, so it is reasonable to expect that the lengths of the wires would also be fairly close to each other, which is just what we find.

25.7. **IDENTIFY** and **SET UP:** Apply $I = \dfrac{dQ}{dt}$ to find the charge dQ in time dt. Integrate to find the total charge in the whole time interval.

EXECUTE: **(a)** $dQ = I\,dt$.

$$Q = \int_0^{8.0\text{s}} (55\ \text{A} - (0.65\ \text{A/s}^2)t^2)dt = \Big[(55\ \text{A})t - (0.217\ \text{A/s}^2)t^3\Big]_0^{8.0\ \text{s}}.$$

$Q = (55\ \text{A})(8.0\ \text{s}) - (0.217\ \text{A/s}^2)(8.0\ \text{s})^3 = 330\ \text{C}.$

(b) $I = \dfrac{Q}{t} = \dfrac{330\ \text{C}}{8.0\ \text{s}} = 41\ \text{A}.$

EVALUATE: The current decreases from 55 A to 13.4 A during the interval. The decrease is not linear and the average current is not equal to $(55\text{A} + 13.4\ \text{A})/2$.

25.8. IDENTIFY: $I = Q/t$. Positive charge flowing in one direction is equivalent to negative charge flowing in the opposite direction, so the two currents due to Cl^- and Na^+ are in the same direction and add.

SET UP: Na^+ and Cl^- each have magnitude of charge $|q| = +e$.

EXECUTE: **(a)** $Q_{total} = (n_{Cl} + n_{Na})e = (3.92\times10^{16} + 2.68\times10^{16})(1.60\times10^{-19}\text{ C}) = 0.0106\text{ C}$. Then $I = \dfrac{Q_{total}}{t} = \dfrac{0.0106\text{ C}}{1.00\text{ s}} = 0.0106\text{ A} = 10.6\text{ mA}$.

(b) Current flows, by convention, in the direction of positive charge. Thus, current flows with Na^+ toward the negative electrode.

EVALUATE: The Cl^- ions have negative charge and move in the direction opposite to the conventional current direction.

25.9. IDENTIFY and SET UP: The number of ions that enter gives the charge that enters the axon in the specified time. $I = \dfrac{\Delta Q}{\Delta t}$.

EXECUTE: $\Delta Q = (5.6\times10^{11}\text{ ions})(1.60\times10^{-19}\text{ C/ion}) = 9.0\times10^{-8}\text{ C}$. $I = \dfrac{\Delta Q}{\Delta t} = \dfrac{9.0\times10^{-8}\text{ C}}{10\times10^{-3}\text{ s}} = 9.0\ \mu\text{A}$.

EVALUATE: This current is much smaller than household currents but are comparable to many currents in electronic equipment.

25.10. IDENTIFY: This problem deals with free-electron density.

SET UP and EXECUTE: First find the number of silver atoms per cubic meter, then use that to get the number of free electrons per cubic meter.

$$n = \left(10.5\times10^3\frac{\text{kg}}{\text{m}^3}\right)\left(\frac{1\text{ mol}}{108\text{ g}}\right)\left(\frac{1000\text{ g}}{1\text{ kg}}\right)\left(\frac{6.022\times10^{23}\text{atoms}}{1\text{ mol}}\right)\left(\frac{1\text{ free electron}}{1\text{ atom}}\right) = 5.85\times10^{28}\frac{\text{el}}{\text{m}^3}.$$ Now

compare this result to the value in Example 25.1. $n_{Ag}/n_{Cu} = 5.85/8.5 = 0.69$, so n_{Ag} is $0.69n_{Cu}$.

EVALUATE: Copper has more free electrons per cubic meter than silver does even though silver is denser than copper.

25.11. IDENTIFY: We want to find the resistivity of the metal.

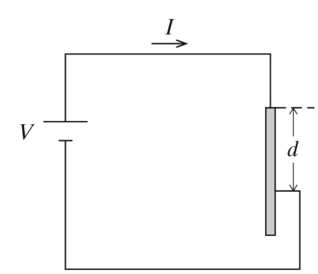

Figure 25.11

SET UP and EXECUTE: First sketch the circuit as in Fig. 25.11. Combine $I = V/R$ and $R = \dfrac{\rho d}{A}$ to relate I to $1/d$. $I = \dfrac{V}{R} = \dfrac{V}{\rho d / A} = \left(\dfrac{VA}{\rho}\right)\dfrac{1}{d}$. A graph of I versus $1/d$ should be a straight line having slope equal to VA/ρ. Thus $\rho = \dfrac{VA}{\text{slope}} = \dfrac{(12.0\text{ V})\pi(0.800\text{ mm})^2}{600\text{ A}\cdot\text{m}} = 4.02\times10^{-8}\ \Omega\cdot\text{m}$.

EVALUATE: From Table 25.1 we see that this resistivity is between that of aluminum and tungsten, so our result is physically reasonable.

25.12. **(a) IDENTIFY:** Start with the definition of resistivity and solve for E.

SET UP: $E = \rho J = \rho I/\pi r^2$.

EXECUTE: $E = (1.72\times10^{-8}\ \Omega\cdot\text{m})(4.50\ \text{A})/[\pi(0.001025\ \text{m})^2] = 2.345\times10^{-2}\ \text{V/m}$, which rounds to 0.0235 V/m.

EVALUATE: The field is quite weak, since the potential would drop only a volt in 43 m of wire.

(b) IDENTIFY: Take the ratio of the field in silver to the field in copper.

SET UP: Take the ratio and solve for the field in silver: $E_S = E_C(\rho_S/\rho_C)$.

EXECUTE: $E_S = (0.02345\ \text{V/m})[(1.47)/(1.72)] = 2.00\times10^{-2}\ \text{V/m}$.

EVALUATE: Since silver is a better conductor than copper, the field in silver is smaller than the field in copper.

25.13. **IDENTIFY:** First use Ohm's law to find the resistance at 20.0°C; then calculate the resistivity from the resistance. Finally use the dependence of resistance on temperature to calculate the temperature coefficient of resistance.

SET UP: Ohm's law is $R = V/I$, $R = \rho L/A$, $R = R_0[1+\alpha(T-T_0)]$, and the radius is one-half the diameter.

EXECUTE: **(a)** At 20.0°C, $R = V/I = (15.0\ \text{V})/(18.5\ \text{A}) = 0.811\ \Omega$. Using $R = \rho L/A$ and solving for ρ gives $\rho = RA/L = R\pi(D/2)^2/L = (0.811\ \Omega)\pi[(0.00500\ \text{m})/2]^2/(1.50\ \text{m}) = 1.06\times10^{-5}\ \Omega\cdot\text{m}$.

(b) At 92.0°C, $R = V/I = (15.0\ \text{V})/(17.2\ \text{A}) = 0.872\ \Omega$. Using $R = R_0[1+\alpha(T-T_0)]$ with T_0 taken as 20.0°C, we have $0.872\ \Omega = (0.811\ \Omega)[1+\alpha(92.0°\text{C} - 20.0°\text{C})]$. This gives $\alpha = 0.00105\ (\text{C}°)^{-1}$.

EVALUATE: The results are typical of ordinary metals.

25.14. **IDENTIFY:** $E = \rho J$, where $J = I/A$. The drift velocity is given by $I = n|q|v_d A$.

SET UP: For copper, $\rho = 1.72\times10^{-8}\ \Omega\cdot\text{m}$. $n = 8.5\times10^{28}/\text{m}^3$.

EXECUTE: **(a)** $J = \dfrac{I}{A} = \dfrac{3.6\ \text{A}}{(2.3\times10^{-3}\ \text{m})^2} = 6.81\times10^5\ \text{A/m}^2$.

(b) $E = \rho J = (1.72\times10^{-8}\ \Omega\cdot\text{m})(6.81\times10^5\ \text{A/m}^2) = 0.012\ \text{V/m}$.

(c) The time to travel the wire's length l is

$$t = \frac{l}{v_d} = \frac{ln|q|A}{I} = \frac{(4.0\ \text{m})(8.5\times10^{28}/\text{m}^3)(1.6\times10^{-19}\ \text{C})(2.3\times10^{-3}\ \text{m})^2}{3.6\ \text{A}} = 8.0\times10^4\ \text{s}.$$

$t = 1333\ \text{min} \approx 22\ \text{hrs!}$

EVALUATE: The currents propagate very quickly along the wire but the individual electrons travel very slowly.

25.15. **IDENTIFY:** Knowing the resistivity of a metal, its geometry and the current through it, we can use Ohm's law to find the potential difference across it.

SET UP: $V = IR$. For copper, Table 25.1 gives that $\rho = 1.72\times10^{-8}\ \Omega\cdot\text{m}$ and for silver, $\rho = 1.47\times10^{-8}\ \Omega\cdot\text{m}$. $R = \dfrac{\rho L}{A}$.

EXECUTE: **(a)** $R = \dfrac{\rho L}{A} = \dfrac{(1.72\times10^{-8}\ \Omega\cdot\text{m})(2.00\ \text{m})}{\pi(0.814\times10^{-3}\ \text{m})^2} = 1.65\times10^{-2}\ \Omega$.

$V = (12.5\times10^{-3}\ \text{A})(1.65\times10^{-2}\ \Omega) = 2.06\times10^{-4}\ \text{V}$.

(b) $V = \dfrac{I\rho L}{A}$. $\dfrac{V}{\rho} = \dfrac{IL}{A} = \text{constant}$, so $\dfrac{V_s}{\rho_s} = \dfrac{V_c}{\rho_c}$.

$$V_s = V_c\left(\frac{\rho_s}{\rho_c}\right) = (2.06\times10^{-4}\ \text{V})\left(\frac{1.47\times10^{-8}\ \Omega\cdot\text{m}}{1.72\times10^{-8}\ \Omega\cdot\text{m}}\right) = 1.76\times10^{-4}\ \text{V}.$$

EVALUATE: The potential difference across a 2-m length of wire is less than 0.2 mV, so normally we do not need to worry about these potential drops in laboratory circuits.

25.16. IDENTIFY: The resistivity of the wire should identify what the material is.
SET UP: $R = \rho L/A$ and the radius of the wire is half its diameter.
EXECUTE: Solve for ρ and substitute the numerical values.

$$\rho = AR/L = \pi(D/2)^2 R/L = \frac{\pi([0.00205\ \text{m}]/2)^2(0.0290\ \Omega)}{6.50\ \text{m}} = 1.47\times10^{-8}\ \Omega\cdot\text{m}$$

EVALUATE: This result is the same as the resistivity of silver, which implies that the material is silver.

25.17. IDENTIFY: We want to compare the electric field in two metals.

SET UP and **EXECUTE:** $\rho = E/J$ and $J = I/A$. $E = \rho J = \rho\left(\dfrac{I}{A}\right) = \dfrac{\rho I}{\pi r^2}$. The current I is the same for both wires, and we get the resistivities from Table 25.1.

$$\frac{E_{\text{Cu}}}{E_{\text{Ag}}} = \frac{\rho_{\text{Cu}} I/\pi r_{\text{Cu}}^2}{\rho_{\text{Ag}} I/\pi r_{\text{Ag}}^2} = \left(\frac{\rho_{\text{Cu}}}{\rho_{\text{Ag}}}\right)\left(\frac{r_{\text{Ag}}}{r_{\text{Cu}}}\right)^2 = \left(\frac{1.72}{1.47}\right)\left(\frac{0.500}{0.800}\right)^2 = 0.457.$$

EVALUATE: The field in copper is about half the field in silver.

25.18. IDENTIFY: The geometry of the wire is changed, so its resistance will also change.

SET UP: $R = \dfrac{\rho L}{A}$. $L_{\text{new}} = 3L$. The volume of the wire remains the same when it is stretched.

EXECUTE: Volume $= LA$ so $LA = L_{\text{new}}A_{\text{new}}$. $A_{\text{new}} = \dfrac{L}{L_{\text{new}}}A = \dfrac{A}{3}$.

$$R_{\text{new}} = \frac{\rho L_{\text{new}}}{A_{\text{new}}} = \frac{\rho(3L)}{A/3} = 9\frac{\rho L}{A} = 9R.$$

EVALUATE: When the length increases the resistance increases and when the area decreases the resistance increases.

25.19. IDENTIFY: $R = \dfrac{\rho L}{A}$.

SET UP: For copper, $\rho = 1.72\times10^{-8}\ \Omega\cdot\text{m}$. $A = \pi r^2$.

EXECUTE: $R = \dfrac{(1.72\times10^{-8}\ \Omega\cdot\text{m})(24.0\ \text{m})}{\pi(1.025\times10^{-3}\ \text{m})^2} = 0.125\ \Omega.$

EVALUATE: The resistance is proportional to the length of the piece of wire.

25.20. IDENTIFY: $R = \dfrac{\rho L}{A} = \dfrac{\rho L}{\pi d^2/4}$.

SET UP: For aluminum, $\rho_{\text{al}} = 2.75\times10^{-8}\ \Omega\cdot\text{m}$. For copper, $\rho_c = 1.72\times10^{-8}\ \Omega\cdot\text{m}$.

EXECUTE: $\dfrac{\rho}{d^2} = \dfrac{R\pi}{4L} =$ constant, so $\dfrac{\rho_{\text{al}}}{d_{\text{al}}^2} = \dfrac{\rho_c}{d_c^2}$.

$$d_c = d_{\text{al}}\sqrt{\frac{\rho_c}{\rho_{\text{al}}}} = (2.14\ \text{mm})\sqrt{\frac{1.72\times10^{-8}\ \Omega\cdot\text{m}}{2.75\times10^{-8}\ \Omega\cdot\text{m}}} = 1.69\ \text{mm}.$$

EVALUATE: Copper has a smaller resistivity, so the copper wire has a smaller diameter in order to have the same resistance as the aluminum wire.

25.21. IDENTIFY and SET UP: The equation $\rho = E/J$ relates the electric field that is given to the current density. $V = EL$ gives the potential difference across a length L of wire and $V = IR$ allows us to calculate R.

EXECUTE: (a) $\rho = E/J$ so $J = E/\rho$.

From Table 25.1 the resistivity for gold is $2.44\times10^{-8}\ \Omega\cdot\text{m}$.

$$J = \frac{E}{\rho} = \frac{0.49\ \text{V/m}}{2.44\times10^{-8}\ \Omega\cdot\text{m}} = 2.008\times10^{7}\ \text{A/m}^2.$$

$I = JA = J\pi r^2 = (2.008\times10^{7}\ \text{A/m}^2)\pi(0.42\times10^{-3}\ \text{m})^2 = 11\ \text{A}.$

(b) $V = EL = (0.49\ \text{V/m})(6.4\ \text{m}) = 3.1\ \text{V}.$

(c) We can use Ohm's law: $V = IR$.

$$R = \frac{V}{I} = \frac{3.1\ \text{V}}{11\ \text{A}} = 0.28\ \Omega.$$

EVALUATE: We can also calculate R from the resistivity and the dimensions of the wire:

$$R = \frac{\rho L}{A} = \frac{\rho L}{\pi r^2} = \frac{(2.44\times10^{-8}\ \Omega\cdot\text{m})(6.4\ \text{m})}{\pi(0.42\times10^{-3}\ \text{m})^2} = 0.28\ \Omega,\ \text{which checks.}$$

25.22. IDENTIFY: Apply $R = \dfrac{\rho L}{A}$ and $V = IR$.

SET UP: $A = \pi r^2$.

EXECUTE: $\rho = \dfrac{RA}{L} = \dfrac{VA}{IL} = \dfrac{(4.50\ \text{V})\pi(6.54\times10^{-4}\ \text{m})^2}{(17.6\ \text{A})(2.50\ \text{m})} = 1.37\times10^{-7}\ \Omega\cdot\text{m}.$

EVALUATE: Our result for ρ shows that the wire is made of a metal with resistivity greater than that of good metallic conductors such as copper and aluminum.

25.23. IDENTIFY: Apply $R = R_0[1+\alpha(T-T_0)]$ to calculate the resistance at the second temperature.

(a) SET UP: $\alpha = 0.0004\ (\text{C}°)^{-1}$ (Table 25.2). Let T_0 be 0.0°C and T be 11.5°C.

EXECUTE: $R_0 = \dfrac{R}{1+\alpha(T-T_0)} = \dfrac{100.0\ \Omega}{1+(0.0004\ (\text{C}°)^{-1}(11.5\ \text{C}°))} = 99.54\ \Omega.$

(b) SET UP: $\alpha = -0.0005\ (\text{C}°)^{-1}$ (Table 25.2). Let $T_0 = 0.0°\text{C}$ and $T = 25.8°\text{C}$.

EXECUTE: $R = R_0[1+\alpha(T-T_0)] = 0.0160\ \Omega[1+(-0.0005\ (\text{C}°)^{-1})(25.8\ \text{C}°)] = 0.0158\ \Omega.$

EVALUATE: Nichrome, like most metallic conductors, has a positive α and its resistance increases with temperature. For carbon, α is negative and its resistance decreases as T increases.

25.24. IDENTIFY: $R_T = R_0[1+\alpha(T-T_0)]$.

SET UP: $R_0 = 217.3\ \Omega$. $R_T = 215.8\ \Omega$. For carbon, $\alpha = -0.00050(\text{C}°)^{-1}$.

EXECUTE: $T - T_0 = \dfrac{(R_T/R_0)-1}{\alpha} = \dfrac{(215.8\ \Omega/217.3\ \Omega)-1}{-0.00050\ (\text{C}°)^{-1}} = 13.8\ \text{C}°.$ $T = 13.8\ \text{C}° + 4.0°\text{C} = 17.8°\text{C}.$

EVALUATE: For carbon, α is negative so R decreases as T increases.

25.25. IDENTIFY: Use $R = \dfrac{\rho L}{A}$ to calculate R and then apply $V = IR$. $P = VI$ and energy $= Pt$.

SET UP: For copper, $\rho = 1.72\times10^{-8}\ \Omega\cdot\text{m}$. $A = \pi r^2$, where $r = 0.050$ m.

EXECUTE: **(a)** $R = \dfrac{\rho L}{A} = \dfrac{(1.72\times10^{-8}\ \Omega\cdot\text{m})(100\times10^{3}\text{m})}{\pi(0.050\ \text{m})^{2}} = 0.219\ \Omega.$

$V = IR = (125\ \text{A})(0.219\ \Omega) = 27.4\ \text{V}.$

(b) $P = VI = (27.4\ \text{V})(125\ \text{A}) = 3422\ \text{W} = 3422\ \text{J/s}$ and energy $= Pt = (3422\ \text{J/s})(3600\ \text{s}) = 1.23\times10^{7}\ \text{J}.$

EVALUATE: The rate of electrical energy loss in the cable is large, over 3 kW.

25.26. **IDENTIFY:** When current passes through a battery in the direction from the $-$ terminal toward the + terminal, the terminal voltage V_{ab} of the battery is $V_{ab} = \mathcal{E} - Ir.$ Also, $V_{ab} = IR,$ the potential across the circuit resistor.

SET UP: $\mathcal{E} = 24.0\ \text{V}.$ $I = 4.00\ \text{A}.$

EXECUTE: **(a)** $V_{ab} = \mathcal{E} - Ir$ gives $r = \dfrac{\mathcal{E} - V_{ab}}{I} = \dfrac{24.0\ \text{V} - 21.2\ \text{V}}{4.00\ \text{A}} = 0.700\ \Omega.$

(b) $V_{ab} - IR = 0$ so $R = \dfrac{V_{ab}}{I} = \dfrac{21.2\ \text{V}}{4.00\ \text{A}} = 5.30\ \Omega.$

EVALUATE: The voltage drop across the internal resistance of the battery causes the terminal voltage of the battery to be less than its emf. The total resistance in the circuit is $R + r = 6.00\ \Omega.$

$I = \dfrac{24.0\ \text{V}}{6.00\ \Omega} = 4.00\ \text{A},$ which agrees with the value specified in the problem.

25.27. **IDENTIFY:** The terminal voltage of the battery is $V_{ab} = \mathcal{E} - Ir.$ The voltmeter reads the potential difference between its terminals.

SET UP: An ideal voltmeter has infinite resistance.

EXECUTE: **(a)** Since an ideal voltmeter has infinite resistance, so there would be NO current through the $2.0\ \Omega$ resistor.

(b) $V_{ab} = \mathcal{E} = 5.0\ \text{V};$ Since there is no current there is no voltage lost over the internal resistance.

(c) The voltmeter reading is therefore 5.0 V since with no current flowing there is no voltage drop across either resistor.

EVALUATE: This not the proper way to connect a voltmeter. If we wish to measure the terminal voltage of the battery in a circuit that does not include the voltmeter, then connect the voltmeter across the terminals of the battery.

25.28. **IDENTIFY:** The *idealized* ammeter has no resistance so there is no potential drop across it. Therefore it acts like a short circuit across the terminals of the battery and removes the $4.00\text{-}\Omega$ resistor from the circuit. Thus the only resistance in the circuit is the $2.00\text{-}\Omega$ internal resistance of the battery.

SET UP: Use Ohm's law: $I = \mathcal{E}/r.$

EXECUTE: **(a)** $I = (10.0\ \text{V})/(2.00\ \Omega) = 5.00\ \text{A}.$

(b) The zero-resistance ammeter is in parallel with the $4.00\text{-}\Omega$ resistor, so all the current goes through the ammeter. If no current goes through the $4.00\text{-}\Omega$ resistor, the potential drop across it must be zero.

(c) The terminal voltage is zero since there is no potential drop across the ammeter.

EVALUATE: An ammeter should *never* be connected this way because it would seriously alter the circuit!

25.29. **IDENTIFY:** The voltmeter reads the potential difference V_{ab} between the terminals of the battery.

SET UP: open circuit: $I = 0.$ The circuit is sketched in Figure 25.29a.

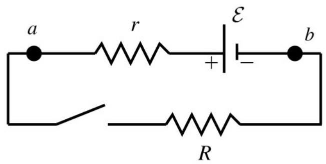

Figure 25.29a

EXECUTE: $V_{ab} = \mathcal{E} = 3.08$ V.

SET UP: switch closed: The circuit is sketched in Figure 25.29b.

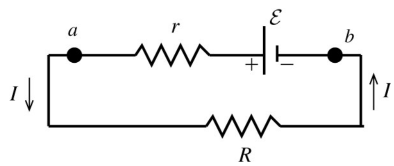

Figure 25.29b

EXECUTE: $V_{ab} = \mathcal{E} - Ir = 2.97$ V.

$r = \dfrac{\mathcal{E} - 2.97\text{ V}}{I}.$

$r = \dfrac{3.08\text{ V} - 2.97\text{ V}}{1.65\text{ A}} = 0.067\ \Omega.$

And $V_{ab} = IR$ so $R = \dfrac{V_{ab}}{I} = \dfrac{2.97\text{ V}}{1.65\text{ A}} = 1.80\ \Omega.$

EVALUATE: When current flows through the battery there is a voltage drop across its internal resistance and its terminal voltage V is less than its emf.

25.30. **IDENTIFY:** The sum of the potential changes around the circuit loop is zero. Potential decreases by IR when going through a resistor in the direction of the current and increases by $\mathcal{E}$ when passing through an emf in the direction from the $-$ to $+$ terminal.

SET UP: The current is counterclockwise, because the 16-V battery determines the direction of current flow.

EXECUTE: $+16.0\text{ V} - 8.0\text{ V} - I(1.6\ \Omega + 5.0\ \Omega + 1.4\ \Omega + 9.0\ \Omega) = 0.$

$$I = \frac{16.0\text{ V} - 8.0\text{ V}}{1.6\ \Omega + 5.0\ \Omega + 1.4\ \Omega + 9.0\ \Omega} = 0.47\text{ A}.$$

(b) $V_b + 16.0\text{ V} - I(1.6\ \Omega) = V_a$, so $V_a - V_b = V_{ab} = 16.0\text{ V} - (1.6\ \Omega)(0.47\text{ A}) = 15.2\text{ V}.$

(c) $V_c + 8.0\text{ V} + I(1.4\ \Omega + 5.0\ \Omega) = V_a$ so $V_{ac} = (5.0\ \Omega)(0.47\text{ A}) + (1.4\ \Omega)(0.47\text{ A}) + 8.0\text{ V} = 11.0\text{ V}.$

(d) The graph is sketched in Figure 25.30.

EVALUATE: $V_{cb} = (0.47\text{ A})(9.0\ \Omega) = 4.2\text{ V}.$ The potential at point b is 15.2 V below the potential at point a and the potential at point c is 11.0 V below the potential at point a, so the potential of point c is $15.2\text{ V} - 11.0\text{ V} = 4.2\text{ V}$ above the potential of point b.

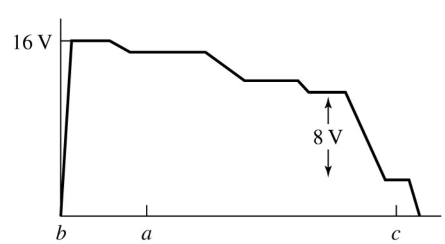

Figure 25.30

25.31. **(a) IDENTIFY and SET UP:** Assume that the current is clockwise. The circuit is sketched in Figure 25.31a.

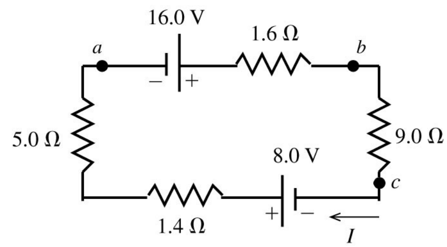

Figure 25.31a

Add up the potential rises and drops as travel clockwise around the circuit.

EXECUTE: $16.0\text{ V} - I(1.6\ \Omega) - I(9.0\ \Omega) + 8.0\text{ V} - I(1.4\ \Omega) - I(5.0\ \Omega) = 0.$

$$I = \frac{16.0\text{ V} + 8.0\text{ V}}{9.0\ \Omega + 1.4\ \Omega + 5.0\ \Omega + 1.6\ \Omega} = \frac{24.0\text{ V}}{17.0\ \Omega} = 1.41\text{ A, clockwise.}$$

EVALUATE: The 16.0-V battery and the 8.0-V battery both drive the current in the same direction.

(b) IDENTIFY and SET UP: Start at point *a* and travel through the battery to point *b*, keeping track of the potential changes. At point *b* the potential is V_b.

EXECUTE: $V_a + 16.0\text{ V} - I(1.6\ \Omega) = V_b.$

$V_a - V_b = -16.0\text{ V} + (1.41\text{ A})(1.6\ \Omega).$

$V_{ab} = -16.0\text{ V} + 2.3\text{ V} = -13.7\text{ V}$ (point *a* is at lower potential; it is the negative terminal). Therefore, $V_{ba} = 13.7\text{V}.$

EVALUATE: Could also go counterclockwise from *a* to *b:*

$V_a + (1.41\text{ A})(5.0\ \Omega) + (1.41\text{ A})(1.4\ \Omega) - 8.0\text{ V} + (1.41\text{ A})(9.0\ \Omega) = V_b.$

$V_{ab} = -13.7\text{ V},$ which checks.

(c) IDENTIFY and SET UP: Start at point *a* and travel through the battery to point *c*, keeping track of the potential changes.

EXECUTE: $V_a + 16.0\text{ V} - I(1.6\ \Omega) - I(9.0\ \Omega) = V_c.$

$V_a - V_c = -16.0\text{ V} + (1.41\text{ A})(1.6\ \Omega + 9.0\ \Omega).$

$V_{ac} = -16.0\text{ V} + 15.0\text{ V} = -1.0\text{ V}$ (point *a* is at lower potential than point *c*).

EVALUATE: Could also go counterclockwise from *a* to *c*:

$V_a + (1.41\text{ A})(5.0\ \Omega) + (1.41\text{ A})(1.4\ \Omega) - 8.0\text{ V} = V_c.$

$V_{ac} = -1.0\text{ V},$ which checks.

(d) Call the potential zero at point *a*. Travel clockwise around the circuit. The graph is sketched in Figure 25.31b.

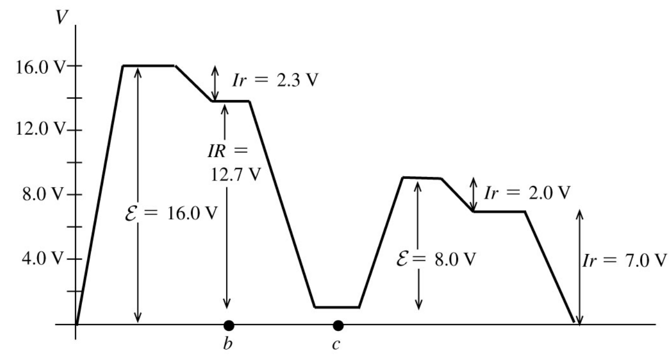

Figure 25.31b

25.32. **IDENTIFY:** This problem involves the internal resistance of a battery.

SET UP: $\mathcal{E} = (R+r)I, I = V_R / R$. The internal resistance is the target variable.

EXECUTE: $I = V_R/R = (27.0\text{ V})/(9.00\ \Omega) = 3.00\text{ A}$. Solve for r: $r = \dfrac{\mathcal{E}}{I} - R$.

$$r = \frac{30.0\text{ V}}{3.00\text{ A}} - 9.00\ \Omega = 1.0\ \Omega.$$

EVALUATE: If there were no internal resistance the current would be (30.0 V)/(9.00 Ω) = 3.33 A and V_R would be 30.0 V. The internal resistance makes a significant difference in the circuit.

25.33. **IDENTIFY:** This problem involves the internal resistance of a battery.

SET UP: $\mathcal{E} = (R+r)I,\ P = I^2R$. The target variable is the external resistance R.

EXECUTE: $P = I^2R = \left(\dfrac{\mathcal{E}}{R+r}\right)^2 R$. $\mathcal{E}^2R = P(R^2 + 2rR + r^2)$. Putting in the given values and solving this quadratic equation for R gives $R = 0.429\ \Omega$ and $R = 21.0\ \Omega$.

EVALUATE: To check, apply $P = I^2R = \left(\dfrac{\mathcal{E}}{R+r}\right)^2 R$ for both resistances.

$$P = I^2R = \left(\frac{24.0\text{ V}}{3.429\ \Omega}\right)^2 (0.429\ \Omega) = 21\text{ W} \text{ and } P = \left(\frac{24.0\text{ V}}{24.0\ \Omega}\right)^2 (21.0\ \Omega) = 21\text{ W}.$$ Both answers check.

25.34. **IDENTIFY** and **SET UP:** The resistance is the same in both cases, and $P = V^2/R$.

EXECUTE: **(a)** Solving $P = V^2/R$ for R, gives $R = V^2/P$. Since the resistance is the same in both cases, we have $\dfrac{V_1^2}{P_1} = \dfrac{V_2^2}{P_2}$. Solving for P_2 gives $P_2 = P_1(V_2/V_1)^2 = (0.0625\text{ W})[(12.5\text{ V})/(1.50\text{ V})]^2 = 4.41$ W.

(b) Solving for V_2 gives $V_2 = V_1\sqrt{\dfrac{P_2}{P_1}} = (1.50\text{ V})\sqrt{\dfrac{5.00\text{ W}}{0.0625\text{ W}}} = 13.4\text{ V}$.

EVALUATE: These calculations are correct assuming that the resistor obeys Ohm's law throughout the range of currents involved.

25.35. **IDENTIFY:** The bulbs are each connected across a 120-V potential difference.

SET UP: Use $P = V^2/R$ to solve for R and Ohm's law $(I = V/R)$ to find the current.

EXECUTE: **(a)** $R = V^2/P = (120\text{ V})^2/(100\text{ W}) = 144\ \Omega$.

(b) $R = V^2/P = (120\text{ V})^2/(60\text{ W}) = 240\ \Omega$.

(c) For the 100-W bulb: $I = V/R = (120\text{ V})/(144\ \Omega) = 0.833\text{ A}$.

For the 60-W bulb: $I = (120\ \text{V})/(240\ \Omega) = 0.500\ \text{A}$.

EVALUATE: The 60-W bulb has *more* resistance than the 100-W bulb, so it draws less current.

25.36. **IDENTIFY:** Across 120 V, a 75-W bulb dissipates 75 W. Use this fact to find its resistance, and then find the power the bulb dissipates across 220 V.

SET UP: $P = V^2/R$, so $R = V^2/P$.

EXECUTE: Across 120 V: $R = (120\ \text{V})^2/(75\ \text{W}) = 192\ \Omega$. Across a 220-V line, its power will be $P = V^2/R = (220\ \text{V})^2/(192\ \Omega) = 252\ \text{W}$.

EVALUATE: The bulb dissipates much more power across 220 V, so it would likely blow out at the higher voltage. An alternative solution to the problem is to take the ratio of the powers.

$\dfrac{P_{220}}{P_{120}} = \dfrac{V_{220}^2/R}{V_{120}^2/R} = \left(\dfrac{V_{220}}{V_{120}}\right)^2 = \left(\dfrac{220}{120}\right)^2$. This gives $P_{220} = (75\ \text{W})\left(\dfrac{220}{120}\right)^2 = 252\ \text{W}$.

25.37. **IDENTIFY:** A "100-W" European bulb dissipates 100 W when used across 220 V.

(a) SET UP: Take the ratio of the power in the U.S. to the power in Europe, as in the alternative method for Problem 25.36, using $P = V^2/R$.

EXECUTE: $\dfrac{P_{\text{US}}}{P_{\text{E}}} = \dfrac{V_{\text{US}}^2/R}{V_{\text{E}}^2/R} = \left(\dfrac{V_{\text{US}}}{V_{\text{E}}}\right)^2 = \left(\dfrac{120\ \text{V}}{220\ \text{V}}\right)^2$. This gives $P_{\text{US}} = (100\ \text{W})\left(\dfrac{120\ \text{V}}{220\ \text{V}}\right)^2 = 29.8\ \text{W}$.

(b) SET UP: Use $P = IV$ to find the current.

EXECUTE: $I = P/V = (29.8\ \text{W})/(120\ \text{V}) = 0.248\ \text{A}$.

EVALUATE: The bulb draws considerably less power in the U.S., so it would be much dimmer than in Europe.

25.38. **IDENTIFY:** $P = VI$. Energy $= Pt$.

SET UP: $P = (9.0\ \text{V})(0.13\ \text{A}) = 1.17\ \text{W}$.

EXECUTE: Energy $= (1.17\ \text{W})(30\ \text{min})(60\ \text{s/min}) = 2100\ \text{J}$.

EVALUATE: The energy consumed is proportional to the voltage, to the current and to the time.

25.39. **IDENTIFY:** Calculate the current in the circuit. The power output of a battery is its terminal voltage times the current through it. The power dissipated in a resistor is I^2R.

SET UP: The sum of the potential changes around the circuit is zero.

EXECUTE: **(a)** $I = \dfrac{8.0\ \text{V}}{17\ \Omega} = 0.47\ \text{A}$. Then $P_{5\Omega} = I^2R = (0.47\ \text{A})^2(5.0\ \Omega) = 1.1\ \text{W}$ and $P_{9\Omega} = I^2R = (0.47\ \text{A})^2(9.0\ \Omega) = 2.0\ \text{W}$, so the total is 3.1 W.

(b) $P_{16\text{V}} = \mathcal{E}I - I^2r = (16\ \text{V})(0.47\ \text{A}) - (0.47\ \text{A})^2(1.6\ \Omega) = 7.2\ \text{W}$.

(c) $P_{8\text{V}} = \mathcal{E}I + Ir^2 = (8.0\ \text{V})(0.47\ \text{A}) + (0.47\ \text{A})^2(1.4\ \Omega) = 4.1\ \text{W}$.

EVALUATE: **(d)** (b) = (a) + (c). The rate at which the 16.0-V battery delivers electrical energy to the circuit equals the rate at which it is consumed in the 8.0-V battery and the 5.0-Ω and 9.0-Ω resistors.

25.40. **IDENTIFY:** Knowing the current and potential difference, we can find the power.

SET UP: $P = VI$ and energy is the product of power and time.

EXECUTE: $P = (500\ \text{V})(80\times10^{-3}\ \text{A}) = 40\ \text{W}$.

Energy $= Pt = (40\ \text{W})(10\times10^{-3}\ \text{s}) = 0.40\ \text{J}$.

EVALUATE: The energy delivered depends not only on the voltage and current but also on the length of the pulse. The pulse is short but the voltage is large.

25.41. **IDENTIFY:** We know the current, voltage and time the current lasts, so we can calculate the power and the energy delivered.

SET UP: Power is energy per unit time. The power delivered by a voltage source is $P = V_{ab}I$.

EXECUTE: **(a)** $P = (25\text{ V})(12\text{ A}) = 300\text{ W}$.

(b) $\text{Energy} = Pt = (300\text{ W})(3.0\times 10^{-3}\text{ s}) = 0.90\text{ J}$.

EVALUATE: The energy is not very great, but it is delivered in a short time (3 ms) so the power is large, which produces a short shock.

25.42. **IDENTIFY** and **SET UP:** The average power delivered by the battery can be calculated in two different ways: $P = \dfrac{\text{energy}}{\text{time}}$ or $P = VI$. The time is 5.25 h, which in seconds is

$5.25\text{ h} = (5.25\text{ h})(3600\text{ s/h}) = 1.89\times 10^4\text{ s}$.

EXECUTE: The average power delivered by the battery is $P = \dfrac{\text{energy}}{\text{time}} = \dfrac{3.15\times 10^4\text{ J}}{1.89\times 10^4\text{ s}} = 1.6667\text{ W}$. Thus, the current must be $I = \dfrac{P}{V} = \dfrac{1.6667\text{ W}}{3.70\text{ V}} = 0.450\text{ A}$.

EVALUATE: The energy stored in the battery can be expressed in joules or watt-hours. The energy is equal to *Pt*, so we can express the stored energy as either $3.15\times 10^4\text{ J}$ or (1.6667 W)(5.25 h) = $8.75\text{ W}\cdot\text{h}$.

25.43. **(a) IDENTIFY** and **SET UP:** $P = VI$ and $\text{energy} = (\text{power})\times(\text{time})$.

EXECUTE: $P = VI = (12\text{ V})(60\text{ A}) = 720\text{ W}$.

The battery can provide this for 1.0 h, so the energy the battery has stored is

$U = Pt = (720\text{ W})(3600\text{ s}) = 2.6\times 10^6\text{ J}$.

(b) IDENTIFY and **SET UP:** For gasoline the heat of combustion is $L_c = 46\times 10^6\text{ J/kg}$. Solve for the mass *m* required to supply the energy calculated in part (a) and use density $\rho = m/V$ to calculate *V*.

EXECUTE: The mass of gasoline that supplies $2.6\times 10^6\text{ J}$ is $m = \dfrac{2.6\times 10^6\text{ J}}{46\times 10^6\text{ J/kg}} = 0.0565\text{ kg}$.

The volume of this mass of gasoline is

$$V = \frac{m}{\rho} = \frac{0.0565\text{ kg}}{900\text{ kg/m}^3} = 6.3\times 10^{-5}\text{ m}^3\left(\frac{1000\text{ L}}{1\text{ m}^3}\right) = 0.063\text{ L}.$$

(c) IDENTIFY and **SET UP:** $\text{Energy} = (\text{power})\times(\text{time})$; the energy is that calculated in part (a).

EXECUTE: $U = Pt,\ t = \dfrac{U}{P} = \dfrac{2.6\times 10^6\text{ J}}{450\text{ W}} = 5800\text{ s} = 97\text{ min} = 1.6\text{ h}$.

EVALUATE: The battery discharges at a rate of 720 W (for 1.0 h) and is charged at a rate of 450 W (for 1.6 h), so it takes longer to charge than to discharge.

25.44. **IDENTIFY:** This problem involves the internal resistance of a battery.

SET UP: $\mathcal{E} = (R + r)I$, $P = I^2R$. The target variable is the emf of the battery.

EXECUTE: Solve $P = I^2R$ for *I*: $I = \sqrt{P/R} = \sqrt{\dfrac{96.0\text{ J/s}}{12.0\ \Omega}} = 2.8284\text{ A}$. Now find the emf:

$\mathcal{E} = (R + r)I =$ (14.0 Ω)(2.8284 A) = 39.6 V.

EVALUATE: The power the battery produces is $P = I\mathcal{E}$ = (2.8284 A)(39.6 V) = 112 W. So the power lost in the internal resistance is 112 W – 96 W = 16 W. We can also get this using $P = I^2R$ = (2.8284 A)^2(2.00 Ω) = 16 W.

25.45. **IDENTIFY:** Some of the power generated by the internal emf of the battery is dissipated across the battery's internal resistance, so it is not available to the bulb.

SET UP: Use $P = I^2R$ and take the ratio of the power dissipated in the internal resistance r to the total power.

EXECUTE: $\dfrac{P_r}{P_{\text{Total}}} = \dfrac{I^2r}{I^2(r+R)} = \dfrac{r}{r+R} = \dfrac{3.5\ \Omega}{28.5\ \Omega} = 0.123 = 12.3\%.$

EVALUATE: About 88% of the power of the battery goes to the bulb. The rest appears as heat in the internal resistance.

25.46. **IDENTIFY:** The power delivered to the bulb is I^2R. Energy $= Pt$.

SET UP: The circuit is sketched in Figure 25.46. r_{total} is the combined internal resistance of both batteries.

EXECUTE: **(a)** $r_{\text{total}} = 0$. The sum of the potential changes around the circuit is zero, so $1.5\ \text{V} + 1.5\ \text{V} - I(17\ \Omega) = 0$. $I = 0.1765\ \text{A}$. $P = I^2R = (0.1765\ \text{A})^2(17\ \Omega) = 0.530\ \text{W}$. This is also $(3.0\ \text{V})(0.1765\ \text{A})$.

(b) Energy $= (0.530\ \text{W})(5.0\ \text{h})(3600\ \text{s/h}) = 9540\ \text{J}$.

(c) $P = \dfrac{0.530\ \text{W}}{2} = 0.265\ \text{W}$. $P = I^2R$ so $I = \sqrt{\dfrac{P}{R}} = \sqrt{\dfrac{0.265\ \text{W}}{17\ \Omega}} = 0.125\ \text{A}$.

The sum of the potential changes around the circuit is zero, so $1.5\ \text{V} + 1.5\ \text{V} - IR - Ir_{\text{total}} = 0$.

$r_{\text{total}} = \dfrac{3.0\ \text{V} - (0.125\ \text{A})(17\ \Omega)}{0.125\ \text{A}} = 7.0\ \Omega.$

EVALUATE: When the power to the bulb has decreased to half its initial value, the total internal resistance of the two batteries is nearly half the resistance of the bulb. Compared to a single battery, using two identical batteries in series doubles the emf but also doubles the total internal resistance.

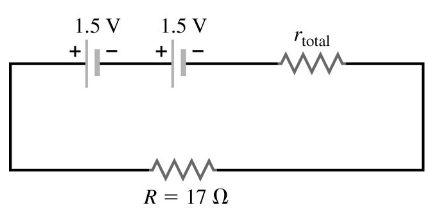

Figure 25.46

25.47. **IDENTIFY:** Solve for the current I in the circuit. Apply $P = VI = I^2R$ to the specified circuit elements to find the rates of energy conversion.

SET UP: The circuit is sketched in Figure 25.47.

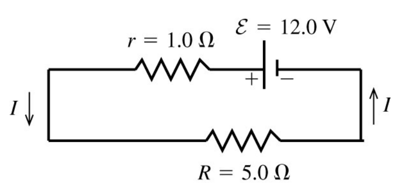

Figure 25.47

EXECUTE: Compute I:

$\mathcal{E} - Ir - IR = 0.$

$I = \dfrac{\mathcal{E}}{r+R} = \dfrac{12.0\ \text{V}}{1.0\ \Omega + 5.0\ \Omega} = 2.00\ \text{A}.$

(a) The rate of conversion of chemical energy to electrical energy in the emf of the battery is $P = \mathcal{E}I = (12.0\ \text{V})(2.00\ \text{A}) = 24.0\ \text{W}$.

(b) The rate of dissipation of electrical energy in the internal resistance of the battery is $P = I^2 r = (2.00\ \text{A})^2 (1.0\ \Omega) = 4.0\ \text{W}$.

(c) The rate of dissipation of electrical energy in the external resistor R is $P = I^2 R = (2.00\ \text{A})^2 (5.0\ \Omega) = 20.0\ \text{W}$.

EVALUATE: The rate of production of electrical energy in the circuit is 24.0 W. The total rate of consumption of electrical energy in the circuit is $4.00\ \text{W} + 20.0\ \text{W} = 24.0\ \text{W}$. Equal rates of production and consumption of electrical energy are required by energy conservation.

25.48. **IDENTIFY:** $P = I^2 R = \dfrac{V^2}{R} = VI$. $V = IR$.

SET UP: The heater consumes 540 W when $V = 120$ V. Energy $= Pt$.

EXECUTE: **(a)** $P = \dfrac{V^2}{R}$ so $R = \dfrac{V^2}{P} = \dfrac{(120\ \text{V})^2}{540\ \text{W}} = 26.7\ \Omega$.

(b) $P = VI$ so $I = \dfrac{P}{V} = \dfrac{540\ \text{W}}{120\ \text{V}} = 4.50\ \text{A}$.

(c) Assuming that R remains $26.7\ \Omega$, $P = \dfrac{V^2}{R} = \dfrac{(110\ \text{V})^2}{26.7\ \Omega} = 453\ \text{W}$. P is smaller by a factor of $(110/120)^2$.

EVALUATE: **(d)** With the lower line voltage the current will decrease and the operating temperature will decrease. R will be less than $26.7\ \Omega$ and the power consumed will be greater than the value calculated in part (c).

25.49. **IDENTIFY:** The resistivity is $\rho = \dfrac{m}{ne^2\tau}$.

SET UP: For silicon, $\rho = 2300\ \Omega \cdot \text{m}$.

EXECUTE: **(a)** $\tau = \dfrac{m}{ne^2\rho} = \dfrac{9.11\times10^{-31}\ \text{kg}}{(1.0\times10^{16}\ \text{m}^{-3})(1.60\times10^{-19}\ \text{C})^2(2300\ \Omega\cdot\text{m})} = 1.55\times10^{-12}\ \text{s}$.

EVALUATE: **(b)** The number of free electrons in copper $(8.5\times10^{28}\ \text{m}^{-3})$ is much larger than in pure silicon $(1.0\times10^{16}\ \text{m}^{-3})$. A smaller density of current carriers means a higher resistivity.

25.50. **IDENTIFY:** We are investigating a cell phone.

SET UP and **EXECUTE:** **(a)** Charge capacity = 2600 mAh, energy = 9.88 Wh, and potential rating = 3.8 V.

(b) 2600 mAh = (2.6 A)(3600 s) = 9360 C.

(c) (9.88 Wh)(9.88 J/s)(3600 s) = 35.6 kJ.

(d) qV = (9360 C)(3.8 V) = 35.6 kJ. They are equivalent.

(e) $C = Q/V$ = (9360 C)/(3.8 V) = 2460 F.

(f) $U = mc\Delta T \rightarrow \Delta T = U / mc$. m = 1.0 kg. $\Delta T = \dfrac{35.6\ \text{kJ}}{(1.0\ \text{kg})(4190\ \text{J/kg}\cdot\text{K})} = 8.5\ \text{C}°$.

EVALUATE: A capacitance of 2460 F would be very large!

25.51. **(a) IDENTIFY** and **SET UP:** Use $V_{ab} = \mathcal{E} - rI$.

EXECUTE: $\rho = \dfrac{RA}{L} = \dfrac{(0.104\ \Omega)\pi(1.25\times10^{-3}\ \text{m})^2}{14.0\ \text{m}} = 3.65\times10^{-8}\ \Omega\cdot\text{m}$.

EVALUATE: This value is similar to that for good metallic conductors in Table 25.1.

(b) IDENTIFY and **SET UP:** Use $V = EL$ to calculate E and then Ohm's law gives I.

EXECUTE: $V = EL = (1.28\ \text{V/m})(14.0\ \text{m}) = 17.9\ \text{V}$.

$I = \dfrac{V}{R} = \dfrac{17.9\text{ V}}{0.104\ \Omega} = 172\text{ A}.$

EVALUATE: We could do the calculation another way:

$E = \rho J$ so $J = \dfrac{E}{\rho} = \dfrac{1.28\text{ V/m}}{3.65\times10^{-8}\ \Omega\cdot\text{m}} = 3.51\times10^{7}\ \text{A/m}^2.$

$I = JA = (3.51\times10^{7}\ \text{A/m}^2)\pi(1.25\times10^{-3}\ \text{m})^2 = 172\text{ A},$ which checks.

(c) IDENTIFY and SET UP: Calculate $J = I/A$ or $J = E/\rho$ and then use Eq. (25.3) for the target variable v_d.

EXECUTE: $J = n|q|v_\text{d} = nev_\text{d}.$

$v_\text{d} = \dfrac{J}{ne} = \dfrac{3.51\times10^{7}\ \text{A/m}^2}{(8.5\times10^{28}\ \text{m}^{-3})(1.602\times10^{-19}\ \text{C})} = 2.58\times10^{-3}\ \text{m/s} = 2.58\ \text{mm/s}.$

EVALUATE: Even for this very large current the drift speed is small.

25.52. **IDENTIFY:** We are investigating a hot water heater.

SET UP and EXECUTE: **(a)** Estimate: 50 gal = (50)(3.788 L) = 190 L.

(b) $Q = mc\Delta T$ = (190 kg)(4190 J/kg · K)(25 C°) = 20 MJ.

(c) $P = Q/t$ = (20 MJ)/[(1.5)(3600 s)] = 3.7 kW.

(d) $I = P/V$ = (3.7 kW)/(220 V) = 17 A.

(e) $R = V/I$ = (220 V)/(17 A) = 13 Ω.

EVALUATE: Since $P = V^2/R$, for a given voltage we need a small resistance to have a large power.

25.53. **IDENTIFY and SET UP:** With the voltmeter connected across the terminals of the battery there is no current through the battery and the voltmeter reading is the battery emf; $\mathcal{E} = 12.6\text{ V}.$

With a wire of resistance R connected to the battery current I flows and $\mathcal{E} - Ir - IR = 0,$ where r is the internal resistance of the battery. Apply this equation to each piece of wire to get two equations in the two unknowns.

EXECUTE: Call the resistance of the 20.0-m piece R_1; then the resistance of the 40.0-m piece is $R_2 = 2R_1.$

$\mathcal{E} - I_1 r - I_1 R_1 = 0;\quad 12.6\text{ V} - (7.00\text{ A})r - (7.00\text{ A})R_1 = 0.$

$\mathcal{E} - I_2 r - I_2(2R_2) = 0;\quad 12.6\text{ V} - (4.20\text{ A})r - (4.20\text{ A})(2R_1) = 0.$

Solving these two equations in two unknowns gives $R_1 = 1.20\ \Omega.$ This is the resistance of 20.0 m, so the resistance of one meter is $[1.20\ \Omega/(20.0\text{ m})](1.00\text{ m}) = 0.060\ \Omega.$

EVALUATE: We can also solve for r and we get $r = 0.600\ \Omega.$ When measuring small resistances, the internal resistance of the battery has a large effect.

25.54. **IDENTIFY:** As the resistance R varies, the current in the circuit also varies, which causes the potential drop across the internal resistance of the battery to vary. The largest current will occur when $R = 0,$ and the smallest current will occur when $R \to \infty.$ The largest terminal voltage will occur when the current is zero ($R \to \infty$) and the smallest terminal voltage will be when the current is a maximum ($R = 0$).

SET UP: If $\mathcal{E}$ is the internal emf of the battery and r is its internal resistance, then $V_{ab} = \mathcal{E} - rI.$

EXECUTE: **(a)** As $R \to \infty,$ $I \to 0,$ so $V_{ab} \to \mathcal{E} = 15.0\text{ V},$ which is the largest reading of the voltmeter. When $R = 0,$ the current is largest at $(15.0\text{ V})/(4.00\ \Omega) = 3.75\text{ A},$ so the smallest terminal voltage is $V_{ab} = \mathcal{E} - rI = 15.0\text{ V} - (4.00\ \Omega)(3.75\text{ A}) = 0.$

(b) From part (a), the maximum current is 3.75 A when $R = 0,$ and the minimum current is 0.00 A when $R \to \infty.$

(c) The graphs are sketched in the Figure 25.54.

EVALUATE: Increasing the resistance R increases the terminal voltage, but at the same time it decreases the current in the circuit.

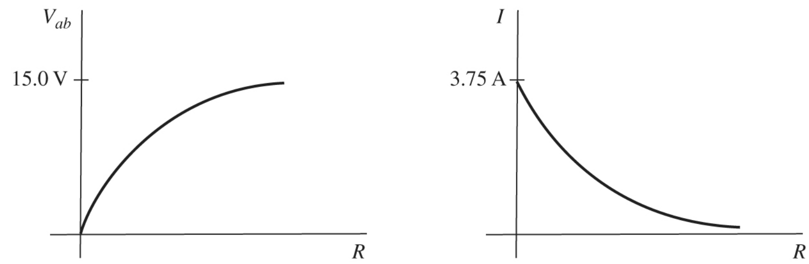

Figure 25.54

25.55. **IDENTIFY:** Conservation of charge requires that the current be the same in both sections of the wire. $E = \rho J = \dfrac{\rho I}{A}$. For each section, $V = IR = JAR = \left(\dfrac{EA}{\rho}\right)\left(\dfrac{\rho L}{A}\right) = EL$. The voltages across each section add.

SET UP: $A = (\pi/4)D^2$, where D is the diameter.

EXECUTE: **(a)** The current must be the same in both sections of the wire, so the current in the thin end is 2.5 mA.

(b) $E_{1.6\text{mm}} = \rho J = \dfrac{\rho I}{A} = \dfrac{(1.72\times10^{-8}\ \Omega\cdot\text{m})(2.5\times10^{-3}\ \text{A})}{(\pi/4)(1.6\times10^{-3}\ \text{m})^2} = 2.14\times10^{-5}\ \text{V/m}.$

(c) $E_{0.8\text{mm}} = \rho J = \dfrac{\rho I}{A} = \dfrac{(1.72\times10^{-8}\ \Omega\cdot\text{m})(2.5\times10^{-3}\ \text{A})}{(\pi/4)(0.80\times10^{-3}\ \text{m})^2} = 8.55\times10^{-5}\ \text{V/m}.$ This is $4E_{1.6\text{mm}}$.

(d)
$V = E_{1.6\text{mm}}L_{1.6\text{ mm}} + E_{0.8\text{ mm}}L_{0.8\text{ mm}}.$ $V = (2.14\times10^{-5}\ \text{V/m})(1.20\ \text{m}) + (8.55\times10^{-5}\ \text{V/m})(1.80\ \text{m}) = 1.80\times10^{-4}\ \text{V}.$

EVALUATE: The currents are the same but the current density is larger in the thinner section and the electric field is larger there.

25.56. **IDENTIFY** and **SET UP:** The voltage is the same at both temperatures since the same battery is used. The power is $P = V^2/R$ and $R = R_0(1+\alpha\Delta T)$.

EXECUTE: Since the voltage is the same, we have $V^2 = P_{80}R_{80} = P_{150}R_{150}$. Therefore $P_{80}R_0[1+\alpha(T_{80}-T_0)] = P_{150}R_0[1+\alpha(T_{150}-T_0)]$. Solving for P_{150} and putting in the numbers gives

$$P_{150} = P_{80}\frac{1+\alpha(T_{80}-T_0)}{1+\alpha(T_{150}-T_0)} = (480\ \text{W})\frac{1 + (0.0045\ \text{K}^{-1})(80°\text{C} - 20°\text{C})}{1 + (0.0045\ \text{K}^{-1})(150°\text{C} - 20°\text{C})} = 385\ \text{W}.$$

EVALUATE: This result assumes that α is the same at all the temperatures.

25.57. **IDENTIFY:** Knowing the current and the time for which it lasts, plus the resistance of the body, we can calculate the energy delivered.

SET UP: Electric energy is deposited in his body at the rate $P = I^2R$. Heat energy Q produces a temperature change ΔT according to $Q = mc\Delta T$, where $c = 4190\ \text{J/kg}\cdot\text{C°}$.

EXECUTE: **(a)** $P = I^2R = (25{,}000\ \text{A})^2(1.0\ \text{k}\Omega) = 6.25\times10^{11}\ \text{W}$. The energy deposited is $Pt = (6.15\times10^{11}\ \text{W})(40\times10^{-6}\ \text{s}) = 2.5\times10^{7}\ \text{J}$. Find ΔT when $Q = 2.5\times10^7\ \text{J}$.

$$\Delta T = \frac{Q}{mc} = \frac{2.5\times10^7\ \text{J}}{(75\ \text{kg})(4190\ \text{J/kg}\cdot\text{C°})} = 80\ \text{C°}.$$

(b) An increase of only $63\ \text{C°}$ brings the water in the body to the boiling point; part of the person's body will be vaporized.

EVALUATE: Even this approximate calculation shows that being hit by lightning is very dangerous.

25.58. **IDENTIFY:** The current in the circuit depends on R and on the internal resistance of the battery, as well as the emf of the battery. It is only the current in R that dissipates energy in the resistor R.

SET UP: $I = \dfrac{\mathcal{E}}{R+r}$, where $\mathcal{E}$ is the emf of the battery, and $P = I^2 R$.

EXECUTE: $P = I^2 R = \dfrac{\mathcal{E}^2}{(R+r)^2} R$, which gives $\mathcal{E}^2 R = (R^2 + 2Rr + r^2)P$.

$$R^2 + \left(2r - \frac{\mathcal{E}^2}{P}\right)R + r^2 = 0. \quad R = \frac{1}{2}\left[\left(\frac{\mathcal{E}^2}{P} - 2r\right) \pm \sqrt{\left(\frac{\mathcal{E}^2}{P} - 2r\right)^2 - 4r^2}\right].$$

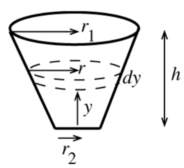
$$R = \frac{1}{2}\left[\left(\frac{(12.0\text{ V})^2}{80.0\text{ W}} - 2(0.40\,\Omega)\right) \pm \sqrt{\left(\frac{(12.0\text{ V})^2}{80.0\text{ W}} - 2(0.40\,\Omega)\right)^2 - 4(0.40\,\Omega)^2}\right].$$

$R = 0.50\,\Omega \pm 0.30\,\Omega$. $R = 0.20\,\Omega$ and $R = 0.80\,\Omega$.

EVALUATE: There are two values for R because there are two ways for the power dissipated in R to be 80 W. The power is $P = I^2 R$, so we can have a small $R(0.20\,\Omega)$ and large current, or a larger $R(0.80\,\Omega)$ and a smaller current.

25.59. **(a) IDENTIFY:** Apply $R = \dfrac{\rho L}{A}$ to calculate the resistance of each thin disk and then integrate over the truncated cone to find the total resistance.

SET UP:



EXECUTE: The radius of a truncated cone a distance y above the bottom is given by $r = r_2 + (y/h)(r_1 - r_2) = r_2 + y\beta$ with $\beta = (r_1 - r_2)/h$.

Figure 25.59

Consider a thin slice a distance y above the bottom. The slice has thickness dy and radius r (see Figure 25.59.) The resistance of the slice is $dR = \dfrac{\rho dy}{A} = \dfrac{\rho dy}{\pi r^2} = \dfrac{\rho dy}{\pi(r_2 + \beta y)^2}$.

The total resistance of the cone if obtained by integrating over these thin slices:

$$R = \int dR = \frac{\rho}{\pi}\int_0^h \frac{dy}{(r_2 + \beta y)^2} = \frac{\rho}{\pi}\left[-\frac{1}{\beta}(r_2 + y\beta)^{-1}\right]_0^h = -\frac{\rho}{\pi\beta}\left[\frac{1}{r_2 + h\beta} - \frac{1}{r_2}\right].$$

But $r_2 + h\beta = r_1$.

$$R = \frac{\rho}{\pi\beta}\left[\frac{1}{r_2} - \frac{1}{r_1}\right] = \frac{\rho}{\pi}\left(\frac{h}{r_1 - r_2}\right)\left(\frac{r_1 - r_2}{r_1 r_2}\right) = \frac{\rho h}{\pi r_1 r_2}.$$

(b) EVALUATE: Let $r_1 = r_2 = r$. Then $R = \rho h/\pi r^2 = \rho L/A$ where $A = \pi r^2$ and $L = h$. This agrees with $R = \dfrac{\rho L}{A}$.

25.60. **IDENTIFY:** Divide the region into thin spherical shells of radius r and thickness dr. The total resistance is the sum of the resistances of the thin shells and can be obtained by integration.

SET UP: $I = V/R$ and $J = I/4\pi r^2$, where $4\pi r^2$ is the surface area of a shell of radius r.

EXECUTE: **(a)** $dR = \dfrac{\rho dr}{4\pi r^2} \Rightarrow R = \dfrac{\rho}{4\pi}\displaystyle\int_a^b \dfrac{dr}{r^2} = -\dfrac{\rho}{4\pi}\dfrac{1}{r}\Bigg|_a^b = \dfrac{\rho}{4\pi}\left(\dfrac{1}{a}-\dfrac{1}{b}\right) = \dfrac{\rho}{4\pi}\left(\dfrac{b-a}{ab}\right).$

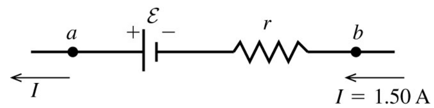
(b) $I = \dfrac{V_{ab}}{R} = \dfrac{V_{ab}4\pi ab}{\rho(b-a)}$ and $J = \dfrac{I}{A} = \dfrac{V_{ab}4\pi ab}{\rho(b-a)4\pi r^2} = \dfrac{V_{ab}ab}{\rho(b-a)r^2}.$

(c) If the thickness of the shells is small, then $4\pi ab \approx 4\pi a^2$ is the surface area of the conducting material. $R = \dfrac{\rho}{4\pi}\left(\dfrac{1}{a}-\dfrac{1}{b}\right) = \dfrac{\rho(b-a)}{4\pi ab} \approx \dfrac{\rho L}{4\pi a^2} = \dfrac{\rho L}{A},$ where $L = b-a.$

EVALUATE: The current density in the material is proportional to $1/r^2$.

25.61. **IDENTIFY:** In each case write the terminal voltage in terms of $\mathcal{E}$, I, and r. Since I is known, this gives two equations in the two unknowns $\mathcal{E}$ and r.

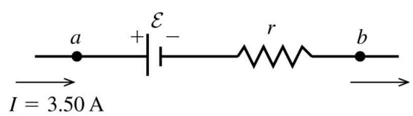
SET UP: The battery with the 1.50-A current is sketched in Figure 25.61a.



$V_{ab} = 8.40$ V.
$V_{ab} = \mathcal{E} - Ir.$
$\mathcal{E} - (1.50\text{ A})r = 8.40$ V.

Figure 25.61a

The battery with the 3.50-A current is sketched in Figure 25.61b.



$V_{ab} = 10.2$ V.
$V_{ab} = \mathcal{E} + Ir.$
$\mathcal{E} + (3.50\text{ A})r = 10.2$ V.

Figure 25.61b

EXECUTE: **(a)** Solve the first equation for $\mathcal{E}$ and use that result in the second equation:
$\mathcal{E} = 8.40\text{ V} + (1.50\text{ A})r.$

$8.40\text{ V} + (1.50\text{ A})r + (3.50\text{ A})r = 10.2\text{ V}.$

$(5.00\text{ A})r = 1.8\text{ V}$ so $r = \dfrac{1.8\text{ V}}{5.00\text{ A}} = 0.36\ \Omega.$

(b) Then $\mathcal{E} = 8.40\text{ V} + (1.50\text{ A})r = 8.40\text{ V} + (1.50\text{ A})(0.36\ \Omega) = 8.94\text{ V}.$

EVALUATE: When the current passes through the emf in the direction from $-$ to $+$, the terminal voltage is less than the emf and when it passes through from $+$ to $-$, the terminal voltage is greater than the emf.

25.62. **IDENTIFY:** Consider the potential changes around the circuit. For a complete loop the sum of the potential changes is zero.

SET UP: There is a potential drop of IR when you pass through a resistor in the direction of the current.

EXECUTE: **(a)** $I = \dfrac{8.0\text{ V} - 4.0\text{ V}}{24.0\ \Omega} = 0.167\text{ A}.$ $V_d + 8.00\text{ V} - I(0.50\ \Omega + 8.00\ \Omega) = V_a,$ so

$V_{ad} = 8.00\text{ V} - (0.167\text{ A})(8.50\ \Omega) = 6.58\text{ V}.$

(b) The terminal voltage is $V_{bc} = V_b - V_c.$ $V_c + 4.00\text{ V} + I(0.50\ \Omega) = V_b$ and

$V_{bc} = +4.00\text{ V} + (0.167\text{ A})(0.50\ \Omega) = +4.08\text{ V}.$

(c) Adding another battery at point d in the opposite sense to the 8.0-V battery produces a counterclockwise current with magnitude $I = \dfrac{10.3\ \text{V} - 8.0\ \text{V} + 4.0\ \text{V}}{24.5\ \Omega} = 0.257\ \text{A}$. Then

$V_c + 4.00\ \text{V} - I(0.50\ \Omega) = V_b$ and $V_{bc} = 4.00\ \text{V} - (0.257\ \text{A})(0.50\ \Omega) = 3.87\ \text{V}$.

EVALUATE: When current enters the battery at its negative terminal, as in part (c), the terminal voltage is less than its emf. When current enters the battery at the positive terminal, as in part (b), the terminal voltage is greater than its emf.

25.63. **IDENTIFY:** $R = \dfrac{\rho L}{A}$. $V = IR$. $P = I^2 R$.

SET UP: The area of the end of a cylinder of radius r is πr^2.

EXECUTE: **(a)** $R = \dfrac{(5.0\ \Omega \cdot \text{m})(1.6\ \text{m})}{\pi (0.050\ \text{m})^2} = 1.0 \times 10^3\ \Omega$.

(b) $V = IR = (100 \times 10^{-3}\ \text{A})(1.0 \times 10^3\ \Omega) = 100\ \text{V}$.

(c) $P = I^2 R = (100 \times 10^{-3}\ \text{A})^2 (1.0 \times 10^3\ \Omega) = 10\ \text{W}$.

EVALUATE: The resistance between the hands when the skin is wet is about a factor of ten less than when the skin is dry (Problem 25.64).

25.64. **IDENTIFY:** $V = IR$. $P = I^2 R$.

SET UP: The total resistance is the resistance of the person plus the internal resistance of the power supply.

EXECUTE: **(a)** $I = \dfrac{V}{R_{\text{tot}}} = \dfrac{14 \times 10^3\ \text{V}}{10 \times 10^3\ \Omega + 2000\ \Omega} = 1.17\ \text{A}$.

(b) $P = I^2 R = (1.17\ \text{A})^2 (10 \times 10^3\ \Omega) = 1.37 \times 10^4\ \text{J} = 13.7\ \text{kJ}$.

(c) $R_{\text{tot}} = \dfrac{V}{I} = \dfrac{14 \times 10^3\ \text{V}}{1.00 \times 10^{-3}\ \text{A}} = 14 \times 10^6\ \Omega$. The resistance of the power supply would need to be $14 \times 10^6\ \Omega - 10 \times 10^3\ \Omega = 14 \times 10^6\ \Omega = 14\ \text{M}\Omega$.

EVALUATE: The current through the body in part (a) is large enough to be fatal.

25.65. **IDENTIFY:** The cost of operating an appliance is proportional to the amount of energy consumed. The energy depends on the power the item consumes and the length of time for which it is operated.

SET UP: At a constant power, the energy is equal to Pt, and the total cost is the cost per kilowatt-hour (kWh) times the energy (in kWh).

EXECUTE: **(a)** Use the fact that $1.00\ \text{k Wh} = (1000\ \text{J/s})(3600\ \text{s}) = 3.60 \times 10^6\ \text{J}$, and one year contains $3.156 \times 10^7\ \text{s}$.

$$(75\ \text{J/s})\left(\frac{3.156 \times 10^7\ \text{s}}{1\ \text{yr}}\right)\left(\frac{\$0.120}{3.60 \times 10^6\ \text{J}}\right) = \$78.90.$$

(b) At $8\ \text{h/day}$, the refrigerator runs for 1/3 of a year. Using the same procedure as above gives

$$(400\ \text{J/s})\left(\frac{1}{3}\right)\left(\frac{3.156 \times 10^7\ \text{s}}{1\ \text{yr}}\right)\left(\frac{\$0.120}{3.60 \times 10^6\ \text{J}}\right) = \$140.27.$$

EVALUATE: Electric lights can be a substantial part of the cost of electricity in the home if they are left on for a long time!

25.66. **(a) IDENTIFY:** The rate of heating (power) in the cable depends on the potential difference across the cable and the resistance of the cable.

SET UP: The power is $P = V^2/R$ and the resistance is $R = \rho L/A$. The diameter D of the cable is twice its radius. $P = \dfrac{V^2}{R} = \dfrac{V^2}{(\rho L/A)} = \dfrac{AV^2}{\rho L} = \dfrac{\pi r^2 V^2}{\rho L}$. The electric field in the cable is equal to the potential difference across its ends divided by the length of the cable: $E = V/L$.

EXECUTE: Solving for r and using the resistivity of copper gives

$$r = \sqrt{\frac{P\rho L}{\pi V^2}} = \sqrt{\frac{(90.0\text{ W})(1.72\times 10^{-8}\ \Omega\cdot\text{m})(1500\text{ m})}{\pi(220.0\text{ V})^2}} = 1.236\times 10^{-4}\text{ m} = 0.1236\text{ mm}.$$

$D = 2r = 0.247$ mm.

(b) IDENTIFY and **SET UP:** $E = V/L$.

EXECUTE: $E = (220\text{ V})/(1500\text{ m}) = 0.147$ V/m.

EVALUATE: This would be an extremely thin (and hence fragile) cable.

25.67. **(a) IDENTIFY:** Since the resistivity is a function of the position along the length of the cylinder, we must integrate to find the resistance.

SET UP: The resistance of a cross-section of thickness dx is $dR = \rho dx/A$.

EXECUTE: Using the given function for the resistivity and integrating gives

$$R = \int \frac{\rho dx}{A} = \int_0^L \frac{(a + bx^2)dx}{\pi r^2} = \frac{aL + bL^3/3}{\pi r^2}.$$

Now get the constants a and b: $\rho(0) = a = 2.25\times 10^{-8}\ \Omega\cdot\text{m}$ and $\rho(L) = a + bL^2$ gives $8.50\times 10^{-8}\ \Omega\cdot\text{m} = 2.25\times 10^{-8}\ \Omega\cdot\text{m} + b(1.50\text{ m})^2$ which gives $b = 2.78\times 10^{-8}\ \Omega/\text{m}$. Now use the above result to find R.

$$R = \frac{(2.25\times 10^{-8}\ \Omega\cdot\text{m})(1.50\text{ m}) + (2.78\times 10^{-8}\ \Omega/\text{m})(1.50\text{ m})^3/3}{\pi(0.0110\text{ m})^2} = 1.71\times 10^{-4}\ \Omega = 171\ \mu\Omega.$$

(b) IDENTIFY: Use the definition of resistivity to find the electric field at the midpoint of the cylinder, where $x = L/2$.

SET UP: $E = \rho J$. Evaluate the resistivity, using the given formula, for $x = L/2$.

EXECUTE: At the midpoint, $x = L/2$, giving $E = \dfrac{\rho I}{\pi r^2} = \dfrac{[a + b(L/2)^2]I}{\pi r^2}$.

$$E = \frac{[2.25\times 10^{-8}\ \Omega\cdot\text{m} + (2.78\times 10^{-8}\ \Omega/\text{m})(0.750\text{ m})^2](1.75\text{ A})}{\pi(0.0110\text{ m})^2} = 1.76\times 10^{-4}\text{ V/m} = 176\ \mu\text{V/m}$$

(c) IDENTIFY: For the first segment, the result is the same as in part (a) except that the upper limit of the integral is $L/2$ instead of L.

SET UP: Integrating using the upper limit of $L/2$ gives $R_1 = \dfrac{a(L/2) + (b/3)(L^3/8)}{\pi r^2}$.

EXECUTE: Substituting the numbers gives

$$R_1 = \frac{(2.25\times 10^{-8}\ \Omega\cdot\text{m})(0.750\text{ m}) + (2.78\times 10^{-8}\ \Omega/\text{m})/3((1.50\text{ m})^3/8)}{\pi(0.0110\text{ m})^2} = 5.47\times 10^{-5}\ \Omega = 54.7\ \mu\Omega.$$

The resistance R_2 of the second half is equal to the total resistance minus the resistance of the first half.

$R_2 = R - R_1 = 1.71\times 10^{-4}\ \Omega - 5.47\times 10^{-5}\ \Omega = 1.16\times 10^{-4}\ \Omega = 116\ \mu\Omega.$

EVALUATE: The second half has a greater resistance than the first half because the resistance increases with distance along the cylinder.

25.68. **IDENTIFY:** Compact fluorescent bulbs draw much less power than incandescent bulbs and last much longer. Hence they cost less to operate.

SET UP: A kWh is power of 1 kW for a time of 1 h. $P = \dfrac{V^2}{R}$.

EXECUTE: **(a)** In 3.0 yr the bulbs are on for $(3.0\text{ yr})(365.24\text{ days/yr})(4.0\text{ h/day}) = 4.38\times10^3\text{ h}$.

Compact bulb: The energy used is $(23\text{ W})(4.38\times10^3\text{ h}) = 1.01\times10^5\text{ Wh} = 101\text{ kWh}$. The cost of this energy is $(\$0.080/\text{kWh})(101\text{ kWh}) = \$8.08$. One bulb will last longer than this. The bulb cost is \$11.00, so the total cost is \$19.08.

Incandescent bulb: The energy used is $(100\text{ W})(4.38\times10^3\text{ h}) = 4.38\times10^5\text{ Wh} = 438\text{ kWh}$. The cost of this energy is $(\$0.080/\text{kWh})(438\text{ kWh}) = \$35.04$. Six bulbs will be used during this time and the bulb cost will be \$4.50. The total cost will be \$39.54.

(b) The compact bulb will save $\$39.54 - \$19.08 = \$20.46$.

(c) $R = \dfrac{V^2}{P} = \dfrac{(120\text{ V})^2}{23\text{ W}} = 626\ \Omega$.

EVALUATE: The initial cost of the bulb is much greater for the compact fluorescent bulb but the savings soon repay the cost of the bulb. The compact bulb should last for over six years, so over a 6-year period the savings per year will be even greater. The cost of compact fluorescent bulbs has come down dramatically, so the savings today would be considerably greater than indicated here.

25.69. **IDENTIFY:** This problem involves capacitance, dielectrics, and resistance.

SET UP: $C = \dfrac{\epsilon_0 A}{d}$, $R = \dfrac{\rho L}{A}$, $P = I^2R$, $\rho = (s_0/s)\ \Omega\cdot\text{m}$.

EXECUTE: **(a)** We want the salinity s when the ammeter reads 484 mA. Using $V = (R + R_{\text{can}})I$ gives 10.0 V = (15.0 Ω + R_{can}) (0.484 A). R_{can} = 5.66 Ω. $R_{\text{can}} = \dfrac{\rho L}{A} = \left(\dfrac{s_0}{s}\right)\dfrac{L}{\pi r^2}$, so $s = \dfrac{s_0 L}{\pi r^2 R_{\text{can}}} =$

$$\frac{(6.30\text{ ppt }\Omega\cdot\text{m})(0.0300\text{ m})}{\pi(0.0500\text{ m})^2(5.66\ \Omega)} = 4.25\text{ ppt}.$$

(b) We want the charge on the left capacitor. Treat the can like an ideal parallel-plate capacitor, so $C = \dfrac{\epsilon_0 AK}{d} = \dfrac{\epsilon_0 \pi r^2 K}{L}$. $V_{\text{can}} = R_{\text{can}}I$ = (5.66 Ω)(0.484 A) = 2.739 V. Now use $Q = CV_{\text{can}}$.

$$Q = \left(\frac{\epsilon_0 \pi r^2 K}{L}\right)V_{\text{can}} = \left(\frac{\epsilon_0 \pi(0.0500\text{ m})^2(80.4)}{0.0300\text{ m}}\right)(2.739\text{ V}) = 510\text{ pC}.$$

(c) We want the power generated in the saline solution. $P = I^2R_{\text{can}} = (0.484\text{ A})^2(5.66\ \Omega) = 1.33\text{ W}$.

(d) We want the salinity level s. $P = V^2/R$, so if R and R_{can} each dissipate half the power of the battery, they must have equal resistances. Therefore $R_{\text{can}} = R = 15.0\ \Omega$. From part (a) we have

$$s = \frac{s_0 L}{\pi r^2 R_{\text{can}}} = \frac{(6.30\text{ ppt }\Omega\cdot\text{m})(0.0300\text{ m})}{\pi(0.0500\text{ m})^2(15.0\ \Omega)} = 1.60\text{ ppt}.$$

EVALUATE: The measurements needed to calculate the salinity s (V, I, and R) are easily made with simple meters, so s could easily be determined by this method.

25.70. **IDENTIFY:** No current flows to the capacitors when they are fully charged.

SET UP: $V_R = RI$ and $V_C = Q/C$.

EXECUTE: **(a)** $V_{C_1} = \dfrac{Q_1}{C_1} = \dfrac{18.0\ \mu\text{C}}{3.00\ \mu\text{F}} = 6.00\text{ V}$. $V_{C_2} = V_{C_1} = 6.00\text{ V}$.

$Q_2 = C_2V_{C_2} = (6.00\ \mu\text{F})(6.00\text{ V}) = 36.0\ \mu\text{C}$.

(b) No current flows to the capacitors when they are fully charged, so $\mathcal{E} = IR_1 + IR_2$.

$V_{R_2} = V_{C_1} = 6.00\text{ V}$. $I = \dfrac{V_{R_2}}{R_2} = \dfrac{6.00\text{ V}}{2.00\ \Omega} = 3.00\text{ A}$.

$$R_1 = \frac{\mathcal{E} - IR_2}{I} = \frac{72.0\text{ V} - 6.00\text{ V}}{3.00\text{ A}} = 22.0\ \Omega.$$

EVALUATE: When a capacitor is fully charged, it acts like an open circuit and prevents any current from flowing though it.

25.71. IDENTIFY: No current flows through the capacitor when it is fully charged.

SET UP: With the capacitor fully charged, $I = \dfrac{\mathcal{E}}{R_1 + R_2}$. $V_R = IR$ and $V_C = Q/C$.

EXECUTE: $V_C = \dfrac{Q}{C} = \dfrac{36.0\ \mu\text{C}}{9.00\ \mu\text{F}} = 4.00\ \text{V}$. $V_{R_1} = V_C = 4.00\ \text{V}$ and $I = \dfrac{V_{R_1}}{R_1} = \dfrac{4.00\ \text{V}}{6.00\ \Omega} = 0.667\ \text{A}$.

$V_{R_2} = IR_2 = (0.667\ \text{A})(4.00\ \Omega) = 2.668\ \text{V}$. $\mathcal{E} = V_{R_1} + V_{R_2} = 4.00\ \text{V} + 2.668\ \text{V} = 6.67\ \text{V}$.

EVALUATE: When a capacitor is fully charged, it acts like an open circuit and prevents any current from flowing though it.

25.72. IDENTIFY and SET UP: Ohm's law applies. The terminal voltage V_{ab} is less than the internal emf $\mathcal{E}$ due to voltage losses in the internal resistance *r* of the battery when current *I* is flowing in the circuit. $V_{ab} = \mathcal{E} - rI$.

EXECUTE: **(a)** The equation $V_{ab} = \mathcal{E} - rI$ applies to this circuit, so a graph of V_{ab} versus *I* should be a straight line with a slope equal to $-r$ and a *y*-intercept equal to $\mathcal{E}$. Using points where the graph crosses grid lines, the slope is: $\text{slope} = \dfrac{22.0\ \text{V} - 30.0\ \text{V}}{7.00\ \text{A} - 3.00\ \text{A}} = -2.00\ \text{V/A}$. Therefore $r = -(-2.00\ \text{V/A}) = 2.00\ \Omega$.

The equation of the graph is $V_{ab} = \mathcal{E} - rI$, so we can solve for $\mathcal{E}$ and use a point on the graph to calculate $\mathcal{E}$. This gives

$\mathcal{E} = V_{ab} + rI = 30.0\ \text{V} + (2.00\ \Omega)(3.00\ \text{A}) = 36.0\ \text{V}$.

(b) $R = V_{ab}/I$ and $I = \dfrac{\mathcal{E} - V_{ab}}{r}$, so $R = \dfrac{V_{ab}}{\dfrac{\mathcal{E} - V_{ab}}{r}} = \dfrac{rV_{ab}}{\mathcal{E} - V_{ab}}$. Putting in the numbers gives

$R = (2.00\ \Omega)(0.800)(36.0\ \text{V})/[36.0\ \text{V} - (0.800)(36.0\ \text{V})] = 8.00\ \Omega$.

EVALUATE: For large currents, the terminal voltage can be much less than the internal emf, as shown by the graph with the problem.

25.73. IDENTIFY: According to Ohm's law, $R = \dfrac{V_{ab}}{I}$ = constant, and a graph of V_{ab} versus *I* will be a straight line with positive slope passing through the origin.

SET UP and EXECUTE: **(a)** Figure 25.73a shows the graphs of V_{ab} versus *I* and *R* versus *I* for resistor A.

Figure 25.73b shows these graphs for resistor B.

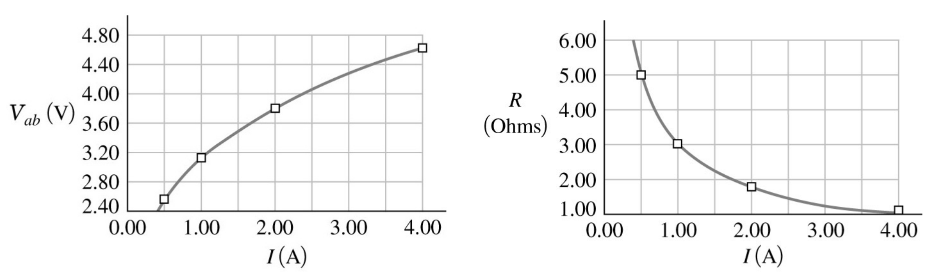


Figure 25.73a

(b) In Figure 25.73a, the graph of V_{ab} versus *I* is not a straight line so resistor A does not obey Ohm's law. In the graph of *R* versus *I*, *R* is not constant; it decreases as *I* increases.

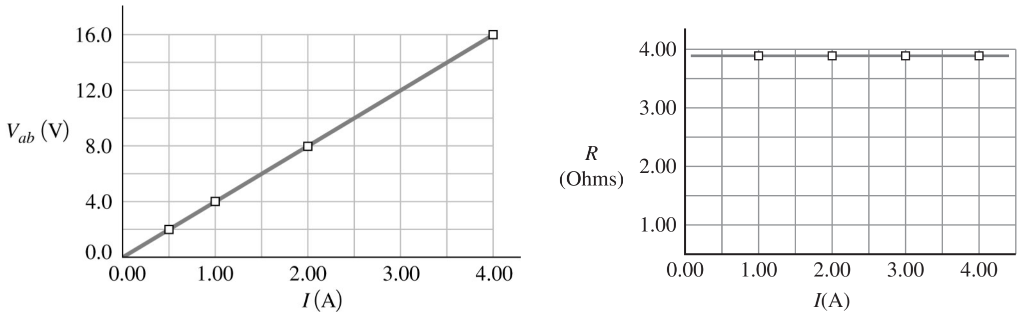

Figure 25.73b

(c) In Figure 25.73b, the graph of V_{ab} versus I is a straight line with positive slope passing through the origin, so resistor B obeys Ohm's law. The graph of R versus I is a horizontal line. This means that R is constant, which is consistent with Ohm's law.

(d) We use $P = IV$. From the graph of V_{ab} versus I in Figure 25.73a, we read that $I = 2.35$ A when $V = 4.00$ V. Therefore $P = IV = (2.35\text{ A})(4.00\text{ V}) = 9.40$ W.

(e) We use $P = V^2/R$. From the graph of R versus I in Figure 25.73b, we find that $R = 3.88\ \Omega$. Thus $P = V^2/R = (4.00\text{ V})^2/(3.88\ \Omega) = 4.12$ W.

EVALUATE: Since resistor B obeys Ohm's law $V_{ab} = RI$, R is the slope of the graph of V_{ab} versus I in Figure 25.73b. The given data points lie on the line, so we use them to calculate the slope.

slope = $R = \dfrac{15.52\text{ V} - 1.94\text{ V}}{4.00\text{ A} - 0.50\text{ A}} = 3.88\ \Omega.$ This value is the same as the one we got from the graph of R versus I in Figure 25.73b, so our results agree.

25.74. IDENTIFY: The power supplied to the house is $P = VI$. The rate at which electrical energy is dissipated in the wires is I^2R, where $R = \dfrac{\rho L}{A}$.

SET UP: For copper, $\rho = 1.72\times10^{-8}\ \Omega\cdot\text{m}$.

EXECUTE: **(a)** The line voltage, current to be drawn, and wire diameter are what must be considered in household wiring.

(b) $P = VI$ gives $I = \dfrac{P}{V} = \dfrac{4200\text{ W}}{120\text{ V}} = 35\text{ A},$ so the 8-gauge wire is necessary, since it can carry up to 40 A.

(c) $P = I^2R = \dfrac{I^2\rho L}{A} = \dfrac{(35\text{ A})^2\,(1.72\times10^{-8}\ \Omega\cdot\text{m})(42.0\text{ m})}{(\pi/4)(0.00326\text{ m})^{\,2}} = 106\text{ W}.$

(d) If 6-gauge wire is used, $P = \dfrac{I^2\rho L}{A} = \dfrac{(35\text{ A})^2\,(1.72\times10^{-8}\ \Omega\cdot\text{m})\,(42\text{ m})}{(\pi/4)\,(0.00412\text{ m})^2} = 66\text{ W}.$ The decrease in energy consumption is $\Delta E = \Delta P t = (40\text{ W})(365\text{ days/yr})\,(12\text{ h/day}) = 175\text{ kWh/yr}$ and the savings is $(175\text{ kWh/yr})(\$0.11/\text{kWh}) = \$19.25$ per year.

EVALUATE: The cost of the 4200 W used by the appliances is \$2020. The savings is about 1%.

25.75. IDENTIFY: This problem involves resistivity.

SET UP: $E = c/r$, $R = \dfrac{\rho\ell}{A}$.

EXECUTE: **(a)** The outer conductor is at a higher potential than the inner conductor, so the electric field points inward toward the central axis.

(b) The target variable is c, where $E = c/r$. $V = \int_{r_{\text{inner}}}^{r_{\text{outer}}} E_r dr = \int_{r_{\text{inner}}}^{r_{\text{outer}}} \frac{c}{r} dr = c\ln\left(r_{\text{outer}} / r_{\text{inner}}\right)$, which gives

$$c = \frac{V}{\ln\left(r_{\text{outer}} / r_{\text{inner}}\right)}.$$

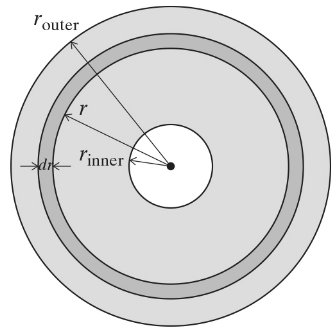

Figure 25.75

(c) We want the resistance of this device. Break the material into infinitesimal coaxial cylindrical shells of radius r, length L, and thickness dr as shown in Fig. 25.75. Apply $R = \frac{\rho \ell}{A}$ where $\ell = dr$ and $A = 2\pi rL$. Doing so gives $R = \int_{r_{\text{inner}}}^{r_{\text{outer}}} \frac{\rho dr}{2\pi rL} = \frac{\rho}{2\pi L}\ln\left(r_{\text{outer}} / r_{\text{inner}}\right)$.

(d) We want the resistivity so that $R = 6.80$ kΩ. Solve the result from (c) for ρ and put in the given quantities, giving $\rho = \frac{2\pi LR}{\ln\left(r_{\text{outer}} / r_{\text{inner}}\right)} = 616\ \Omega \cdot \text{m}$.

EVALUATE: From Table 25.1 we see that this resistivity would be about ¼ that of pure silicon but much less than for insulators and much greater than for conductors.

25.76. **IDENTIFY:** In this problem we investigate the resistance of a light bulb filament as it varies with temperature.

SET UP: $R = \frac{\rho L}{A}$, $R(T) = R_0\left[1 + \alpha\left(T - T_0\right)\right]$, $P = I^2R$.

EXECUTE: **(a)** The target variable is the resistance at 20.0°C. Use $R = \frac{\rho L}{A}$ with ρ at its 20.0°C value. Putting in the given numbers gives $R_{20} = 18.3\ \Omega$.

(b) The target variable is the current when $V = 120$ V. First find T as a function of I. The graph of T versus I is a straight line passing through (0 A, 20.0°C) and (1.00 A, 2520°C), so its slope is 2500°C/A and its T-intercept is 20.0°C. Using the slope-intercept equation of a straight line, the equation is $T(I) = (2500°\text{C/A})I + 20.0°\text{C}$. Using $T_0 = 20.0°\text{C}$, the resistance as a function of temperature is $R(T) = R_{20}\left[1 + \alpha\left(T - 20.0°\text{C}\right)\right]$ and a comparable equation hold for the resistivity. Now combine our equation for $T(I)$ with $R(T)$ to find R as a function of I. $R(I) = R_{20}\left\{1 + \alpha\left[\left(2500°\text{C/A}\right)I + 20.0°\text{C}\right]\right\}$.

Using $V = RI$ gives $V = R_{20}\left\{1 + \alpha\left[\left(2500°\text{C/A}\right)I + 20.0°\text{C}\right]\right\}I$. Now solve for I when $V = 120$ V.

$120\ \text{V} = (18.3\ \Omega)\left\{1 + (0.0045 / \text{C°})\left[\left(2500°\text{C/A}\right)I + 20.0°\text{C}\right]\right\}I$. The positive solution to this quadratic equation is $I = 716$ mA which rounds to 720 mA.

(c) We want R when V is 120 V. $R = V/I = (120\ \text{V})/(0.716\ \text{A}) = 167\ \Omega$.

(d) We want the energy dissipated during 1 minute. $U = Pt = I^2Rt$. Using the results from (b) and (c) gives $U = (0.716\text{ A})^2(167\ \Omega)(60\text{ s}) = 5140\text{ J} = 5.14\text{ kJ}$.
(e) We want the energy when $V = 60$ V. Use $P = IV$ where $V = 60$ V. Get I using the method of part (b) with $V = 60$ V, which gives $I = 0.49355$ A. $R = V/I = (60\text{ V})/(0.49355\text{ A}) = 121.6\ \Omega$. The energy is $U = Pt = I^2Rt = (0.49355\text{ A})^2(121.6\ \Omega)(60\text{ s}) = 1.78$ kJ.
EVALUATE: Our results show that temperature variation can have significant effects on circuits.

25.77. **IDENTIFY:** Apply $R = \dfrac{\rho L}{A}$ to find the resistance of a thin slice of the rod and integrate to find the total R. $V = IR$. Also find $R(x)$, the resistance of a length x of the rod.
SET UP: $E(x) = \rho(x)J$

EXECUTE: **(a)** $dR = \dfrac{\rho dx}{A} = \dfrac{\rho_0 \exp[-x/L]\,dx}{A}$ so

$R = \dfrac{\rho_0}{A}\int_0^L \exp\left[-x/L\right] dx = \dfrac{\rho_0}{A}[-L\exp(-x/L)]_0^L = \dfrac{\rho_0 L}{A}(1-e^{-1})$ and $I = \dfrac{V_0}{R} = \dfrac{V_0 A}{\rho_0 L(1-e^{-1})}$. With an upper limit of x rather than L in the integration, $R(x) = \dfrac{\rho_0 L}{A}(1-e^{-x/L})$.

(b) $E(x) = \rho(x)J = \dfrac{I\,\rho_0 e^{-x/L}}{A} = \dfrac{V_0 e^{-x/L}}{L(1-e^{-1})}$.

(c) $V = V_0 - IR(x)$. $V = V_0 - \left(\dfrac{V_0 A}{\rho_0 L[1-e^{-1}]}\right)\left(\dfrac{\rho_0 L}{A}\right)(1-e^{-x/L}) = V_0\dfrac{(e^{-x/L}-e^{-1})}{(1-e^{-1})}$.

(d) Graphs of resistivity, electric field, and potential from $x = 0$ to L are given in Figure 25.77. Each quantity is given in terms of the indicated unit.
EVALUATE: The current is the same at all points in the rod. Where the resistivity is larger the electric field must be larger, in order to produce the same current density.

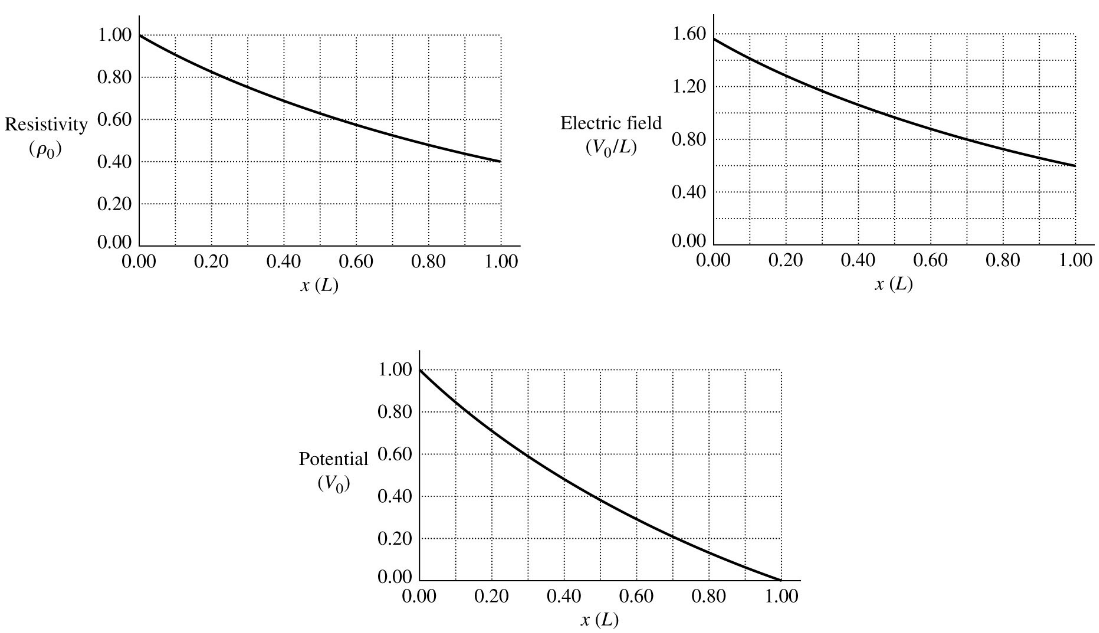

Figure 25.77

25.78. **IDENTIFY** and **SET UP:** The power output P of the source is the power delivered to the resistor R, so P is the power output of the internal emf $\mathcal{E}$ minus the power consumed by the internal resistance r. Therefore $P = \mathcal{E}I - I^2r$. For the entire circuit, $\mathcal{E} = (R + r)I$.

EXECUTE: **(a)** Combining $P = I^2/R$ and $\mathcal{E} = (R + r)I$ gives $P = \left(\dfrac{\mathcal{E}}{R+r}\right)^2 R = \dfrac{\mathcal{E}^2 R}{(R+r)^2}$. From this result, we can see that as $R \to 0,\quad P \to 0.$

(b) Using the same equation as in (a), we see that as $R \to \infty,\quad P \to \dfrac{\mathcal{E}^2}{R} \to 0.$

(c) In (a) we showed that $P = \dfrac{\mathcal{E}^2 R}{(R+r)^2}$. For maximum power, $dP/dR = 0$.

$$\frac{dP}{dR} = \mathcal{E}^2\left[-\frac{2R}{(R+r)^3} + \frac{1}{(R+r)^2}\right] = 0 \qquad \to \qquad \frac{2R}{R+r} = 1 \qquad \to \qquad R = r.$$

The maximum power is therefore

$$P_{\max} = \left.\frac{R\mathcal{E}^2}{(R+r)^2}\right|_{R=r} = \frac{r\mathcal{E}^2}{(2r)^2} = \frac{\mathcal{E}^2}{4r}.$$

(d) Use $P = \dfrac{\mathcal{E}^2 R}{(R+r)^2}$ to calculate P.

<u>For $R = 2.00\ \Omega$</u>: $P_2 = (64.0\text{ V})^2(2.00\ \Omega)/(6.00\ \Omega)^2 = 228$ W.
<u>For $R = 4.00\ \Omega$</u>: $P_4 = (64.0\text{ V})^2(4.00\ \Omega)/(8.00\ \Omega)^2 = 256$ W.
<u>For $R = 6.00\ \Omega$</u>: $P_6 = (64.0\text{ V})^2(6.00\ \Omega)/(10.0\ \Omega)^2 = 246$ W.

EVALUATE: The maximum power in (d) occurred when $R = r = 4.00\ \Omega$, so it is consistent with the result from (c). The equation we found, $P_{\max} = \dfrac{\mathcal{E}^2}{4r}$, gives $P_{\max} = (64.0\text{ V})^2/[4(4.00\ \Omega)] = 256$ W, which agrees with our calculation in (d). When R is smaller than r, I is large and the I^2r losses in the battery are large. When R is larger than r, I is small and the power output $\mathcal{E}I$ of the battery emf is small.

25.79. **IDENTIFY** and **SET UP:** $R = \dfrac{\rho L}{A}$.

EXECUTE: From the equation $R = \dfrac{\rho L}{A}$, if we double the length of a resistor and change nothing else, the resistance will double. But from the data table given in the problem, we see that doubling the length of the thread causes its resistance to do much more than double. For example, at 5 mm the resistance is $9\times10^9\ \Omega$ and at 11 mm (approximately double) the resistance is $63\times10^9\ \Omega$, which is much more than twice the resistance at 5 mm. Therefore as the thread stretches, its coating gets thinner, which decreases its cross-sectional area. This decreased area contributes significantly to the increase in resistance. Therefore choice (c) is correct.

EVALUATE: The cross-sectional area of the coating depends on the square of the radius of the thread, so a decrease in the radius has a very large effect on the resistance.

25.80. **IDENTIFY** and **SET UP:** Use data from the table for 5 mm and 13 mm to compare the resistance. $R = \dfrac{\rho L}{A}$.

EXECUTE: $\dfrac{R_{13}}{R_5} = \dfrac{102}{9} = \dfrac{\dfrac{\rho(13\text{ mm})}{A_5}}{\dfrac{\rho(5\text{ mm})}{A_{13}}} = \dfrac{13A_5}{5A_{13}}$. Solving for A_{13} gives

$$A_{13} = A_5\left(\frac{13}{5}\right)\left(\frac{9}{102}\right) = 0.23 \approx \frac{1}{4},$$ which is choice (b).

EVALUATE: It is reasonable that $A_{13} < A_5$ because the thread and its coating stretch out and get thinner.

25.81. **IDENTIFY** and **SET UP:** Apply Ohm's law, $V = RI$. The minimum resistance will give the maximum current. Get data from the table in the problem.

EXECUTE: $I_{max} = V/R_{min} = (9\text{ V})/(9\times10^9\ \Omega) = 1\times10^{-9}\text{ A} = 1\text{ nA}$, which is choice (d).

EVALUATE: This is a very small current, but the thread of a spider web is very thin.

25.82. **IDENTIFY** and **SET UP:** An electrically neutral conductor contains equal amounts of positive and negative charge, and these charges can move if a charged object comes near to them.

EXECUTE: If a positively charged object comes near to the web, it attracts negative charges in the web. The attraction between these negative charges in the web and the positive charges in the charged object pull the web toward the object. If a negatively charged object comes near the web, it repels negative charges in the web, leaving the web positively charged near the object. The attraction between the negatively charged object and the positive side of the web pulls the web toward the object. This is best explained by choice (d).

EVALUATE: This is similar to the principle of charging by induction. The amounts of charge are small, but the web is moved because it is extremely light.

26

DIRECT-CURRENT CIRCUITS

VP26.2.1. **IDENTIFY:** We have resistors in series and parallel.

SET UP: Parallel: $1/R_{eq} = 1/R_1 + 1/R_2 + \cdots$, series: $R_{eq} = R_1 + R_2 + \cdots$. We want the equivalent resistance in each combination.

EXECUTE: **(a)** Series: $R_{eq} = 1.00\ \Omega + 2.00\ \Omega + 4.00\ \Omega = 7.00\ \Omega$.

(b) Parallel: $1/R_{eq} = 1/(1.00\ \Omega) + 1/(2.00\ \Omega) + 1/(4.00\ \Omega)$. $R_{eq} = 0.571\ \Omega$.

(c) Series/parallel combination: R_2 and R_3 in parallel. $1/R_p = 1/(2.00\ \Omega) + 1/(4.00\ \Omega)$. $R_p = 1.33\ \Omega$. $R_{eq} = R_1 + R_p = 1.00\ \Omega + 1.33\ \Omega = 2.33\ \Omega$.

(d) Series/parallel combination: R_2 and R_3 in series: $R_s = 2.00\ \Omega + 4.00\ \Omega = 6.00\ \Omega$. The parallel combination: $1/R_{eq} = 1/R_1 + 1/R_s = 1/(1.00\ \Omega) + 1/(6.00\ \Omega)$. $R_{eq} = 0.857\ \Omega$.

EVALUATE: Note that for a parallel combination the equivalent resistance is *less than* the *smallest* resistance. For a series combination, R_{eq} is *greater than* the *largest* resistance.

VP26.2.2. **IDENTIFY:** We have resistors in series and parallel and a battery.

SET UP: Parallel: $1/R_{eq} = 1/R_1 + 1/R_2 + \cdots$, series: $R_{eq} = R_1 + R_2 + \cdots$. We want the currents.

EXECUTE: **(a)** We want the current through the battery. First find R_{eq} for the circuit. R_2 and R_3 are in series, so $R_s = 11.0\ \Omega$. This combination is in parallel with R_1 so $1/R_{eq} = 1/R_1 + 1/R_s$. This gives $1/R_{eq} = 1/(4.00\ \Omega) + 1/(11.0\ \Omega)$. $R_{eq} = 2.933\ \Omega$. $= (24.0\ \text{V})/(2.933\ \Omega) = 8.18\ \text{A}$.

(b) We want the current through R_1. $I_1 = \mathcal{E}/R_1 = (24.0\ \text{V})/(4.00\ \Omega) = 6.00\ \text{A}$.

(c) We want the current through R_2. $I_2 = \mathcal{E}/(R_2 + R_3) = (24.0\ \text{V})/(11.0\ \Omega) = 2.18\ \text{A}$.

(d) We want the current through R_3. The resistors are in series so $I_3 = I_2 = 2.18\ \text{A}$.

EVALUATE: Check: $I_1 + I_2 = 6.00\ \text{A} + 2.18\ \text{A} = 8.18\ \text{A}$, which is the current from the battery as it should be.

VP26.2.3. **IDENTIFY:** We have three resistors in parallel across a battery. We want the power in each circuit element.

SET UP: $P = I^2R = V^2/R = IV$. $1/R_{eq} = 1/R_1 + 1/R_2 + \cdots$ The potential difference is 12.0 V across each resistor.

EXECUTE: **(a)** We want $P_{battery}$. First get the equivalent resistance to find the current the battery puts out. $1/R_{eq} = 1/(7.00\ \Omega) + 1/(8.00\ \Omega) + 1/(9.00\ \Omega)$. $R_{eq} = 2.64\ \Omega$. Now find I. $I = \mathcal{E}/R_{eq} = (12.0\ \text{V})/(2.64\ \Omega) = 4.548\ \text{A}$. $P_{battery} = I\mathcal{E} = (4.548\ \text{A})(12.0\ \text{V}) = 54.6\ \text{W}$.

(b) We want the power dissipated in R_1. $P_1 = \mathcal{E}^2/R_1 = (12.0\ \text{V})^2/(7.00\ \Omega) = 20.6\ \text{W}$.

(c) $P_2 = (24.0\ \text{V})^2/(8.00\ \Omega) = 18.0\ \text{W}$.

(d) $P_3 = (12.0\ \text{V})^2/(9.00\ \Omega) = 16.0\ \text{W}$.

EVALUATE: The total power dissipated in the resistors is 20.6 W + 18.0 W + 16.0 W = 54.6 W, which is the power output of the battery. This agrees with energy conservation.

VP26.2.4. **IDENTIFY:** We have a series/parallel resistor combination across a battery. We want the power in each circuit element.

SET UP: $P = I^2R = V^2/R = IV$. $1/R_{eq} = 1/R_1 + 1/R_2 + \cdots$. $V = RI$.

EXECUTE: **(a)** We want $P_{battery}$. First get the equivalent resistance of the circuit. For the parallel part: $1/R_p = 1/(6.00\ \Omega) + 1/(7.00\ \Omega)$. $R_p = 3.231\ \Omega$. $R_{eq} = 5.00\ \Omega + 3.231\ \Omega = 8.23\ \Omega$. $I = \mathcal{E}/R_{eq} = (9.00\ \text{V})/(8.23\ \Omega) = 1.0935$ A. $P_{battery} = I\mathcal{E} = (1.0935\ \text{A})(9.00\ \text{V}) = 9.84$ W.

(b) We want P_1. $P_1 = I_1^2R_1 = I^2R_1 = (1.0935\ \text{A})^2(5.00\ \Omega) = 5.98$ W.

(c) We want P_2. $V_2 = \mathcal{E} - V_1 = \mathcal{E} - R_1I_1 = 9.00\ \text{V} - (5.00\ \Omega)(1.0935\ \text{A}) = 3.5325$ V. $P_2 = V_2^2/R_2 = (3.5325\ \text{V})^2/(6.00\ \Omega) = 2.08$ W.

(d) $P_3 = (3.5325\ \text{V})^2/(7.00\ \Omega) = 1.78$ W.

EVALUATE: Check: $P_1 + P_2 + P_3 = 5.98\ \text{W} + 2.08\ \text{W} + 1.78\ \text{W} = 9.84$ W, which is the battery power, as it should be by energy conservation.

VP26.7.1. **IDENTIFY:** We have a circuit with two batteries. Kirchhoff's rules apply.

SET UP: $P = IV = I^2R$.

EXECUTE: **(a)** We want the current. Make a loop using the same path as in Fig. 26.10(a) in the text. This gives: $12\ \text{V} - (2\ \Omega)I - (3\ \Omega)I - (4\ \Omega)I + 4\ \text{V} - (7\ \Omega)I = 0$. $I = 1$ A.

(b) $V_{ab} = V_a - V_b = (7\ \Omega)(1\ \text{A}) - 4\ \text{V} + (4\ \Omega)(1\ \text{A}) = +7$ V.

(c) We want the power. $P_4 = I\mathcal{E}_4 = (1\ \text{A})(4\ \text{V}) = 4$ W. $P_{12} = (1\ \text{A})(12\ \text{V}) = 12$ W.

EVALUATE: Check: Power dissipated in the resistors is $I^2R = (1\ \text{A})^2(16\ \Omega) = 16$ W. The power output of the batteries is 4W + 12 W = 16 W. They agree, as they should by energy conservation.

VP26.7.2. **IDENTIFY:** This problem requires Kirchhoff's rules.

SET UP: Refer to Fig. 26.6(a) in the text.

EXECUTE: **(a)** We want $V_{ab} = V_a - V_b$. $I_R = I_1 + I_2 = 1.55$ A. Go from b to a through R. This gives $V_{ab} = (5.00\ \Omega)(1.55\ \text{A}) = +7.75$ V.

(b) We want r_1. $V_{ac} = V_{ab} = 7.75$ V. Go from $c \to a$: $8.00\ \text{V} - r_1(0.200\ \text{A}) = 7.75$ V. $r_1 = 1.25\ \Omega$.

(c) We want r_2. $V_{ab} = 9.00\ \text{V} - r_2(1.35\ \text{A}) = 7.75$ V. $r_2 = 0.926\ \Omega$.

EVALUATE: Check for r_1: Make a loop from $c \to a \to b \to c$ through R, giving $+8.00\ \text{V} - r_1(0.200\ \text{A}) - (5.00\ \Omega)(1.55\ \text{A}) = 0$, which gives $r_1 = 1.25\ \Omega$, in agreement with our result.

VP26.7.3. **IDENTIFY:** We need to use Kirchhoff's rules and want to find the power in each resistor.

SET UP: Refer to Fig. 26.12 in the text and the equations in Example 26.6. We first must find the currents, as in the example in the text. Using the same loops, we find that Equations (1), (3), and $(1')$ are the same as in the example. Equation (2) becomes: $-I_2(1\ \Omega) - (I_2 + I_3)(3\ \Omega) + 13\ \text{V} = 0$. Equation $(2')$ becomes: $13\ \text{V} = I_1(4\ \Omega) + I_3(7\ \Omega)$. Solve these equations as was shown in the example. The results are: $I_1 = 5.778$ A, $I_2 = 4.333$ A, and $I_3 = -1.445$ A. Now we can find the powers.

EXECUTE: **(a)** $P_{ca} = I_1^2(1\ \Omega) = (5.778\ \text{A})^2(1\ \Omega) = 33.4$ W.

(b) $P_{cb} = I_2^2(1\ \Omega) = (4.333\ \text{A})^2(1\ \Omega) = 18.8$ W.

(c) $P_{ab} = I_3^2(1\ \Omega) = (-1.445\ \text{A})^2(1\ \Omega) = 2.09$ W.

(d) $P_{ad} = (I_1 - I_3)^2(1\ \Omega) = [5.778\ \text{A} - (-1.445\ \text{A})](1\ \Omega) = 2.09$ W.

(e) $P_{bd} = (I_2 + I_3)^2(3\ \Omega) = (4.333\ \text{A} - 1.445\ \text{A})^2(3\ \Omega) = 25.0$ W.

EVALUATE: Check: $P_R = 33.4\ \text{W} + 18.8\ \text{W} + 2.09\ \text{W} + 52.2\ \text{W} + 25.0\ \text{W} = 131$ W. The power the battery produces is $P_{battery} = I\mathcal{E} = (I_1 + I_2)\mathcal{E} = (5.778\ \text{A} + 4.333\ \text{A})(13\ \text{V}) = 131$ W. Our results are consistent with the conservation of energy.

VP26.7.4. **IDENTIFY:** Kirchhoff's rules apply to this circuit. We want the currents.

SET UP: Refer to Fig. VP26.7.4. Use the same approach as shown in Fig. 26.9(a) in the text.

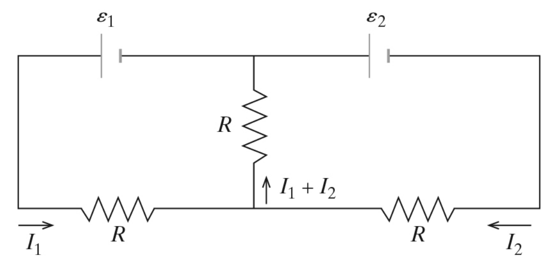

Figure VP26.7.4

EXECUTE: Take a counterclockwise loop in the left half of the circuit, which gives $\mathcal{E}_1 - RI_1 - (I_1 + I_2)R = 0.$ This simplifies to s $\mathcal{E}_1 = 2RI_1 + RI_2$ (Eq. 1)

Take a counterclockwise loop in the right half of the circuit, which gives $\mathcal{E}_2 + R(I_1 + I_2) + I_2R = 0.$ This simplifies to $\mathcal{E}_2 = -RI_1 - 2RI_2$ (Eq. 2)

The junction rule gives $I_3 = I_1 + I_2$ (Eq. 3)

Solving these three equations by substitution (or any other method) gives the following results:

(a) $I_1 = \dfrac{2\mathcal{E}_1 + \mathcal{E}_2}{3R}.$

(b) $I_2 = -\dfrac{\mathcal{E}_1 + 2\mathcal{E}_2}{3R}.$

(c) $I_3 = -\dfrac{\mathcal{E}_1 - \mathcal{E}_2}{3R}.$

EVALUATE: It is not possible to solve a circuit like this with simple series/parallel reduction.

VP26.13.1. **IDENTIFY:** This circuit is a charging capacitor in an *R-C* circuit.

SET UP: $q = Q_f(1 - e^{-t/RC}),\ i = I_0 e^{-t/RC},\ \tau = RC.$

EXECUTE: **(a)** We want the final charge. The current has stopped, so $\mathcal{E} = V_C = Q_f/C$. Therefore $Q_f = C\mathcal{E} = (3.20\ \mu\text{F})(9.00\ \text{V}) = 28.8\ \mu\text{C}$.

(b) We want the initial current. Initially $q_C = 0$, so $\mathcal{E} = V_R = RI_0$. $I_0 = \mathcal{E}/R = (9.00\ \text{V})/(10.0\ \text{M}\Omega) = 0.900\ \mu\text{A}$.

(c) We want the time constant. $\tau = RC = (10.0\ \text{M}\Omega)(3.20\ \mu\text{F}) = 32.0\ \text{s}$.

(d) We want q/Q_f at $t = 18.0$ s. Using $q = Q_f(1 - e^{-t/RC})$ gives $q/Q_f = 1 - e^{-(18.0\ \text{s})/(32.0\ \text{s})} = 0.430$.

(e) We want i/I_0 at 18.0 s. Using $i = I_0 e^{-t/RC}$ gives $i/I_0 = e^{-(18.0\ \text{s})/(32.0\ \text{s})} = 0.570$.

EVALUATE: As the current in the circuit decreases the charge on the capacitor increases. Both of them follow a form of exponential change.

VP26.13.2. **IDENTIFY:** This circuit is a discharging capacitor in an *R-C* circuit.

SET UP: $i = I_0 e^{-t/RC}$, $q = Q_0 e^{-t/RC}$

EXECUTE: **(a)** We want the time when $q = 1.20\ \mu\text{C}$. Solve $q = Q_0 e^{-t/RC}$ for t by taking logarithms, giving $t = -RC \ln(q/Q_0) = -(4.00\ \text{M}\Omega)(2.20\ \mu\text{C}) \ln(1.20/4.20) = 11.0$ s.

(b) We want the current at $t = 11.0$ s. $i = I_0 e^{-t/RC}$. From (a), $e^{-t/RC} = q/Q_0 = 1.20/4.20 = 0.2857$. Find I_0:

$$I_0 = \frac{V_0}{R} = \frac{Q_0/C}{R} = \frac{4.20\ \mu\text{C}}{(4.00\ \text{M}\Omega)(2.20\ \mu\text{F})} = 4.77\times10^{-7}\ \text{A}.\ i = (4.77\times10^{-7}\ \text{A})(0.2857) = 1.36\times10^{-7}\ \text{A}.$$

EVALUATE: For a discharging capacitor, both the current and the charge on the capacitor plates decrease exponentially.

VP26.13.3. **IDENTIFY:** We have a discharging capacitor.

SET UP: $i = I_0 e^{-t/RC}$, $q = Q_0 e^{-t/RC}$

EXECUTE: **(a)** We want the resistance. Solving $q = Q_0 e^{-t/RC}$ for R gives

$$R = -\frac{t}{C\ln(q/Q_0)} = -\frac{17.0 \text{ s}}{(8.00\ \mu\text{F})\ln(1.10/5.50)} = 1.32\ \text{M}\Omega.$$

(b) We want I_0. $I_0 = \dfrac{V_0}{R} = \dfrac{Q_0/C}{R} = \dfrac{5.50\ \mu\text{C}}{(1.32\ \text{M}\Omega)(8.00\ \mu F)} = 5.21\times10^{-7}$ A.

(c) We want the current at t = 17.0 s. $i = I_0 e^{-t/RC} = 1.04\times10^{-7}$ A using the given and calculated values for t, R, C and I_0.

EVALUATE: At t = 17.0 s, check V_C and V_R. $V_C = q/C$ = (1.10 μC)/(8.00 μF) = 0.1375 V. $V_R = Ri$ = (1.32 MΩ) (1.04×10^{-7} A) = 0.1374 V. They agree, as they should. The tiny difference is due to rounding.

VP26.13.4. **IDENTIFY:** This problem involves a capacitor that charges and then discharges.

SET UP and **EXECUTE:** **(a)** We want the charge at 51.0 s. We have a charging capacitor so $q = C\mathcal{E}(1-e^{-t/RC})$. Using t = 51.0 s, R = 5.00 MΩ, and the other given values, we get q = 61.2 μC.

(b) We want q 70.0 s after closing the switch. We have a discharging capacitor with Q_0 = 61.2 μC. Using $q = Q_0 e^{-t/RC}$ with t = 70.0 s, R = 6.00 MΩ and the other given values, we get q = 9.89 μC.

EVALUATE: The charging time constant is different from the discharging time constant because the resistance is different in the two cases.

26.1. **IDENTIFY:** The newly-formed wire is a combination of series and parallel resistors.

SET UP: Each of the three linear segments has resistance $R/3$. The circle is two $R/6$ resistors in parallel.

EXECUTE: The resistance of the circle is $R/12$ since it consists of two $R/6$ resistors in parallel. The equivalent resistance is two $R/3$ resistors in series with an $R/12$ resistor, giving $R_{\text{equiv}} = R/3 + R/3 + R/12 = 3R/4.$

EVALUATE: The equivalent resistance of the original wire has been reduced because the circle's resistance is less than it was as a linear wire.

26.2. **IDENTIFY:** It may appear that the meter measures X directly. But note that X is in parallel with three other resistors, so the meter measures the equivalent parallel resistance between ab.

SET UP: We use the formula for resistors in parallel.

EXECUTE: $1/(2.00\ \Omega) = 1/X + 1/(15.0\ \Omega) + 1/(5.0\ \Omega) + 1/(10.0\ \Omega)$, so $X = 7.5\ \Omega$.

EVALUATE: X is *greater* than the equivalent parallel resistance of $2.00\ \Omega$.

26.3. **IDENTIFY:** The emf of the battery remains constant, but changing the resistance across it changes its power output.

SET UP: The power consumption in a resistor is $P = \dfrac{V^2}{R}$.

EXECUTE: With just R_1, $P_1 = \dfrac{V^2}{R_1}$ and $V = \sqrt{P_1R_1} = \sqrt{(36.0\ \text{W})(25.0\ \Omega)} = 30.0\ \text{V}$ is the battery voltage. With R_2 added, $R_{\text{tot}} = 40.0\ \Omega$. $P = \dfrac{V^2}{R_{\text{tot}}} = \dfrac{(30.0\ \text{V})^2}{40.0\ \Omega} = 22.5\ \text{W}$.

EVALUATE: The two resistors in series dissipate electrical energy at a smaller rate than R_1 alone.

26.4. **IDENTIFY:** For resistors in parallel the voltages are the same and equal to the voltage across the equivalent resistance.

SET UP: $V = IR.$ $\dfrac{1}{R_{eq}} = \dfrac{1}{R_1} + \dfrac{1}{R_2}.$

EXECUTE: **(a)** $R_{eq} = \left(\dfrac{1}{42\ \Omega} + \dfrac{1}{20\ \Omega}\right)^{-1} = 13.548\ \Omega,$ which rounds to 13 Ω.

(b) $I = \dfrac{V}{R_{eq}} = \dfrac{240\ \text{V}}{13.548\ \Omega} = 17.7\ \text{A},$ which rounds to 18 A.

(c) $I_{42\Omega} = \dfrac{V}{R} = \dfrac{240\ \text{V}}{42\ \Omega} = 5.7\ \text{A};$ $I_{20\Omega} = \dfrac{V}{R} = \dfrac{240\ \text{V}}{20\ \Omega} = 12\ \text{A}.$

EVALUATE: More current flows through the resistor that has the smaller R.

26.5. **IDENTIFY:** The equivalent resistance will vary for the different connections because the series-parallel combinations vary, and hence the current will vary.

SET UP: First calculate the equivalent resistance using the series-parallel formulas, then use Ohm's law $(V = RI)$ to find the current.

EXECUTE: **(a)** $1/R = 1/(15.0\ \Omega) + 1/(30.0\ \Omega)$ gives $R = 10.0\ \Omega.$ $I = V/R = (35.0\ \text{V})/(10.0\ \Omega) = 3.50\ \text{A}.$

(b) $1/R = 1/(10.0\ \Omega) + 1/(35.0\ \Omega)$ gives $R = 7.78\ \Omega.$ $I = (35.0\ \text{V})/(7.78\ \Omega) = 4.50\ \text{A}.$

(c) $1/R = 1/(20.0\ \Omega) + 1/(25.0\ \Omega)$ gives $R = 11.11\ \Omega,$ so $I = (35.0\ \text{V})/(11.11\ \Omega) = 3.15\ \text{A}.$

(d) From part (b), the resistance of the triangle alone is 7.78 Ω. Adding the 3.00-Ω internal resistance of the battery gives an equivalent resistance for the circuit of 10.78 Ω. Therefore the current is $I = (35.0\text{V})/(10.78\ \Omega) = 3.25\ \text{A}.$

EVALUATE: It makes a big difference how the triangle is connected to the battery.

26.6. **IDENTIFY:** The potential drop is the same across the resistors in parallel, and the current into the parallel combination is the same as the current through the 45.0-Ω resistor.

(a) SET UP: Apply Ohm's law in the parallel branch to find the current through the 45.0-Ω resistor. Then apply Ohm's law to the 45.0-Ω resistor to find the potential drop across it.

EXECUTE: The potential drop across the 25.0-Ω resistor is $V_{25} = (25.0\ \Omega)(1.25\ \text{A}) = 31.25\ \text{V}.$ The potential drop across each of the parallel branches is 31.25 V. For the 15.0-Ω resistor: $I_{15} = (31.25\text{V})/(15.0\ \Omega) = 2.083\ \text{A}.$ The resistance of the $10.0\text{-}\Omega + 15.0\text{-}\Omega$ combination is $25.0\ \Omega,$ so the current through it must be the same as the current through the upper 25.0-Ω resistor: $I_{10+15} = 1.25\ \text{A}.$ The sum of currents in the parallel branch will be the current through the 45.0-Ω resistor.

$$I_{Total} = 1.25\ \text{A} + 2.083\ \text{A} + 1.25\ \text{A} = 4.58\ \text{A}.$$

Apply Ohm's law to the 45.0-Ω resistor: $V_{45} = (4.58\ \text{A})(45.0\ \Omega) = 206\ \text{V}.$

(b) SET UP: First find the equivalent resistance of the circuit and then apply Ohm's law to it.

EXECUTE: The resistance of the parallel branch is $1/R = 1/(25.0\ \Omega) + 1/(15.0\ \Omega) + 1/(25.0\ \Omega),$ so $R = 6.82\ \Omega.$ The equivalent resistance of the circuit is $6.82\ \Omega + 45.0\ \Omega + 35.00\ \Omega = 86.82\ \Omega.$ Ohm's law gives $V_{Bat} = (86.62\ \Omega)(4.58\ \text{A}) = 398\ \text{V}.$

EVALUATE: The emf of the battery is the sum of the potential drops across each of the three segments (parallel branch and two series resistors).

26.7. **IDENTIFY:** First do as much series-parallel reduction as possible.

SET UP: The 45.0-Ω and 15.0-Ω resistors are in parallel, so first reduce them to a single equivalent resistance. Then find the equivalent series resistance of the circuit.

EXECUTE: $1/R_p = 1/(45.0\ \Omega) + 1/(15.0\ \Omega)$ and $R_p = 11.25\ \Omega.$ The total equivalent resistance is $18.0\ \Omega + 11.25\ \Omega + 3.26\ \Omega = 32.5\ \Omega.$ Ohm's law gives $I = (25.0\ \text{V})/(32.5\ \Omega) = 0.769\ \text{A}.$

EVALUATE: The circuit appears complicated until we realize that the 45.0-Ω and 15.0-Ω resistors are in parallel.

26.8. IDENTIFY: We are measuring an unknown resistance using Ohm's law.
SET UP and **EXECUTE:** We want R_1. For resistors in parallel $1/R_{\text{eq}} = 1/R_1 + 1/R_2 + \cdots$ The graph plots I versus V, so we need to find a relationship between those variables. Ohm's law gives $I = \dfrac{V}{R_{\text{eq}}} = V\left(\dfrac{1}{R_1} + \dfrac{1}{R_2}\right)$. So a graph of I versus V should be a straight line having slope equal to $\dfrac{1}{R_1} + \dfrac{1}{R_2}$. Solve for R_1: $R_1 = \dfrac{1}{\text{slope} - 1/R_2} = \dfrac{1}{0.208\ \Omega^{-1} - 1/(8.00\ \Omega)} = 12.0\ \Omega.$
EVALUATE: This procedure might be useful if R_1 were not accessible to direct measurement, or if one lacked a working ohmmeter.

26.9. IDENTIFY: We have a combination of resistors in a circuit.
SET UP and **EXECUTE:** **(a)** We want the current. The potential difference is the same across all the resistors in parallel, so $I = \dfrac{\mathcal{E}}{R}$ for each of the resistors since they are equal.

(b) We want the current. $R_{\text{eq}} = R_1 + R_2 + \cdots = 6R$. $I = \dfrac{\mathcal{E}}{6R}$. The same current flows through all of the series resistors.

(c) Parallel: $P_{\text{p}} = \dfrac{\mathcal{E}^2}{R}$ in each resistor.

Series: $P_{\text{s}} = I^2 R = \left(\dfrac{\mathcal{E}}{6R}\right)^2 R = \dfrac{\mathcal{E}^2}{36R}.$

The power is greatest in the parallel connection.

EVALUATE: An alternate approach in (c): $P_{\text{s}} = \dfrac{V_R^2}{R} = \dfrac{(\mathcal{E}/6)^2}{R} = \dfrac{\mathcal{E}^2}{36R}$, which agrees with our result.

26.10. IDENTIFY: The current, and hence the power, depends on the potential difference across the resistor.
SET UP: $P = V^2/R$.
EXECUTE: **(a)** $V = \sqrt{PR} = \sqrt{(5.0\ \text{W})(15{,}000\ \Omega)} = 274\ \text{V}$.

(b) $P = V^2/R = (120\ \text{V})^2/(9{,}000\ \Omega) = 1.6\ \text{W}$.

(c) SET UP: If the larger resistor generates 2.00 W, the smaller one will generate less and hence will be safe. Therefore the maximum power in the larger resistor must be 2.00 W. Use $P = I^2 R$ to find the maximum current through the series combination and use Ohm's law to find the potential difference across the combination.
EXECUTE: $P = I^2 R$ gives $I = \sqrt{P/R} = \sqrt{(2.00\ \text{W})/(150\ \Omega)} = 0.115\ \text{A}$. The same current flows through both resistors, and their equivalent resistance is $250\ \Omega$. Ohm's law gives $V = IR = (0.115\ \text{A})(250\ \Omega) = 28.8\ \text{V}$. Therefore $P_{150} = 2.00\ \text{W}$ and $P_{100} = I^2 R = (0.115\ \text{A})^2 (100\ \Omega) = 1.32\ \text{W}$.
EVALUATE: If the resistors in a series combination all have the same power rating, it is the *largest* resistance that limits the amount of current.

26.11. IDENTIFY and **SET UP:** Ohm's law applies to the resistors, the potential drop across resistors in parallel is the same for each of them, and at a junction the currents in must equal the currents out.
EXECUTE: **(a)** $V_2 = I_2 R_2 = (4.00\ \text{A})(6.00\ \Omega) = 24.0\ \text{V}$. $V_1 = V_2 = 24.0\ \text{V}$.

$I_1 = \dfrac{V_1}{R_1} = \dfrac{24.0\ \text{V}}{3.00\ \Omega} = 8.00\ \text{A}.\ \ I_3 = I_1 + I_2 = 4.00\ \text{A} + 8.00\ \text{A} = 12.0\ \text{A}.$

(b) $V_3 = I_3 R_3 = (12.0\ \text{A})(5.00\ \Omega) = 60.0\ \text{V}.\ \ \mathcal{E} = V_1 + V_3 = 24.0\ \text{V} + 60.0\ \text{V} = 84.0\ \text{V}.$

EVALUATE: Series/parallel reduction was not necessary in this case.

26.12. **IDENTIFY** and **SET UP:** Ohm's law applies to the resistors, and at a junction the currents in must equal the currents out.

EXECUTE: $V_1 = I_1 R_1 = (1.50\ \text{A})(5.00\ \Omega) = 7.50\ \text{V}.\ \ V_2 = 7.50\ \text{V}.\ \ I_1 + I_2 = I_3$ so

$I_2 = I_3 - I_1 = 4.50\ \text{A} - 1.50\ \text{A} = 3.00\ \text{A}.\ \ R_2 = \dfrac{V_2}{I_2} = \dfrac{7.50\ \text{V}}{3.00\ \text{A}} = 2.50\ \Omega.$

$V_3 = \mathcal{E} - V_1 = 35.0\ \text{V} - 7.50\ \text{V} = 27.5\ \text{V}.\ \ R_3 = \dfrac{V_3}{I_3} = \dfrac{27.5\ \text{V}}{4.50\ \text{A}} = 6.11\ \Omega.$

EVALUATE: Series/parallel reduction was not necessary in this case.

26.13. **IDENTIFY:** For resistors in parallel, the voltages are the same and the currents add. $\dfrac{1}{R_{\text{eq}}} = \dfrac{1}{R_1} + \dfrac{1}{R_2}$ so

$R_{\text{eq}} = \dfrac{R_1 R_2}{R_1 + R_2}$, For resistors in series, the currents are the same and the voltages add. $R_{\text{eq}} = R_1 + R_2$.

SET UP: The rules for combining resistors in series and parallel lead to the sequences of equivalent circuits shown in Figure 26.13.

EXECUTE: In Figure 26.13c, $I = \dfrac{60.0\ \text{V}}{5.00\ \Omega} = 12.0\ \text{A}$. This is the current through each of the resistors in Figure 26.13b. $V_{12} = IR_{12} = (12.0\ \text{A})(2.00\ \Omega) = 24.0\ \text{V}.\ \ V_{34} = IR_{34} = (12.0\ \text{A})(3.00\ \Omega) = 36.0\ \text{V}$. Note that $V_{12} + V_{34} = 60.0\ \text{V}$. V_{12} is the voltage across R_1 and across R_2, so $I_1 = \dfrac{V_{12}}{R_1} = \dfrac{24.0\ \text{V}}{3.00\ \Omega} = 8.00\ \text{A}$ and V_{34} is the voltage across R_3 and across R_4, so $I_3 = \dfrac{V_{34}}{R_3} = \dfrac{36.0\ \text{V}}{12.0\ \Omega} = 3.00\ \text{A}$ and

$I_4 = \dfrac{V_{34}}{R_4} = \dfrac{36.0\ \text{V}}{4.00\ \Omega} = 9.00\ \text{A}.$

EVALUATE: Note that $I_1 + I_2 = I_3 + I_4$.

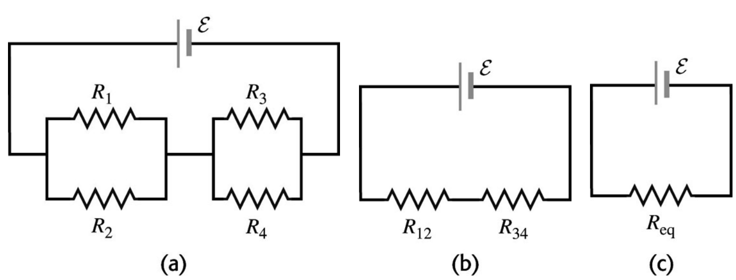

Figure 26.13

26.14. **IDENTIFY:** Replace the series combinations of resistors by their equivalents. In the resulting parallel network the battery voltage is the voltage across each resistor.

SET UP: The circuit is sketched in Figure 26.14a.

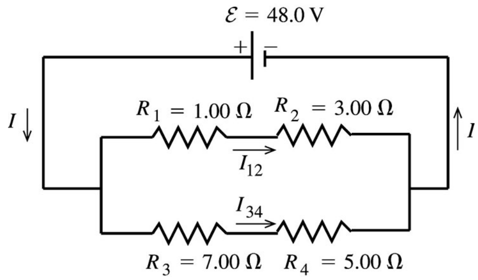

Figure 26.14a

EXECUTE: R_1 and R_2 in series have an equivalent resistance of $R_{12} = R_1 + R_2 = 4.00\ \Omega$. R_3 and R_4 in series have an equivalent resistance of $R_{34} = R_3 + R_4 = 12.0\ \Omega$.

The circuit is equivalent to the circuit sketched in Figure 26.14b.

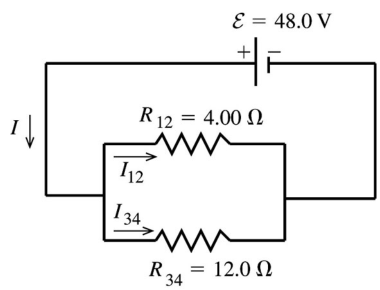

Figure 26.14b

R_{12} and R_{34} in parallel are equivalent to R_{eq} given by $\dfrac{1}{R_{eq}} = \dfrac{1}{R_{12}} + \dfrac{1}{R_{34}} = \dfrac{R_{12}+R_{34}}{R_{12}R_{34}}$.

$R_{eq} = \dfrac{R_{12}R_{34}}{R_{12}+R_{34}}$. $R_{eq} = \dfrac{(4.00\ \Omega)(12.0\ \Omega)}{4.00\ \Omega + 12.0\ \Omega} = 3.00\ \Omega$.

The voltage across each bred belowanch of the parallel combination is $\mathcal{E}$, so $\mathcal{E} - I_{12}R_{12} = 0$.

$$I_{12} = \frac{\mathcal{E}}{R_{12}} = \frac{48.0\ \text{V}}{4.00\ \Omega} = 12.0\ \text{A}.$$

$$\mathcal{E} - I_{34}R_{34} = 0 \text{ so } I_{34} = \frac{\mathcal{E}}{R_{34}} = \frac{48.0\ \text{V}}{12.0\ \Omega} = 4.0\ \text{A}.$$

The current is 12.0 A through the 1.00-Ω and 3.00-Ω resistors, and it is 4.0 A through the 7.00-Ω and 5.00-Ω resistors.

EVALUATE: The current through the battery is $I = I_{12} + I_{34} = 12.0\ \text{A} + 4.0\ \text{A} = 16.0\ \text{A}$, and this is equal to $\mathcal{E}/R_{eq} = 48.0\ \text{V}/3.00\ \Omega = 16.0\ \text{A}$.

26.15. **IDENTIFY:** In both circuits, with and without R_4, replace series and parallel combinations of resistors by their equivalents. Calculate the currents and voltages in the equivalent circuit and infer from this the currents and voltages in the original circuit. Use $P = I^2R$ to calculate the power dissipated in each bulb.
(a) SET UP: The circuit is sketched in Figure 26.15a.

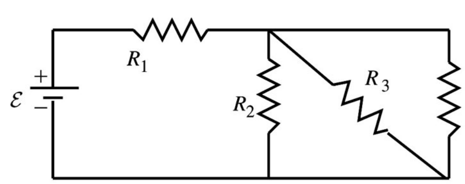

Figure 26.15a

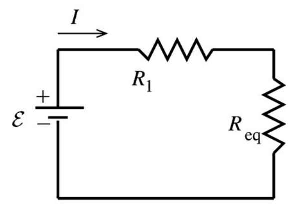
EXECUTE: R_2, R_3, and R_4 are in parallel, so their equivalent resistance R_{eq} is given by

$$\frac{1}{R_{eq}} = \frac{1}{R_2} + \frac{1}{R_3} + \frac{1}{R_4}.$$

$\frac{1}{R_{eq}} = \frac{3}{4.50\ \Omega}$ and $R_{eq} = 1.50\ \Omega.$

The equivalent circuit is drawn in Figure 26.15b.



$\mathcal{E} - I(R_1 + R_{eq}) = 0.$

$I = \frac{\mathcal{E}}{R_1 + R_{eq}}.$

Figure 26.15b

$I = \frac{9.00\ \text{V}}{4.50\ \Omega + 1.50\ \Omega} = 1.50\ \text{A}$ and $I_1 = 1.50\ \text{A}.$

Then $V_1 = I_1 R_1 = (1.50\ \text{A})(4.50\ \Omega) = 6.75\ \text{V}.$

$I_{eq} = 1.50\ \text{A},\ V_{eq} = I_{eq} R_{eq} = (1.50\ \text{A})(1.50\ \Omega) = 2.25\ \text{V}.$

For resistors in parallel the voltages are equal and are the same as the voltage across the equivalent resistor, so $V_2 = V_3 = V_4 = 2.25\ \text{V}.$

$I_2 = \frac{V_2}{R_2} = \frac{2.25\ \text{V}}{4.50\ \Omega} = 0.500\ \text{A},\ I_3 = \frac{V_3}{R_3} = 0.500\ \text{A},\ I_4 = \frac{V_4}{R_4} = 0.500\ \text{A}.$

EVALUATE: Note that $I_2 + I_3 + I_4 = 1.50\ \text{A},$ which is I_{eq}. For resistors in parallel the currents add and their sum is the current through the equivalent resistor.

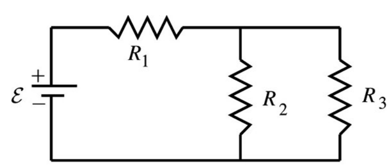
(b) SET UP: $P = I^2 R.$

EXECUTE: $P_1 = (1.50\ \text{A})^2 (4.50\ \Omega) = 10.1\ \text{W}.$

$P_2 = P_3 = P_4 = (0.500\ \text{A})^2 (4.50\ \Omega) = 1.125\ \text{W},$ which rounds to 1.12 W. R_1 glows brightest.

EVALUATE: Note that $P_2 + P_3 + P_4 = 3.37\ \text{W}$. This equals $P_{eq} = I_{eq}^2 R_{eq} = (1.50\ \text{A})^2 (1.50\ \Omega) = 3.37\ \text{W},$ the power dissipated in the equivalent resistor.

(c) SET UP: With R_4 removed the circuit becomes the circuit in Figure 26.15c.

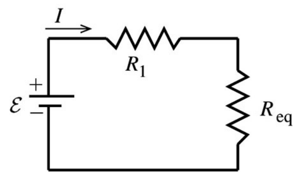


EXECUTE: R_2 and R_3 are in parallel and their equivalent resistance R_{eq} is given by

$\frac{1}{R_{eq}} = \frac{1}{R_2} + \frac{1}{R_3} = \frac{2}{4.50\ \Omega}$ and $R_{eq} = 2.25\ \Omega.$

Figure 26.15c

The equivalent circuit is shown in Figure 26.15d.



$$\mathcal{E} - I(R_1 + R_{eq}) = 0.$$

$$I = \frac{\mathcal{E}}{R_1 + R_{eq}}.$$

$$I = \frac{9.00\text{ V}}{4.50\ \Omega + 2.25\ \Omega} = 1.333\text{ A}.$$

Figure 26.15d

$I_1 = 1.33$ A, $V_1 = I_1R_1 = (1.333\text{ A})(4.50\ \Omega) = 6.00$ V.

$I_{eq} = 1.33$ A, $V_{eq} = I_{eq}R_{eq} = (1.333\text{ A})(2.25\ \Omega) = 3.00$ V and $V_2 = V_3 = 3.00$ V.

$I_2 = \dfrac{V_2}{R_2} = \dfrac{3.00\text{ V}}{4.50\ \Omega} = 0.667$ A, $I_3 = \dfrac{V_3}{R_3} = 0.667$ A.

(d) SET UP: $P = I^2R$.

EXECUTE: $P_1 = (1.333\text{ A})^2(4.50\ \Omega) = 8.00$ W.

$P_2 = P_3 = (0.667\text{ A})^2(4.50\ \Omega) = 2.00$ W.

EVALUATE: **(e)** When R_4 is removed, P_1 decreases and P_2 and P_3 increase. Bulb R_1 glows less brightly and bulbs R_2 and R_3 glow more brightly. When R_4 is removed the equivalent resistance of the circuit increases and the current through R_1 decreases. But in the parallel combination this current divides into two equal currents rather than three, so the currents through R_2 and R_3 increase. Can also see this by noting that with R_4 removed and less current through R_1 the voltage drop across R_1 is less so the voltage drop across R_2 and across R_3 must become larger.

26.16. **IDENTIFY:** Apply Ohm's law to each resistor.

SET UP: For resistors in parallel the voltages are the same and the currents add. For resistors in series the currents are the same and the voltages add.

EXECUTE: From Ohm's law, the voltage drop across the $6.00\text{-}\Omega$ resistor is $V = IR = (4.00\text{ A})(6.00\ \Omega) = 24.0$ V. The voltage drop across the $8.00\text{-}\Omega$ resistor is the same, since these two resistors are wired in parallel. The current through the $8.00\text{-}\Omega$ resistor is then $I = V/R = 24.0\text{ V}/8.00\ \Omega = 3.00$ A. The current through the $25.0\text{-}\Omega$ resistor is the sum of the current through these two resistors: 7.00 A. The voltage drop across the $25.0\text{-}\Omega$ resistor is $V = IR = (7.00\text{ A})(25.0\ \Omega) = 175$ V, and total voltage drop across the top branch of the circuit is $175\text{ V} + 24.0\text{ V} = 199$ V, which is also the voltage drop across the $20.0\text{-}\Omega$ resistor. The current through the $20.0\text{-}\Omega$ resistor is then $I = V/R = 199\text{ V}/20\ \Omega = 9.95$ A.

EVALUATE: The total current through the battery is $7.00\text{ A} + 9.95\text{ A} = 16.95$ A. Note that we did not need to calculate the emf of the battery.

26.17. **IDENTIFY:** Apply Ohm's law to each resistor.

SET UP: For resistors in parallel the voltages are the same and the currents add. For resistors in series the currents are the same and the voltages add.

EXECUTE: The current through the $2.00\text{-}\Omega$ resistor is 6.00 A. Current through the $1.00\text{-}\Omega$ resistor also is 6.00 A and the voltage is 6.00 V. Voltage across the $6.00\text{-}\Omega$ resistor is $12.0\text{ V} + 6.0\text{ V} = 18.0$ V. Current through the $6.00\text{-}\Omega$ resistor is $(18.0\text{ V})/(6.00\ \Omega) = 3.00$ A. The battery emf is 18.0 V.

EVALUATE: The current through the battery is $6.00\text{ A} + 3.00\text{ A} = 9.00\text{ A}$. The equivalent resistor of the resistor network is $2.00\ \Omega$, and this equals $(18.0\text{ V})/(9.00\text{ A})$.

26.18. **IDENTIFY:** Ohm's law applies to each resistor. In one case, the resistors are connected in series, and in the other case they are in parallel.

SET UP: $V = RI$, $\dfrac{1}{R_{\text{eq}}} = \dfrac{1}{R_1} + \dfrac{1}{R_2} + \dots$ (in parallel), $R_{\text{eq}} = R_1 + R_2 + \dots$ (in series). Figure 26.18 shows the equivalent circuit when S is open and when S is closed.

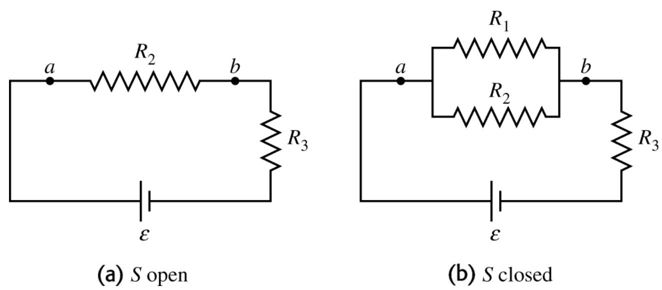


Figure 26.18

EXECUTE: **(a)** <u>S open</u>: We use the circuit in Figure 26.18a. R_2 and R_3 are in series. Ohm's law gives $\mathcal{E} = (R_2 + R_3)I$.

$I = \mathcal{E}/(R_2 + R_3) = (36.0\ V)/(9.00\ \Omega) = 4.00\text{ A}$.

$V_{ab} = R_2I = (6.00\ \Omega)(4.00\text{ A}) = 24.0\text{ V}$.

<u>S closed</u>: We use the circuit in Figure 26.18b. R_1 and R_2 are in parallel, and this combination is in series with R_3. For the parallel branch

$\dfrac{1}{R_{\text{eq}}} = \dfrac{1}{R_1} + \dfrac{1}{R_2} + \dots = 1/(4.00\ \Omega) + 1/(6.00\ \Omega)$, which gives $R_{\text{eq}} = 2.40\ \Omega$. The equivalent resistance R of the circuit is $2.40\ \Omega + 3.00\ \Omega = 5.40\ \Omega$. The current is $I = \mathcal{E}/R = (36.0\text{ V})/(5.40\ \Omega) = 6.667\text{ A}$. Therefore $V_{ab} = IR_{\text{eq}} = (6.667\text{ A})(2.40\ \Omega) = 16.0\text{ V}$.

(b) <u>S open</u>: From part (a), we know that $I_2 = 4.00\text{ A}$ through R_2. Since S is open, no current can flow through R_1, so $I_1 = 0$, $I_2 = I_3 = 4.00\text{ A}$.

<u>S closed</u>: $I_1 = V_{ab}/R_1 = (16.0\text{ V})/(4.00\ \Omega) = 4.00\text{ A}$. $I_2 = V_{ab}/R_2 = (16.0\text{ V})/(6.00\ \Omega) = 2.67\text{ A}$.

$I_3 = I_1 + I_2 = 4.00\text{ A} + 2.67\text{ A} = 6.67\text{ A}$.

I_1 increased from 0 to 4.00 A.

I_2 decreased from 4.00 A to 2.67 A.

I_3 increased from 4.00 A to 6.67 A.

EVALUATE: With S closed, $V_{ab} + V_3 = 16.0\text{ V} + (3.00\ \Omega)(6.67\text{ A}) = 36.0\text{ V}$, which is equal to $\mathcal{E}$, as it should be.

26.19. **IDENTIFY** and **SET UP:** Replace series and parallel combinations of resistors by their equivalents until the circuit is reduced to a single loop. Use the loop equation to find the current through the $20.0\text{-}\Omega$ resistor. Set $P = I^2R$ for the $20.0\text{-}\Omega$ resistor equal to the rate Q/t at which heat goes into the water and set $Q = mc\Delta T$.

EXECUTE: Replace the network by the equivalent resistor, as shown in Figure 26.19.

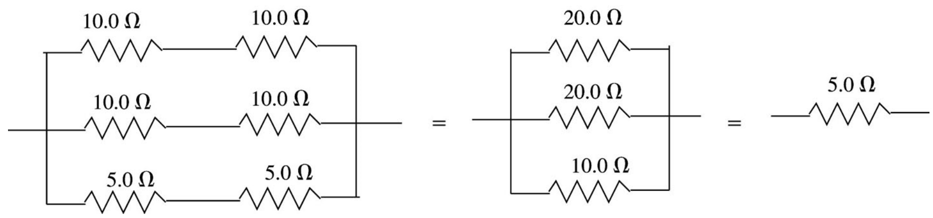

Figure 26.19

$30.0\text{ V} - I(20.0\,\Omega + 5.0\,\Omega + 5.0\,\Omega) = 0;\ I = 1.00\text{ A}.$

For the $20.0\text{-}\Omega$ resistor thermal energy is generated at the rate $P = I^2R = 20.0\text{ W}.$

$Q = Pt$ and $Q = mc\Delta T$ gives $t = \dfrac{mc\Delta T}{P} = \dfrac{(0.100\text{ kg})(4190\text{ J/kg}\cdot\text{ K})(48.0\text{ C}°)}{20.0\text{ W}} = 1.01\times 10^3\text{ s}.$

EVALUATE: The battery is supplying heat at the rate $P = \mathcal{E}I = 30.0\text{ W}.$ In the series circuit, more energy is dissipated in the larger resistor $(20.0\,\Omega)$ than in the smaller ones $(5.00\,\Omega).$

26.20. IDENTIFY: $P = I^2R$ determines R_1. $R_1, R_2,$ and the $10.0\text{-}\Omega$ resistor are all in parallel so have the same voltage. Apply the junction rule to find the current through R_2.

SET UP: $P = I^2R$ for a resistor and $P = \mathcal{E}I$ for an emf. The emf inputs electrical energy into the circuit and electrical energy is removed in the resistors.

EXECUTE: **(a)** $P_1 = I_1^2R_1$. $15.0\text{ W} = (2.00\text{ A})^2 R_1$ so $R_1 = 3.75\ \Omega.$ R_1 and $10.0\,\Omega$ are in parallel, so $(10.0\,\Omega)I_{10} = (3.75\,\Omega)(2.00\text{ A})$ so $I_{10} = 0.750\text{ A}.$ So $I_2 = 3.50\text{ A} - I_1 - I_{10} =$ 3.50 A – 2.00 A – 0.750 A = 0.750 A. R_1 and R_2 are in parallel, so $(0.750\text{ A})R_2 = (2.00\text{ A})(3.75\,\Omega)$ which gives $R_2 = 10.0\,\Omega.$

(b) $\mathcal{E} = V_1 = (2.00\text{ A})(3.75\ \Omega) = 7.50\text{ V}.$

(c) From part (a), $I_2 = 0.750\text{ A}, I_{10} = 0.750\text{ A}.$

(d) $P_1 = 15.0\text{ W}$ (given). $P_2 = I_2^2R_2 = (0.750\text{ A})^2(10.0\,\Omega) = 5.625\text{ W},$ which rounds to 5.63 W.

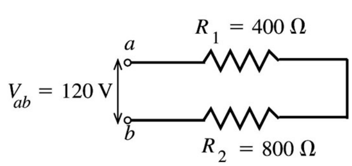
$P_{10} = I_{10}^2R_{10} = (0.750\text{ A})^2(10.0\,\Omega) = 5.625\text{ W}.$ The total rate at which the resistors remove electrical energy is $P_{\text{Resist}} = 15.0\text{ W} + 5.625\text{ W} + 5.625\text{ W} = 26.25\text{ W},$ which rounds to 26.3 W.

The total rate at which the battery inputs electrical energy is $P_{\text{Battery}} = I\mathcal{E} = (3.50\text{ A})(7.50\text{ V}) =$ 26.3 W. Therefore $P_{\text{Resist}} = P_{\text{Battery}}$, which agrees with conservation of energy.

EVALUATE: The three resistors are in parallel, so the voltage for each is the battery voltage, 7.50 V. The currents in the three resistors add to give the current in the battery.

26.21. IDENTIFY: For resistors in series, the voltages add and the current is the same. For resistors in parallel, the voltages are the same and the currents add. $P = I^2R.$

(a) SET UP: The circuit is sketched in Figure 26.21a.



For resistors in series the current is the same through each.

Figure 26.21a

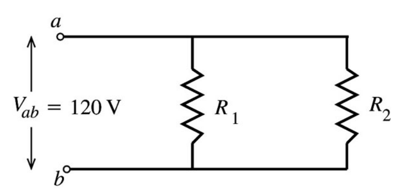
EXECUTE: $R_{eq} = R_1 + R_2 = 1200\ \Omega$. $I = \dfrac{V}{R_{eq}} = \dfrac{120\text{ V}}{1200\ \Omega} = 0.100\text{ A}$. This is the current drawn from the line.

(b) $P_1 = I_1^2 R_1 = (0.100\text{ A})^2 (400\ \Omega) = 4.0\text{ W}$.

$P_2 = I_2^2 R_2 = (0.100\text{ A})^2 (800\ \Omega) = 8.0\text{ W}$.

(c) $P_{out} = P_1 + P_2 = 12.0\text{ W}$, the total power dissipated in both bulbs. Note that $P_{in} = V_{ab} I = (120\text{ V})(0.100\text{ A}) = 12.0\text{ W}$, the power delivered by the potential source, equals P_{out}.

(d) SET UP: The circuit is sketched in Figure 26.21b.



For resistors in parallel the voltage across each resistor is the same.

Figure 26.21b

EXECUTE: $I_1 = \dfrac{V_1}{R_1} = \dfrac{120\text{ V}}{400\ \Omega} = 0.300\text{ A}, I_2 = \dfrac{V_2}{R_2} = \dfrac{120\text{ V}}{800\ \Omega} = 0.150\text{ A}$.

EVALUATE: Note that each current is larger than the current when the resistors are connected in series.

EXECUTE: **(e)** $P_1 = I_1^2 R_1 = (0.300\text{ A})^2 (400\ \Omega) = 36.0\text{ W}$.

$P_2 = I_2^2 R_2 = (0.150\text{ A})^2 (800\ \Omega) = 18.0\text{ W}$.

(f) $P_{out} = P_1 + P_2 = 54.0\text{ W}$.

EVALUATE: Note that the total current drawn from the line is $I = I_1 + I_2 = 0.450\text{ A}$. The power input from the line is $P_{in} = V_{ab} I = (120\text{ V})(0.450\text{ A}) = 54.0\text{ W}$, which equals the total power dissipated by the bulbs.

(g) The bulb that is dissipating the most power glows most brightly. For the series connection the currents are the same and by $P = I^2 R$ the bulb with the larger *R* has the larger *P*; the $800\text{-}\Omega$ bulb glows more brightly. For the parallel combination the voltages are the same and by $P = V^2/R$ the bulb with the smaller *R* has the larger *P*; the $400\text{-}\Omega$ bulb glows more brightly.

(h) The total power output P_{out} equals $P_{in} = V_{ab} I$, so P_{out} is larger for the parallel connection where the current drawn from the line is larger (because the equivalent resistance is smaller.)

26.22. IDENTIFY: This circuit cannot be reduced using series/parallel combinations, so we apply Kirchhoff's rules. The target variables are the currents in each segment.

SET UP: Assume the unknown currents have the directions shown in Figure 26.22. We have used the junction rule to write the current through the 10.0 V battery as $I_1 + I_2$. There are two unknowns, I_1 and I_2, so we will need two equations. Three possible circuit loops are shown in the figure.

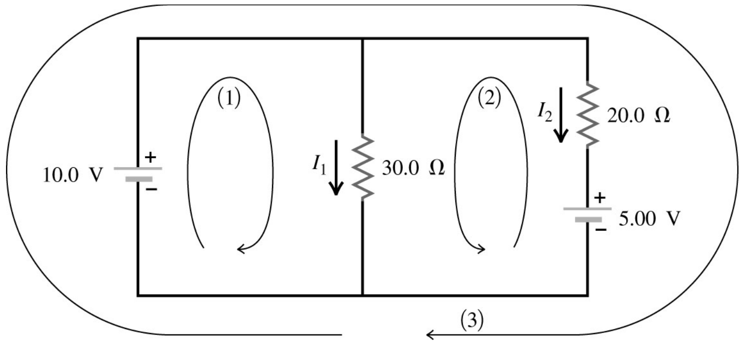


Figure 26.22

EXECUTE: **(a)** Apply the loop rule to loop (1), going around the loop in the direction shown: $+10.0\text{ V} - (30.0\ \Omega)I_1 = 0$ and $I_1 = 0.333$ A.

(b) Apply the loop rule to loop (3): $+10.0\text{ V} - (20.0\ \Omega)I_2 - 5.00\text{ V} = 0$ and $I_2 = 0.250$ A.

(c) $I_1 + I_2 = 0.333\text{ A} + 0.250\text{ A} = 0.583$ A.

EVALUATE: For loop (2) we get
$+5.00\text{ V} + I_2(20.0\ \Omega) - I_1(30.0\ \Omega) = 5.00\text{ V} + (0.250\text{ A})(20.0\ \Omega) - (0.333\text{ A})(30.0\ \Omega) =$
$5.00\text{ V} + 5.00\text{ V} - 10.0\text{ V} = 0$, so that with the currents we have calculated the loop rule is satisfied for this third loop.

26.23. **IDENTIFY:** Apply Kirchhoff's junction rule at point *a* to find the current through *R*. Apply Kirchhoff's loop rule to loops (1) and (2) shown in Figure 26.23a to calculate *R* and $\mathcal{E}$. Travel around each loop in the direction shown.
SET UP:

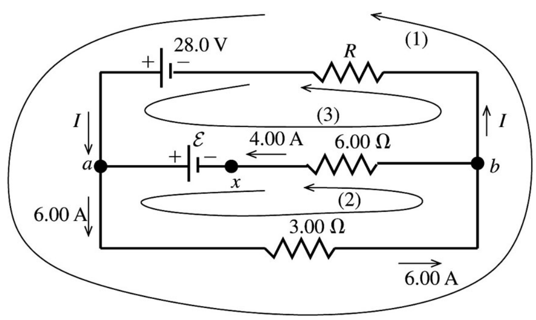

Figure 26.23a

EXECUTE: **(a)** Apply Kirchhoff's junction rule to point *a*: $\sum I = 0$ so $I + 4.00\text{ A} - 6.00\text{ A} = 0$
$I = 2.00$ A (in the direction shown in the diagram).

(b) Apply Kirchhoff's loop rule to loop (1): $-(6.00\text{ A})(3.00\ \Omega) - (2.00\text{ A})R + 28.0\text{ V} = 0$

$-18.0\text{ V} - (2.00\ \Omega)R + 28.0\text{ V} = 0$.

$$R = \frac{28.0\text{ V} - 18.0\text{ V}}{2.00\text{ A}} = 5.00\ \Omega.$$

(c) Apply Kirchhoff's loop rule to loop (2): $-(6.00\text{ A})(3.00\ \Omega) - (4.00\text{ A})(6.00\ \Omega) + \varepsilon = 0$.

$\mathcal{E} = 18.0\text{ V} + 24.0\text{ V} = 42.0$ V.

EVALUATE: We can check that the loop rule is satisfied for loop (3), as a check of our work:
$28.0\text{ V} - \mathcal{E} + (4.00\text{ A})(6.00\ \Omega) - (2.00\text{ A})R = 0$.

$28.0\text{ V} - 42.0\text{ V} + 24.0\text{ V} - (2.00\text{ A})(5.00\ \Omega) = 0$.

$52.0\text{ V} = 42.0\text{ V} + 10.0\text{ V}.$

$52.0\text{ V} = 52.0\text{ V},$ so the loop rule is satisfied for this loop.

(d) IDENTIFY: If the circuit is broken at point *x* there can be no current in the $6.00\text{-}\Omega$ resistor. There is now only a single current path and we can apply the loop rule to this path.

SET UP: The circuit is sketched in Figure 26.23b.

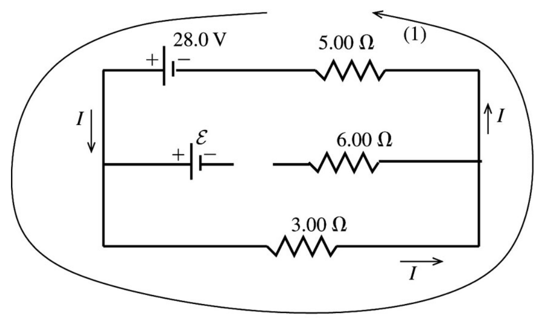

Figure 26.23b

EXECUTE: $+28.0\text{ V} - (3.00\,\Omega)I - (5.00\,\Omega)I = 0.$

$I = \dfrac{28.0\text{ V}}{8.00\,\Omega} = 3.50\text{ A}.$

EVALUATE: Breaking the circuit at *x* removes the 42.0-V emf from the circuit and the current through the $3.00\text{-}\Omega$ resistor is reduced.

26.24. IDENTIFY: Apply Kirchhoff's loop rule and junction rule.

SET UP: The circuit diagram is given in Figure 26.24. The junction rule has been used to find the magnitude and direction of the current in the middle branch of the circuit. There are no remaining unknown currents.

EXECUTE: The loop rule applied to loop (1) gives:

$+20.0\text{V} - (1.00\text{ A})(1.00\,\Omega) + (1.00\text{ A})(4.00\,\Omega) + (1.00\text{ A})(1.00\,\Omega) - \mathcal{E}_1 - (1.00\text{ A})(6.00\,\Omega) = 0.$

$\mathcal{E}_1 = 20.0\text{ V} - 1.00\text{ V} + 4.00\text{ V} + 1.00\text{ V} - 6.00\text{ V} = 18.0\text{ V}.$ The loop rule applied to loop (2) gives:

$+20.0\text{ V} - (1.00\text{ A})(1.00\,\Omega) - (2.00\text{ A})(1.00\,\Omega) - \mathcal{E}_2 - (2.00\text{ A})(2.00\,\Omega) - (1.00\text{ A})(6.00\,\Omega) = 0.$

$\mathcal{E}_2 = 20.0\text{ V} - 1.00\text{ V} - 2.00\text{ V} - 4.00\text{ V} - 6.00\text{ V} = 7.0\text{ V}.$ Going from *b* to *a* along the lower branch,

$V_b + (2.00\text{ A})(2.00\,\Omega) + 7.0\text{ V} + (2.00\text{ A})(1.00\,\Omega) = V_a \cdot V_b - V_a = -13.0\text{ V};$ point *b* is at 13.0 V lower potential than point *a*.

EVALUATE: We can also calculate $V_b - V_a$ by going from *b* to *a* along the upper branch of the circuit.

$V_b - (1.00\text{ A})(6.00\,\Omega) + 20.0\text{ V} - (1.00\text{ A})(1.00\,\Omega) = V_a$ and $V_b - V_a = -13.0\text{ V}.$ This agrees with $V_b - V_a$ calculated along a different path between *b* and *a*.

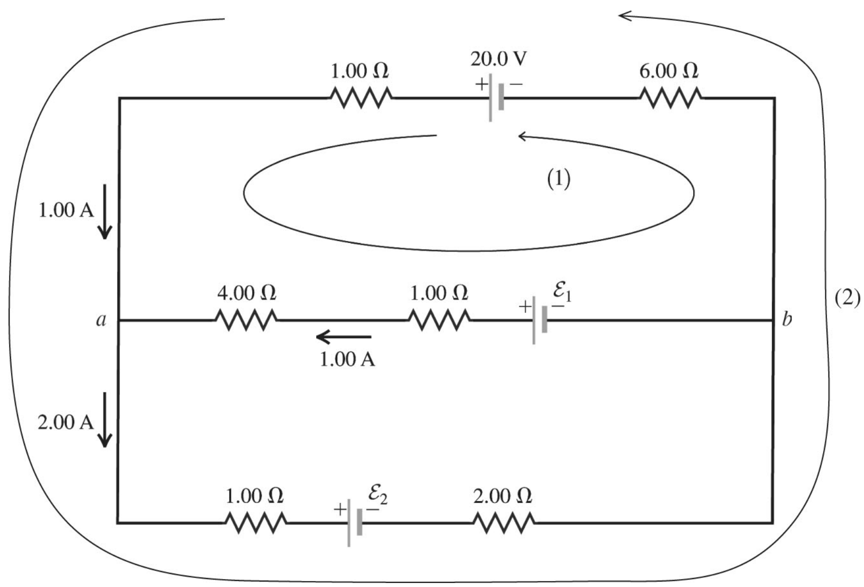

Figure 26.24

26.25. **IDENTIFY:** Apply Kirchhoff's junction rule at points *a*, *b*, *c*, and *d* to calculate the unknown currents. Then apply the loop rule to three loops to calculate $\mathcal{E}_1, \mathcal{E}_2$, and *R*.

SET UP: The circuit is sketched in Figure 26.25.

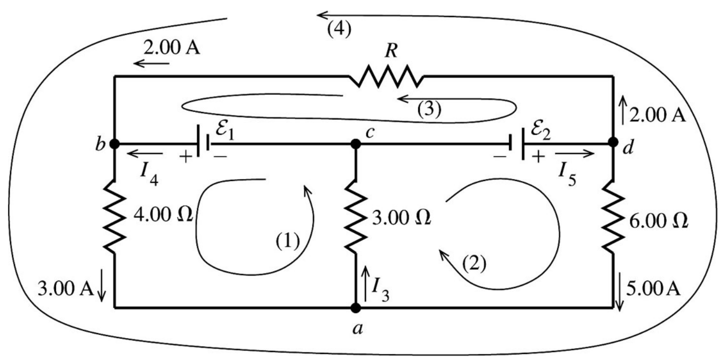

Figure 26.25

(a) EXECUTE: Apply the junction rule to point *a*: $3.00\text{ A} + 5.00\text{ A} - I_3 = 0$.

$I_3 = 8.00\text{ A}$.

Apply the junction rule to point *b*: $2.00\text{ A} + I_4 - 3.00\text{ A} = 0$.

$I_4 = 1.00\text{ A}$.

Apply the junction rule to point *c*: $I_3 - I_4 - I_5 = 0$.

$I_5 = I_3 - I_4 = 8.00\text{ A} - 1.00\text{ A} = 7.00\text{ A}$.

EVALUATE: As a check, apply the junction rule to point *d*: $I_5 - 2.00\text{ A} - 5.00\text{ A} = 0$.

$I_5 = 7.00\text{ A}$.

(b) EXECUTE: Apply the loop rule to loop (1): $\mathcal{E}_1 - (3.00\text{ A})(4.00\,\Omega) - I_3(3.00\,\Omega) = 0$.

$\mathcal{E}_1 = 12.0\text{ V} + (8.00\text{ A})(3.00\,\Omega) = 36.0\text{ V}$.

Apply the loop rule to loop (2): $\mathcal{E}_2 - (5.00\text{ A})(6.00\,\Omega) - I_3(3.00\,\Omega) = 0$.

$\mathcal{E}_2 = 30.0\text{ V} + (8.00\text{ A})(3.00\ \Omega) = 54.0\text{ V}.$

(c) EXECUTE: Apply the loop rule to loop (3): $-(2.00\text{ A})R - \mathcal{E}_1 + \mathcal{E}_2 = 0.$

$$R = \frac{\mathcal{E}_2 - \mathcal{E}_1}{2.00\text{ A}} = \frac{54.0\text{ V} - 36.0\text{ V}}{2.00\text{ A}} = 9.00\ \Omega.$$

EVALUATE: Apply the loop rule to loop (4) as a check of our calculations:
$-(2.00\text{ A})R - (3.00\text{ A})(4.00\ \Omega) + (5.00\text{ A})(6.00\ \Omega) = 0.$

$-(2.00\text{ A})(9.00\ \Omega) - 12.0\text{ V} + 30.0\text{ V} = 0.$

$-18.0\text{ V} + 18.0\text{ V} = 0.$

26.26. **IDENTIFY:** Use Kirchhoff's rules to find the currents.
SET UP: Since the 10.0-V battery has the larger voltage, assume I_1 is to the left through the 10-V battery, I_2 is to the right through the 5-V battery, and I_3 is to the right through the 10-Ω resistor. Go around each loop in the counterclockwise direction.
EXECUTE: **(a)** Upper loop: $10.0\text{ V} - (2.00\ \Omega + 3.00\ \Omega)I_1 - (1.00\ \Omega + 4.00\ \Omega)I_2 - 5.00\text{ V} = 0.$ This gives $5.0\text{ V} - (5.00\ \Omega)I_1 - (5.00\ \Omega)I_2 = 0,$ and $\Rightarrow I_1 + I_2 = 1.00\text{ A}.$

Lower loop: $5.00\text{ V} + (1.00\ \Omega + 4.00\ \Omega)I_2 - (10.0\ \Omega)I_3 = 0.$ This gives $5.00\text{ V} + (5.00\ \Omega)I_2 - (10.0\ \Omega)I_3 = 0,$ and $I_2 - 2I_3 = -1.00\text{ A}.$

Along with $I_1 = I_2 + I_3$, we can solve for the three currents and find:
$I_1 = 0.800\text{ A}, I_2 = 0.200\text{ A}, I_3 = 0.600\text{ A}.$

(b) $V_{ab} = -(0.200\text{ A})(4.00\ \Omega) - (0.800\text{ A})(3.00\ \Omega) = -3.20\text{ V}.$

EVALUATE: Traveling from *b* to *a* through the 4.00-Ω and 3.00-Ω resistors you pass through the resistors in the direction of the current and the potential decreases. Therefore point *b* is at higher potential than point *a*.

26.27. **IDENTIFY:** Apply the junction rule to reduce the number of unknown currents. Apply the loop rule to two loops to obtain two equations for the unknown currents I_1 and I_2.
(a) SET UP: The circuit is sketched in Figure 26.27.

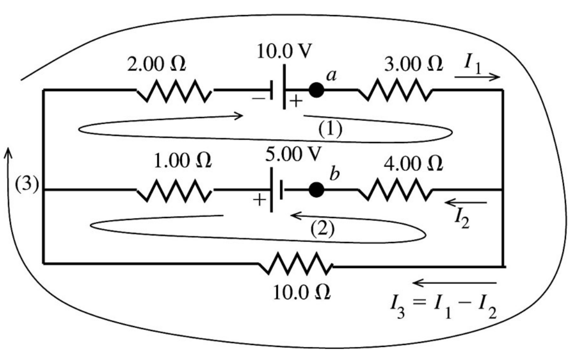

Figure 26.27

Let I_1 be the current in the 3.00-Ω resistor and I_2 be the current in the 4.00-Ω resistor and assume that these currents are in the directions shown. Then the current in the 10.0-Ω resistor is $I_3 = I_1 - I_2$, in the direction shown, where we have used Kirchhoff's junction rule to relate I_3 to I_1 and I_2. If we get a negative answer for any of these currents we know the current is actually in the opposite direction to what we have assumed. Three loops and directions to travel around the loops are shown in the circiut diagram in Figure 26.27. Apply Kirchhoff's loop rule to each loop.
EXECUTE: Loop (1):
$+10.0\text{ V} - I_1(3.00\ \Omega) - I_2(4.00\ \Omega) + 5.00\text{ V} - I_2(1.00\ \Omega) - I_1(2.00\ \Omega) = 0.$

$15.00\text{ V}-(5.00\ \Omega)I_1-(5.00\ \Omega)I_2=0.$

$3.00\text{ A}-I_1-I_2=0.$

Loop (2):

$+5.00\text{ V}-I_2(1.00\ \Omega)+(I_1-I_2)10.0\ \Omega-I_2(4.00\ \Omega)=0.$

$5.00\text{ V}+(10.0\ \Omega)I_1-(15.0\ \Omega)I_2=0.$

$1.00\text{ A}+2.00I_1-3.00I_2=0.$

The first equation says $I_2=3.00\text{ A}-I_1.$

Use this in the second equation: $1.00\text{ A}+2.00I_1-9.00\text{ A}+3.00I_1=0.$

$5.00I_1=8.00\text{ A}, I_1=1.60\text{ A}.$

Then $I_2=3.00\text{ A}-I_1=3.00\text{ A}-1.60\text{ A}=1.40\text{ A}.$

$I_3=I_1-I_2=1.60\text{ A}-1.40\text{ A}=0.20\text{ A}.$

EVALUATE: Loop (3) can be used as a check.

$+10.0\text{ V}-(1.60\text{ A})(3.00\ \Omega)-(0.20\text{ A})(10.00\ \Omega)-(1.60\text{ A})(2.00\ \Omega)=0.$

$10.0\text{ V}=4.8\text{ V}+2.0\text{ V}+3.2\text{ V}.$

$10.0\text{ V}=10.0\text{ V}.$

We find that with our calculated currents the loop rule is satisfied for loop (3). Also, all the currents came out to be positive, so the current directions in the circuit diagram are correct.

(b) IDENTIFY and **SET UP:** To find $V_{ab}=V_a-V_b$ start at point *b* and travel to point *a*. Many different routes can be taken from *b* to *a* and all must yield the same result for V_{ab}.

EXECUTE: Travel through the $4.00\text{-}\Omega$ resistor and then through the $3.00\text{-}\Omega$ resistor:

$V_b+I_2(4.00\ \Omega)+I_1(3.00\ \Omega)=V_a.$

$V_a-V_b=(1.40\text{ A})(4.00\ \Omega)+(1.60\text{ A})(3.00\ \Omega)=5.60\text{ V}+4.8\text{ V}=10.4\text{ V}$ (point *a* is at higher potential than point *b*).

EVALUATE: Alternatively, travel through the 5.00-V emf, the $1.00\text{-}\Omega$ resistor, the $2.00\text{-}\Omega$ resistor, and the 10.0-V emf.

$V_b+5.00\text{ V}-I_2(1.00\ \Omega)-I_1(2.00\ \Omega)+10.0\text{ V}=V_a.$

$V_a-V_b=15.0\text{ V}-(1.40\text{ A})(1.00\ \Omega)-(1.60\text{ A})(2.00\ \Omega)=15.0\text{ V}-1.40\text{ V}-3.20\text{ V}=10.4\text{ V},$ the same as before.

26.28. IDENTIFY: Use Kirchhoff's rules to find the currents.

SET UP: Since the 15.0-V battery has the largest voltage, assume I_1 is to the right through the 10.0-V battery, I_2 is to the left through the 15.0-V battery, and I_3 is to the right through the $10.00\text{-}\Omega$ resistor. Go around each loop in the counterclockwise direction.

EXECUTE: (a) Upper loop: $10.0\text{ V}+(2.00\ \Omega+3.00\ \Omega)I_1+(1.00\ \Omega+4.00\ \Omega)I_2-15.00\text{ V}=0.$

$-5.00\text{ V}+(5.00\ \Omega)I_1+(5.00\ \Omega)I_2=0,$ so $I_1+I_2=+1.00\text{A}.$

Lower loop: $15.00\text{ V}-(1.00\ \Omega+4.00\ \Omega)I_2-(10.0\ \Omega)I_3=0.$

$15.00\text{ V}-(5.00\ \Omega)I_2-(10.0\ \Omega)I_3=0,$ so $I_2+2I_3=3.00\text{ A}.$

Along with $I_2=I_1+I_3,$ we can solve for the three currents and find

$I_1=0.00\text{ A}, I_2=+1.00\text{ A (to the left)}, I_3=+1.00\text{ A (to the right)}.$

(b) $V_{ab}=I_2(4.00\ \Omega)+I_1(3.00\ \Omega)=(1.00\text{ A})(4.00\ \Omega)+(0.00\text{ A})(3.00\ \Omega)=4.00\text{ V}.$

EVALUATE: Traveling from *b* to *a* through the $4.00\text{-}\Omega$ and $3.00\text{-}\Omega$ resistors you pass through each resistor opposite to the direction of the current and the potential increases; point *a* is at higher potential than point *b*.

26.29. **(a) IDENTIFY:** With the switch open, the circuit can be solved using series-parallel reduction.
SET UP: Find the current through the unknown battery using Ohm's law. Then use the equivalent resistance of the circuit to find the emf of the battery.
EXECUTE: The $30.0\text{-}\Omega$ and $50.0\text{-}\Omega$ resistors are in series, and hence have the same current. Using Ohm's law $I_{50} = (15.0\text{ V})/(50.0\ \Omega) = 0.300\text{ A} = I_{30}$. The potential drop across the $75.0\text{-}\Omega$ resistor is the same as the potential drop across the $80.0\text{-}\Omega$ series combination. We can use this fact to find the current through the $75.0\text{-}\Omega$ resistor using Ohm's law: $V_{75} = V_{80} = (0.300\text{ A})(80.0\ \Omega) = 24.0\text{ V}$ and
$I_{75} = (24.0\text{ V})/(75.0\ \Omega) = 0.320\text{ A}$.
The current through the unknown battery is the sum of the two currents we just found:
$I_{\text{Total}} = 0.300\text{ A} + 0.320\text{ A} = 0.620\text{ A}$.
The equivalent resistance of the resistors in parallel is $1/R_{\text{p}} = 1/(75.0\ \Omega) + 1/(80.0\ \Omega)$. This gives
$R_{\text{p}} = 38.7\ \Omega$. The equivalent resistance "seen" by the battery is $R_{\text{equiv}} = 20.0\ \Omega + 38.7\ \Omega = 58.7\ \Omega$.
Applying Ohm's law to the battery gives $\mathcal{E} = R_{\text{equiv}} I_{\text{Total}} = (58.7\ \Omega)(0.620\text{ A}) = 36.4\text{ V}$.
(b) IDENTIFY: With the switch closed, the 25.0-V battery is connected across the $50.0\text{-}\Omega$ resistor.
SET UP: Take a loop around the right part of the circuit.
EXECUTE: Ohm's law gives $I = (25.0\text{ V})/(50.0\ \Omega) = 0.500\text{ A}$.
EVALUATE: The current through the $50.0\text{-}\Omega$ resistor, and the rest of the circuit, depends on whether or not the switch is open.

26.30. **IDENTIFY:** We need to use Kirchhoff's rules.
SET UP: Take a loop around the outside of the circuit, apply the junction rule at the upper junction, and then take a loop around the right side of the circuit.
EXECUTE: The outside loop gives $75.0\text{ V} - (12.0\ \Omega)(1.50\text{ A}) - (48.0\ \Omega)I_{48} = 0$, so $I_{48} = 1.188\text{ A}$. At a junction we have $1.50\text{A} = I_{\mathcal{E}} + 1.188\text{ A}$, and $I_{\mathcal{E}} = 0.313\text{ A}$. A loop around the right part of the circuit gives $\mathcal{E} - (48\ \Omega)(1.188\text{ A}) + (15.0\ \Omega)(0.313\text{ A})$. $\mathcal{E} = 52.3\text{ V}$, with the polarity shown in the figure in the problem.
EVALUATE: The unknown battery has a smaller emf than the known one, so the current through it goes against its polarity.

26.31. **(a) IDENTIFY:** With the switch open, we have a series circuit with two batteries.
SET UP: Take a loop to find the current, then use Ohm's law to find the potential difference between *a* and *b*.
EXECUTE: Taking the loop: $I = (40.0\text{ V})/(175\ \Omega) = 0.229\text{ A}$. The potential difference between *a* and *b* is $V_b - V_a = +15.0\text{ V} - (75.0\ \Omega)(0.229\text{ A}) = -2.14\text{ V}$.
EVALUATE: The minus sign means that *a* is at a higher potential than *b*.
(b) IDENTIFY: With the switch closed, the ammeter part of the circuit divides the original circuit into two circuits. We can apply Kirchhoff's rules to both parts.
SET UP: Take loops around the left and right parts of the circuit, and then look at the current at the junction.
EXECUTE: The left-hand loop gives $I_{100} = (25.0\text{ V})/(100.0\ \Omega) = 0.250\text{ A}$. The right-hand loop gives $I_{75} = (15.0\text{ V})/(75.0\ \Omega) = 0.200\text{ A}$. At the junction just above the switch we have $I_{100} = 0.250\text{ A}$ (in) and $I_{75} = 0.200\text{ A (out)}$, so $I_{\text{A}} = 0.250\text{ A} - 0.200\text{ A} = 0.050\text{ A}$, downward. The voltmeter reads zero because the potential difference across it is zero with the switch closed.
EVALUATE: The ideal ammeter acts like a short circuit, making *a* and *b* at the same potential. Hence the voltmeter reads zero.

26.32. IDENTIFY: We first reduce the parallel combination of the $20.0\text{-}\Omega$ resistors and then apply Kirchhoff's rules.

SET UP: $P = I^2R$ so the power consumption of the $6.0\text{-}\Omega$ resistor allows us to calculate the current through it. Unknown currents I_1, I_2, and I_3 are shown in Figure 26.32. The junction rule says that $I_1 = I_2 + I_3$. In Figure 26.34 the two $20.0\text{-}\Omega$ resistors in parallel have been replaced by their equivalent $(10.0\ \Omega)$.

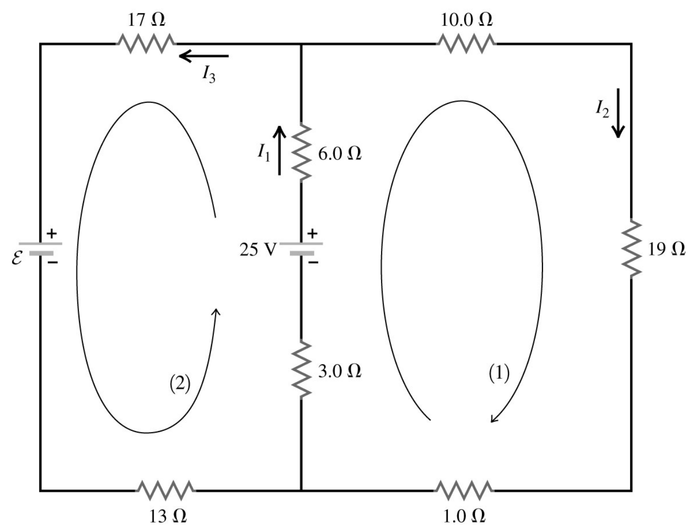

Figure 26.32

EXECUTE: (a) $P = I^2R$ gives $I_1 = \sqrt{\dfrac{P}{R}} = \sqrt{\dfrac{24\ \text{J/s}}{6.0\ \Omega}} = 2.0\ \text{A}$. The loop rule applied to loop (1) gives:

$-(2.0\ \text{A})(3.0\ \Omega) - (2.0\ \text{A})(6.0\ \Omega) + 25\ \text{V} - I_2(10.0\ \Omega + 19.0\ \Omega + 1.0\ \Omega) = 0.$

$I_2 = \dfrac{25\ \text{V} - 18\ \text{V}}{30.0\ \Omega} = 0.233\ \text{A}.$

(b) $I_3 = I_1 - I_2 = 2.0\ \text{A} - 0.233\ \text{A} = 1.77\ \text{A}$. The loop rule applied to loop (2) gives:

$-(2.0\ \text{A})(3.0\ \Omega + 6.0\ \Omega) + 25\ \text{V} - (1.77\ \text{A})(17\ \Omega) - \mathcal{E} - (1.77\ \text{A})(13\ \Omega) = 0.$

$\mathcal{E} = 25\ \text{V} - 18\ \text{V} - 53.1\ \text{V} = -46.1\ \text{V}$. The emf is 46.1 V.

EVALUATE: Because of the minus sign for the emf, the polarity of the battery is opposite to what is shown in the figure in the problem; the + terminal is adjacent to the $13\text{-}\Omega$ resistor.

26.33. IDENTIFY: To construct an ammeter, add a shunt resistor in parallel with the galvanometer coil. To construct a voltmeter, add a resistor in series with the galvanometer coil.

SET UP: The full-scale deflection current is $500\ \mu\text{A}$ and the coil resistance is $25.0\ \Omega$.

EXECUTE: (a) For a 20-mA ammeter, the two resistances are in parallel and the voltages across each are the same. $V_c = V_s$ gives $I_cR_c = I_sR_s$. $(500\times10^{-6}\ \text{A})(25.0\ \Omega) = (20\times10^{-3}\ \text{A} - 500\times10^{-6}\ \text{A})R_s$ and $R_s = 0.641\ \Omega$.

(b) For a 500-mV voltmeter, the resistances are in series and the current is the same through each:

$V_{ab} = I(R_c + R_s)$ and $R_s = \dfrac{V_{ab}}{I} - R_c = \dfrac{500\times10^{-3}\ \text{V}}{500\times10^{-6}\ \text{A}} - 25.0\ \Omega = 975\ \Omega.$

EVALUATE: The equivalent resistance of the voltmeter is $R_{eq} = R_s + R_c = 1000\ \Omega$. The equivalent resistance of the ammeter is given by $\frac{1}{R_{eq}} = \frac{1}{R_{sh}} + \frac{1}{R_c}$ and $R_{eq} = 0.625\ \Omega$. The voltmeter is a high-resistance device and the ammeter is a low-resistance device.

26.34. IDENTIFY: The galvanometer is represented in the circuit as a resistance R_G. Use the junction rule to relate the current through the galvanometer and the current through the shunt resistor. The voltage drop across each parallel path is the same; use this to write an equation for the resistance *R*.

SET UP: The circuit is sketched in Figure 26.34.

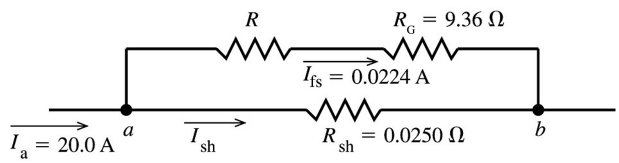

Figure 26.34

We want that $I_a = 20.0$ A in the external circuit to produce $I_{fs} = 0.0224$ A through the galvanometer coil.

EXECUTE: Applying the junction rule to point *a* gives $I_a - I_{fs} - I_{sh} = 0$.

$I_{sh} = I_a - I_{fs} = 20.0\text{ A} - 0.0224\text{ A} = 19.98\text{ A}$.

The potential difference V_{ab} between points *a* and *b* must be the same for both paths between these two points: $I_{fs}(R + R_G) = I_{sh}R_{sh}$.

$$R = \frac{I_{sh}R_{sh}}{I_{fs}} - R_G = \frac{(19.98\text{ A})(0.0250\ \Omega)}{0.0224\text{ A}} - 9.36\ \Omega = 22.30\ \Omega - 9.36\ \Omega = 12.9\ \Omega.$$

EVALUATE: $R_{sh} << R + R_G$; most of the current goes through the shunt. Adding *R* decreases the fraction of the current that goes through R_G.

26.35. IDENTIFY: The meter introduces resistance into the circuit, which affects the current through the $5.00\text{-k}\Omega$ resistor and hence the potential drop across it.

SET UP: Use Ohm's law to find the current through the $5.00\text{-k}\Omega$ resistor and then the potential drop across it.

EXECUTE: **(a)** The parallel resistance with the voltmeter is $3.33\text{ k}\Omega$, so the total equivalent resistance across the battery is $9.33\text{ k}\Omega$, giving $I = (50.0\text{ V})/(9.33\text{ k}\Omega) = 5.36\text{ mA}$. Ohm's law gives the potential drop across the $5.00\text{-k}\Omega$ resistor: $V_{5\text{ k}\Omega} = (3.33\text{ k}\Omega)(5.36\text{ mA}) = 17.9\text{ V}$.

(b) The current in the circuit is now $I = (50.0\text{ V})/(11.0\text{ k}\Omega) = 4.55\text{ mA}$.

$V_{5\text{ k}\Omega} = (5.00\text{ k}\Omega)(4.55\text{ mA}) = 22.7\text{ V}$.

(c) % error $= (22.7\text{ V} - 17.9\text{ V})/(22.7\text{ V}) = 0.214 = 21.4\%$. (We carried extra decimal places for accuracy since we had to subtract our answers.)

EVALUATE: The presence of the meter made a very large percent error in the reading of the "true" potential across the resistor.

26.36. IDENTIFY: We are measuring a capacitor in a circuit. We measure the time $T_{1/2}$ for the voltage to decrease to $V_0/2$ and then graph $T_{1/2}$ versus *R*.

SET UP: We need to find a relationship between $T_{1/2}$ and *R* to interpret the graph.

EXECUTE: For discharging $V = V_0 e^{-t/RC}$. $V_{1/2} = \frac{1}{2}V_0 = V_0 e^{-T_{1/2}/RC}$. Solve for $T_{1/2}$ by taking logarithms.

$T_{1/2} = (C \ln 2)R$, so a graph of $T_{1/2}$ versus R should be a straight line having slope equal to $C \ln 2$. C = (slope)/(ln 2) = (5.00 μF)/(ln 2) = 7.21 μF.

EVALUATE: Note that $T_{1/2}$ is *not* the time constant.

26.37. **IDENTIFY:** The capacitor discharges exponentially through the voltmeter. Since the potential difference across the capacitor is directly proportional to the charge on the plates, the voltage across the plates decreases exponentially with the same time constant as the charge.

SET UP: The reading of the voltmeter obeys the equation $V = V_{0e}^{-t/RC}$, where RC is the time constant.

EXECUTE: **(a)** Solving for C and evaluating the result when $t = 4.00\text{ s}$ gives

$$C = \frac{t}{R\ln(V/V_0)} = \frac{4.00\text{ s}}{(3.40\times10^6\ \Omega)\ln\left(\dfrac{12.0\text{ V}}{3.00\text{ V}}\right)} = 8.49\times10^{-7}\text{ F}.$$

(b) $\tau = RC = (3.40\times10^6\ \Omega)(8.49\times10^{-7}\ \text{F}) = 2.89\text{ s}.$

EVALUATE: In most laboratory circuits, time constants are much shorter than this one.

26.38. **IDENTIFY:** When S is closed, charge starts to flow and charge the capacitor until the potential difference across the capacitor is equal to the emf of the battery.

SET UP: $V_R = RI$, $V_C = \mathcal{E}(1 - e^{-t/RC})$, and $U_C = Q^2/2C$.

EXECUTE: **(a)** Kirchhoff's loop rule gives $V_C + V_R = \mathcal{E}$,

so $I = (\mathcal{E} - V_C)/R$ = (36.0 V – 8.00 V)/(120 Ω) = 0.2333 A, which rounds to 0.233 A.

(b) From $V_C = \mathcal{E}(1 - e^{-t/RC})$, we get $e^{-t/RC} = 1 - V_C/\mathcal{E}$. Taking logs gives $-t/RC = \ln(1 - V_C/\mathcal{E})$. Solving for t gives t = –(120 Ω)(5.00 μF) ln[1 – (8.00 V)/(36.0 V)] = 151 μs.

(c) $U_C = Q^2/2C$, so $P_C = dU_C/dt = (Q/C)\,dQ/dt = V_C I$ = (8.00 V)(0.2333 A) = 1.87 W.

EVALUATE: $P_C + P_R = P_C + I^2R$ = 1.87 W + (0.2333 A)^2(120 Ω) = 8.40 W. $P_{\mathcal{E}} = I\mathcal{E}$ = (0.2333 A)(36.0 V) = 8.40 W. These results for the power agree, as they should by conservation of energy.

26.39. **IDENTIFY:** An uncharged capacitor is placed into a circuit. Apply the loop rule at each time.

SET UP: The voltage across a capacitor is $V_C = q/C$.

EXECUTE: **(a)** At the instant the circuit is completed, there is no voltage across the capacitor, since it has no charge stored.

(b) Since s the full battery voltage appears across the resistor $V_R = \mathcal{E} = 245\text{ V}$.

(c) There is no charge on the capacitor.

(d) The current through the resistor is $i = \dfrac{\mathcal{E}}{R_{\text{total}}} = \dfrac{245\text{ V}}{7500\ \Omega} = 0.0327\text{ A} = 32.7\text{ mA}.$

(e) After a long time has passed the full battery voltage is across the capacitor and $i = 0$. The voltage across the capacitor balances the emf: $V_C = 245\text{ V}$. The voltage across the resistor is zero. The capacitor's charge is $q = CV_C = (4.60\times10^{-6}\text{ F})(245\text{ V}) = 1.13\times10^{-3}\text{ C}$. The current in the circuit is zero.

EVALUATE: The current in the circuit starts at 0.0327 A and decays to zero. The charge on the capacitor starts at zero and rises to $q = 1.13\times10^{-3}\text{ C}$.

26.40. **IDENTIFY:** Once the switch S is closed, current starts to flow and charge the capacitor.

SET UP: $P = IV$, $V_R = RI$, $U_C = Q^2/2C$, $Q = C\mathcal{E}(1 - e^{-t/RC})$, $(1 - e^{-t/RC})$, and $I = (\mathcal{E}/R)\,e^{-t/RC}$.

EXECUTE: **(a)** $\mathcal{E} = V_R + V_C = IR + Q/C$ = (3.00 A)(12.0 Ω) + (40.0 μC)/(5.00 μF) = 44.0 V.

(b) The current is $I = (\mathcal{E}/R)\,e^{-t/RC}$. The current is 3.00 A when Q = 40.0 μC, so

$3.00\text{ A} = [(44.0\ V)/(12.0\ \Omega)]e^{-t/RC}$. Taking logs and solving for t gives

$-t/RC = \ln(36.0/44.0)$.

$t = -(12.0\ \Omega)(5.00\ \mu\text{F})\ \ln(36.0/44.0) = 12.0\ \mu\text{s}$.

(c) (i) The power in the capacitor is $P_C = dU/dt = d(Q^2/2C)/dt = (Q/C)\ dQ/dt = QI/C$, so

$P_C = (40.0\ \mu C)(3.00\ A)/(5.00\ \mu F) = 24.0$ W.

(ii) $P_{\mathcal{E}} = I\mathcal{E} = (3.00\ \text{A})(44.0\ \text{V}) = 132$ W.

EVALUATE: In (c), when $I = 3.00$ A, $P_R = I^2R = (3.00\ A)^2(12.0\ \Omega) = 108\ W$. Therefore $P_R + P_C = 108$ W + 24.0 W = 132 W, which is equal to $P_{\mathcal{E}}$, as it should be by energy conservation. In (b), we can use the equation $Q = C\mathcal{E}(1 - e^{-t/RC})$ to calculate Q when $t = 12.0\ \mu$s; it should be 40.0 μC. We have $Q = (44.0\ \text{V})(5.00\ \mu\text{F})(1 - e^{-(12.0\ \mu s)/[(12.0\ \Omega)(5.00\ \mu F)]}) = 40.0\ \mu\text{C}$, as expected.

26.41. **IDENTIFY:** The capacitors, which are in parallel, will discharge exponentially through the resistors.

SET UP: Since V is proportional to Q, V must obey the same exponential equation as Q, $V = V_0 e^{-t/RC}$. The current is $I = (V_0/R)\ e^{-t/RC}$.

EXECUTE: **(a)** Solve for time when the potential across each capacitor is 10.0 V:

$t = -RC\ \ln(V/V_0) = -(80.0\ \Omega)(35.0\ \mu\text{F})\ \ln(10/45) = 4210\ \mu\text{s} = 4.21$ ms.

(b) $I = (V_0/R)\ e^{-t/RC}$. Using the above values, with $V_0 = 45.0$ V, gives $I = 0.125$ A.

EVALUATE: Since the current and the potential both obey the same exponential equation, they are both reduced by the same factor (0.222) in 4.21 ms.

26.42. **IDENTIFY:** For a charging capacitor $q(t) = C\mathcal{E}(1 - e^{-t/\tau})$ and $i(t) = \dfrac{\mathcal{E}}{R}e^{-t/\tau}$.

SET UP: The time constant is $RC = (0.895\times10^6\ \Omega)\ (12.4\times10^{-6}\ \text{F}) = 11.1$ s.

EXECUTE: **(a)** At $t = 0$ s: $q = C\mathcal{E}(1 - e^{-t/RC}) = 0$.

At $t = 5$ s: $q = C\mathcal{E}(1 - e^{-t/RC}) = (12.4\times10^{-6}\ \text{F})(60.0\ \text{V})(1 - e^{-(5.0\ \text{s})/(11.1\ \text{s})}) = 2.70\times10^{-4}$ C.

At $t = 10$ s: $q = C\mathcal{E}(1 - e^{-t/RC}) = (12.4\times10^{-6}\ \text{F})(60.0\ \text{V})(1 - e^{-(10.0\ \text{s})/(11.1\ \text{s})}) = 4.42\times10^{-4}$ C.

At $t = 20$ s: $q = C\mathcal{E}(1 - e^{-t/RC}) = (12.4\times10^{-6}\ \text{F})(60.0\ \text{V})(1 - e^{-(20.0\ \text{s})/(11.1\ \text{s})}) = 6.21\times10^{-4}$ C.

At $t = 100$ s: $q = C\mathcal{E}(1 - e^{-t/RC}) = (12.4\times10^{-6}\ \text{F})(60.0\ \text{V})(1 - e^{-(100\ \text{s})/(11.1\ \text{s})}) = 7.44\times10^{-4}$ C.

(b) The current at time t is given by: $i = \dfrac{\mathcal{E}}{R}e^{-t/RC}$.

At $t = 0$ s: $i = \dfrac{60.0\ \text{V}}{8.95\times10^5\ \Omega}e^{-0/11.1} = 6.70\times10^{-5}$ A.

At $t = 5$ s: $i = \dfrac{60.0\ \text{V}}{8.95\times10^5\ \Omega}e^{-5/11.1} = 4.27\times10^{-5}$ A.

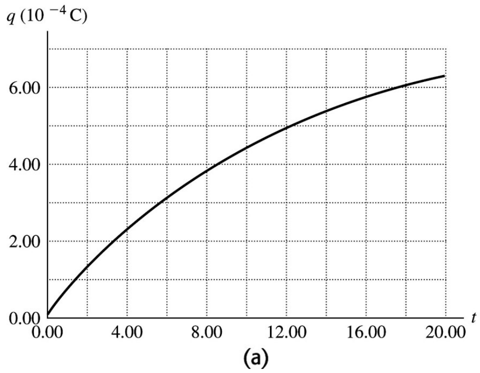
At $t = 10$ s: $i = \dfrac{60.0\ \text{V}}{8.95\times10^5\ \Omega}e^{-10/11.1} = 2.72\times10^{-5}$ A.

At $t = 20$ s: $i = \dfrac{60.0\ \text{V}}{8.95\times10^5\ \Omega}e^{-20/11.1} = 1.11\times10^{-5}$ A.

At $t = 100$ s: $i = \dfrac{60.0\ \text{V}}{8.95\times10^5\ \Omega}e^{-100/11.1} = 8.20\times10^{-9}$ A.

(c) The graphs of $q(t)$ and $i(t)$ are given in Figure 26.42a and b.

EVALUATE: The charge on the capacitor increases in time as the current decreases.



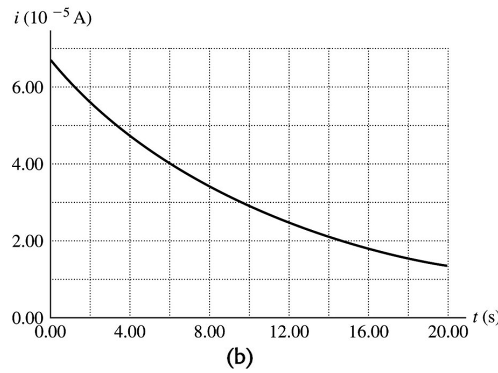


Figure 26.42

26.43. **IDENTIFY** and **SET UP:** Apply Kirchhoff's loop rule. The voltage across the resistor depends on the current through it and the voltage across the capacitor depends on the charge on its plates.

EXECUTE: $\mathcal{E} - V_R - V_C = 0.$

$\mathcal{E} = 120$ V, $V_R = IR = (0.900 \text{ A})(80.0\,\Omega) = 72$ V, so $V_C = 48$ V.

$Q = CV = (4.00\times 10^{-6} \text{ F})(48 \text{ V}) = 192\,\mu\text{C}.$

EVALUATE: The initial charge is zero and the final charge is $C\mathcal{E} = 480\,\mu\text{C}$. Since current is flowing at the instant considered in the problem the capacitor is still being charged and its charge has not reached its final value.

26.44. **IDENTIFY:** We have two capacitors charging through a resistor.

SET UP: We want the time constant if the capacitors are in series and if they are in parallel. $\tau = RC$. $1/C_{\text{eq}} = 1/C_1 + 1/C_2 + \cdots$ (series) and $C_{\text{eq}} = C_1 + C_2 + \cdots$ (parallel).

EXECUTE: **(a)** Series: $1/C_{\text{eq}} = 1/C_1 + 1/C_2 + \cdots = 1/C + 1/C = 2/C$. $C_{\text{eq}} = C/2$. $\tau = RC_{\text{eq}} = RC/2$.

(b) Parallel: $C_{\text{eq}} = C_1 + C_2 + \cdots = C + C = 2C$. $\tau = RC_{\text{eq}} = R(2C) = 2RC$.

(c) The series connection has the shorter time constant so the current decreases faster. This means that V_{-R} also decreases faster since $V_R = IR$. So the answer is *series*.

EVALUATE: There is a factor of 4 difference in the time constants. The series circuit changes much faster than the parallel circuit.

26.45. **IDENTIFY:** The stored energy is proportional to the square of the charge on the capacitor, so it will obey an exponential equation, but not the same equation as the charge.

SET UP: The energy stored in the capacitor is $U = Q^2/2C$ and the charge on the plates is $Q_0 e^{-t/RC}$. The current is $I = I_0 e^{-t/RC}$.

EXECUTE: $U = Q^2/2C = (Q_0 e^{-t/RC})^2/2C = U_0 e^{-2t/RC}$. When the capacitor has lost 80% of its stored energy, the energy is 20% of the initial energy, which is $U_0/5. U_0/5 = U_0\ e^{-2t/RC}$ gives $t = (RC/2)\ \ln 5 = (25.0\ \Omega)(4.62 \text{ pF})(\ln 5)/2 = 92.9$ ps.

At this time, the current is $I = I_0\ e^{-t/RC} = (Q_0/RC)\ e^{-t/RC}$, so

$$I = (3.5 \text{ nC})/[(25.0\ \Omega)(4.62 \text{ pF})]\ e^{-(92.9 \text{ ps})/[(25.0\ \Omega)(4.62 \text{ pF})]} = 13.6 \text{ A}.$$

EVALUATE: When the energy is reduced by 80%, neither the current nor the charge are reduced by that percent.

26.46. **IDENTIFY:** The charge is increasing while the current is decreasing. Both obey exponential equations, but they are not the same equation.

SET UP: The charge obeys the equation $Q = Q_{\max}(1 - e^{-t/RC})$, but the equation for the current is $I = I_{\max}e^{-t/RC}$.

EXECUTE: When the charge has reached $\frac{1}{4}$ of its maximum value, we have $Q_{\max}/4 = Q_{\max}(1 - e^{-t/RC})$, which says that the exponential term has the value $e^{-t/RC} = \frac{3}{4}$. The current at this time is $I = I_{\max}e^{-t/RC} = I_{\max}(3/4) = (3/4)[(10.0\ \text{V})/(12.0\ \Omega)] = 0.625\ \text{A}$.

EVALUATE: Notice that the current will be $\frac{3}{4}$, not $\frac{1}{4}$, of its maximum value when the charge is $\frac{1}{4}$ of its maximum. Although current and charge both obey exponential equations, the equations have different forms for a charging capacitor.

26.47. **IDENTIFY:** In both cases, simplify the complicated circuit by eliminating the appropriate circuit elements. The potential across an uncharged capacitor is initially zero, so it behaves like a short circuit. A fully charged capacitor allows no current to flow through it.

(a) SET UP: Just after closing the switch, the uncharged capacitors all behave like short circuits, so any resistors in parallel with them are eliminated from the circuit.

EXECUTE: The equivalent circuit consists of $50\ \Omega$ and $25\ \Omega$ in parallel, with this combination in series with $75\ \Omega$, $15\ \Omega$, and the 100-V battery. The equivalent resistance is $90\ \Omega + 16.7\ \Omega = 106.7\ \Omega$, which gives $I = (100\ \text{V})/(106.7\ \Omega) = 0.937\ \text{A}$.

(b) SET UP: Long after closing the switch, the capacitors are essentially charged up and behave like open circuits since no charge can flow through them. They effectively eliminate any resistors in series with them since no current can flow through these resistors.

EXECUTE: The equivalent circuit consists of resistances of $75\ \Omega$, $15\ \Omega$, and three 25-Ω resistors, all in series with the 100-V battery, for a total resistance of $165\ \Omega$. Therefore $I = (100\text{V})/(165\ \Omega) = 0.606\ \text{A}$.

EVALUATE: The initial and final behavior of the circuit can be calculated quite easily using simple series-parallel circuit analysis. Intermediate times would require much more difficult calculations!

26.48. **IDENTIFY:** Both the charge and energy decay exponentially, but not with the same time constant since the energy is proportional to the *square* of the charge.

SET UP: The charge obeys the equation $Q = Q_0e^{-t/RC}$ but the energy obeys the equation $U = Q^2/2C = (Q_0e^{-t/RC})^2/2C = U_0e^{-2t/RC}$.

EXECUTE: **(a)** The charge is reduced by half: $Q_0/2 = Q_0e^{-t/RC}$. This gives $t = RC\ \ln 2 = (225\ \Omega)(12.0\ \mu\text{F})(\ln 2) = 1.871\ \text{ms}$, which rounds to 1.87 ms.

(b) The energy is reduced by half: $U_0/2 = U_0e^{-2t/RC}$. This gives $t = (RC\ \ln 2)/2 = (1.871\ \text{ms})/2 = 0.936\ \text{ms}$.

EVALUATE: The energy decreases faster than the charge because it is proportional to the square of the charge.

26.49. **IDENTIFY:** When the capacitor is fully charged the voltage V across the capacitor equals the battery emf and $Q = CV$. For a charging capacitor, $q = Q(1 - e^{-t/RC})$.

SET UP: $\ln e^x = x$.

EXECUTE: **(a)** $Q = CV = (5.90\times10^{-6}\ \text{F})(28.0\ \text{V}) = 1.65\times10^{-4}\ \text{C} = 165\ \mu\text{C}$.

(b) $q = Q(1 - e^{-t/RC})$, so $e^{-t/RC} = 1 - \dfrac{q}{Q}$ and $R = \dfrac{-t}{C\ln(1 - q/Q)}$. After

$$t = 3\times10^{-3}\ \text{s}: R = \frac{-3\times10^{-3}\ \text{s}}{(5.90\times10^{-6}\ \text{F})(\ln(1 - 110/165))} = 463\ \Omega.$$

(c) If the charge is to be 99% of final value: $\frac{q}{Q} = (1 - e^{-t/RC})$ gives

$t = -RC \ln(1 - q/Q) = -(463\ \Omega)(5.90\times10^{-6}\ \text{F})\ln(0.01) = 0.0126\ \text{s} = 12.6\ \text{ms}.$

EVALUATE: The time constant is $\tau = RC = 2.73$ ms. The time in part (b) is a bit more than one time constant and the time in part (c) is about 4.6 time constants.

26.50. **IDENTIFY:** We have a capacitor discharging through a resistor.

SET UP: $i = I_0 e^{-t/RC}$ and $q = Q_0 e^{-t/RC}$. When the current is 0.180 A, we want the charge and time.

EXECUTE: **(a)** $V_C = V_R$, so $q/C = RI$. $q = RIC = (185\ \Omega)(0.180\ \text{A})(6.00\ \mu\text{F}) = 200\ \mu\text{C}$.

(b) $i = I_0 e^{-t/RC}$, where $I_0 = V_0/R = (50.0\ \text{V})/(185\ \Omega) = 0.2703$ A. Use logarithms to solve for t.

$t = -RC\ln(i/I_0) = -(185\ \Omega)(6.00\ \mu\text{F})\ln(0.180/0.2703) = 451\ \mu\text{s}.$

EVALUATE: Check: At the time in (b), q should be 200 μC. Putting the numbers into $q = Q_0 e^{-t/RC}$ gives 200 μC, so our result checks.

26.51. **IDENTIFY** and **SET UP:** The heater and hair dryer are in parallel so the voltage across each is 120 V and the current through the fuse is the sum of the currents through each appliance. As the power consumed by the dryer increases, the current through it increases. The maximum power setting is the highest one for which the current through the fuse is less than 20 A.

EXECUTE: Find the current through the heater. $P = VI$ so $I = P/V = (1500\ \text{W})/(120\ \text{V}) = 12.5$ A. The maximum total current allowed is 20 A, so the current through the dryer must be less than $20\ \text{A} - 12.5\ \text{A} = 7.5$ A. The power dissipated by the dryer if the current has this value is $P = VI = (120\ \text{V})(7.5\ \text{A}) = 900$ W. For P at this value or larger the circuit breaker trips.

EVALUATE: $P = V^2/R$ and for the dryer V is a constant 120 V. The higher power settings correspond to a smaller resistance R and larger current through the device.

26.52. **IDENTIFY:** $P = VI = I^2R$

SET UP: Problem 25.76 says that for 12-gauge wire the maximum safe current is 25 A.

EXECUTE: **(a)** $I = \frac{P}{V} = \frac{4100\ \text{W}}{240\ \text{V}} = 17.1$ A. So we need at least 14-gauge wire (good up to 18 A). 12-gauge is also ok (good up to 25 A).

(b) $P = \frac{V^2}{R}$ and $R = \frac{V^2}{P} = \frac{(240\ \text{V})^2}{4100\ \text{W}} = 14\ \Omega.$

(c) At 11¢ per kWh, for 1 hour the cost is $(11¢/\text{kWh})(1\ \text{h})(4.1\ \text{kW}) = 45¢$.

EVALUATE: The cost to operate the device is proportional to its power consumption.

26.53. **IDENTIFY:** We have a capacitor charging through a resistor.

SET UP: $i = I_0 e^{-t/RC}$, $U_C = \frac{1}{2}CV^2$, $P_{\mathcal{E}} = i\mathcal{E}$, and $P = i^2R$. Our target variable is the energy.

EXECUTE: **(a)** We want the energy in the capacitor. When fully charged, $i = 0$ so $V_C = \mathcal{E}$. Thus $U_C = \frac{1}{2}C\mathcal{E}^2$.

(b) $P_{\mathcal{E}} = i\mathcal{E}$. Since i is variable, we need to integrate to find the energy.

$U_{\mathcal{E}} = \int_0^\infty i\mathcal{E}dt = \int_0^\infty I_0 e^{-t/RC}dt = I_0\mathcal{E}(-RC)e^{-t/RC}\Big|_0^\infty = I_0\mathcal{E}RC.\ \ I_0 = \frac{\mathcal{E}}{R}$ so $U_{\mathcal{E}} = C\mathcal{E}^2$.

(c) $P_R = i^2R$, so $U_R = \int_0^\infty i^2Rdt = \int_0^\infty \left(I_0 e^{-t/RC}\right)^2 Rdt = I_0^2R\int_0^\infty e^{-2t/RC}dt = \left(I_0^2R\right)\left(\frac{RC}{2}\right).\ \ I_0 = \frac{\mathcal{E}}{R}$ so $U_R = \frac{1}{2}C\mathcal{E}^2$.

(d) $\dfrac{U_C}{U_\mathcal{E}}=\dfrac{\frac{1}{2}C\mathcal{E}^2}{C\mathcal{E}^2}=\dfrac{1}{2}$. $\dfrac{U_R}{U_\mathcal{E}}=\dfrac{\frac{1}{2}C\mathcal{E}^2}{C\mathcal{E}^2}=\dfrac{1}{2}$. Half the energy is stored in the capacitor and half is dissipated in the resistor.

EVALUATE: The result in (d) is compatible with energy conservation.

26.54. IDENTIFY: We need to do series/parallel reduction to solve this circuit.

SET UP: $P=\dfrac{\mathcal{E}^2}{R}$, where R is the equivalent resistance of the network. For resistors in series, $R_{\text{eq}}=R_1+R_2$, and for resistors in parallel $1/R_{\text{P}}=1/R_1+1/R_2$.

EXECUTE: $R=\dfrac{\mathcal{E}^2}{P}=\dfrac{(48.0\text{ V})^2}{295\text{ W}}=7.810\ \Omega$. $R_{12}=R_1+R_2=8.00\ \Omega$. $R=R_{123}+R_4$.

$R_{123}=R-R_4=7.810\ \Omega-3.00\ \Omega=4.810\ \Omega$. $\dfrac{1}{R_{12}}+\dfrac{1}{R_3}=\dfrac{1}{R_{123}}$. $\dfrac{1}{R_3}=\dfrac{1}{R_{123}}-\dfrac{1}{R_{12}}=\dfrac{R_{12}-R_{123}}{R_{123}R_{12}}$.

$R_3=\dfrac{R_{123}R_{12}}{R_{12}-R_{123}}=\dfrac{(4.810\ \Omega)(8.00\ \Omega)}{8.00\ \Omega-4.810\ \Omega}=12.1\ \Omega$.

EVALUATE: The resistance R_3 is greater than R, since the equivalent parallel resistance is less than any of the resistors in parallel.

26.55. IDENTIFY: This problem requires Kirchhoff's rules. The target variables are the currents.

SET UP: Refer to Fig. 26.6(a) in the textbook and use the same loops shown there. For the currents choose I_1 downward through r_1, I_2 upward through r_2, and I_R downward through R. Do all the loops in a counterclockwise sense, as in the textbook. Now apply Kirchhoff's rules.

EXECUTE: <u>Junction rule</u>: $I_2 = I_1 + I_R$.

<u>Loop s</u>: $-r_2I_2-\mathcal{E}_1+RI_R=0 \quad\rightarrow\quad -(2.00\ \Omega)I_1 - 24.0\text{ V} + (20.0\ \Omega)I_R = 0$.

<u>Loop 2</u>: $\mathcal{E}_2-r_2I_2-r_1I_1-\mathcal{E}_1=0 \quad\rightarrow\quad 36.0\text{ V} - (2.00\ \Omega)I_2 - (2.00\ \Omega)I_1 - 24.0\text{ V} = 0$.

<u>Loop 3</u>: $+r_2I_2-\mathcal{E}_2+RI_R=0 \quad\rightarrow\quad (2.00\ \Omega)I_2 - 36.0\text{ V} + (20.0\ \Omega)I_R = 0$.

Solve these equations by substitution (or any other method) and obtain the following answers.

(a) $I–_1 = 2.29$ A.

(b) $I_2 = 3.71$ A.

(c) $I_R = 1.43$ A.

EVALUATE: Check: $I_1 + I_R = 2.29\text{ A} + 1.43\text{ A} = 3.72$ A. This agrees with our answer in (b).The slight difference is due to rounding during calculations.

26.56. IDENTIFY: Half the current flows through each parallel resistor and the full current flows through the third resistor, that is in series with the parallel combination. Therefore, only the series resistor will be at its maximum power.

SET UP: $P=I^2R$.

EXECUTE: The maximum allowed power is when the total current is the maximum allowed value of Then half the current flows through the parallel resistors and the maximum power is

$P_{\max}=(I/2)^2R+(I/2)^2R+I^2R=\frac{3}{2}I^2R=\frac{3}{2}(4.47\text{ A})^2(2.4\ \Omega)=72\text{ W}$.

EVALUATE: If all three resistors were in series or all three were in parallel, then the maximum power would be $3(48\text{ W})=144\text{ W}$. For the network in this problem, the maximum power is half this value.

26.57. (a) IDENTIFY: Break the circuit between points a and b means no current in the middle branch that contains the 3.00-Ω resistor and the 10.0-V battery. The circuit therefore has a single current path. Find the current, so that potential drops across the resistors can be calculated. Calculate V_{ab} by traveling from a to b, keeping track of the potential changes along the path taken.

SET UP: The circuit is sketched in Figure 26.57a.

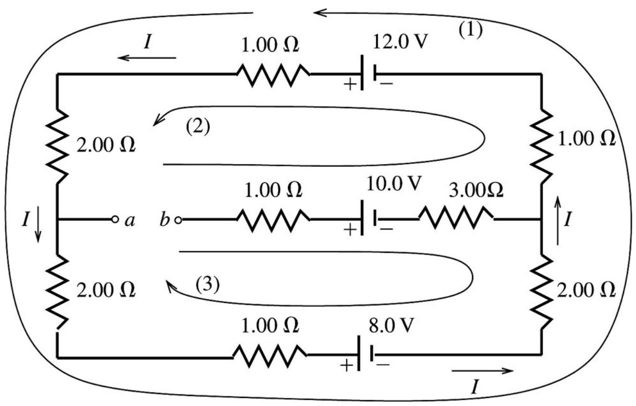

Figure 26.57a

EXECUTE: Apply Kirchhoff's loop rule to loop (1).
$+12.0\text{ V} - I(1.00\,\Omega + 2.00\,\Omega + 2.00\,\Omega + 1.00\,\Omega) - 8.0\text{ V} - I(2.00\,\Omega + 1.00\,\Omega) = 0.$

$I = \dfrac{12.0\text{ V} - 8.0\text{ V}}{9.00\,\Omega} = 0.4444\text{ A}.$

To find V_{ab} start at point b and travel to a, adding up the potential rises and drops. Travel on path (2) shown on the diagram. The $1.00\text{-}\Omega$ and $3.00\text{-}\Omega$ resistors in the middle branch have no current through them and hence no voltage across them. Therefore,

$V_b - 10.0\text{ V} + 12.0\text{ V} - I(1.00\,\Omega + 1.00\,\Omega + 2.00\,\Omega) = V_a$; thus

$V_a - V_b = 2.0\text{ V} - (0.4444\text{ A})(4.00\,\Omega) = +0.22\text{ V}$ (point a is at higher potential).

EVALUATE: As a check on this calculation we also compute V_{ab} by traveling from b to a on path (3).

$V_b - 10.0\text{ V} + 8.0\text{ V} + I(2.00\,\Omega + 1.00\,\Omega + 2.00\,\Omega) = V_a.$

$V_{ab} = -2.00\text{ V} + (0.4444\text{ A})(5.00\,\Omega) = +0.22\text{ V}$, which checks.

(b) IDENTIFY and **SET UP:** With points a and b connected by a wire there are three current branches, as shown in Figure 26.57b.

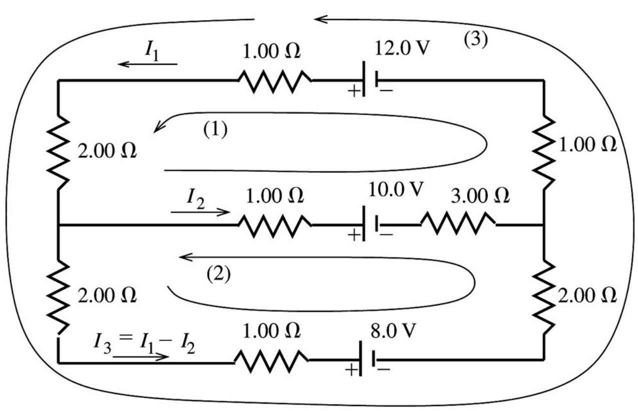

Figure 26.57b

The junction rule has been used to write the third current (in the 8.0-V battery) in terms of the other currents. Apply the loop rule to loops (1) and (2) to obtain two equations for the two unknowns I_1 and I_2.

EXECUTE: Apply the loop rule to loop (1).

$12.0\text{ V} - I_1(1.00\,\Omega) - I_1(2.00\,\Omega) - I_2(1.00\,\Omega) - 10.0\text{ V} - I_2(3.00\,\Omega) - I_1(1.00\,\Omega) = 0$

$2.0\text{ V} - I_1(4.00\,\Omega) - I_2(4.00\,\Omega) = 0$

$(2.00\,\Omega)I_1 + (2.00\,\Omega)I_2 = 1.0\text{ V}$ eq. (1)

Apply the loop rule to loop (2).

$-(I_1 - I_2)(2.00\,\Omega) - (I_1 - I_2)(1.00\,\Omega) - 8.0\text{ V} - (I_1 - I_2)(2.00\,\Omega) + I_2(3.00\,\Omega) + 10.0\text{ V} + I_2(1.00\,\Omega) = 0$

$2.0\text{ V} - (5.00\,\Omega)I_1 + (9.00\,\Omega)I_2 = 0$ eq. (2)

Solve eq. (1) for I_2 and use this to replace I_2 in eq. (2).

$I_2 = 0.50\text{ A} - I_1$

$2.0\text{ V} - (5.00\,\Omega)I_1 + (9.00\,\Omega)(0.50\text{ A} - I_1) = 0$

$(14.0\,\Omega)I_1 = 6.50\text{ V}$ so $I_1 = (6.50\text{ V})/(14.0\,\Omega) = 0.464\text{ A}$

$I_2 = 0.500\text{ A} - 0.464\text{ A} = 0.036\text{ A}.$

The current in the 12.0-V battery is $I_1 = 0.464\text{ A}$

EVALUATE: We can apply the loop rule to loop (3) as a check.

$+12.0\text{ V} - I_1(1.00\,\Omega + 2.00\,\Omega + 1.00\,\Omega) - (I_1 - I_2)(2.00\,\Omega + 1.00\,\Omega + 2.00\,\Omega) - 8.0\text{ V} = 4.0\text{ V} - 1.86\text{ V} - 2.14\text{ V} = 0,$ as it should.

26.58. **IDENTIFY:** Heat, which is generated in the resistor, melts the ice.

SET UP: Find the rate at which heat is generated in the $20.0\text{-}\Omega$ resistor using $P = V^2/R$. Then use the heat of fusion of ice to find the rate at which the ice melts. The heat dH to melt a mass of ice dm is $dH = L_F\ dm$, where L_F is the latent heat of fusion. The rate at which heat enters the ice, dH/dt, is the power P in the resistor, so $P = L_F\ dm/dt$. Therefore the rate of melting of the ice is $dm/dt = P/L_F$.

EXECUTE: The equivalent resistance of the parallel branch is $5.00\ \Omega$, so the total resistance in the circuit is $35.0\ \Omega$. Therefore the total current in the circuit is $I_{\text{Total}} = (45.0\text{ V})/(35.0\ \Omega) = 1.286\text{ A}$. The potential difference across the $20.0\text{-}\Omega$ resistor in the ice is the same as the potential difference across the parallel branch: $V_{\text{ice}} = I_{\text{Total}}R_p = (1.286\text{ A})(5.00\ \Omega) = 6.429\text{ V}$. The rate of heating of the ice is

$P_{\text{ice}} = V_{\text{ice}}^2/R = (6.429\text{ V})^2/(20.0\ \Omega) = 2.066\text{ W}$. This power goes into to heat to melt the ice, so

$dm/dt = P/L_F = (2.066\text{ W})/(3.34\times10^5\text{ J/kg}) = 6.19\times10^{-6}\text{ kg/s} = 6.19\times10^{-3}\text{ g/s}.$

EVALUATE: The melt rate is about 6 mg/s, which is not much. It would take 1000 s to melt just 6 g of ice.

25.59. **IDENTIFY:** Apply Kirchhoff's junction rule to express the currents through the $5.00\text{-}\Omega$ and $8.00\text{-}\Omega$ resistors in terms of I_1, I_2, and I_3. Apply the loop rule to three loops to get three equations in the three unknown currents.

SET UP: The circuit is sketched in Figure 26.59.

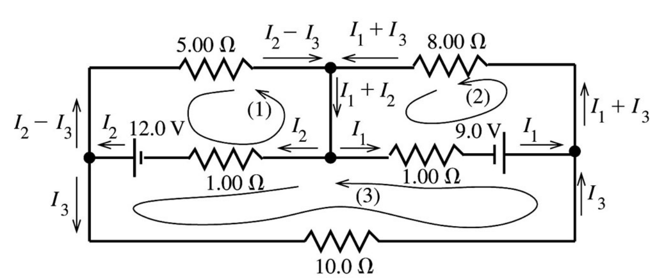

Figure 26.59

The current in each branch has been written in terms of I_1, I_2, and I_3 such that the junction rule is satisfied at each junction point.

EXECUTE: Apply the loop rule to loop (1).

$-12.0\text{ V} + I_2(1.00\,\Omega) + (I_2 - I_3)(5.00\,\Omega) = 0$

$I_2(6.00\,\Omega) - I_3(5.00\,\Omega) = 12.0\text{ V}$ eq. (1)

Apply the loop rule to loop (2).

$-I_1(1.00\,\Omega) + 9.00\text{ V} - (I_1 + I_3)(8.00\,\Omega) = 0$

$I_1(9.00\,\Omega) + I_3(8.00\,\Omega) = 9.00\text{ V}$ eq. (2)

Apply the loop rule to loop (3).

$-I_3(10.0\,\Omega) - 9.00\text{ V} + I_1(1.00\,\Omega) - I_2(1.00\,\Omega) + 12.0\text{ V} = 0$

$-I_1(1.00\,\Omega) + I_2(1.00\,\Omega) + I_3(10.0\,\Omega) = 3.00\text{ V}$ eq. (3)

Eq. (1) gives $I_2 = 2.00\text{ A} + \frac{5}{6}I_3$; eq. (2) gives $I_1 = 1.00\text{ A} - \frac{8}{9}I_3$.

Using these results in eq. (3) gives

$-(1.00\text{ A} - \frac{8}{9}I_3)(1.00\,\Omega) + (2.00\text{ A} + \frac{5}{6}I_3)(1.00\,\Omega) + I_3(10.0\,\Omega) = 3.00\text{ V}.$

$(\frac{16+15+180}{18})I_3 = 2.00\text{ A};\ I_3 = \frac{18}{211}(2.00\text{ A}) = 0.171\text{ A}.$

Then $I_2 = 2.00\text{ A} + \frac{5}{6}I_3 = 2.00\text{ A} + \frac{5}{6}(0.171\text{ A}) = 2.14\text{ A}$ and

$I_1 = 1.00\text{ A} - \frac{8}{9}I_3 = 1.00\text{ A} - \frac{8}{9}(0.171\text{ A}) = 0.848\text{ A}.$

EVALUATE: We could check that the loop rule is satisfied for a loop that goes through the $5.00\text{-}\Omega$, $8.00\text{-}\Omega$ and $10.0\text{-}\Omega$ resistors. Going around the loop clockwise:

$-(I_2 - I_3)(5.00\,\Omega) + (I_1 + I_3)(8.00\,\Omega) + I_3(10.0\,\Omega) = -9.85\text{ V} + 8.15\text{ V} + 1.71\text{ V}$, which does equal zero, apart from rounding.

26.60. IDENTIFY: Apply the junction rule and the loop rule to the circuit.

SET UP: Because of the polarity of each emf, the current in the $7.00\text{-}\Omega$ resistor must be in the direction shown in Figure 26.60a. Let I be the current in the 24.0-V battery.

EXECUTE: The loop rule applied to loop (1) gives: $+24.0\text{ V} - (1.80\text{ A})(7.00\,\Omega) - I(3.00\,\Omega) = 0.$

$I = 3.80\text{ A}.$ The junction rule then says that the current in the middle branch is 2.00 A, as shown in Figure 26.64b. The loop rule applied to loop (2) gives: $+\mathcal{E} - (1.80\text{ A})(7.00\,\Omega) + (2.00\text{ A})(2.00\,\Omega) = 0$ and $\mathcal{E} = 8.6\text{ V}.$

EVALUATE: We can check our results by applying the loop rule to loop (3) in Figure 26.60b:

$+24.0\text{ V} - \mathcal{E} - (2.00\text{ A})(2.00\,\Omega) - (3.80\text{ A})(3.00\,\Omega) = 0$ and $\mathcal{E} = 24.0\text{ V} - 4.0\text{ V} - 11.4\text{ V} = 8.6\text{ V}$, which agrees with our result from loop (2).

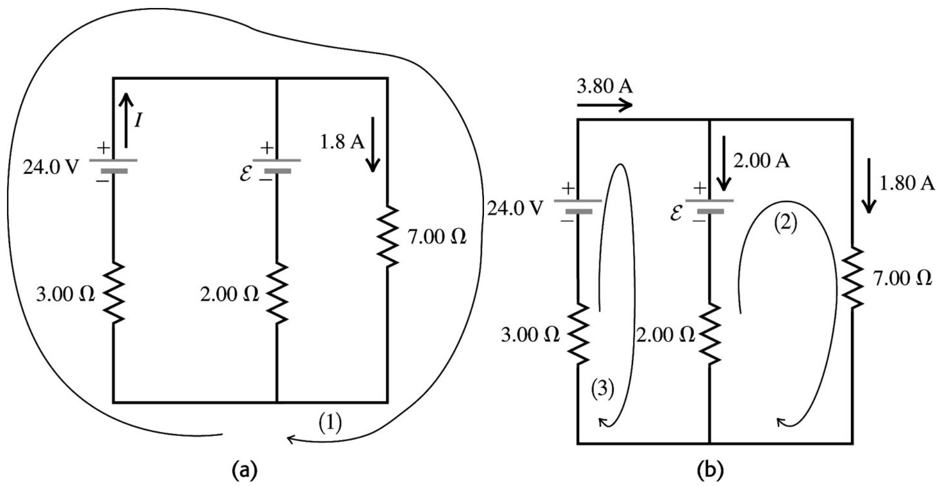

Figure 26.60

26.61. **IDENTIFY:** This problem involves resistivity and a resistor in a circuit.

SET UP and **EXECUTE:** $R = \dfrac{\rho L}{A}$.

(a) Estimate: Diameter = 0.50 mm.

(b) Solve $R = \dfrac{\rho L}{A}$ for R/L giving $\dfrac{R}{L} = \dfrac{\rho}{A} = \dfrac{\rho}{\pi r^2} = \dfrac{1.72 \times 10^{-8}\ \Omega \cdot \text{m}}{\pi (0.25\ \text{mm})^2} = 0.088\ \Omega/\text{m}.$

(c) $IR = 1.0$ V, so $(1.0\ \text{A})R = 1.0$ V, which gives $R = 1.0\ \Omega$. $(R/L)L = R$, so $(0.088\ \Omega/\text{m})L = 1.0\ \Omega$. This gives $L = 11$ m.

EVALUATE: The wire must be tightly wound to be 11 m (≈35 ft) long.

26.62. **IDENTIFY:** Apply the loop and junction rules.

SET UP: Use the currents as defined on the circuit diagram in Figure 26.62 and obtain three equations to solve for the currents.

EXECUTE: **(a)** Left loop: $14 - I_1 - 2(I_1 - I_2) = 0$ and $3I_1 - 2I_2 = 14$.

Top loop: $-2(I - I_1) + I_2 + I_1 = 0$ and $-2I + 3I_1 + I_2 = 0$.

Bottom loop: $-(I - I_1 + I_2) + 2(I_1 - I_2) - I_2 = 0$ and $-I + 3I_1 - 4I_2 = 0$.

Solving these equations for the currents we find: $I = I_{\text{battery}} = 10.0$ A; $I_1 = I_{R_1} = 6.0$ A; $I_2 = I_{R_3} = 2.0$ A.

So the other currents are: $I_{R_2} = I - I_1 = 4.0$ A; $I_{R_4} = I_1 - I_2 = 4.0$ A; $I_{R_5} = I - I_1 + I_2 = 6.0$ A.

(b) $R_{\text{eq}} = \dfrac{V}{I} = \dfrac{14.0\ \text{V}}{10.0\ \text{A}} = 1.40\ \Omega.$

EVALUATE: It isn't possible to simplify the resistor network using the rules for resistors in series and parallel. But the equivalent resistance is still defined by $V = IR_{\text{eq}}$.

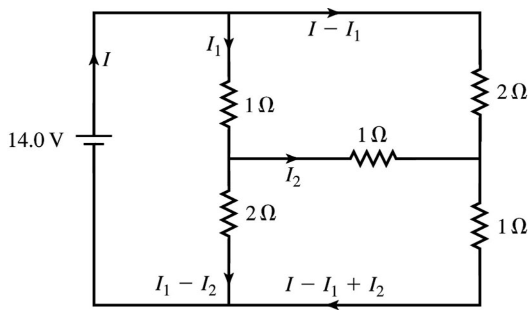

Figure 26.62

26.63. **IDENTIFY:** Simplify the resistor networks as much as possible using the rule for series and parallel combinations of resistors. Then apply Kirchhoff's laws.
SET UP: First do the series/parallel reduction. This gives the circuit in Figure 26.63. The rate at which the $10.0\text{-}\Omega$ resistor generates thermal energy is $P = I^2 R$.
EXECUTE: **(a)** Apply Kirchhoff's laws and solve for $\mathcal{E}$.
$\Delta V_{\text{adefa}} = 0\text{: } -(20\ \Omega)(2\text{ A}) - 5\text{ V} - (20\ \Omega)I_2 = 0.$
This gives $I_2 = -2.25\text{ A}$. Then $I_1 + I_2 = 2\text{ A}$ gives $I_1 = 2\text{ A} - (-2.25\text{ A}) = 4.25\text{ A}$.
$\Delta V_{\text{abcdefa}} = 0\text{: } (15\ \Omega)(4.25\text{ A}) + \mathcal{E} - (20\ \Omega)(-2.25\text{ A}) = 0$. This gives $\mathcal{E} = -109\text{ V}$. Since $\mathcal{E}$ is calculated to be negative, its polarity should be reversed.
(b) The parallel network that contains the $10.0\text{-}\Omega$ resistor in one branch has an equivalent resistance of $10\ \Omega$. The voltage across each branch of the parallel network is $V_{\text{par}} = RI = (10\ \Omega)(2\text{A}) = 20\text{ V}$. The current in the upper branch is $I = \dfrac{V}{R} = \dfrac{20\text{ V}}{30\ \Omega} = \dfrac{2}{3}\text{ A}$. $Pt = E$, so $I^2\ Rt = E$, where $E = 60.0\text{ J}$.

$\left(\tfrac{2}{3}\text{A}\right)^2 (10\ \Omega)t = 60\text{ J}$, and $t = 13.5\text{ s}$.

EVALUATE: For the $10.0\text{-}\Omega$ resistor, $P = I^2 R = 4.44\text{ W}$. The total rate at which electrical energy is inputted to the circuit in the emf is $(5.0\text{ V})(2.0\text{ A}) + (109\text{ V})(4.25\text{ A}) = 473\text{ J}$. Only a small fraction of the energy is dissipated in the $10.0\text{-}\Omega$ resistor.

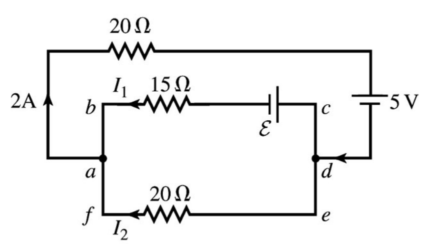

Figure 26.63

26.64. **IDENTIFY:** The resistor R_2 can vary between $3.00\ \Omega$ and $24.0\ \Omega$. R_2 is in parallel with R_1, so as R_2 is changed it affects the current in R_1 and hence the power dissipated in R_1. Ohm's law and Kirchhoff's rules apply.
SET UP: $\dfrac{1}{R_{\text{eq}}} = \dfrac{1}{R_1} + \dfrac{1}{R_2} + \ldots$, $V_R = IR$, $P_R = I^2R$.

EXECUTE: $P_1 = V_1^2/R_1$, so P_1 is largest when V_1 is largest. By Kirchhoff's loop rule,

$\mathcal{E} - V_1 - V_3 = 0$, so $V_1 = \mathcal{E} - V_3$, which means that V_1 is largest when V_3 is smallest.
$V_3 = IR_3 = \mathcal{E}/(R_{eq} + R_3)$, where R_{eq} is the equivalent resistance of the R_1-R_2 combination. Since they are in parallel, $\dfrac{1}{R_{eq}} = \dfrac{1}{R_1} + \dfrac{1}{R_2}$, which gives $R_{eq} = \dfrac{R_1R_2}{R_1 + R_2}$. The smallest V_3 is for the smallest I, which occurs for the largest $R_{eq} = \dfrac{R_1R_2}{R_1 + R_2} = \dfrac{R_1}{\dfrac{R_1}{R_2} + 1}$.

As we can see, the largest R_{eq} occurs when R_2 is largest, which is $R_2 = 24.0\ \Omega$.
The equivalent parallel resistance is then
$R_{eq} = \dfrac{R_1R_2}{R_1 + R_2} = (6.00\ \Omega)(24.0\ \Omega)/(6.00\ \Omega + 24.0\ \Omega) = 4.80\ \Omega$.
The current I is then
$I = \mathcal{E}/(R_{eq} + R_3) = (24.0\ \text{V})/(4.80\ \Omega + 12.0\ \Omega) = 1.429\ \text{A}$.
$V_3 = IR_3 = (1.429\ \text{A})(12.0\ \Omega) = 17.148\ \text{V}$.
The potential difference across R_1 is
$V_1 = \mathcal{E} - V_3 = 24.0\ \text{V} - 17.148\ \text{V} = 6.852\ \text{V}$.
The power dissipated in R_1 is
$P_1 = V_1^2/R_1 = (6.852\ \text{V})^2/(6.00\ \Omega) = 7.83\ \text{W}$.

EVALUATE: Since all the circuit elements except for R_2 are fixed, varying R_2 affects the current in the circuit as well as the current through R_1.

26.65. **IDENTIFY** and **SET UP:** We want to estimate the cost to use some electrical appliances. The estimates and calculated results are shown in the table in part (a).

EXECUTE: **(a)** See the accompanying table.

Appliance	Voltage V	Current I	Time T	Power $P = IV$	Energy $U = PT$
Refrigerator	120 V	7.2 A	24 h	864 W	21 kWh
Water heater	240 V	20 A	4 h	4800 W	19 kWh
Electric oven	240 V	16 A	1 h	3840 W	3.8 kWh
Dishwasher	120 V	10 A	2 h	1200 W	2.4 kWh
Clothes washer	120 V	10 A	2/15 h	1200 W	0.2 kWh
Clothes dryer	120 V	26 A	¼ h	3120 W	0.8 kWh
15 light bulbs	120 V	7.5 A	7 h	900 W	6.3 kWh
Stereo system	120 V	0.2	2 h	24 W	0.05 kWh

The total energy is about 54 kWh.
(b) (54 kWh/day)(30 days/mo)($0.12/kWh) = $194/month.

EVALUATE: The refrigerator and water heater are by far the most costly to use, but listening to music costs hardly anything!

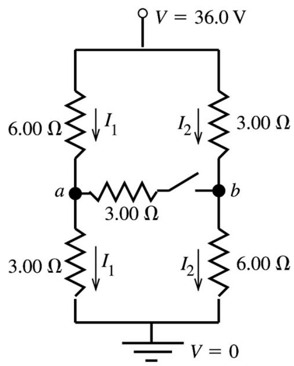
26.66. **IDENTIFY:** The current through the 40.0-Ω resistor equals the current through the emf, and the current through each of the other resistors is less than or equal to this current. So, set $P_{40} = 2.00\ \text{W}$, and use this to solve for the current I through the emf. If $P_{40} = 2.00\ \text{W}$, then P for each of the other resistors is less than 2.00 W.

SET UP: Use the equivalent resistance for series and parallel combinations to simplify the circuit.

EXECUTE: $I^2R = P$ gives $I^2(40\ \Omega) = 2.00\ \text{W}$, and $I = 0.2236\ \text{A}$. Now use series/parallel reduction to simplify the circuit. The upper parallel branch is $6.38\ \Omega$ and the lower one is $25\ \Omega$. The series sum is now $126\ \Omega$. Ohm's law gives $\mathcal{E} = (126\ \Omega)(0.2236\ \text{A}) = 28.2\ \text{V}$.

EVALUATE: The power input from the emf is $\mathcal{E}I = 6.30\text{ W}$, so nearly one-third of the total power is dissipated in the $40.0\text{-}\Omega$ resistor.

26.67. **(a) IDENTIFY** and **SET UP:** The circuit is sketched in Figure 26.67a.



With the switch open there is no current through it and there are only the two currents I_1 and I_2 indicated in the sketch.

Figure 26.67a

The potential drop across each parallel branch is 36.0 V. Use this fact to calculate I_1 and I_2. Then travel from point *a* to point *b* and keep track of the potential rises and drops in order to calculate V_{ab}.

EXECUTE: $-I_1(6.00\,\Omega + 3.00\,\Omega) + 36.0\text{ V} = 0.$

$$I_1 = \frac{36.0\text{ V}}{6.00\ \Omega + 3.00\,\Omega} = 4.00\text{ A.}$$

$$-I_2(3.00\,\Omega + 6.00\,\Omega) + 36.0\text{ V} = 0.$$

$$I_2 = \frac{36.0\text{ V}}{3.00\ \Omega + 6.00\,\Omega} = 4.00\text{ A.}$$

To calculate $V_{ab} = V_a - V_b$ start at point *b* and travel to point *a*, adding up all the potential rises and drops along the way. We can do this by going from *b* up through the $3.00\text{-}\Omega$ resistor:

$V_b + I_2(3.00\,\Omega) - I_1(6.00\,\Omega) = V_a$.

$V_a - V_b = (4.00\text{ A})(3.00\,\Omega) - (4.00\text{ A})(6.00\,\Omega) = 12.0\text{ V} - 24.0\text{ V} = -12.0\text{ V}.$

$V_{ab} = -12.0\text{ V}$ (point *a* is 12.0 V lower in potential than point *b*).

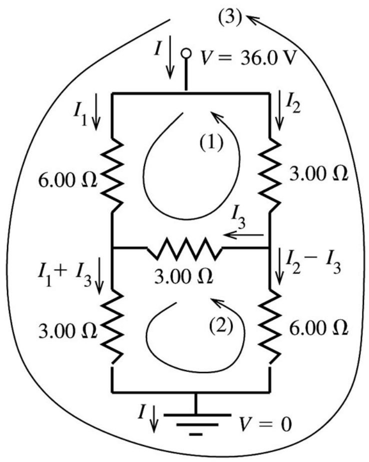
EVALUATE: Alternatively, we can go from point *b* down through the $6.00\text{-}\Omega$ resistor.

$V_b - I_2(6.00\,\Omega) + I_1(3.00\,\Omega) = V_a$.

$V_a - V_b = -(4.00\text{ A})(6.00\,\Omega) + (4.00\text{ A})(3.00\,\Omega) = -24.0\text{ V} + 12.0\text{ V} = -12.0\text{ V}$, which checks.

(b) IDENTIFY: Now there are multiple current paths, as shown in Figure 26.67b. Use the junction rule to write the current in each branch in terms of three unknown currents I_1, I_2, and I_3. Apply the loop rule to three loops to get three equations for the three unknowns. The target variable is I_3, the current through the switch. R_{eq} is calculated from $V = IR_{\text{eq}}$, where *I* is the total current that passes through the network.

SET UP:



The three unknown currents $I_1, I_2,$ and I_3 are labeled on Figure 26.67b.

Figure 26.67b

EXECUTE: Apply the loop rule to loops (1), (2) and (3).

Loop (1): $-I_1(6.00\ \Omega)+I_3(3.00\ \Omega)+I_2(3.00\ \Omega)=0$

$I_2 = 2I_1 - I_3$ eq. (1)

Loop (2): $-(I_1+I_3)(3.00\ \Omega)+(I_2-I_3)(6.00\ \Omega)-I_3(3.00\ \Omega)=0$

$6I_2 - 12I_3 - 3I_1 = 0$ so $2I_2 - 4I_3 - I_1 = 0$

Use eq (1) to replace I_2:

$4I_1 - 2I_3 - 4I_3 - I_1 = 0$

$3I_1 = 6I_3$ and $I_1 = 2I_3$ eq. (2)

Loop (3): This loop is completed through the battery (not shown), in the direction from the $-$ to the $+$ terminal.

$-I_1(6.00\ \Omega)-(I_1+I_3)(3.00\ \Omega)+36.0\text{ V}=0$

$9I_1 + 3I_3 = 36.0\text{ A}$ and $3I_1 + I_3 = 12.0\text{ A}$ eq. (3)

Use eq. (2) in eq. (3) to replace I_1:

$3(2I_3)+I_3 = 12.0\text{ A}$

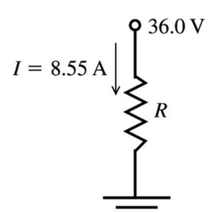
$I_3 = 12.0\text{ A}/7 = 1.71\text{ A}$

$I_1 = 2I_3 = 3.42\text{ A}$

$I_2 = 2I_1 - I_3 = 2(3.42\text{ A}) - 1.71\text{ A} = 5.13\text{ A}$

The current through the switch is $I_3 = 1.71\text{ A}$.

(c) SET UP and **EXECUTE:** From the results in part (a) the current through the battery is $I = I_1 + I_2 = 3.42\text{ A} + 5.13\text{ A} = 8.55\text{ A}$. The equivalent circuit is a single resistor that produces the same current through the 36.0-V battery, as shown in Figure 26.67c.



$-IR + 36.0\text{ V} = 0.$

$$R = \frac{36.0\text{ V}}{I} = \frac{36.0\text{ V}}{8.55\text{ A}} = 4.21\ \Omega.$$

Figure 26.67c

EVALUATE: With the switch open (part a), point b is at higher potential than point a, so when the switch is closed the current flows in the direction from b to a. With the switch closed the circuit cannot be simplified using series and parallel combinations but there is still an equivalent resistance that represents the network.

26.68. **IDENTIFY:** $P_{\text{tot}} = \dfrac{V^2}{R_{\text{eq}}}$.

SET UP: Let R be the resistance of each resistor.

EXECUTE: When the resistors are in series, $R_{\text{eq}} = 3R$ and $P_{\text{s}} = \dfrac{V^2}{3R}$. When the resistors are in parallel,

$R_{\text{eq}} = R/3$. $P_{\text{p}} = \dfrac{V^2}{R/3} = 3\dfrac{V^2}{R} = 9P_{\text{s}} = 9(45.0\ \text{W}) = 405\ \text{W}$.

EVALUATE: In parallel, the voltage across each resistor is the full applied voltage V. In series, the voltage across each resistor is $V/3$ and each resistor dissipates less power.

26.69. **IDENTIFY:** We have an R-C circuit with a discharging capacitor.

SET UP: $q = Q_0 e^{-t/RC}$, $C = \dfrac{\epsilon_0 AK}{d}$, $R = \dfrac{\rho L}{A}$, $\tau = RC$.

EXECUTE: **(a)** We want the time constant. When S is opened, we have a discharging capacitor.

$\tau = RC = \left(\dfrac{\rho d}{A}\right)\left(\dfrac{\epsilon_0 AK}{d}\right) = \epsilon_0 \rho K$.

(b) We want Q_0 if $V = 5.00$ V. $Q_0 = CV = \dfrac{\epsilon_0 AKV}{d} = 1.28$ nC using the given numbers.

(c) At what time will q be $Q_0/2$? Solve $q = Q_0 e^{-t/RC} = Q_0 e^{-t/\tau}$ for t using logarithms. At this time $q = Q_0/2$. $t = \tau \ln 2 = \epsilon_0 \rho K \ln 2 = 165$ s using the given numbers.

(d) We want the current. $V_R = V_C$ so $RI = \dfrac{q}{C} = \dfrac{Q_0}{2C}$. $I = \dfrac{Q_0}{2RC} = \dfrac{Q_0}{2\epsilon_0 K\rho}$ using the result from (a).

Putting in the given numbers gives $I = 2.68$ pA.

EVALUATE: The current in (d) is very small, but the dielectric has a very large resistivity so the result is reasonable. The leakage current is the reason that capacitors in electrical devices eventually discharge if the device has been turned off for a long time.

26.70. **IDENTIFY** and **SET UP:** Just after the switch is closed the charge on the capacitor is zero, the voltage across the capacitor is zero and the capacitor can be replaced by a wire in analyzing the circuit. After a long time the current to the capacitor is zero, so the current through R_3 is zero. After a long time the capacitor can be replaced by a break in the circuit.

EXECUTE: **(a)** Ignoring the capacitor for the moment, the equivalent resistance of the two parallel resistors is $\dfrac{1}{R_{\text{eq}}} = \dfrac{1}{6.00\ \Omega} + \dfrac{1}{3.00\ \Omega} = \dfrac{3}{6.00\ \Omega}$; $R_{\text{eq}} = 2.00\ \Omega$. In the absence of the capacitor, the total current in the circuit (the current through the $8.00\text{-}\Omega$ resistor) would be

$i = \dfrac{\mathcal{E}}{R} = \dfrac{42.0\ \text{V}}{8.00\ \Omega + 2.00\ \Omega} = 4.20\ \text{A}$, of which 2/3, or 2.80 A, would go through the $3.00\text{-}\Omega$ resistor and 1/3, or 1.40 A, would go through the 6.00-Ω resistor. Since the current through the capacitor is given by $i = \dfrac{V}{R}e^{-t/RC}$, at the instant $t = 0$ the circuit behaves as through the capacitor were not present, so the currents through the various resistors are as calculated above.

(b) Once the capacitor is fully charged, no current flows through that part of the circuit. The 8.00-Ω and the 6.00-Ω resistors are now in series, and the current through them is $i = \mathcal{E}/R = (42.0\ \text{V})/(8.00\ \Omega +$

$6.00\ \Omega) = 3.00$ A. The voltage drop across both the $6.00\text{-}\Omega$ resistor and the capacitor is thus $V = iR = (3.00\ \text{A})(6.00\ \Omega) = 18.0$ V. (There is no current through the $3.00\text{-}\Omega$ resistor and so no voltage drop across it.) The charge on the capacitor is $Q = CV = (4.00\times10^{-6}\ \text{F})(18.0\ \text{V}) = 7.2\times10^{-5}$ C.

EVALUATE: The equivalent resistance of R_2 and R_3 in parallel is less than R_3, so initially the current through R_1 is larger than its value after a long time has elapsed.

26.71. **IDENTIFY:** We have a capacitor that contains a dielectric and is in a series circuit with a resistor and a battery.

SET UP and **EXECUTE:** **(a)** We want the charge. $Q_0 = CV_0$. $C = \dfrac{\epsilon_0 A}{d}$ = 1.18 pF using the given A and d. Q_0 = (1.18 pF)(10.0 V) = 11.8 pC.

(b) The target variable is the current. $V_C = Ed = (E_0/K)d = V_0/K$. For the complete circuit $\mathcal{E} = RI + V_C = RI + V_0/K = RI + \mathcal{E}/K$. $I = \dfrac{\mathcal{E}}{R}\left(1-\dfrac{1}{K}\right) = \dfrac{10.0\ \text{V}}{10.0\ \Omega}\left(1-\dfrac{1}{12.0}\right) = 0.917$ A.

(c) We want the initial energy in the capacitor. $U_C = \dfrac{1}{2}CV_C^2 = \dfrac{1}{2}(KC_0)\left(\dfrac{V_0}{K}\right)^2 = \dfrac{U_0}{K} = 4.92$ pJ. (This result also tells us that the stored energy before the dielectric was inserted was U_0 = (12.0)(4.92 pJ) = 59.0 pJ.)

(d) We want the final energy in the capacitor. $U_\text{f} = \dfrac{1}{2}CV_\text{f}^2 = \dfrac{1}{2}(KC_0)\mathcal{E}^2 = KU_0$.

$\Delta U = KU_0 - U_0$ = (12.0)(59.0 pJ) – 4.92 pJ = 703 pJ.

(e) We want the total energy supplied by the battery. $U_\mathcal{E} = \int P_\mathcal{E}dt = \int i\mathcal{E}dt$. $i = I_0e^{-t/RC} = I_0e^{-t/RKC_0}$.

Therefore $U_\mathcal{E} = \int_0^\infty I_0e^{-t/RKC_0}\mathcal{E}dt = I_0KRC_0\mathcal{E} = (0.917\ \text{A})(12.0)(10.0\ \Omega)(1.18\ \text{pF})(10.0\ \text{V})$ = 1298 pJ, which rounds to 1300 pJ.

(f) We want the energy dissipated in the resistor. $U_R = \int P_R dt = \int i^2 R dt \int_0^\infty \left(I_0e^{-t/RKC_0}\right)^2 dt = \dfrac{I_0^2R^2C_0K}{2} =$ 595 pJ using the given numbers.

EVALUATE: Check: $U_C + U_R$ = 703 pJ + 595 pJ = 1298 pJ = $U_\mathcal{E}$, which is consistent with energy conservation.

26.72. **IDENTIFY** and **SET UP:** $P_R = i^2R$, $\mathcal{E} - iR - \dfrac{q}{C} = 0$, and $U_C = \dfrac{q^2}{2C}$.

EXECUTE: $P_R = i^2R$ so $i = \sqrt{\dfrac{P_R}{R}} = \sqrt{\dfrac{300\ \text{W}}{5.00\ \Omega}} = 7.746$ A. $\mathcal{E} - iR - \dfrac{q}{C} = 0$ so

$q = C(\mathcal{E} - iR) = (6.00\times10^{-6}\ \text{F})[50.0\ \text{V} - (7.746\ \text{A})(5.00\ \Omega)] = 6.762\times10^{-5}$ C.

$$U_C = \frac{q^2}{2C} = \frac{(6.762\times10^{-5}\ \text{C})^2}{2(6.00\times10^{-6}\ \text{F})} = 3.81\times10^{-4}\ \text{J}.$$

EVALUATE: The energy stored in the capacitor can be returned to a circuit as current, but the energy dissipated in a resistor cannot.

26.73. **IDENTIFY:** Connecting the voltmeter between point b and ground gives a resistor network and we can solve for the current through each resistor. The voltmeter reading equals the potential drop across the 200-kΩ resistor.

SET UP: For two resistors in parallel, $\dfrac{1}{R_\text{eq}} = \dfrac{1}{R_1} + \dfrac{1}{R_2}$. For two resistors in series, $R_\text{eq} = R_1 + R_2$.

EXECUTE: **(a)** $R_{\text{eq}} = 100\text{ k}\Omega + \left(\dfrac{1}{200\text{ k}\Omega} + \dfrac{1}{50\text{ k}\Omega}\right)^{-1} = 140\text{ k}\Omega$. The total current is

$I = \dfrac{0.400\text{ kV}}{140\text{ k}\Omega} = 2.86\times10^{-3}\text{ A}$. The voltage across the $200\text{-k}\Omega$ resistor is

$V_{200\text{ k}\Omega} = IR = (2.86\times10^{-3}\text{ A})\left(\dfrac{1}{200\text{ k}\Omega} + \dfrac{1}{50\text{ k}\Omega}\right)^{-1} = 114.4\text{ V}.$

(b) If the resistance of the voltmeter is $5.00\times10^{6}\ \Omega$, then we carry out the same calculations as above to find $R_{\text{eq}} = 292\text{ k}\Omega$, $I = 1.37\times10^{-3}\text{ A}$ and $V_{200\text{ k}\Omega} = 263\text{ V}$.

(c) If the resistance of the voltmeter is infinite, then we find $R_{\text{eq}} = 300\text{ k}\Omega$, $I = 1.33\times10^{-3}\text{ A}$ and $V_{200\text{k}\Omega} = 266\text{ V}$.

EVALUATE: When a voltmeter of finite resistance is connected to a circuit, current flows through the voltmeter and the presence of the voltmeter alters the currents and voltages in the original circuit. The effect of the voltmeter on the circuit decreases as the resistance of the voltmeter increases.

26.74. **IDENTIFY** and **SET UP:** Zero current through the galvanometer means the current I_1 through *N* is also the current through *M* and the current I_2 through *P* is the same as the current through *X*. And it means that points *b* and *c* are at the same potential, so $I_1N = I_2P$.

EXECUTE: **(a)** The voltage between points *a* and *d* is $\mathcal{E}$, so $I_1 = \dfrac{\mathcal{E}}{N+M}$ and $I_2 = \dfrac{\mathcal{E}}{P+X}$. Using these expressions in $I_1N = I_2P$ gives $\dfrac{\mathcal{E}}{N+M}N = \dfrac{\mathcal{E}}{P+X}P$. $N(P+X) = P(N+M)$. $NX = PM$ and $X = MP/N$.

(b) $X = \dfrac{MP}{N} = \dfrac{(850.0\ \Omega)(33.48\ \Omega)}{15.00\ \Omega} = 1897\ \Omega$

EVALUATE: The measurement of *X* does not require that we know the value of the emf.

26.75. **IDENTIFY:** With *S* open and after equilibrium has been reached, no current flows and the voltage across each capacitor is 18.0 V. When *S* is closed, current *I* flows through the $6.00\text{-}\Omega$ and $3.00\text{-}\Omega$ resistors.

SET UP: With the switch closed, *a* and *b* are at the same potential and the voltage across the $6.00\text{-}\Omega$ resistor equals the voltage across the $6.00\text{-}\mu\text{F}$ capacitor and the voltage is the same across the $3.00\text{-}\mu\text{F}$ capacitor and $3.00\text{-}\Omega$ resistor.

EXECUTE: **(a)** With an open switch: $V_{ab} = \varepsilon = 18.0\text{ V}$.

(b) Point *a* is at a higher potential since it is directly connected to the positive terminal of the battery.

(c) When the switch is closed $18.0\text{ V} = I(6.00\ \Omega + 3.00\ \Omega)$. $I = 2.00\text{ A}$ and $V_b = (2.00\text{ A})(3.00\ \Omega) = 6.00\text{ V}$.

(d) Initially the capacitor's charges were $Q_3 = CV = (3.00\times10^{-6}\text{ F})(18.0\text{ V}) = 5.40\times10^{-5}\text{ C}$ and $Q_6 = CV = (6.00\times10^{-6}\text{ F})(18.0\text{ V}) = 1.08\times10^{-4}\text{ C}$. After the switch is closed $Q_3 = CV = (3.00\times10^{-6}\text{ F})(18.0\text{ V} - 12.0\text{ V}) = 1.80\times10^{-5}\text{ C}$ and $Q_6 = CV = (6.00\times10^{-6}\text{ F})(18.0\text{ V} - 6.0\text{ V}) = 7.20\times10^{-5}\text{ C}$. Both capacitors lose $3.60\times10^{-5}\text{ C}$ $= 36.0\ \mu\text{C}$.

EVALUATE: The voltage across each capacitor decreases when the switch is closed, because there is then current through each resistor and therefore a potential drop across each resistor.

26.76. IDENTIFY: The energy stored in a capacitor is $U = q^2/2C$. The electrical power dissipated in the resistor is $P = i^2R$.

SET UP: For a discharging capacitor, $i = -\dfrac{q}{RC}$.

EXECUTE: **(a)** $U_0 = \dfrac{Q_0^2}{2C} = \dfrac{(0.0069\text{ C})^2}{2(4.62\times 10^{-6}\text{ F})} = 5.15\text{ J}.$

(b) $P_0 = I_0^2R = \left(\dfrac{Q_0}{RC}\right)^2 R = \dfrac{(0.0069\text{ C})^2}{(850\ \Omega)(4.62\times 10^{-6}\text{ F})^2} = 2620\text{ W}.$

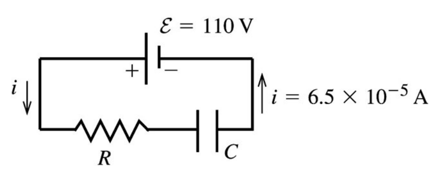
(c) Since $U = q^2/2C$, when $U \to U_0/2, q \to Q_0/\sqrt{2}$. Since $q = Q_0e^{-t/RC}$, this means that $e^{-t/RC} = 1/\sqrt{2}$. Therefore the current is $i = i_0e^{-t/RC} = i_0/\sqrt{2}$. Therefore

$P_R = \left(\dfrac{i_0}{\sqrt{2}}\right)^2 R = \dfrac{1}{2}\left(\dfrac{V_0}{R}\right)^2 R = \dfrac{1}{2}\left(\dfrac{Q_0}{RC}\right)^2 R = \dfrac{1}{RC}\left(\dfrac{Q_0^2}{2C}\right) = \dfrac{U_0}{RC}$. Putting in the numbers gives

$P_R = \dfrac{5.15\text{ J}}{(850\ \Omega)(4.62\ \mu\text{F})} = 1310\text{ W}.$

EVALUATE: All the energy originally stored in the capacitor is eventually dissipated as current flows through the resistor.

26.77. IDENTIFY: Apply the loop rule to the circuit. The initial current determines *R*. We can then use the time constant to calculate *C*.
SET UP: The circuit is sketched in Figure 26.77.



Initially, the charge of the capacitor is zero, so by $V = q/C$ the voltage across the capacitor is zero.

Figure 26.77

EXECUTE: The loop rule therefore gives $\mathcal{E} - iR = 0$ and $R = \dfrac{\mathcal{E}}{i} = \dfrac{110\text{ V}}{6.5\times 10^{-5}\text{ A}} = 1.7\times 10^6\ \Omega.$

The time constant is given by $\tau = RC$, so $C = \dfrac{\tau}{R} = \dfrac{5.2\text{ s}}{1.7\times 10^6\ \Omega} = 3.1\ \mu\text{F}.$

EVALUATE: The resistance is large so the initial current is small and the time constant is large.

26.78. IDENTIFY and SET UP: When the switch *S* is closed, current begins to flow as the capacitor plates discharge. The current in the circuit is $i = (Q_0/RC)e^{-t/RC}$.

EXECUTE: **(a)** Taking logs of the equation for *i* gives ln(*i*) = ln(Q_0/*RC*) – *t*/*RC*. A graph of ln(*i*) versus *t* will be a straight line with slope equal to –1/*RC*.
(b) Using the points (1.50 ms, –3.0) and (3.00 ms, –4.0) on the graph in the problem, the slope is
slope = $\dfrac{-4.0-(-3.0)}{3.00\text{ ms} - 1.50\text{ ms}} = -0.667\ (\text{ms})^{-1} = -667\text{ s}^{-1}$. Therefore
$-1/RC = -667\text{ s}^{-1}$.
$C = 1/[(196\ \Omega)(667\text{ s}^{-1})] = 7.65\times 10^{-6}$ F, which rounds to 7.7 μF.
Using point (1.50 ms, –3.0) on the graph, the equation of the graph gives
–3.0 = ln(Q_0/*RC*) – (1.50 ms)/*RC*.
Simplifying and rearranging gives
–2.0 = ln(Q_0/*RC*).

$Q_0 = RC\ e^{-2.0} = (196\ \Omega)(7.65\ \mu F)\ e^{-2.0} = 203\ \mu C,$ which rounds to 200 μC.

(c) Taking a loop around the circuit gives

$V_R + V_C = 0.$

$-IR + Q/C = 0.$

$Q = RCI = (196\ \Omega)(7.65\ \mu\text{F})(0.0500\ \text{A}) = 75\mu C.$

(d) From (c), we have $Q = RCI$, so $I = Q/RC = (500\mu C)/[(196\ \Omega)(7.65\ \mu\text{F})] = 0.33$ A.

EVALUATE: The accuracy of the answers depends on how well we can get information from the graph with the problem, so answers may differ slightly from those given here.

26.79. **IDENTIFY** and **SET UP:** Kirchhoff's rules apply to the circuit. Taking a loop around the circuit gives $\mathcal{E} - Ri - q/C = 0.$

EXECUTE: **(a)** Solving the loop equation for q gives $q = q = \mathcal{E}C - RCi.$ A graph of q as a function of i should be a straight line with slope equal to $-RC$ and y-intercept equal to $\mathcal{E}C.$ Figure 26.79 shows this graph.

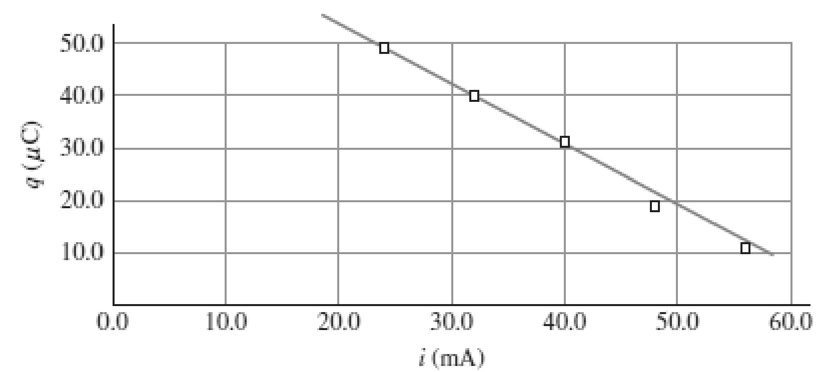


Figure 26.79

The best-fit slope of this graph is -1.233×10^{-3} C/A, and the y-intercept is 7.054×10^{-5} C.

(b) $RC = -\text{slope} = -(-1.233\times10^{-3}\ \text{C/A})$, which gives

$R = (-1.233\times10^{-3}\ \text{C/A})/(5.00\times10^{-6}\ \text{F}) = 246.6\ \Omega$, which rounds to 247 Ω.

The y-intercept is $\mathcal{E}C$, so

$7.054 \times 10^{-5}\ \text{C} = \mathcal{E}\ (5.00 \times 10^{-6}\ \text{F}).$

$\mathcal{E} = 15.9$ V.

(c) $V_C = \mathcal{E}(1 - e^{-t/RC}).$

$V_C/\mathcal{E} = 1 - e^{-t/RC} = (10.0\ \text{V})(15.9\ \text{V}).$

Solving for t gives

$t = (247\ \Omega)(5.00\ \mu\text{F})\ \ln(0.3714) = 1223\ \mu\text{s}$, which rounds to 1.22 ms.

(d) $V_R = \mathcal{E} - V_C = 15.9\ \text{V} - 4.00\ \text{V} = 11.9$ V.

EVALUATE: As time increases, the potential difference across the capacitor increases as it gets charged, but the potential difference across the resistor decreases as the current decreases.

26.80. **IDENTIFY** and **SET UP:** When connected in series across a 48.0-V battery, R_1 and R_2 dissipate 48.0 W of power, and when in parallel across the same battery, they dissipate a total of 256 W. $PR = I^2R = V^2/R$.

EXECUTE: **(a)** In series: $I = \mathcal{E}/(R_1 + R_2).$

$P_s = I^2(R_1 + R_2) = [\mathcal{E}/(R_1 + R_2)]2(R_1 + R_2) = \mathcal{E}^2/(R_1 + R_2).$

$48.0\ \text{W} = (48.0\ \text{V})^2/(R_1 + R_2).$

$R_1 + R_2 = 48.0\ \Omega.$

In parallel: $P_p = I_1^2 R_1 + I_2^2 R_2 = \dfrac{\mathcal{E}^2}{R_1^2} R_1 + \dfrac{\mathcal{E}^2}{R_2^2} R_2 = \mathcal{E}^2 \left(\dfrac{1}{R_1} + \dfrac{1}{R_2} \right) = \mathcal{E}^2 \left(\dfrac{R_1 + R_2}{R_1 R_2} \right) = 256 \text{ W}.$

Therefore $(48.0 \text{ V})^2 \left(\dfrac{R_1 R_2}{R_1 + R_2} \right) = 256 \text{ W}.$ Using $R_1 + R_2 = 48.0\ \Omega,$ this becomes $R_1 R_2 = 432\ \Omega^2.$

Solving the two equations for R_1 and R_2 simultaneously, we get two sets of answers: $R_1 = 36.0\ \Omega,$ $R_2 = 12.0\ \Omega$ and $R_1 = 12.0\ \Omega,$ $R_2 = 36.0\ \Omega.$ But we are told that that $R_1 > R_2,$ so the solution to use is $R_1 = 36.0\ \Omega,$ $R_2 = 12.0\ \Omega.$

(b) In series, both resistors have the same current. $P = I^2 R,$ so the larger resistor, which is $R_1,$ consumes more power.

(c) In parallel, the potential difference across both resistors is the same. $P = V^2 R,$ so the smaller resistor, which is $R_2,$ consumes more power.

EVALUATE: If we did not know which resistor was larger, we would know that one resistor was 12.0 Ω and the other was 36.0 Ω, but we would not know which one was the larger of the two.

26.81. **IDENTIFY:** This problem requires Kirchhoff's rules.

SET UP: Refer to Fig. 26.81 with the problem in the text. The given relations are:
I: $I_C + I_B = I_E$. II: $V_e = V_b - 0.60$ V. III: $I_C = \beta I_B$ ($\beta << 1$).

Use the following loops:
Loop 1: Clockwise through the small circuit containing V_{in} and the 100 Ω resistor.
Loop 2: Clockwise around the outside of the full circuit.

EXECUTE: **(a)** We want V_{out} in terms of V_{in}. If $\beta \to \infty, I_B = I_C/\beta \to 0,$ so $I_C = I_E.$ Apply Kirchhoff's rules.

Loop 1: $V_{in} - 0.60 \text{ V} - I_E(100\ \Omega) = 0$
Loop 2: $15 \text{ V} - I_C(1 \text{ kV}) - V_{out} = 0$
Using $I_C = I_E$ we get $I_E = (V_{in} - 0.60 \text{ V})/(100\ \Omega)$. Combining and solving gives $V_{out} = 21 \text{ V} - 10V_{in}$.

(b) We want V_{in} so V_{out} is 7.5 V. From (a): $V_{in} = (21 \text{ V} - V_{out})/10 = (21 \text{ V} - 7.5 \text{ V})/10 = 1.35$ V.

(c) The target variable is G. If V_{in} were just 15.0 V, then V_{out} would be $V_{out} = 21 \text{ V} - 10(15.0 \text{ V}) = -129$ V. But with the small $v(t)$, $V_{out} = 21 \text{ V} - 10(V_{in} + v_{in}) = 21 \text{ V} - 10(15.0 \text{ V} + v_{in})$. The coefficient of v_{in} is -10, so $G = -10$.

EVALUATE: Kirchhoff's rules apply to any type of circuit.

26.82. **IDENTIFY:** This problem involves a capacitor in an R-C circuit. We need to use Kirchhoff's rules.

SET UP: Refer to Fig. 26.82 with the problem in the textbook.

EXECUTE: **(a)** We want V_{out}. After a long time, the capacitor is fully charged, so $V_{out} = V_R = IR$.
$I = \mathcal{E}/5R$, so $V_{out} = R(\mathcal{E}/5R) = \mathcal{E}/5 = (15 \text{ V})/5 = 3.0$ V.

(b) We want the time constant τ_{ch} during charging, which is with S open. The resistance in the circuit is $4R$, so $\tau_{ch} = 4RC$.

(c) We want the time constant τ_d during discharging, which is with S closed. Apply Kirchhoff's rules. The current choices are: I_1 is downward through R; I_2 is upward through C, and I_4 is downward through $4R$.

Loop 1: Clockwise through the small circuit with R and C: $I_1 R = q/C$.
Loop 2: Clockwise around the outside of the circuit: $\mathcal{E} - 4RI_4 - q/C = 0.$

Junction rule: $I_4 = I_1 - I_2$.
The capacitor is discharging, so $I_2 = -dq/dt$.

Combining these equations gives $\dfrac{dq}{dt} = \dfrac{\mathcal{E}}{4R} - \dfrac{q}{4RC/5}$. From this result we see that $\tau_d = 4RC/5.$

(d) During the charging-discharging cycle, we want the time between successive 10.0 V output voltages across the capacitor. In one complete cycle, the potential difference across the capacitor discharges from 10.0 V to 5.0 V and then recharges from 5.0 V back to 10.0 V. The time constants in the two parts of the cycle are *not* the same.

Discharging: Using the result of part (c), solve $\frac{dq}{dt} = \frac{\mathcal{E}}{4R} - \frac{q}{4RC/5}$. The circuit discharges from 10.0 V to 5.0 V, so the initial voltage across the capacitor is $V_{0,d} = 10.0$ V. Separate variables and integrate.

$\int \frac{dq}{\mathcal{E}/4R - q/(4RC/5)} = \int dt$ gives $\ln\left(\frac{\mathcal{E}}{4R} - \frac{q}{4RC/5}\right) = t + K$, where K is a constant of integration.

Putting this result into exponential form gives $K' e^{-5t/4RC} = \frac{\mathcal{E}}{4R} - \frac{q}{4RC/5}$, where K' is a constant. When $t = 0$, $q = Q_0$, which gives $K' = \frac{\mathcal{E}}{4R} - \frac{Q_0}{4RC/5}$. Using this result, $V = q/C$, and $V_{0,d} = Q_0/C$ gives

$\left(\frac{\mathcal{E}}{4R} - \frac{V_{0,d}}{4R/5}\right) e^{-5t/4RC} = \frac{\mathcal{E}}{4R} - \frac{V}{4R/5}$. Solving for V (and calling it V_d) and simplifying, we get

$V_d = \frac{\mathcal{E}}{5} + \left(V_{0,d} - \frac{\mathcal{E}}{5}\right) e^{-5t/4RC}$.

(Check: At $t = 0$, $\mathcal{E} = 15$ V and $V_{0,d} = 10.0$ V, which gives $V_d = 10$ V, as it should. For $t \to \infty$ we have $V_d = 3.0$ V, which agrees with our result in part (a).)

Charging: The circuit is a simple series circuit containing the battery, the capacitor, and a resistance $4R$. It charges from 5.0 V to 10.0 V, so $V_{0,ch} = 5.0$ V. Applying Kirchhoff's loop rule gives $\frac{\mathcal{E}}{4R} - \frac{q}{4RC} = \frac{dq}{dt}$.

We solve this differential equation as we did for discharging. Separate variables and integrate, using the initial condition that $V = V_{0,ch}$ when $t = 0$. Carrying out these steps and solving for V_{ch} gives

$V_{ch} = \mathcal{E} - \left(\mathcal{E} - V_{0,ch}\right) e^{-t/4RC}$. (Check: At $t = 0$, $V_{ch} = 15$ V – (15 V – 5.0 V) = 5.0 V, as we should get. As $t \to \infty$, $V_{ch} \to \mathcal{E}$ as it should.) Now we find the time to charge the capacitor from 5.0 V to 10.0 V and to discharge it from 10.0 V to 5.0 V.

Charging from 5.0 V to 10.0 V: Using $V_{ch} = \mathcal{E} - \left(\mathcal{E} - V_{0,ch}\right) e^{-t/4RC}$ with $\mathcal{E} = 15$ V, $V_{0,ch} = 5.0$ V, and $V_{ch} = 10.0$ V, we have 10.0 V = 15 V – (15 V – 5.0 V)$e^{-t/4RC}$. Solving for the charging time t_{ch} gives

$t_{ch} = 4RC \ln 2$.

Discharging from 10.0 V to 5.0 V: Use $V_d = \frac{\mathcal{E}}{5} + \left(V_{0,d} - \frac{\mathcal{E}}{5}\right) e^{-5t/4RC}$ with $\mathcal{E} = 15$ V, $V_{0,d} = 10.0$ V, and $V_d = 5.0$ V, we have 5.0 V = 3.0 V + (10.0 V – 3.0 V)$e^{-5t/4RC}$. Solving for the discharge time t_d gives

$t_d = \frac{4RC}{5} \ln(7/2)$.

The total time T for one cycle is $T = t_d + t_{ch} = \frac{4RC}{5} \ln(7/2) + 4RC \ln 2$. Simplifying gives

$T = \frac{4RC}{5}\left(\ln 7 + 4 \ln 2\right)$.

(e) We want the frequency f of operation. Using $f = 1/T$ with $R = 10.0$ kΩ and $C = 10.0$ μF, we have $T =$ 4(10.0 kΩ)(10.0 μF)(ln 7 + 4 ln 2)/5 = 0.3775 s. $f = 1/T = 1/(0.3775$ s$) = 2.65$ Hz.

EVALUATE: The charging and discharging times are different because the time constants are different.

26.83. IDENTIFY: Consider one segment of the network attached to the rest of the network.

SET UP: We can re-draw the circuit as shown in Figure 26.83.

EXECUTE: $R_T = 2R_1 + \left(\dfrac{1}{R_2} + \dfrac{1}{R_T}\right)^{-1} = 2R_1 + \dfrac{R_2R_T}{R_2 + R_T}$. $R_T{}^2 - 2R_1R_T - 2R_1R_2 = 0$.

$R_T = R_1 \pm \sqrt{R_1{}^2 + 2R_1R_2}$. $R_T > 0$, so $R_T = R_1 + \sqrt{R_1{}^2 + 2R_1R_2}$.

EVALUATE: Even though there are an infinite number of resistors, the equivalent resistance of the network is finite.

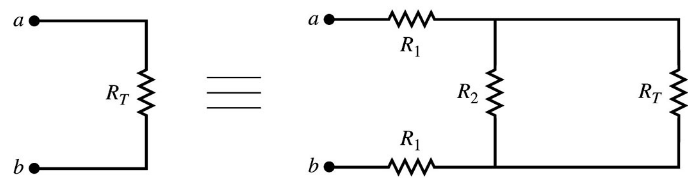

Figure 26.83

26.84. **IDENTIFY:** Assume a voltage V applied between points a and b and consider the currents that flow along each path between a and b.

SET UP: The currents are shown in Figure 26.84.

EXECUTE: Let current I enter at a and exit at b. At a there are three equivalent branches, so current is $I/3$ in each. At the next junction point there are two equivalent branches so each gets current $I/6$. Then at b there are three equivalent branches with current $I/3$ in each. The voltage drop from a to b then is $V = \left(\dfrac{I}{3}\right)R + \left(\dfrac{I}{6}\right)R + \left(\dfrac{I}{3}\right)R = \frac{5}{6}IR$. This must be the same as $V = IR_{\text{eq}}$, so $R_{\text{eq}} = \frac{5}{6}R$.

EVALUATE: The equivalent resistance is less than R, even though there are 12 resistors in the network.

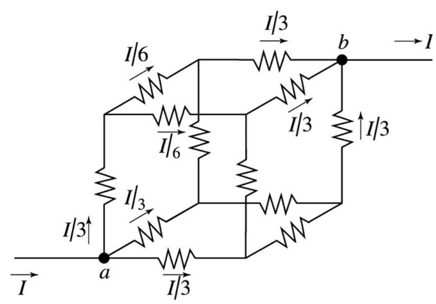

Figure 26.84

26.85. **IDENTIFY:** The network is the same as the one in Challenge Problem 26.83, and that problem shows that the equivalent resistance of the network is $R_T = \sqrt{R_1^2 + 2R_1R_2}$.

SET UP: The circuit can be redrawn as shown in Figure 26.85.

EXECUTE: **(a)** $V_{cd} = V_{ab}\dfrac{R_{\text{eq}}}{2R_1 + R_{\text{eq}}} = V_{ab}\dfrac{1}{2R_1/R_{\text{eq}} + 1}$ and $R_{\text{eq}} = \dfrac{R_2R_T}{R_2 + R_T}$. But $\beta = \dfrac{2R_1(R_T + R_2)}{R_TR_2} = \dfrac{2R_1}{R_{\text{eq}}}$, so $V_{cd} = V_{ab}\dfrac{1}{1+\beta}$.

(b) $V_1 = \dfrac{V_0}{(1+\beta)} \Rightarrow V_2 = \dfrac{V_1}{(1+\beta)} = \dfrac{V_0}{(1+\beta)^2} \Rightarrow V_n = \dfrac{V_{n-1}}{(1+\beta)} = \dfrac{V_0}{(1+\beta)^n}$.

If $R_1 = R_2$, then $R_T = R_1 + \sqrt{R_1^{\ 2} + 2R_1R_1} = R_1(1+\sqrt{3})$ and $\beta = \dfrac{2(2+\sqrt{3})}{1+\sqrt{3}} = 2.73$. So, for the nth segment to have 1% of the original voltage, we need: $\dfrac{1}{(1+\beta)^n} = \dfrac{1}{(1+2.73)^n} \le 0.01$. This says $n = 4$, and then $V_4 = 0.005V_0$.

(c) $R_T = R_1 + \sqrt{R_1^{\ 2} + 2R_1R_2}$ gives $R_T = 6400\ \Omega + \sqrt{(6400\ \Omega)^2 + 2(6400\ \Omega)(8.0\times10^8\ \Omega)} = 3.2\times10^6\ \Omega$ and $\beta = \dfrac{2(6400\ \Omega)(3.2\times10^6\ \Omega + 8.0\times10^8\ \Omega)}{(3.2\times10^6\ \Omega)(8.0\times10^8\ \Omega)} = 4.0\times10^{-3}$.

(d) Along a length of 2.0 mm of axon, there are 2000 segments each 1.0 μm long. The voltage therefore attenuates by $V_{2000} = \dfrac{V_0}{(1+\beta)^{2000}}$, so $\dfrac{V_{2000}}{V_0} = \dfrac{1}{(1+4.0\times10^{-3})^{2000}} = 3.4\times10^{-4}$.

(e) If $R_2 = 3.3\times10^{12}\ \Omega$, then $R_T = 2.1\times10^8\ \Omega$ and $\beta = 6.2\times10^{-5}$. This gives $\dfrac{V_{2000}}{V_0} = \dfrac{1}{(1+6.2\times10^{-5})^{2000}} = 0.88$.

EVALUATE: As R_2 increases, β decreases and the potential difference decrease from one section to the next is less.

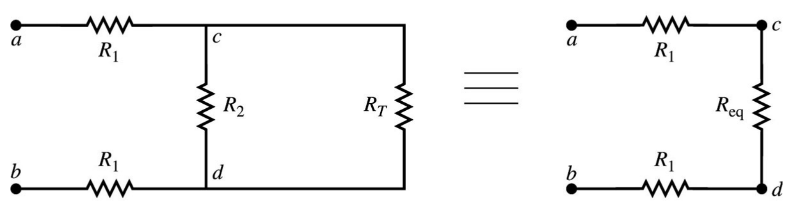

Figure 26.85

26.86. IDENTIFY and SET UP: $R = \dfrac{\rho L}{A}$.

EXECUTE: Solve for ρ: $\rho = \dfrac{AR}{L} = \dfrac{\pi r^2 R}{L} = \dfrac{\pi(0.3\ \text{nm})^2(1\times10^{11}\ \Omega)}{12\ \text{nm}} =\ 2.4\ \Omega\cdot\text{m}\ \Omega \approx 2\ \Omega\cdot\text{m}$, which is choice (c).

EVALUATE: According to the information in Table 25.1, this resistivity is much greater than that of conductors but much less than that of insulators. It is closer to that of semiconductors.

26.87. IDENTIFY and SET UP: The channels are all in parallel. For n identical resistors R in parallel, $\dfrac{1}{R_{\text{eq}}} = \dfrac{1}{R_1} + \dfrac{1}{R_2} + \ldots = \dfrac{1}{R} + \dfrac{1}{R} + \ldots = \dfrac{n}{R}$, so $R_{\text{eq}} = R/n$. $I = jA$.

EXECUTE: $I = jA = V/\text{R}_{\text{eq}} = V/(R/n) = nV/R$.

$jR/V = n/A = (5\ \text{mA/cm}^2)(10^{11}\ \Omega)/(50\ \text{mV}) = 10^{10}/\text{cm}^2 = 100/\mu\text{m}^2$, which is choice (d).

EVALUATE: A density of 100 per μm^2 seems plausible, since these are microscopic structures.

26.88. IDENTIFY and SET UP: $\tau = RC$. The resistance is $1\times10^{11}\ \Omega$. C is the capacitance per area divided by the number density of channels, which is 100/μm^2 from Problem 26.87.

EXECUTE: $C = (1\ \mu\text{F/cm}^2)/(100/\mu\text{m}^2) = 10^{-16}$ F. The time constant is

$\tau = RC = (1\times10^{11}\ \Omega)(10^{-16}\ \text{F}) = 1\times10^{-5}\ \text{s} = 10\ \mu s$, which is choice (b).

EVALUATE: This time constant is comparable to that of typical laboratory RC circuits.

27

MAGNETIC FIELD AND MAGNETIC FORCES

VP27.1.1. **IDENTIFY:** We want the magnitude and direction of the magnetic force on a moving electron.
SET UP: The magnitude is $F = |q|vB\sin\phi$ and the right-hand rule gives the direction.

EXECUTE: **(a)** $F = |q|vB\sin\phi = e(220\text{ km/s})(1.55\text{ T})\sin(50.0°) = 4.18\times10^{-14}$ N.

(b) If the charge were positive, the direction of the force would be the same as the direction of the cross product $\vec{F} = q\vec{v}\times\vec{B}$, which is in the $+z$-direction. But electrons are negative, so the force is in the opposite direction, which is the $-z$-direction.

EVALUATE: If the electron were replaced by a proton, the force would have the same magnitude but would point in the $+z$-direction.

VP27.1.2. **IDENTIFY:** We are dealing with the magnetic force on a moving particle.
SET UP: $F = |q|vB\sin\phi$. We want the charge of the particle.

EXECUTE: Solve for q: Using the given quantities gives $q = \dfrac{F}{vB\sin\phi} = 2.91\times10^{-15}$ C.

EVALUATE: We do not know the direction of the force so we cannot determine the sign of the charge.

VP27.1.3. **IDENTIFY:** This problem involves the magnetic force on a moving particle.
SET UP: $\vec{F} = q\vec{v}\times\vec{B}$, $F = |q|vB\sin\phi$. We want the magnitude and direction of the magnetic field.

EXECUTE: **(a)** Solve $F = |q|vB\sin\phi$ for B and use the given quantities. $B = \dfrac{F}{|q|v\sin\phi} = 0.0175$ T.

(b) Using the right-hand rule for the cross-product, we see that the force is in the $+z$-direction since q is positive.

EVALUATE: An electron would experience a force in the $-y$-direction since it is negatively charged.

VP27.1.4. **IDENTIFY:** This problem involves the magnetic force on a moving particle.
SET UP: $\vec{F} = q\vec{v}\times\vec{B}$, $F = |q|vB\sin\phi$, and the right-hand rule gives the direction of the force. We want the magnitude of the magnetic field and the direction of the force.

EXECUTE: **(a)** Solve for B and use the given numbers with $\phi = 53.1°$. $B = \dfrac{F}{|q|v\sin\phi} = 0.189$ T.

(b) The cross product points in the $-y$-direction, so that is the force direction since the ions are positive.

EVALUATE: Negatively charged ions would feel a force in the $+y$-direction.

VP27.6.1. **IDENTIFY:** The proton makes a circular path in the magnetic field.
SET UP: We want the radius of the path, the angular speed of the proton, and the frequency of its motion. $R = mv/|q|B$, $v = R\omega$, and $f = \omega/2\pi$.

EXECUTE: **(a)** Using $R = mv/|q|B$ and the given numbers gives $R = 0.435$ mm.

(b) Use $\omega = v/R$ and the given numbers to get $\omega = 2.87\times10^7$ rad/s.

(c) Use $f = \omega/2\pi =$ $(2.87\times10^7$ rad/s$)/2\pi = 4.57\times10^6$ Hz.

EVALUATE: Electrons would have a radius much smaller than that of the protons because they have the same magnitude charge as protons but much smaller mass.

VP27.6.2. **IDENTIFY:** We are dealing with the helical motion of a proton in a magnetic field.
SET UP: See Fig. VP27.6.2. $R = mv_x/|q|B$.

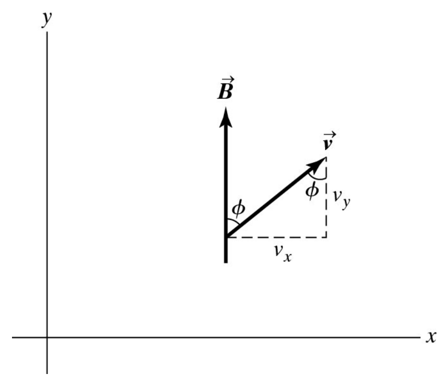

Figure VP27.6.2

EXECUTE: **(a)** We want the radius. $R = mv_x/|q|B = 0.348$ mm using the given numbers.

(b) We want the distance the proton moves along the helix in one revolution.

$\omega = v_x/R = 2\pi/T. T = 2\pi R/v_x$. $y = v_yT = v_y\left(\dfrac{2\pi R}{v_x}\right)$. Using the components given and $R = 0.348$ mm gives $y = 1.64$ mm.

(c) We want the magnitude of the magnetic force. $F = ev_xB = 4.80\times10^{-16}$ N using the given quantities.

EVALUATE: Only the velocity component perpendicular to the magnetic field causes circular motion. The component parallel to the field causes the path to be a helix rather than simply a circle.

VP27.6.3. **IDENTIFY:** This problem involves a velocity selector.
SET UP: $F_{magn} = |q|vB\sin\phi$ and $F_{el} = |q|E$.

EXECUTE: **(a)** We want the speed. $|q|E = |q|vB\sin\phi$. Using the numbers with $\phi = 90°$ gives $v = 8.00\times10^5$ m/s.

(b) We want the direction of motion. The particle should travel perpendicular to both fields so that the electric and magnetic forces are in opposite directions. So it should travel in the $-y$-direction.

(c) We want the direction it would deflect. The magnetic force is now greater than the electric force, so it will deflect in the direction of the magnetic force, which is in the $-x$-direction.

EVALUATE: Careful! The direction of the magnetic *force* is not the same as the direction of the magnetic *field*.

VP27.6.4. **IDENTIFY:** This problem is about a mass spectrometer.
SET UP and **EXECUTE:** **(a)** We want the radius for ^{16}O ions. $R_{16} = m_{16}v/|q|B = 6.65$ cm using the given numbers.

(b) We want the radius for ^{18}O ions. $R_{18} = m_{18}v/|q|B = 7.48$ cm using the given numbers.

EVALUATE: The distance between the two ions at the detector is $d = 2R_{18} - 2R_{16} =$ $2(7.48\text{ cm} - 6.65\text{ cm}) = 1.66$ cm. This separation would be very easy to measure.

VP27.7.1. **IDENTIFY:** This problem involves the magnetic force on a current-carrying wire.

SET UP: $\vec{F} = I\vec{l} \times \vec{B}$, $F = IlB\sin\phi$.

EXECUTE: **(a)** We want the magnitude of the force. Use $F = IlB\sin\phi$ with $\phi = 160°$ and the other given numbers, giving $F = 2.44$ mN.

(b) We want the direction of the force. Apply the right-hand rule for $\vec{l} \times \vec{B}$, which tells us that the force is in the $+z$-direction.

EVALUATE: The force is small, but it would be readily observable with a thin light wire.

VP27.7.2. **IDENTIFY:** This problem involves the magnetic force on a current-carrying wire.

SET UP: $\vec{F} = I\vec{l} \times \vec{B}$, $F = IlB\sin\phi$. We want the magnitude and direction of the current. First sketch the force and magnetic field as in Fig. VP27.7.2.

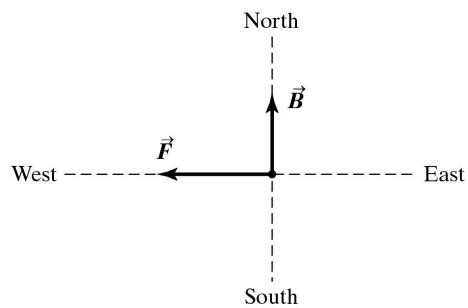

Figure VP27.7.2

EXECUTE: **(a)** Use $F = IlB\sin\phi$ with $\phi = 90°$ and the other numbers, giving $I = 1.60$ A.

(b) $\vec{l} \times \vec{B}$ points to the west, so $\vec{l}$ must point vertically downward, which means that the current I is traveling vertically *upward*.

EVALUATE: If I were downward, the magnetic force would be toward the east.

VP27.7.3. **IDENTIFY:** This problem involves the magnetic force on a current-carrying wire.

SET UP: $\vec{F} = I\vec{l} \times \vec{B}$. We want the components and magnitude of the force. First write the force in terms of its components and the unit vectors. $\vec{F} = I\vec{l} \times \vec{B} = I(l_x\hat{\boldsymbol{i}} + l_y\hat{\boldsymbol{j}}) \times B_z\hat{\boldsymbol{k}}$. Using the cross products of the unit vectors, this reduces to $\vec{F} = I\vec{l} \times \vec{B} = IB_z(l_y\hat{\boldsymbol{i}} - l_x\hat{\boldsymbol{j}})$.

EXECUTE: **(a)** $F_x = IB_z l_y = (1.20\text{ A})(0.0175\text{ T})(-0.120\text{ m}) = -2.52$ mN.

(b) $F_y = -IB_z l_x = -(1.20\text{ A})(0.0175\text{ T})(0.200\text{ m}) = -4.20$ mN.

(c) $F_z = 0$.

(d) $F = \sqrt{F_x^2 + F_y^2 + F_z^2} = 4.90$ mN using the components we just found.

EVALUATE: When working in three dimensions, it is usually easier to use components than to try to visualize the vectors.

VP27.7.4. **IDENTIFY:** This problem involves the magnetic force on a current-carrying wire.

SET UP: $F = IlB\sin\phi$. We want the *two* possible angles between direction of the current and the magnetic field.

EXECUTE: Solve for ϕ: $\phi = \text{a}\left(\dfrac{F}{IlB}\right) = \arcsin\left(\dfrac{0.0250\text{ N}}{(3.40\text{ A})(0.280\text{ m})(0.0400\text{ T})}\right) = 41.0°$. But $\sin(180° - 41.0°) = \sin 41.0°$, so the two angles are 41.0° and 139.0°.

EVALUATE: Physically the two angles correspond to the current running in opposite directions in the same magnetic field.

27.1. **IDENTIFY** and **SET UP:** Apply $\vec{F} = q\vec{v} \times \vec{B}$ to calculate $\vec{F}$. Use the cross products of unit vectors from Chapter 1. $\vec{v} = (+4.19 \times 10^4 \text{ m/s})\hat{i} + (-3.85 \times 10^4 \text{ m/s})\hat{j}$.

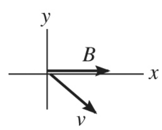
(a) EXECUTE: $\vec{B} = (1.40 \text{ T})\hat{i}$.

$\vec{F} = q\vec{v} \times \vec{B} = (-1.24 \times 10^{-8} \text{ C})(1.40 \text{ T})[(4.19 \times 10^4 \text{ m/s})\hat{i} \times \hat{i} - (3.85 \times 10^4 \text{ m/s})\hat{j} \times \hat{i}]$.

$\hat{i} \times \hat{i} = 0$, $\hat{j} \times \hat{i} = -\hat{k}$.

$\vec{F} = (-1.24 \times 10^{-8} \text{ C})(1.40 \text{ T})(-3.85 \times 10^4 \text{ m/s})(-\hat{k}) = (-6.68 \times 10^{-4} \text{ N})\hat{k}$.

EVALUATE: The directions of $\vec{v}$ and $\vec{B}$ are shown in Figure 27.1a.



The right-hand rule gives that $\vec{v} \times \vec{B}$ is directed out of the paper ($+z$-direction). The charge is negative so $\vec{F}$ is opposite to $\vec{v} \times \vec{B}$.

Figure 27.1a

$\vec{F}$ is in the $-z$-direction. This agrees with the direction calculated with unit vectors.

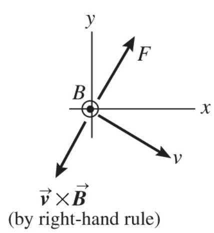
(b) EXECUTE: $\vec{B} = (1.40 \text{ T})\hat{k}$.

$\vec{F} = q\vec{v} \times \vec{B} = (-1.24 \times 10^{-8} \text{ C})(1.40 \text{ T})[(+4.19 \times 10^4 \text{ m/s})\hat{i} \times \hat{k} - (3.85 \times 10^4 \text{ m/s})\hat{j} \times \hat{k}]$.

$\hat{i} \times \hat{k} = -\hat{j}$, $\hat{j} \times \hat{k} = \hat{i}$.

$\vec{F} = (-7.27 \times 10^{-4} \text{ N})(-\hat{j}) + (6.68 \times 10^{-4} \text{ N})\hat{i} = [(6.68 \times 10^{-4} \text{ N})\hat{i} + (7.27 \times 10^{-4} \text{ N})\hat{j}]$.

EVALUATE: The directions of $\vec{v}$ and $\vec{B}$ are shown in Figure 27.1b.



The direction of $\vec{F}$ is opposite to $\vec{v} \times \vec{B}$ since q is negative. The direction of $\vec{F}$ computed from the right-hand rule agrees qualitatively with the direction calculated with unit vectors.

Figure 27.1b

27.2. **IDENTIFY:** The net force must be zero, so the magnetic and gravity forces must be equal in magnitude and opposite in direction.

SET UP: The gravity force is downward so the force from the magnetic field must be upward. The charge's velocity and the forces are shown in Figure 27.2. Since the charge is negative, the magnetic force is opposite to the right-hand rule direction. The minimum magnetic field is when the field is perpendicular to $\vec{v}$. The force is also perpendicular to $\vec{B}$, so $\vec{B}$ is either eastward or westward.

EXECUTE: If $\vec{B}$ is eastward, the right-hand rule direction is into the page and $\vec{F}_B$ is out of the page, as required. Therefore, $\vec{B}$ is eastward. $mg = |q|vB\sin\phi$. $\phi = 90°$ and

$$B = \frac{mg}{v|q|} = \frac{(0.195 \times 10^{-3} \text{ kg})(9.80 \text{ m/s}^2)}{(4.00 \times 10^4 \text{ m/s})(2.50 \times 10^{-8} \text{ C})} = 1.91 \text{ T}.$$

EVALUATE: The magnetic field could also have a component along the north-south direction, that would not contribute to the force, but then the field wouldn't have minimum magnitude.

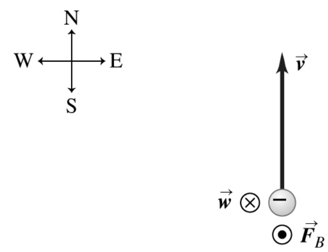


Figure 27.2

27.3. **IDENTIFY:** The force $\vec{F}$ on the particle is in the direction of the deflection of the particle. Apply the right-hand rule to the directions of $\vec{v}$ and $\vec{B}$. See if your thumb is in the direction of $\vec{F}$, or opposite to that direction. Use $F = |q|vB\sin\phi$ with $\phi = 90°$ to calculate F.

SET UP: The directions of $\vec{v}$, $\vec{B}$, and $\vec{F}$ are shown in Figure 27.3.

EXECUTE: **(a)** When you apply the right-hand rule to $\vec{v}$ and $\vec{B}$, your thumb points east. $\vec{F}$ is in this direction, so the charge is positive.

(b) $F = |q|vB\sin\phi = (8.50\times10^{-6}\text{ C})(4.75\times10^{3}\text{ m/s})(1.25\text{ T})\sin 90° = 0.0505\text{ N}$

EVALUATE: If the particle had negative charge and $\vec{v}$ and $\vec{B}$ are unchanged, the particle would be deflected toward the west.

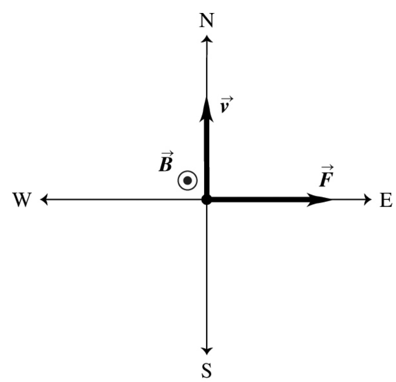

Figure 27.3

27.4. **IDENTIFY:** Apply Newton's second law, with the force being the magnetic force.
SET UP: $\hat{\boldsymbol{j}}\times\hat{\boldsymbol{i}} = -\hat{\boldsymbol{k}}$.

EXECUTE: $\vec{F} = m\vec{a} = q\vec{v}\times\vec{B}$ gives $\vec{a} = \dfrac{q\vec{v}\times\vec{B}}{m}$ and

$$\vec{a} = \frac{(1.22\times10^{-8}\text{ C})(3.0\times10^{4}\text{ m/s})(1.63\text{ T})(\hat{\boldsymbol{j}}\times\hat{\boldsymbol{i}})}{1.81\times10^{-3}\text{ kg}} = -(0.330\text{ m/s}^2)\hat{\boldsymbol{k}}.$$

EVALUATE: The acceleration is in the $-z$-direction and is perpendicular to both $\vec{v}$ and $\vec{B}$.

27.5. **IDENTIFY:** This problem involves the magnetic force on a moving charge.
SET UP: $\vec{F} = q\vec{v}\times\vec{B}$, $F = |q|vB\sin\phi$. We want the velocity.
EXECUTE: Solve $F = |q|vB\sin\phi$ for v. Using the given numbers with $\phi = 90°$ and $q = e$ we get $v = \dfrac{F}{eB}$ = 172 m/s. By the right-hand rule, the velocity would have to be in the $+x$-direction for a positive charge, so for an electron it must be in the $-x$-direction.
EVALUATE: The force on a proton would have the same magnitude but opposite direction.

27.6. **IDENTIFY:** Apply Newton's second law and $F = |q|vB\sin\phi.$

SET UP: ϕ is the angle between the direction of $\vec{v}$ and the direction of $\vec{B}$.

EXECUTE: **(a)** The smallest possible acceleration is zero, when the motion is parallel to the magnetic field. The greatest acceleration is when the velocity and magnetic field are at right angles:

$$a = \frac{|q|vB}{m} = \frac{(1.6\times10^{-19}\text{ C})(1.40\times10^{6}\text{ m/s})(7.4\times10^{-2}\text{ T})}{(9.11\times10^{-31}\text{ kg})} = 1.82\times10^{16}\text{ m/s}^2.$$

(b) If $a = \frac{1}{4}(1.82\times10^{16}\text{ m/s}^2) = \dfrac{|q|vB\sin\phi}{m}$, then $\sin\phi = 0.25$ and $\phi = 14.5°$.

EVALUATE: The force and acceleration decrease as the angle ϕ approaches zero.

27.7. **IDENTIFY:** Apply $\vec{F} = q\vec{v}\times\vec{B}$ to the force on the proton and to the force on the electron. Solve for the components of $\vec{B}$ and use them to find its magnitude and direction.

SET UP: $\vec{F}$ is perpendicular to both $\vec{v}$ and $\vec{B}$. Since the force on the proton is in the $+y$-direction, $B_y = 0$ and $\vec{B} = B_x\hat{i} + B_z\hat{k}$. For the proton, $\vec{v}_\text{p} = (1.50\text{ km/s})\hat{i} = v_\text{p}\hat{i}$ and $\vec{F}_\text{p} = (2.25\times10^{-16}\text{ N})\hat{j} = F_\text{p}\hat{j}$. For the electron, $\vec{v}_\text{e} = -(4.75\text{ km/s})\hat{k} = -v_\text{e}\hat{k}$ and $\vec{F}_\text{e} = (8.50\times10^{-16}\text{ N})\hat{j} = F_\text{e}\hat{j}$. The magnetic force is $\vec{F} = q\vec{v}\times\vec{B}$.

EXECUTE: **(a)** For the proton, $\vec{F}_\text{p} = q\vec{v}_\text{p}\times\vec{B}$ gives $F_\text{p}\hat{j} = ev_\text{p}\hat{i}\times(B_x\hat{i} + B_z\hat{k}) = -ev_\text{p}B_z\hat{j}$. Solving for B_z gives $B_z = -\dfrac{F_\text{p}}{ev_\text{p}} = -\dfrac{2.25\times10^{-16}\text{ N}}{(1.60\times10^{-19}\text{ C})(1500\text{ m/s})} = -0.9375\text{ T}$. For the electron, $\vec{F}_\text{e} = -e\vec{v}_\text{e}\times\vec{B}$, which gives $F_\text{e}\hat{j} = (-e)(-v_\text{e}\hat{k})\times(B_x\hat{i} + B_z\hat{k}) = ev_\text{e}B_x\hat{j}$. Solving for B_x gives

$B_x = \dfrac{F_\text{e}}{ev_\text{e}} = \dfrac{8.50\times10^{-16}\text{ N}}{(1.60\times10^{-19}\text{ C})(4750\text{ m/s})} = 1.118\text{ T}$. Therefore $\vec{B} = 1.118\text{ T}\hat{i} - 0.9375\text{ T}\hat{k}$. The magnitude of the field is $B = \sqrt{B_x^2 + B_z^2} = \sqrt{(1.118\text{ T})^2 + (-0.9375\text{ T})^2} = 1.46\text{ T}$. Calling θ the angle that the magnetic field makes with the $+x$-axis, we have $\tan\theta = \dfrac{B_z}{B_x} = \dfrac{-0.9375\text{ T}}{1.118\text{ T}} = -0.8386$, so $\theta = -40.0°$.

Therefore the magnetic field is in the xz-plane directed at 40.0° from the $+x$-axis toward the $-z$-axis, having a magnitude of 1.46 T.

(b) $\vec{B} = B_x\hat{i} + B_z\hat{k}$ and $\vec{v} = (3.2\text{ km/s})(-\hat{j})$.

$\vec{F} = q\vec{v}\times\vec{B} = (-e)(3.2\text{ km/s})(-\hat{j})\times(B_x\hat{i} + B_z\hat{k}) = e(3.2\times10^{3}\text{ m/s})[B_x(-\hat{k}) + B_z\hat{i}]$.

$\vec{F} = e(3.2\times10^{3}\text{ m/s})(-1.118\text{ T}\hat{k} - 0.9375\text{ T}\hat{i}) = -4.80\times10^{-16}\text{ N}\hat{i} - 5.724\times10^{-16}\text{ N}\hat{k}$.

$F = \sqrt{F_x^2 + F_z^2} = 7.47\times10^{-16}\text{ N}$. Calling θ the angle that the force makes with the $-x$-axis, we have $\tan\theta = \dfrac{F_z}{F_x} = \dfrac{-5.724\times10^{-16}\text{ N}}{-4.800\times10^{-16}\text{ N}}$, which gives $\theta = 50.0°$. The force is in the xz-plane and is directed at 50.0° from the $-x$-axis toward either the $-z$-axis.

EVALUATE: The force on the electrons in parts (a) and (b) are comparable in magnitude because the electron speeds are comparable in both cases.

27.8. **IDENTIFY** and **SET UP:** $\vec{F} = q\vec{v}\times\vec{B} = qB_z[v_x(\hat{i}\times\hat{k}) + v_y(\hat{j}\times\hat{k}) + v_z(\hat{k}\times\hat{k})] = qB_z[v_x(-\hat{j}) + v_y(\hat{i})]$.

EXECUTE: **(a)** Set the expression for $\vec{F}$ equal to the given value of $\vec{F}$ to obtain:

$$v_x = \frac{F_y}{-qB_z} = \frac{(7.40\times10^{-7}\text{ N})}{-(-5.60\times10^{-9}\text{ C})(-1.25\text{ T})} = -106\text{ m/s}.$$

$$v_y = \frac{F_x}{qB_z} = \frac{-(3.40\times10^{-7}\text{ N})}{(-5.60\times10^{-9}\text{ C})(-1.25\text{ T})} = -48.6\text{ m/s.}$$

(b) v_z does not contribute to the force, so is not determined by a measurement of $\vec{F}$.

(c) $\vec{v}\cdot\vec{F} = v_xF_x + v_yF_y + v_zF_z = \frac{F_y}{-qB_z}F_x + \frac{F_x}{qB_z}F_y = 0;\ \theta = 90°.$

EVALUATE: The force is perpendicular to both $\vec{v}$ and $\vec{B}$, so $\vec{B}\cdot\vec{F}$ is also zero.

27.9. IDENTIFY and **SET UP:** $\Phi_B = \int \vec{B}\cdot d\vec{A}$.

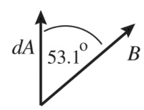
Circular area in the xy-plane, so $A = \pi r^2 = \pi(0.0650\text{ m})^2 = 0.01327\text{ m}^2$ and $d\vec{A}$ is in the z-direction. Use Eq. (1.18) to calculate the scalar product.

EXECUTE: (a) $\vec{B} = (0.230\text{ T})\hat{k}$; $\vec{B}$ and $d\vec{A}$ are parallel $(\phi = 0°)$ so $\vec{B}\cdot d\vec{A} = B\,dA$.

B is constant over the circular area so

$$\Phi_B = \int \vec{B}\cdot d\vec{A} = \int B\,dA = B\int dA = BA = (0.230\text{ T})(0.01327\text{ m}^2) = 3.05\times10^{-3}\text{ Wb.}$$

(b) The directions of $\vec{B}$ and $d\vec{A}$ are shown in Figure 27.9a.



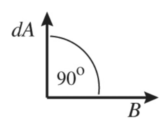
$\vec{B}\cdot d\vec{A} = B\cos\phi\, dA$
with $\phi = 53.1°$.

Figure 27.9a

B and ϕ are constant over the circular area so $\Phi_B = \int \vec{B}\cdot d\vec{A} = \int B\cos\phi\, dA = B\cos\phi \int dA = B\cos\phi A$

$$\Phi_B = (0.230\text{ T})\cos 53.1°(0.01327\text{ m}^2) = 1.83\times10^{-3}\text{ Wb.}$$

(c) The directions of $\vec{B}$ and $d\vec{A}$ are shown in Figure 27.9b.



$\vec{B}\cdot d\vec{A} = 0$ since $d\vec{A}$ and $\vec{B}$ are perpendic
$\Phi_B = \int \vec{B}\cdot d\vec{A} = 0.$

Figure 27.9b

EVALUATE: Magnetic flux is a measure of how many magnetic field lines pass through the surface. It is maximum when $\vec{B}$ is perpendicular to the plane of the loop (part a) and is zero when $\vec{B}$ is parallel to the plane of the loop (part c).

27.10. IDENTIFY: Knowing the area of a surface and the magnetic field it is in, we want to calculate the flux through it.

SET UP: $d\vec{A} = dA\hat{k}$, so $d\Phi_B = \vec{B}\cdot d\vec{A} = B_z dA$.

EXECUTE: $\Phi_B = B_zA = (-0.500\text{ T})(0.0340\text{ m})^2 = -5.78\times10^{-4}\text{ T}\cdot\text{m}^2$. $|\Phi_B| = 5.78\times10^{-4}$ Wb.

EVALUATE: Since the field is uniform over the surface, it is not necessary to integrate to find the flux.

27.11. IDENTIFY: The total flux through the bottle is zero because it is a closed surface.

SET UP: The total flux through the bottle is the flux through the plastic plus the flux through the open cap, so the sum of these must be zero. $\Phi_{\text{plastic}} + \Phi_{\text{cap}} = 0$.

$$\Phi_{\text{plastic}} = -\Phi_{\text{cap}} = -BA\cos\phi = -B(\pi r^2)\cos\phi.$$

EXECUTE: Substituting the numbers gives $\Phi_{\text{plastic}} = -(1.75\text{ T})\pi(0.0125\text{ m})^2\cos 25° = -7.8\times10^{-4}$ Wb.

EVALUATE: It would be very difficult to calculate the flux through the plastic directly because of the complicated shape of the bottle, but with a little thought we can find this flux through a simple calculation.

27.12. IDENTIFY: Knowing the area of a surface and the magnetic flux through it, we want to find the magnetic field needed to produce this flux.
SET UP: $\Phi_B = BA\cos\phi$ where $\phi = 60.0°$.
EXECUTE: Solving $\Phi_B = BA\cos\phi$ for B gives

$$B = \frac{\Phi_B}{A\cos\phi} = \frac{3.10\times10^{-4}\ \text{Wb}}{(0.0280\ \text{m})(0.0320\ \text{m})\cos 60.0°} = 0.692\ \text{T}.$$

EVALUATE: This is a fairly strong magnetic field, but not impossible to achieve in modern laboratories.

27.13. IDENTIFY: When $\vec{B}$ is uniform across the surface, $\Phi_B = \vec{B}\cdot\vec{A} = BA\cos\phi.$

SET UP: $\vec{A}$ is normal to the surface and is directed outward from the enclosed volume. For surface *abcd*, $\vec{A} = -A\hat{i}$. For surface *befc*, $\vec{A} = -A\hat{k}$. For surface *aefd*, $\cos\phi = 3/5$ and the flux is positive.

EXECUTE: (a) $\Phi_B(abcd) = \vec{B}\cdot\vec{A} = 0.$

(b) $\Phi_B(befc) = \vec{B}\cdot\vec{A} = -(0.128\ \text{T})(0.300\ \text{m})(0.300\ \text{m}) = -0.0115\ \text{Wb}.$

(c) $\Phi_B(aefd) = \vec{B}\cdot\vec{A} = BA\cos\phi = \frac{3}{5}(0.128\ \text{T})(0.500\ \text{m})(0.300\ \text{m}) = +0.0115\ \text{Wb}.$

(d) The net flux through the rest of the surfaces is zero since they are parallel to the *x*-axis. The total flux is the sum of all parts above, which is zero.
EVALUATE: The total flux through any closed surface, that encloses a volume, is zero.

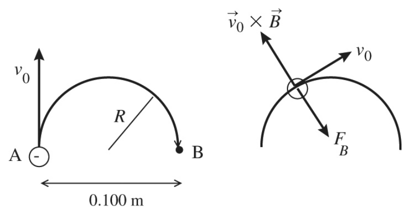
27.14. IDENTIFY: Newton's second law gives $|q|vB = mv^2/R.$ The speed v is constant and equals v_0. The direction of the magnetic force must be in the direction of the acceleration and is toward the center of the semicircular path.
SET UP: A proton has $q = +1.60\times10^{-19}$ C and $m = 1.67\times10^{-27}$ kg. The direction of the magnetic force is given by the right-hand rule.

EXECUTE: (a) $B = \dfrac{mv}{qR} = \dfrac{(1.67\times10^{-27}\ \text{kg})(1.41\times10^{6}\ \text{m/s})}{(1.60\times10^{-19}\ \text{C})(0.0500\ \text{m})} = 0.294\ \text{T}.$

The direction of the magnetic field is out of the page (the charge is positive), in order for $\vec{F}$ to be directed to the right at point *A*.
(b) The time to complete half a circle is $t = \pi R/v_0 = 1.11\times10^{-7}$ s.

EVALUATE: The magnetic field required to produce this path for a proton has a different magnitude (because of the different mass) and opposite direction (because of opposite sign of the charge) than the field required to produce the path for an electron.

27.15. (a) IDENTIFY: Apply $\vec{F} = q\vec{v}\times\vec{B}$ to relate the magnetic force $\vec{F}$ to the directions of $\vec{v}$ and $\vec{B}$. The electron has negative charge so $\vec{F}$ is opposite to the direction of $\vec{v}\times\vec{B}$. For motion in an arc of a circle the acceleration is toward the center of the arc so $\vec{F}$ must be in this direction. $a = v^2/R.$
SET UP:



As the electron moves in the semicircle, its velocity is tangent to the circular path. The direction of $\vec{v}_0 \times \vec{B}$ at a point along the path is shown in Figure 27.15.

Figure 27.15

EXECUTE: For circular motion the acceleration of the electron $\vec{a}_{\text{rad}}$ is directed in toward the center of the circle. Thus the force $\vec{F}_B$ exerted by the magnetic field, since it is the only force on the electron, must be radially inward. Since q is negative, $\vec{F}_B$ is opposite to the direction given by the right-hand rule for $\vec{v}_0 \times \vec{B}$. Thus $\vec{B}$ is directed into the page. Apply Newton's second law to calculate the magnitude of $\vec{B}$: $\sum \vec{F} = m\vec{a}$ gives $\sum F_{\text{rad}} = ma \quad F_B = m(v^2/R)$.

$F_B = |q| vB\sin\phi = |q| vB$, so $|q| vB = m(v^2/R)$.

$$B = \frac{mv}{|q|R} = \frac{(9.109\times10^{-31}\text{ kg})(1.41\times10^{6}\text{ m/s})}{(1.602\times10^{-19}\text{ C})(0.050\text{ m})} = 1.60\times10^{-4}\text{ T}.$$

(b) IDENTIFY and **SET UP:** The speed of the electron as it moves along the path is constant. ($\vec{F}_B$ changes the direction of $\vec{v}$ but not its magnitude.) The time is given by the distance divided by v_0.

EXECUTE: The distance along the semicircular path is πR, so $t = \dfrac{\pi R}{v_0} = \dfrac{\pi(0.050\text{ m})}{1.41\times10^{6}\text{ m/s}} = 1.11\times10^{-7}$ s.

EVALUATE: The magnetic field required increases when v increases or R decreases and also depends on the mass to charge ratio of the particle.

27.16. **IDENTIFY:** Since the particle moves perpendicular to the uniform magnetic field, the radius of its path is $R = \dfrac{mv}{|q|B}$. The magnetic force is perpendicular to both $\vec{v}$ and $\vec{B}$.

SET UP: The alpha particle has charge $q = +2e = 3.20\times10^{-19}$ C.

EXECUTE: **(a)** $R = \dfrac{(6.64\times10^{-27}\text{ kg})(35.6\times10^{3}\text{ m/s})}{(3.20\times10^{-19}\text{ C})(1.80\text{ T})} = 4.104\times10^{-4}\text{ m} = 0.4104\text{ mm}.$ The alpha particle moves in a circular arc of diameter $2R = 2(0.4104\text{ mm}) = 0.821$ mm.

(b) For a very short time interval the displacement of the particle is in the direction of the velocity. The magnetic force is always perpendicular to this direction so it does no work. The work-energy theorem therefore says that the kinetic energy of the particle, and hence its speed, is constant.

(c) The acceleration is

$a = \dfrac{F_B}{m} = \dfrac{|q|vB\sin\phi}{m} = \dfrac{(3.20\times10^{-19}\text{ C})(35.6\times10^{3}\text{ m/s})(1.80\text{ T})\sin 90^\circ}{6.64\times10^{-27}\text{ kg}} = 3.09\times10^{12}\text{ m/s}^2.$ We can also use $a = \dfrac{v^2}{R}$ and the result of part (a) to calculate $a = \dfrac{(35.6\times10^{3}\text{ m/s})^2}{4.104\times10^{-4}\text{ m}} = 3.09\times10^{12}\text{ m/s}^2$, the same result. The acceleration is perpendicular to $\vec{v}$ and $\vec{B}$ and so is horizontal, toward the center of curvature of the particle's path.

EVALUATE: **(d)** The unbalanced force $(\vec{F}_B)$ is perpendicular to $\vec{v}$, so it changes the direction of $\vec{v}$ but not its magnitude, which is the speed.

27.17. **IDENTIFY** and **SET UP:** Use conservation of energy to find the speed of the ball when it reaches the bottom of the shaft. The right-hand rule gives the direction of $\vec{F}$ and $F = |q|v B \sin\phi$ gives its magnitude. The number of excess electrons determines the charge of the ball.

EXECUTE: $q = (4.00\times 10^{8})(-1.602\times 10^{-19}\text{ C}) = -6.408\times 10^{-11}\text{ C}.$

speed at bottom of shaft: $\frac{1}{2}mv^2 = mgy;\ v = \sqrt{2gy} = 49.5\text{ m/s}.$

$\vec{v}$ is downward and $\vec{B}$ is west, so $\vec{v}\times\vec{B}$ is north. Since $q < 0$, $\vec{F}$ is south.

$F = |q|vB\sin\theta = (6.408\times 10^{-11}\text{ C})(49.5\text{ m/s})(0.250\text{ T})\sin 90° = 7.93\times 10^{-10}\text{ N}.$

EVALUATE: Both the charge and speed of the ball are relatively small so the magnetic force is small, much less than the gravity force of 1.5 N.

27.18. **IDENTIFY:** The magnetic field acts perpendicular to the velocity, causing the ion to move in a circular path but not changing its speed.

SET UP: $R = \dfrac{mv}{|q|B}$ and $K = \frac{1}{2}mv^2$. $K = 5.0\text{ MeV} = 8.0\times 10^{-13}\text{ J}.$

EXECUTE: **(a)** Solving $K = \frac{1}{2}mv^2$ for v gives $v = \sqrt{2K/m}.$

$v = [2(8.0\times 10^{-13}\text{ J})/(1.67\times 10^{-27}\text{ kg})]^{1/2} = 3.095\times 10^{7}\text{ m/s},$ which rounds to $3.1\times 10^{7}\text{ m/s}.$

(b) Using $R = \dfrac{mv}{|q|B} = (1.67\times 10^{-27}\text{ kg})(3.095\times 10^{7}\text{ m/s})/[(1.602\times 10^{-19}\text{ C})(1.9\text{ T})] = 0.17\text{ m} = 17\text{ cm}.$

EVALUATE: If the hydride ions were accelerated to 20 MeV, which is 4 times the value used here, their speed would be twice as great, so the radius of their path would also be twice as great.

27.19. **IDENTIFY:** For motion in an arc of a circle, $a = \dfrac{v^2}{R}$ and the net force is radially inward, toward the center of the circle.

SET UP: The direction of the force is shown in Figure 27.19. The mass of a proton is 1.67×10^{-27} kg.

EXECUTE: **(a)** $\vec{F}$ is opposite to the right-hand rule direction, so the charge is negative. $\vec{F} = m\vec{a}$ gives $|q|vB\sin\phi = m\dfrac{v^2}{R}$. $\phi = 90°$ and $v = \dfrac{|q|BR}{m} = \dfrac{3(1.60\times 10^{-19}\text{ C})(0.250\text{ T})(0.475\text{ m})}{12(1.67\times 10^{-27}\text{ kg})} = 2.84\times 10^{6}\text{ m/s}.$

(b) $F_B = |q|vB\sin\phi = 3(1.60\times 10^{-19}\text{ C})(2.84\times 10^{6}\text{ m/s})(0.250\text{ T})\sin 90° = 3.41\times 10^{-13}\text{ N}.$

$w = mg = 12(1.67\times 10^{-27}\text{ kg})(9.80\text{ m/s}^2) = 1.96\times 10^{-25}\text{ N}.$ The magnetic force is much larger than the weight of the particle, so it is a very good approximation to neglect gravity.

EVALUATE: **(c)** The magnetic force is always perpendicular to the path and does no work. The particles move with constant speed.

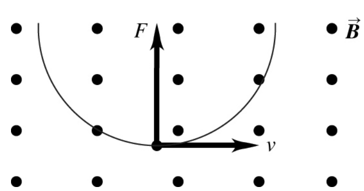


Figure 27.19

27.20. **(a) IDENTIFY** and **SET UP:** Apply Newton's second law, with $a = v^2/R$ since the path of the particle is circular.

EXECUTE: $\sum\vec{F} = m\vec{a}$ says $|q|vB = m(v^2/R).$

$v = \dfrac{|q|BR}{m} = \dfrac{(1.602\times10^{-19}\text{ C})(2.50\text{ T})(6.96\times10^{-3}\text{ m})}{3.34\times10^{-27}\text{ kg}} = 8.35\times10^{5}\text{ m/s.}$

(b) IDENTIFY and SET UP: The speed is constant so $t = \text{distance}/v$.

EXECUTE: $t = \dfrac{\pi R}{v} = \dfrac{\pi(6.96\times10^{-3}\text{ m})}{8.35\times10^{5}\text{ m/s}} = 2.62\times10^{-8}\text{ s.}$

(c) IDENTIFY and SET UP: kinetic energy gained = electric potential energy lost.

EXECUTE: $\frac{1}{2}mv^2 = |q|V.$

$V = \dfrac{mv^2}{2|q|} = \dfrac{(3.34\times10^{-27}\text{ kg})(8.35\times10^{5}\text{ m/s})^2}{2(1.602\times10^{-19}\text{ C})} = 7.27\times10^{3}\text{ V} = 7.27\text{ kV.}$

EVALUATE: The deutron has a much larger mass to charge ratio than an electron so a much larger B is required for the same v and R. The deutron has positive charge so gains kinetic energy when it goes from high potential to low potential.

27.21. IDENTIFY: When a particle of charge $-e$ is accelerated through a potential difference of magnitude V, it gains kinetic energy eV. When it moves in a circular path of radius R, its acceleration is $\dfrac{v^2}{R}$.

SET UP: An electron has charge $q = -e = -1.60\times10^{-19}\text{ C}$ and mass $9.11\times10^{-31}\text{ kg}$.

EXECUTE: $\frac{1}{2}mv^2 = eV$ and $v = \sqrt{\dfrac{2eV}{m}} = \sqrt{\dfrac{2(1.60\times10^{-19}\text{ C})(2.00\times10^{3}\text{ V})}{9.11\times10^{-31}\text{ kg}}} = 2.65\times10^{7}\text{ m/s.}$ $\vec{F} = m\vec{a}$ gives $|q|vB\sin\phi = m\dfrac{v^2}{R}$. $\phi = 90°$ and $B = \dfrac{mv}{|q|R} = \dfrac{(9.11\times10^{-31}\text{ kg})(2.65\times10^{7}\text{ m/s})}{(1.60\times10^{-19}\text{ C})(0.180\text{ m})} = 8.38\times10^{-4}\text{ T.}$

EVALUATE: The smaller the radius of the circular path, the larger the magnitude of the magnetic field that is required.

27.22. IDENTIFY: The magnetic force on the beam bends it through a quarter circle.
SET UP: The distance that particles in the beam travel is $s = R\theta$, and the radius of the quarter circle is $R = mv/qB$.

EXECUTE: Solving for R gives $R = s/\theta = s/(\pi/2) = 1.18\text{ cm}/(\pi/2) = 0.751\text{ cm}$. Solving for the magnetic field: $B = mv/qR = (1.67\times10^{-27}\text{ kg})(1200\text{ m/s})/[(1.60\times10^{-19}\text{ C})(0.00751\text{ m})] = 1.67\times10^{-3}\text{ T.}$

EVALUATE: This field is about 10 times stronger than the earth's magnetic field, but much weaker than many laboratory fields.

27.23. IDENTIFY: For no deflection the magnetic and electric forces must be equal in magnitude and opposite in direction.
SET UP: $v = E/B$ for no deflection.

EXECUTE: To pass undeflected in both cases, $E = vB = (5.85\times10^{3}\text{ m/s})(1.35\text{ T}) = 7898\text{ N/C}$.

(a) If $q = 0.640\times10^{-9}\text{ C}$, the electric field direction is given by $-(\hat{\boldsymbol{j}}\times(-\hat{\boldsymbol{k}})) = \hat{\boldsymbol{i}}$, since it must point in the opposite direction to the magnetic force.
(b) If $q = -0.320\times10^{-9}\text{ C}$, the electric field direction is given by $((-\hat{\boldsymbol{j}})\times(-\hat{\boldsymbol{k}})) = \hat{\boldsymbol{i}}$, since the electric force must point in the opposite direction as the magnetic force. Since the particle has negative charge, the electric force is opposite to the direction of the electric field and the magnetic force is opposite to the direction it has in part (a).
EVALUATE: The same configuration of electric and magnetic fields works as a velocity selector for both positively and negatively charged particles.

27.24. **IDENTIFY:** For no deflection the magnetic and electric forces must be equal in magnitude and opposite in direction.

SET UP: $v = E/B$ for no deflection. With only the magnetic force, $|q|vB = mv^2/R$.

EXECUTE: **(a)** $v = E/B = (1.56\times10^4\text{ V/m})/(4.62\times10^{-3}\text{ T}) = 3.38\times10^6\text{ m/s}$.

(b) The directions of the three vectors $\vec{v}$, $\vec{E}$, and $\vec{B}$ are sketched in Figure 27.24.

(c) $R = \dfrac{mv}{|q|B} = \dfrac{(9.11\times10^{-31}\text{ kg})(3.38\times10^6\text{ m/s})}{(1.60\times10^{-19}\text{ C})(4.62\times10^{-3}\text{ T})} = 4.17\times10^{-3}\text{ m}$.

$T = \dfrac{2\pi m}{|q|B} = \dfrac{2\pi R}{v} = \dfrac{2\pi(4.17\times10^{-3}\text{ m})}{(3.38\times10^6\text{ m/s})} = 7.74\times10^{-9}\text{ s}$.

EVALUATE: For the field directions shown in Figure 27.24, the electric force is toward the top of the page and the magnetic force is toward the bottom of the page.

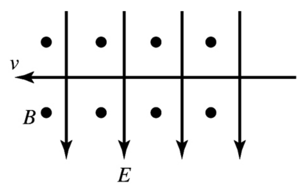

Figure 27.24

27.25. **IDENTIFY:** For the alpha particles to emerge from the plates undeflected, the magnetic force on them must exactly cancel the electric force. The battery produces an electric field between the plates, which acts on the alpha particles.

SET UP: First use energy conservation to find the speed of the alpha particles as they enter the region between the plates: $qV = 1/2\ mv^2$. The electric field between the plates due to the battery is $E = V_\text{b}/d$. For the alpha particles not to be deflected, the magnetic force must cancel the electric force, so $qvB = qE$, giving $B = E/v$.

EXECUTE: Solve for the speed of the alpha particles just as they enter the region between the plates. Their charge is $2e$.

$$v_\alpha = \sqrt{\frac{2(2e)V}{m}} = \sqrt{\frac{4(1.60\times10^{-19}\text{ C})(1750\text{ V})}{6.64\times10^{-27}\text{ kg}}} = 4.11\times10^5\text{ m/s}.$$

The electric field between the plates, produced by the battery, is
$E = V_\text{b}/d = (150\text{ V})/(0.00820\text{ m}) = 18{,}300\text{ V/m}$.

The magnetic force must cancel the electric force:
$B = E/v_\alpha = (18{,}300\text{ V/m})/(4.11\times10^5\text{ m/s}) = 0.0445\text{ T}$.

The magnetic field is perpendicular to the electric field. If the charges are moving to the right and the electric field points upward, the magnetic field is out of the page.

EVALUATE: The sign of the charge of the alpha particle does not enter the problem, so negative charges of the same magnitude would also not be deflected.

27.26. **IDENTIFY** and **SET UP:** For a velocity selector, $E = vB$. For parallel plates with opposite charge, $V = Ed$.

EXECUTE: **(a)** $E = vB = (1.82\times10^6\text{ m/s})(0.510\text{ T}) = 9.28\times10^5\text{ V/m}$.

(b) $V = Ed = (9.28\times10^5\text{ V/m})(5.20\times10^{-3}\text{ m}) = 4.83\text{ kV}$.

EVALUATE: Any charged particle with $v = 1.82\times10^6\text{ m/s}$ will pass through undeflected, regardless of the sign and magnitude of its charge.

27.27. **IDENTIFY:** The velocity selector eliminates all ions not having the desired velocity. Then the magnetic field bends the ions in a circular arc.

SET UP: In a velocity selector, $E = vB$. For motion in a circular arc in a magnetic field of magnitude B, $R = \dfrac{mv}{|q|B}$. The ion has charge $+e$.

EXECUTE: **(a)** $v = \dfrac{E}{B} = \dfrac{155\ \text{V/m}}{0.0315\ \text{T}} = 4.92\times10^3\ \text{m/s}$.

(b) $m = \dfrac{R|q|B}{v} = \dfrac{(0.175\ \text{m})(1.60\times10^{-19}\ \text{C})(0.0175\ \text{T})}{4.92\times10^3\ \text{m/s}} = 9.96\times10^{-26}\ \text{kg}$.

EVALUATE: Ions with larger ratio $\dfrac{m}{|q|}$ will move in a path of larger radius.

27.28. **IDENTIFY:** A mass spectrometer separates ions by mass. Since ^{14}N and ^{15}N have different masses they will be separated and the relative amounts of these isotopes can be determined.

SET UP: $R = \dfrac{mv}{|q|B}$. For $m = 1.99\times10^{-26}\ \text{kg}$ (^{12}C), $R_{12} = 12.5\ \text{cm}$. The separation of the isotopes at the detector is $2(R_{15} - R_{14})$.

EXECUTE: Since $R = \dfrac{mv}{|q|B}$, $\dfrac{R}{m} = \dfrac{v}{|q|B} = \text{constant}$. Therefore $\dfrac{R_{14}}{m_{14}} = \dfrac{R_{12}}{m_{12}}$ which gives

$R_{14} = R_{12}\left(\dfrac{m_{14}}{m_{12}}\right) = (12.5\ \text{cm})\left(\dfrac{2.32\times10^{-26}\ \text{kg}}{1.99\times10^{-26}\ \text{kg}}\right) = 14.6\ \text{cm}$ and

$R_{15} = R_{12}\left(\dfrac{m_{15}}{m_{12}}\right) = (12.5\ \text{cm})\left(\dfrac{2.49\times10^{-26}\ \text{kg}}{1.99\times10^{-26}\ \text{kg}}\right) = 15.6\ \text{cm}$. The separation of the isotopes at the detector is $2(R_{15} - R_{14}) = 2(15.6\ \text{cm} - 14.6\ \text{cm}) = 2.0\ \text{cm}$.

EVALUATE: The separation is large enough to be easily detectable. Since the diameter of the ion path is large, about 30 cm, the uniform magnetic field within the instrument must extend over a large area.

27.29. **IDENTIFY:** Apply $F = IlB\sin\phi$.

SET UP: Label the three segments in the field as a, b, and c. Let x be the length of segment a. Segment b has length 0.300 m and segment c has length $0.600\ \text{m} - x$. Figure 27.29a shows the direction of the force on each segment. For each segment, $\phi = 90°$. The total force on the wire is the vector sum of the forces on each segment.

EXECUTE: $F_a = IlB = (4.50\ \text{A})x(0.240\ \text{T})$. $F_c = (4.50\ \text{A})(0.600\ \text{m} - x)(0.240\ \text{T})$. Since $\vec{F}_a$ and $\vec{F}_c$ are in the same direction their vector sum has magnitude $F_{ac} = F_a + F_c = (4.50\ \text{A})(0.600\ \text{m})(0.240\ \text{T}) = 0.648\ \text{N}$ and is directed toward the bottom of the page in Figure 27.29a. $F_b = (4.50\ \text{A})(0.300\ \text{m})(0.240\ \text{T}) = 0.324\ \text{N}$ and is directed to the right. The vector addition diagram for $\vec{F}_{ac}$ and $\vec{F}_b$ is given in Figure 27.29b.

$F = \sqrt{F_{ac}^2 + F_b^2} = \sqrt{(0.648\ \text{N})^2 + (0.324\ \text{N})^2} = 0.724\ \text{N}$. $\tan\theta = \dfrac{F_{ac}}{F_b} = \dfrac{0.648\ \text{N}}{0.324\ \text{N}}$ and $\theta = 63.4°$. The net force has magnitude 0.724 N and its direction is specified by $\theta = 63.4°$ in Figure 27.29b.

EVALUATE: All three current segments are perpendicular to the magnetic field, so $\phi = 90°$ for each in the force equation. The direction of the force on a segment depends on the direction of the current for that segment.

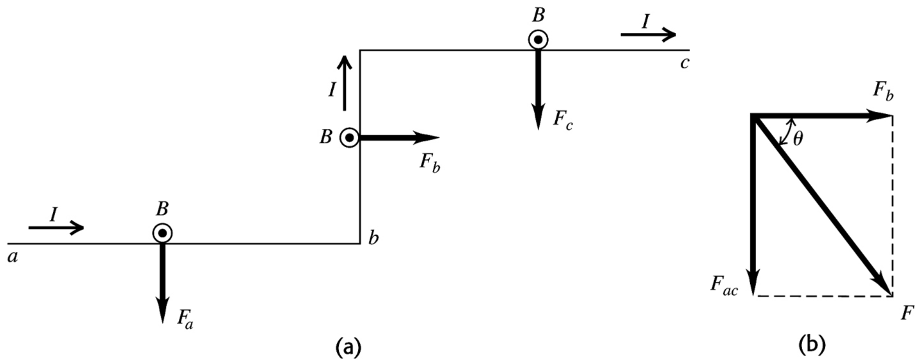

Figure 27.29

27.30. **IDENTIFY:** The earth's magnetic field exerts a force on the moving charges in the wire.

SET UP: $F = IlB\sin\phi$. The direction of $\vec{F}$ is determined by applying the right-hand rule to the directions of I and $\vec{B}$. $1 \text{ gauss} = 10^{-4} \text{ T}$.

EXECUTE: **(a)** The directions of I and $\vec{B}$ are sketched in Figure 27.30a. $\phi = 90°$ so $F = (1.5 \text{ A})(2.5 \text{ m})(0.55\times10^{-4} \text{ T}) = 2.1\times10^{-4} \text{ N}$. The right-hand rule says that $\vec{F}$ is directed out of the page, so it is upward.

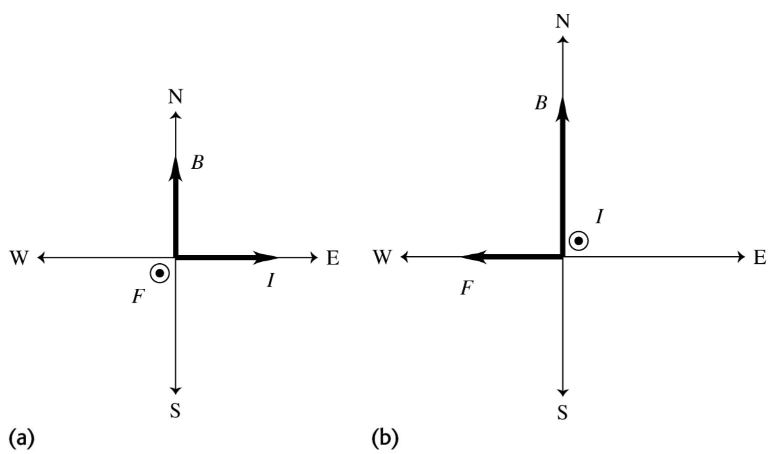

Figure 27.30

(b) The directions of I and $\vec{B}$ are sketched in Figure 27.30b. $\phi = 90°$ and $F = 2.1\times10^{-4} \text{ N}$. $\vec{F}$ is directed east to west.

(c) $\vec{B}$ and the direction of the current are antiparallel. $\phi = 180°$ so $F = 0$.

(d) The magnetic force of $2.1\times10^{-4} \text{ N}$ is not large enough to cause significant effects.

EVALUATE: The magnetic force is a maximum when the directions of I and $\vec{B}$ are perpendicular and it is zero when the current and magnetic field are either parallel or antiparallel.

27.31. **IDENTIFY** and **SET UP:** The magnetic force is given by $F = IlB\sin\phi$. $F_I = mg$ when the bar is just ready to levitate. When I becomes larger, $F_I > mg$ and $F_I - mg$ is the net force that accelerates the bar upward. Use Newton's second law to find the acceleration.

EXECUTE: **(a)** $IlB = mg$, $I = \dfrac{mg}{lB} = \dfrac{(0.750 \text{ kg})(9.80 \text{ m/s}^2)}{(0.500 \text{ m})(0.450 \text{ T})} = 32.67 \text{ A}$.

$V = IR = (32.67 \text{ A})(25.0\ \Omega) = 817 \text{ V}$.

(b) $R = 2.0\ \Omega, I = \mathcal{E}/R = (816.7\ \text{V})/(2.0\ \Omega) = 408\ \text{A}.$

$F_I = IlB = 92\ \text{N}.$

$a = (F_I - mg)/m = 113\ \text{m/s}^2.$

EVALUATE: I increases by over an order of magnitude when R changes to $F_I >> mg$ and a is an order of magnitude larger than g.

27.32. **IDENTIFY:** Apply $F = IlB\sin\phi.$

SET UP: $l = 0.0500\ \text{m}$ is the length of wire in the magnetic field. Since the wire is perpendicular to $\vec{B}$, $\phi = 90°.$

EXECUTE: $F = IlB = (10.8\ \text{A})(0.0500\ \text{m})(0.550\ \text{T}) = 0.297\ \text{N}.$

EVALUATE: The force per unit length of wire is proportional to both B and I.

27.33. **IDENTIFY:** The magnetic force $\vec{F}_B$ must be upward and equal to mg. The direction of $\vec{F}_B$ is determined by the direction of I in the circuit.

SET UP: $F_B = IlB\sin\phi$, with $\phi = 90°$. $I = \dfrac{V}{R}$, where V is the battery voltage.

EXECUTE: **(a)** The forces are shown in Figure 27.33. The current I in the bar must be to the right to produce $\vec{F}_B$ upward. To produce current in this direction, point a must be the positive terminal of the battery.

(b) $F_B = mg.\ \ IlB = mg.\ \ m = \dfrac{IlB}{g} = \dfrac{VlB}{Rg} = \dfrac{(175\ \text{V})(0.600\ \text{m})(1.50\ \text{T})}{(5.00\ \Omega)(9.80\ \text{m/s}^2)} = 3.21\ \text{kg}.$

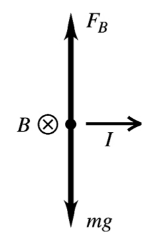

Figure 27.33

EVALUATE: If the battery had opposite polarity, with point a as the negative terminal, then the current would be clockwise and the magnetic force would be downward.

27.34. **IDENTIFY** and **SET UP:** $F = IlB\sin\phi$. The direction of $\vec{F}$ is given by applying the right-hand rule to the directions of I and $\vec{B}$.

EXECUTE: **(a)** The current and field directions are shown in Figure 27.34a. The right-hand rule gives that $\vec{F}$ is directed to the south, as shown. $\phi = 90°$ and

$F = (2.60\ \text{A})(1.00 \times 10^{-2}\ \text{m})(0.588\ \text{T}) = 0.0153\ \text{N}.$

(b) The right-hand rule gives that $\vec{F}$ is directed to the west, as shown in Figure 27.34b. $\phi = 90°$ and $F = 0.0153\ \text{N}$, the same as in part (a).

(c) The current and field directions are shown in Figure 27.34c. The right-hand rule gives that $\vec{F}$ is $60.0°$ north of west. $\phi = 90°$ so $F = 0.0153\ \text{N}$, the same as in part (a).

EVALUATE: In each case the current direction is perpendicular to the magnetic field. The magnitude of the magnetic force is the same in each case but its direction depends on the direction of the magnetic field.

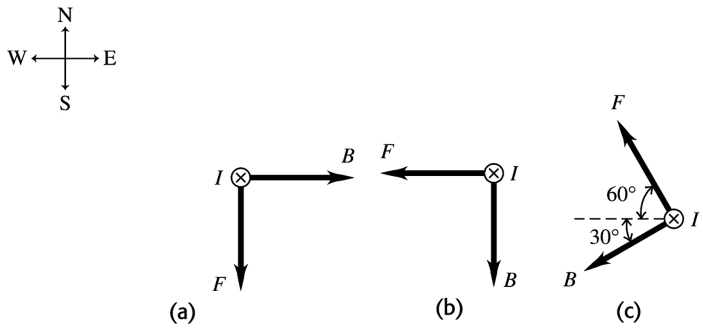

Figure 27.34

27.35. **IDENTIFY:** We are dealing with the magnetic dipole moment and torque.

SET UP: $\vec{\mu} = I\vec{A}$, $\mu = INA$, $\vec{\tau} = \vec{\mu} \times \vec{B}$.

EXECUTE: **(a)** We want *N*. Use $\mu = INA$ with the given numbers. $N = \mu/IA = 55$ turns.

(b) We want the direction of the current. If the fingers of the right hand curl counterclockwise, the thumb points toward the observer, so the current is *counterclockwise*.

(c) We want the torque. $\tau = \mu B \sin\phi = (0.194\ \text{A} \cdot \text{m}^2)(45.0\ \text{T})(\sin 90°) = 8.73\ \text{N} \cdot \text{m}$. $\vec{\tau} = \vec{\mu} \times \vec{B}$ is perpendicular to $\vec{\mu}$ and points *upward*.

EVALUATE: Even for a very large magnetic field like this one, the torque is small because the area is very small.

27.36. **IDENTIFY:** $\tau = IAB\sin\phi$. The magnetic moment of the loop is $\mu = IA$.

SET UP: Since the plane of the loop is parallel to the field, the field is perpendicular to the normal to the loop and $\phi = 90°$.

EXECUTE: **(a)** $\tau = IAB = (6.2\ \text{A})(0.050\ \text{m})(0.080\ \text{m})(0.19\ \text{T}) = 4.7 \times 10^{-3}\ \text{N} \cdot \text{m}$.

(b) $\mu = IA = (6.2\ \text{A})(0.050\ \text{m})(0.080\ \text{m}) = 0.025\ \text{A} \cdot \text{m}^2$.

(c) Maximum area is when the loop is circular. $R = \dfrac{0.050\ \text{m} + 0.080\ \text{m}}{\pi} = 0.0414\ \text{m}$.

$A = \pi R^2 = 5.38 \times 10^{-3}\ \text{m}^2$ and $\tau = (6.2\ \text{A})(5.38 \times 10^{-3}\ \text{m}^2)(0.19\ \text{T}) = 6.34 \times 10^{-3}\ \text{N} \cdot \text{m}$.

EVALUATE: The torque is a maximum when the field is in the plane of the loop and $\phi = 90°$.

27.37. **IDENTIFY:** The wire segments carry a current in an external magnetic field. Only segments *ab* and *cd* will experience a magnetic force since the other two segments carry a current parallel (and antiparallel) to the magnetic field. Only the force on segment *cd* will produce a torque about the hinge.

SET UP: $F = IlB\sin\phi$. The direction of the magnetic force is given by the right-hand rule applied to the directions of *I* and $\vec{B}$. The torque due to a force equals the force times the moment arm, the perpendicular distance between the axis and the line of action of the force.

EXECUTE: **(a)** The direction of the magnetic force on each segment of the circuit is shown in Figure 27.37. For segments *bc* and *da* the current is parallel or antiparallel to the field and the force on these segments is zero.

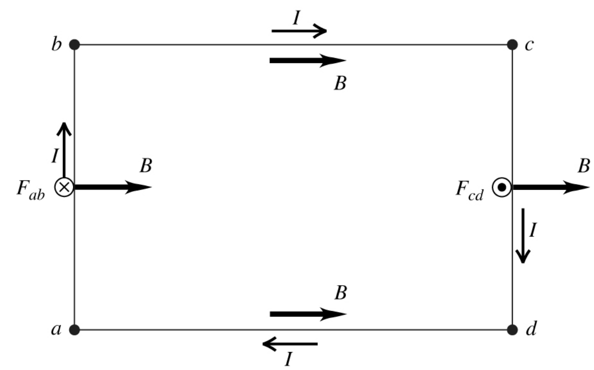

Figure 27.37

(b) $\vec{F}_{ab}$ acts at the hinge and therefore produces no torque. $\vec{F}_{cd}$ tends to rotate the loop about the hinge so it does produce a torque about this axis. $F_{cd} = IlB\sin\phi = (5.00\text{ A})(0.200\text{ m})(1.20\text{ T})\sin 90° = 1.20\text{ N}$

(c) $\tau = Fl = (1.20\text{ N})(0.350\text{ m}) = 0.420\text{ N}\cdot\text{m}.$

EVALUATE: The torque is directed so as to rotate side *cd* out of the plane of the page in Figure 27.37.

27.38. IDENTIFY: $\tau = IAB\sin\phi$, where ϕ is the angle between $\vec{B}$ and the normal to the loop.

SET UP: The coil as viewed along the axis of rotation is shown in Figure 27.38a for its original position and in Figure 27.38b after it has rotated $30.0°$.

EXECUTE: **(a)** The forces on each side of the coil are shown in Figure 27.38a. $\vec{F}_1 + \vec{F}_2 = 0$ and $\vec{F}_3 + \vec{F}_4 = 0$. The net force on the coil is zero. $\phi = 0°$ and $\sin\phi = 0$, so $\tau = 0$. The forces on the coil produce no torque.

(b) The net force is still zero. $\phi = 30.0°$ and the net torque is $\tau = (1)(1.95\text{ A})(0.220\text{ m})(0.350\text{ m})(1.50\text{ T})\sin 30.0° = 0.113\text{ N}\cdot\text{m}$. The net torque is clockwise in Figure 27.38b and is directed so as to increase the angle ϕ.

EVALUATE: For any current loop in a uniform magnetic field the net force on the loop is zero. The torque on the loop depends on the orientation of the plane of the loop relative to the magnetic field direction.

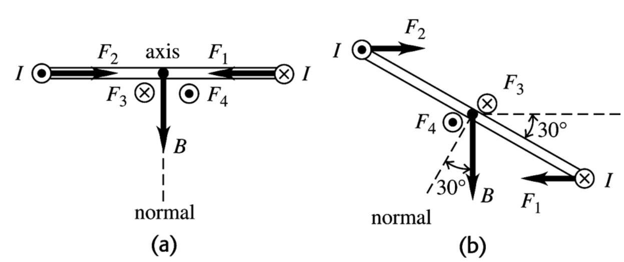

Figure 27.38

27.39. IDENTIFY: The magnetic field exerts a torque on the current-carrying coil, which causes it to turn. We can use the rotational form of Newton's second law to find the angular acceleration of the coil.

SET UP: The magnetic torque is given by $\vec{\tau} = \vec{\mu} \times \vec{B}$, and the rotational form of Newton's second law is $\sum\tau = I\alpha$. The magnetic field is parallel to the plane of the loop.

EXECUTE: **(a)** The coil rotates about axis A_2 because the only torque is along top and bottom sides of the coil.

(b) To find the moment of inertia of the coil, treat the two 1.00-m segments as point-masses (since all the points in them are 0.250 m from the rotation axis) and the two 0.500-m segments as thin uniform bars rotated about their centers. Since the coil is uniform, the mass of each segment is proportional to its fraction of the total perimeter of the coil. Each 1.00-m segment is 1/3 of the total perimeter, so its mass is $(1/3)(210\text{ g}) = 70\text{ g} = 0.070\text{ kg}$. The mass of each 0.500-m segment is half this amount, or 0.035 kg.

The result is

$I = 2(0.070\text{ kg})(0.250\text{ m})^2 + 2\tfrac{1}{12}(0.035\text{ kg})(0.500\text{ m})^2 = 0.0102\text{ kg}\cdot\text{m}^2.$

The torque is

$|\vec{\boldsymbol{\tau}}| = |\vec{\boldsymbol{\mu}}\times\vec{\boldsymbol{B}}| = IAB\sin 90° = (2.00\text{A})(0.500\text{m})(1.00\text{m})(3.00\text{T}) = 3.00\text{ N}\cdot\text{m}.$

Using the above values, the rotational form of Newton's second law gives

$\alpha = \dfrac{\tau}{I} = 290\text{ rad/s}^2.$

EVALUATE: This angular acceleration will not continue because the torque changes as the coil turns.

27.40. **IDENTIFY** and **SET UP:** Both coils A and B have the same area A and N turns, but they carry current in opposite directions in a magnetic field. The torque is $\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{\mu}}\times\vec{\boldsymbol{B}}$ and the potential energy is $U = -\mu B\cos\phi$. The magnetic moment is $\vec{\mu} = I\vec{\boldsymbol{A}}$.

EXECUTE: **(a)** Using the right-hand rule for the magnetic moment, $\vec{\mu}$ points in the –z-direction (into the page) for coil A and in the +z-direction (out of the page) for coil B.

(b) The torque is $\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{\mu}}\times\vec{\boldsymbol{B}}$ which has magnitude $\tau = \mu B\sin\phi$. For coil A, ϕ = 180°, and for coil B, ϕ = 0°. In both cases, sin ϕ = 0, making the torque zero.

(c) <u>For coil A</u>: $U_A = -\mu B\cos\phi = -NIAB\cos 180° = NIAB.$

<u>For coil B</u>: $U_B = -\mu B\cos\phi = -NIAB\cos 0° = -NIAB.$

(d) If coil A is rotated slightly from its equilibrium position, the magnetic field will flip it 180°, so its equilibrium is unstable. But if the same thing it done to coil B, the magnetic field will return it to its original equilibrium position, which makes its equilibrium stable.

EVALUATE: For the stable equilibrium (coil B), its potential energy is a minimum, while for the unstable equilibrium (coil A), its potential energy is a maximum.

27.41. **IDENTIFY:** $\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{\mu}}\times\vec{\boldsymbol{B}}$ and $U = -\mu B\cos\phi$, where $\mu = NIA$. $\tau = \mu B\sin\phi$.

SET UP: ϕ is the angle between $\vec{\boldsymbol{B}}$ and the normal to the plane of the loop.

EXECUTE: **(a)** $\phi = 90°$. $\tau = NIAB\sin(90°) = NIAB$, direction $\hat{\boldsymbol{k}}\times\hat{\boldsymbol{j}} = -\hat{\boldsymbol{i}}$. $U = -\mu B\cos\phi = 0$.

(b) $\phi = 0$. $\tau = NIAB\sin(0) = 0$, no direction. $U = -\mu B\cos\phi = -NIAB$.

(c) $\phi = 90°$. $\tau = NIAB\sin(90°) = NIAB$, direction $-\hat{\boldsymbol{k}}\times\hat{\boldsymbol{j}} = \hat{\boldsymbol{i}}$. $U = -\mu B\cos\phi = 0$.

(d) $\phi = 180°$: $\tau = NIAB\sin(180°) = 0$, no direction, $U = -\mu B\cos(180°) = NIAB$.

EVALUATE: When τ is maximum, $U = 0$. When $|U|$ is maximum, $\tau = 0$.

27.42. **IDENTIFY** and **SET UP:** The potential energy is given by $U = -\vec{\boldsymbol{\mu}}\cdot\vec{\boldsymbol{B}}$. The scalar product depends on the angle between $\vec{\boldsymbol{\mu}}$ and $\vec{\boldsymbol{B}}$.

EXECUTE: For $\vec{\boldsymbol{\mu}}$ and $\vec{\boldsymbol{B}}$ parallel, $\phi = 0°$ and $\vec{\boldsymbol{\mu}}\cdot\vec{\boldsymbol{B}} = \mu B\cos\phi = \mu B$. For $\vec{\boldsymbol{\mu}}$ and $\vec{\boldsymbol{B}}$ antiparallel, $\phi = 180°$ and $\vec{\boldsymbol{\mu}}\cdot\vec{\boldsymbol{B}} = \mu B\cos\phi = -\mu B$.

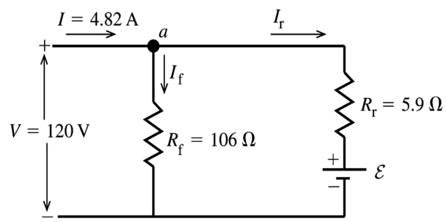
$U_1 = +\mu B,\ U_2 = -\mu B.$

$\Delta U = U_2 - U_1 = -2\mu B = -2(1.45\text{ A}\cdot\text{m}^2)(0.835\text{ T}) = -2.42\text{ J}.$

EVALUATE: U is maximum when $\vec{\boldsymbol{\mu}}$ and $\vec{\boldsymbol{B}}$ are antiparallel and minimum when they are parallel. When the coil is rotated as specified its magnetic potential energy decreases.

27.43. **IDENTIFY:** The circuit consists of two parallel branches with the potential difference of 120 V applied across each. One branch is the rotor, represented by a resistance R_r and an induced emf that opposes the applied potential. Apply the loop rule to each parallel branch and use the junction rule to relate the currents through the field coil and through the rotor to the 4.82 A supplied to the motor.

SET UP: The circuit is sketched in Figure 27.43.



$\mathcal{E}$ is the induced emf developed by the motor. It is directed so as to oppose the current through the rotor.

Figure 27.43

EXECUTE: **(a)** The field coils and the rotor are in parallel with the applied potential difference V, so $V = I_f R_f$. $I_f = \dfrac{V}{R_f} = \dfrac{120\text{ V}}{106\ \Omega} = 1.13\text{ A}.$

(b) Applying the junction rule to point *a* in the circuit diagram gives $I - I_f - I_r = 0$.

$I_r = I - I_f = 4.82\text{ A} - 1.13\text{ A} = 3.69\text{ A}.$

(c) The potential drop across the rotor, $I_r R_r + \mathcal{E}$, must equal the applied potential difference V: $V = I_r R_r + \mathcal{E}$

$\mathcal{E} = V - I_r R_r = 120\text{ V} - (3.69\text{ A})(5.9\ \Omega) = 98.2\text{ V}$

(d) The mechanical power output is the electrical power input minus the rate of dissipation of electrical energy in the resistance of the motor:

electrical power input to the motor

$P_{in} = IV = (4.82\text{ A})(120\text{ V}) = 578\text{ W}.$

electrical power loss in the two resistances

$P_{loss} = I_f^2 R_f + I_r^2 R_r = (1.13\text{ A})^2(106\ \Omega) + (3.69\text{ A})^2(5.9\ \Omega) = 216\text{ W}.$

mechanical power output

$P_{out} = P_{in} - P_{loss} = 578\text{ W} - 216\text{ W} = 362\text{ W}.$

The mechanical power output is the power associated with the induced emf $\mathcal{E}$.

$P_{out} = P_{\mathcal{E}} = \mathcal{E} I_r = (98.2\text{ V})(3.69\text{ A}) = 362\text{ W}$, which agrees with the above calculation.

EVALUATE: The induced emf reduces the amount of current that flows through the rotor. This motor differs from the one described in Example 27.11. In that example the rotor and field coils are connected in series and in this problem they are in parallel.

27.44. **IDENTIFY:** Apply $V_{ab} = \mathcal{E} + Ir$ in order to calculate *I*. The power drawn from the line is $P_{supplied} = IV_{ab}$. The mechanical power is the power supplied minus the $I^2 r$ electrical power loss in the internal resistance of the motor.

SET UP: $V_{ab} = 120\text{ V}$, $\mathcal{E} = 105\text{ V}$, and $r = 3.2\ \Omega$.

EXECUTE: **(a)** $V_{ab} = \mathcal{E} + Ir \Rightarrow I = \dfrac{V_{ab} - \mathcal{E}}{r} = \dfrac{120\text{ V} - 105\text{ V}}{3.2\ \Omega} = 4.7\text{ A}.$

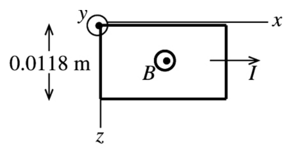
(b) $P_{supplied} = IV_{ab} = (4.7\text{ A})(120\text{ V}) = 564\text{ W}.$

(c) $P_{mech} = IV_{ab} - I^2 r = 564\text{ W} - (4.7\text{ A})^2(3.2\ \Omega) = 493\text{ W}.$

EVALUATE: If the rotor isn't turning, when the motor is first turned on or if the rotor bearings fail, then $\mathcal{E}=0$ and $I=\dfrac{120\text{V}}{3.2\,\Omega}=37.5$ A. This large current causes large I^2r heating and can trip the circuit breaker.

27.45. IDENTIFY: The drift velocity is related to the current density by $J_x = n|q|v_\text{d}$. The electric field is determined by the requirement that the electric and magnetic forces on the current-carrying charges are equal in magnitude and opposite in direction.

SET UP and **EXECUTE:** **(a)** The section of the silver ribbon is sketched in Figure 27.45a.



$J_x = n|q|v_\text{d}$.

so $v_\text{d} = \dfrac{J_x}{n|q|}$.

Figure 27.45a

EXECUTE: $J_x = \dfrac{I}{A} = \dfrac{I}{y_1 z_1} = \dfrac{120\text{ A}}{(0.23\times10^{-3}\text{ m})(0.0118\text{ m})} = 4.42\times10^{7}\text{ A/m}^2.$

$$v_\text{d} = \frac{J_x}{n|q|} = \frac{4.42\times10^{7}\text{ A/m}^2}{(5.85\times10^{28}/\text{m}^3)(1.602\times10^{-19}\text{ C})} = 4.7\times10^{-3}\text{ m/s} = 4.7\text{ mm/s}.$$

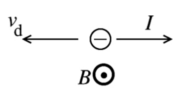
(b) magnitude of $\vec{E}$:

$|q|E_z = |q|v_\text{d}B_y$.

$E_z = v_\text{d}B_y = (4.7\times10^{-3}\text{ m/s})(0.95\text{ T}) = 4.5\times10^{-3}\text{ V/m}.$

direction of $\vec{E}$:

The drift velocity of the electrons is in the opposite direction to the current, as shown in Figure 27.45b.

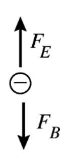


$\vec{v}\times\vec{B}\uparrow$.

$\vec{F}_B = q\vec{v}\times\vec{B} = -e\vec{v}\times\vec{B}\downarrow$.

Figure 27.45b

The directions of the electric and magnetic forces on an electron in the ribbon are shown in Figure 27.45c.



$\vec{F}_E$ must oppose $\vec{F}_B$ so $\vec{F}_E$ is in the $-z$-direction.

Figure 27.45c

$\vec{F}_E = q\vec{E} = -e\vec{E}$ so $\vec{E}$ is opposite to the direction of $\vec{F}_E$ and thus $\vec{E}$ is in the $+z$-direction.

(c) The Hall emf is the potential difference between the two edges of the strip (at $z=0$ and $z=z_1$) that results from the electric field calculated in part (b). $\mathcal{E}_\text{Hall} = Ez_1 = (4.5\times10^{-3}\text{ V/m})(0.0118\text{ m}) = 53\,\mu\text{V}.$

EVALUATE: Even though the current is quite large the Hall emf is very small. Our calculated Hall emf is more than an order of magnitude larger than in Example 27.12. In this problem the magnetic field and current density are larger than in the example, and this leads to a larger Hall emf.

27.46. **IDENTIFY:** Apply $qn = \dfrac{-J_x B_y}{E_z}$.

SET UP: $A = y_1 z_1$. $E = \mathcal{E}/z_1$. $|q| = e$.

EXECUTE: $n = \dfrac{J_x B_y}{|q|E_z} = \dfrac{IB_y}{A|q|E_z} = \dfrac{IB_y z_1}{A|q|\mathcal{E}} = \dfrac{IB_y}{y_1|q|\mathcal{E}}$.

$$n = \frac{(78.0\text{ A})(2.29\text{ T})}{(2.3\times10^{-4}\text{ m})(1.6\times10^{-19}\text{ C})(1.31\times10^{-4}\text{ V})} = 3.7\times10^{28}\text{ electrons/m}^3.$$

EVALUATE: The value of n for this metal is about one-third the value of n calculated in Example 27.12 for copper.

27.47. **IDENTIFY:** This problem involves the magnetic and electric forces on a moving charged particle.
SET UP: First sketch the situation, as in Fig. 27.47a.

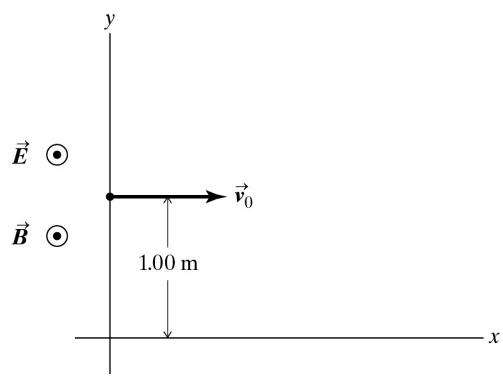


Figure 27.47a

EXECUTE: **(a)** We want the coordinates at t = 0.0200 s. Applying $\sum F_z = qE = ma_z$ gives $a_z = qE/m$.
$z = \frac{1}{2}a_z t^2 = \frac{1}{2}\left(\frac{qE}{m}\right)t^2$ = 9.00 cm using the given quantities. The magnetic field deflects the particle in the $-y$-direction in a circle of radius $R = mv_0/qB$. Using the given numbers gives R = 1.000 m. The circle is centered at the origin. The time T for one circle is $T = \dfrac{2\pi}{\omega} = \dfrac{2\pi m}{qB} =$ 0.2094 s. In 0.0200 s, it has gone through $\dfrac{0.0200}{0.2094} = 0.09549$ of a complete revolution, which is an angle of 34.38°. Fig. 27.47b shows the path of the particle and it x and y coordinates. From this figure, we see that
$x = (1.00\text{ m})\sin\theta = (1.00\text{ m})\sin(34.38°) = 0.565\text{ m}$ and
$y = (1.00\text{ m})\cos\theta = (1.00\text{ m})\cos(34.38°) = 0.825\text{ m}$. Therefore the coordinates of the particle are
x = 0.565 m, y = 0.825 m, z = 0.0900 m.

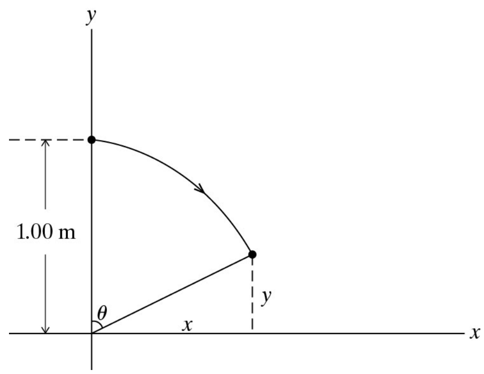

Figure 27.47b

(b) We want the speed at 0.0200 s. Only the electric field changes the speed. Using a_z from (a) gives $v_z = a_z t = \left(\frac{qE}{m}\right)t = 9.00$ m/s. v_x and v_y also change, but $v_x^2 + v_y^2 = v_0^2$, so $v = \sqrt{v_z^2 + v_0^2} =$ 31.3 m/s.

EVALUATE: The z component of velocity keeps increasing. The x and y components change but always combine to give $v_x^2 + v_y^2 = v_0^2$.

27.48. **IDENTIFY:** Apply $\vec{F} = q\vec{v} \times \vec{B}$.

SET UP: $B_x = 0.650$ T. $B_y = 0$ and $B_z = 0$.

EXECUTE: $F_x = q(v_y B_z - v_z B_y) = 0$.

$F_y = q(v_z B_x - v_x B_z) = (7.26\times10^{-8}\ \text{C})(5.85\times10^4\ \text{m/s})(0.650\ \text{T}) = 2.76\times10^{-3}$ N.

$F_z = q(v_x B_y - v_y B_x) = -(7.26\times10^{-8}\ \text{C})(-3.11\times10^4\ \text{m/s})(0.650\ \text{T}) = 1.47\times10^{-3}$ N.

EVALUATE: $\vec{F}$ is perpendicular to both $\vec{v}$ and $\vec{B}$. We can verify that $\vec{F}\cdot\vec{v} = 0$. Since $\vec{B}$ is along the x-axis, v_x does not affect the force components.

27.49. **IDENTIFY:** In part (a), apply conservation of energy to the motion of the two nuclei. In part (b) apply $|q|vB = mv^2/R$.

SET UP: In part (a), let point 1 be when the two nuclei are far apart and let point 2 be when they are at their closest separation.

EXECUTE: **(a)** $K_1 + U_1 = K_2 + U_2$. $U_1 = K_2 = 0$, so $K_1 = U_2$. There are two nuclei having equal kinetic energy, so $\frac{1}{2}mv^2 + \frac{1}{2}mv^2 = ke^2/r$. Solving for v gives

$$v = e\sqrt{\frac{k}{mr}} = (1.602\times10^{-19}\ \text{C})\sqrt{\frac{8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2}{(3.34\times10^{-27}\ \text{kg})(1.0\times10^{-15}\ \text{m})}} = 8.3\times10^6\ \text{m/s}.$$

(b) $\sum\vec{F} = m\vec{a}$ gives $qvB = mv^2/r$. $B = \frac{mv}{qr} = \frac{(3.34\times10^{-27}\ \text{kg})(8.3\times10^6\ \text{m/s})}{(1.602\times10^{-19}\ \text{C})(1.25\ \text{m})} = 0.14$ T.

EVALUATE: The speed calculated in part (a) is large, nearly 3% of the speed of light.

27.50. **IDENTIFY:** The period is $T = 2\pi r/v$, the current is Q/t and the magnetic moment is $\mu = IA$.

SET UP: The electron has charge $-e$. The area enclosed by the orbit is πr^2.

EXECUTE: **(a)** $T = 2\pi r/v = 1.5\times10^{-16}$ s.

(b) Charge $-e$ passes a point on the orbit once during each period, so $I = Q/t = e/t = 1.1$ mA.

(c) $\mu = IA = I\pi r^2 = 9.3\times10^{-24}\ \text{A}\cdot\text{m}^2$.

EVALUATE: Since the electron has negative charge, the direction of the current is opposite to the direction of motion of the electron.

27.51. **IDENTIFY:** We want to determine q/m for a particle using a graphical method.
SET UP and **EXECUTE:** Since we graphed R^2 versus ΔV, we need to relate these variables. If we accelerate the particle through a potential difference ΔV, we have $q\,\Delta V = \dfrac{1}{2}mv^2$. Therefore $q/m = \dfrac{v^2}{2\Delta V}$. In the magnetic field, $R = mv/qB$, so $v = RqB/m$. Combining these results gives $q/m = \dfrac{\left(\dfrac{RqB}{m}\right)^2}{2\Delta V} = \dfrac{R^2(q/m)^2B^2}{2\Delta V}$. Solving for R^2 gives $R^2 = \left(\dfrac{2}{B^2(q/m)}\right)\Delta V$. The graph of R^2 versus ΔV should be a straight line having slope $\dfrac{2}{B^2(q/m)}$. Thus $q/m = \dfrac{2}{B^2(\text{slope})}$. Putting in the numbers with the measured slope gives $q/m = 4.81\times10^7$ C/kg.

EVALUATE: For a proton $q/m = e/m_p = 9.58\times10^7$ C/kg, which is about twice our result. So our answer is reasonable.

27.52. **IDENTIFY** and **SET UP:** The maximum radius of the orbit determines the maximum speed v of the protons. Use Newton's second law and $a_{\text{rad}} = v^2/R$ for circular motion to relate the variables. The energy of the particle is the kinetic energy $K = \frac{1}{2}mv^2$.

EXECUTE: **(a)** $\sum\vec{F} = m\vec{a}$ gives $|q|vB = m(v^2/R)$.

$$v = \frac{|q|BR}{m} = \frac{(1.60\times10^{-19}\text{ C})(0.85\text{ T})(0.40\text{ m})}{1.67\times10^{-27}\text{ kg}} = 3.257\times10^7\text{ m/s}.$$ The kinetic energy of a proton moving with this speed is $K = \frac{1}{2}mv^2 = \frac{1}{2}(1.67\times10^{-27}\text{ kg})(3.257\times10^7\text{ m/s})^2 = 8.9\times10^{-13}\text{ J} = 5.5\text{ MeV}$.

(b) The time for one revolution is the period $T = \dfrac{2\pi R}{v} = \dfrac{2\pi(0.40\text{ m})}{3.257\times10^7\text{ m/s}} = 7.7\times10^{-8}$ s.

(c) $K = \frac{1}{2}mv^2 = \frac{1}{2}m\left(\dfrac{|q|BR}{m}\right)^2 = \frac{1}{2}\dfrac{|q|^2B^2R^2}{m}$. Or, $B = \dfrac{\sqrt{2Km}}{|q|R}$. B is proportional to $\sqrt{K}$, so if K is increased by a factor of 2 then B must be increased by a factor of $\sqrt{2}$. $B = \sqrt{2}(0.85\text{ T}) = 1.2$ T.

(d) $v = \dfrac{|q|BR}{m} = \dfrac{(3.20\times10^{-19}\text{ C})(0.85\text{ T})(0.40\text{ m})}{6.65\times10^{-27}\text{ kg}} = 1.636\times10^7$ m/s

$K = \frac{1}{2}mv^2 = \frac{1}{2}(6.65\times10^{-27}\text{ kg})(1.636\times10^7\text{ m/s})^2 = 8.9\times10^{-13}\text{ J} = 5.5\text{ MeV}$, the same as the maximum energy for protons.

EVALUATE: We can see that the maximum energy must be approximately the same as follows: From part (c), $K = \frac{1}{2}m\left(\dfrac{|q|BR}{m}\right)^2$. For alpha particles $|q|$ is larger by a factor of 2 and m is larger by a factor of 4 (approximately). Thus $|q|^2/m$ is unchanged and K is the same.

27.53. **IDENTIFY:** For the velocity selector, $E = vB$. For circular motion in the field B', $R = \dfrac{mv}{|q|B'}$.

SET UP: $B = B' = 0.682$ T.

EXECUTE: $v = \dfrac{E}{B} = \dfrac{1.88\times10^4 \text{ N/C}}{0.682 \text{ T}} = 2.757\times10^4$ m/s. $R = \dfrac{mv}{qB'}$, so

$$R_{82} = \frac{82(1.66\times10^{-27}\text{ kg})(2.757\times10^4\text{ m/s})}{(1.60\times10^{-19}\text{ C})(0.682\text{ T})} = 0.0344\text{ m} = 3.44\text{ cm}.$$

$$R_{84} = \frac{84(1.66\times10^{-27}\text{ kg})(2.757\times10^4\text{ m/s})}{(1.60\times10^{-19}\text{ C})(0.682\text{ T})} = 0.0352\text{ m} = 3.52\text{ cm}.$$

$$R_{86} = \frac{86(1.66\times10^{-27}\text{ kg})(2.757\times10^4\text{ m/s})}{(1.60\times10^{-19}\text{ C})(0.682\text{ T})} = 0.0361\text{ m} = 3.61\text{ cm}.$$

The distance between two adjacent lines is $2\Delta R = 2(3.52\text{ cm} - 3.44\text{ cm}) = 0.16\text{ cm} = 1.6\text{ mm}$.

EVALUATE: The distance between the ^{82}Kr line and the ^{84}Kr line is 1.6 mm and the distance between the ^{84}Kr line and the ^{86}Kr line is 1.6 mm. Adjacent lines are equally spaced since the ^{82}Kr versus ^{84}Kr and ^{84}Kr versus ^{86}Kr mass differences are the same.

27.54. IDENTIFY: Apply conservation of energy to the acceleration of the ions and Newton's second law to their motion in the magnetic field.

SET UP: The singly ionized ions have $q = +e$. A ^{12}C ion has mass 12 u and a ^{14}C ion has mass 14 u, where $1\text{ u} = 1.66\times10^{-27}$ kg.

EXECUTE: **(a)** During acceleration of the ions, $qV = \frac{1}{2}mv^2$ and $v = \sqrt{\dfrac{2qV}{m}}$. In the magnetic field,

$$R = \frac{mv}{qB} = \frac{m\sqrt{2qV/m}}{qB} \text{ and } m = \frac{qB^2R^2}{2V}.$$

(b) $V = \dfrac{qB^2R^2}{2m} = \dfrac{(1.60\times10^{-19}\text{ C})(0.150\text{ T})^2(0.500\text{ m})^2}{2(12)(1.66\times10^{-27}\text{ kg})} = 2.26\times10^4$ V.

(c) The ions are separated by the differences in the diameters of their paths. $D = 2R = 2\sqrt{\dfrac{2Vm}{qB^2}}$, so

$$\Delta D = D_{14} - D_{12} = 2\sqrt{\frac{2Vm}{qB^2}}\bigg|_{14} - 2\sqrt{\frac{2Vm}{qB^2}}\bigg|_{12} = 2\sqrt{\frac{2V(1\text{ u})}{qB^2}}(\sqrt{14} - \sqrt{12}).$$

$\Delta D = 2\sqrt{\dfrac{2(2.26\times10^4\text{ V})(1.66\times10^{-27}\text{ kg})}{(1.6\times10^{-19}\text{ C})(0.150\text{ T})^2}}(\sqrt{14} - \sqrt{12}) = 8.01\times10^{-2}$ m. This is about 8 cm and is easily distinguishable.

EVALUATE: The speed of the ^{12}C ion is $v = \sqrt{\dfrac{2(1.60\times10^{-19}\text{ C})(2.26\times10^4\text{V})}{12(1.66\times10^{-27}\text{ kg})}} = 6.0\times10^5$ m/s. This is very fast, but well below the speed of light, so relativistic mechanics is not needed.

27.55. IDENTIFY: The force exerted by the magnetic field is given by $F = IlB\sin\phi$. The net force on the wire must be zero.

SET UP: For the wire to remain at rest the force exerted on it by the magnetic field must have a component directed up the incline. To produce a force in this direction, the current in the wire must be directed from right to left in the figure with the problem in the textbook. Or, viewing the wire from its left-hand end the directions are shown in Figure 27.55a.

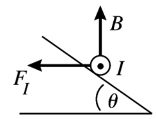

Figure 27.55a

The free-body diagram for the wire is given in Figure 27.55b.

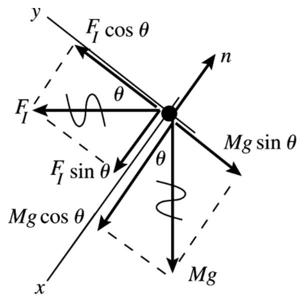

Figure 27.55b

EXECUTE: $\sum F_y = 0.$

$F_I \cos\theta - Mg\sin\theta = 0.$

$F_I = ILB\sin\phi.$

$\phi = 90°$ since $\vec{B}$ is perpendicular to the current direction.

Thus $(ILB)\ \cos\theta - Mg\sin\theta = 0$ and $I = \dfrac{Mg\tan\theta}{LB}.$

EVALUATE: The magnetic and gravitational forces are in perpendicular directions so their components parallel to the incline involve different trig functions. As the tilt angle θ increases there is a larger component of Mg down the incline and the component of F_I up the incline is smaller; I must increase with θ to compensate. As $\theta \to 0$, $I \to 0$ and as $\theta \to 90°$, $I \to \infty$.

27.56. **IDENTIFY:** In the figure shown with the problem in the text, the current in the bar is toward the bottom of the page, so the magnetic force is toward the right. Newton's second law gives the acceleration. The bar is in parallel with the $10.0\text{-}\Omega$ resistor, so we must use circuit analysis to find the initial current through the bar.

SET UP: First find the current. The equivalent resistance across the battery is $30.0\ \Omega$, so the total current is $4.00\,\text{A}$, half of which goes through the bar. Applying Newton's second law to the bar gives $\sum F = ma = F_B = ILB.$

EXECUTE: Equivalent resistance of the $10.0\text{-}\Omega$ resistor and the bar is $5.0\,\Omega$. Current through the $25.0\text{-}\Omega$ resistor is $I_{\text{tot}} = \dfrac{120.0\ \text{V}}{30.0\,\Omega} = 4.00\ \text{A}.$ The current in the bar is 2.00 A, toward the bottom of the page. The force $\vec{F}_I$ that the magnetic field exerts on the bar has magnitude $F_I = IlB$ and is directed to the right. $a = \dfrac{F_I}{m} = \dfrac{IlB}{m} = \dfrac{(2.00\ \text{A})(0.850\ \text{m})(1.60\ \text{T})}{(2.60\ \text{N})/(9.80\ \text{m/s}^2)} = 10.3\ \text{m/s}^2.$ $\vec{a}$ is directed to the right.

EVALUATE: Once the bar has acquired a non-zero speed there will be an induced emf (Chapter 29) and the current and acceleration will start to decrease.

27.57. **IDENTIFY:** $R = \dfrac{mv}{|q|B}.$

SET UP: After completing one semicircle the separation between the ions is the difference in the diameters of their paths, or $2(R_{13} - R_{12})$. A singly ionized ion has charge $+e$.

EXECUTE: **(a)** $B = \dfrac{mv}{|q|R} = \dfrac{(1.99\times10^{-26}\ \text{kg})(8.50\times10^{3}\ \text{m/s})}{(1.60\times10^{-19}\ \text{C})(0.125\ \text{m})} = 8.46\times10^{-3}\ \text{T}.$

(b) The only difference between the two isotopes is their masses. $\dfrac{R}{m}=\dfrac{v}{|q|B}=\text{constant}$ and $\dfrac{R_{12}}{m_{12}}=\dfrac{R_{13}}{m_{13}}$.

$R_{13}=R_{12}\left(\dfrac{m_{13}}{m_{12}}\right)=(12.5\text{ cm})\left(\dfrac{2.16\times10^{-26}\text{ kg}}{1.99\times10^{-26}\text{ kg}}\right)=13.6\text{ cm}.$ The diameter is 27.2 cm.

(c) The separation is $2(R_{13}-R_{12})=2(13.6\text{ cm}-12.5\text{ cm})=2.2\text{ cm}.$ This distance can be easily observed.

EVALUATE: Decreasing the magnetic field increases the separation between the two isotopes at the detector.

27.58. **IDENTIFY:** Turning the charged loop creates a current, and the external magnetic field exerts a torque on that current.

SET UP: The current is $I=q/T=q/(1/f)=qf=q(\omega/2\pi)=q\omega/2\pi.$ The torque is $\tau=\mu B\sin\phi.$

EXECUTE: In this case, $\phi=90°$ and $\mu=IA,$ giving $\tau=IAB.$ Combining the results for the torque and current and using $A=\pi r^2$ gives $\tau=\left(\dfrac{q\omega}{2\pi}\right)\pi r^2B=\tfrac{1}{2}q\omega r^2B.$

EVALUATE: Any moving charge is a current, so turning the loop creates a current causing a magnetic force.

27.59. **IDENTIFY:** The force exerted by the magnetic field is $F=ILB\sin\phi.$ $a=F/m$ and is constant. Apply a constant acceleration equation to relate v and d.

SET UP: $\phi=90°.$ The direction of $\vec{F}$ is given by the right-hand rule.

EXECUTE: **(a)** $F=ILB,$ to the right.

(b) $v_x^2=v_{0x}^2+2a_x(x-x_0)$ gives $v^2=2ad$ and $d=\dfrac{v^2}{2a}=\dfrac{v^2m}{2ILB}.$

(c) $d=\dfrac{(1.12\times10^4\text{ m/s})^2(25\text{ kg})}{2(2000\text{ A})(0.50\text{ m})(0.80\text{ T})}=1.96\times10^6\text{ m}=1960\text{ km}.$

EVALUATE: $a=\dfrac{ILB}{m}=\dfrac{(2.0\times10^3\text{ A})(0.50\text{ m})(0.80\text{ T})}{25\text{ kg}}=32\text{ m/s}^2.$ The acceleration due to gravity is not negligible. Since the bar would have to travel nearly 2000 km, this would not be a very effective launch mechanism using the numbers given.

27.60. **IDENTIFY:** Apply $\vec{F}=I\vec{l}\times\vec{B}.$

SET UP: $\vec{l}=l\hat{k}.$

EXECUTE: **(a)** $\vec{F}=I(l\hat{k})\times\vec{B}=Il[(-B_y)\hat{i}+(B_x)\hat{j}].$ This gives

$F_x=-IlB_y=-(7.40\text{ A})(0.250\text{ m})(-0.985\text{ T})=1.82\text{ N}$ and

$F_y=IlB_x=(7.40\text{ A})(0.250\text{ m})(-0.242\text{ T})=-0.448\text{ N}.$ $F_z=0,$ since the wire is in the z-direction.

(b) $F=\sqrt{F_x^2+F_y^2}=\sqrt{(1.82\text{ N})^2+(0.448\text{ N})^2}=1.88\text{ N}.$

EVALUATE: $\vec{F}$ must be perpendicular to the current direction, so $\vec{F}$ has no z-component.

27.61. **IDENTIFY:** We are dealing with the magnetic force on a curved current-carrying wire.

SET UP and **EXECUTE:** **(a)** Use Example 27.8 as a guide except integrate from $\theta=0$ to $\pi/2$. This gives $F_x=F_y=IRB$, so $F=\sqrt{(IRB)^2+(IRB)^2}=IRB\sqrt{2}=(5.00\text{ A})(0.200\text{ m})(0.800\text{ T})\sqrt{2}=1.13\text{ N}.$ Using the right-hand rule for the magnetic force on a current-carrying wire, we see that the direction of the force is toward the origin.

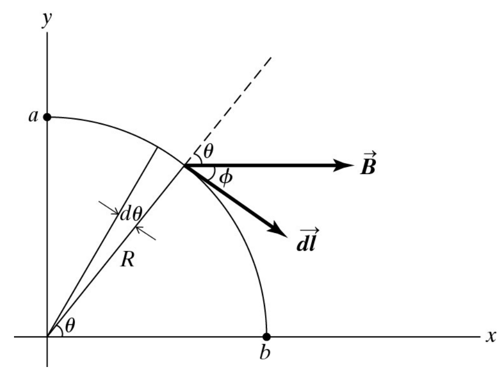

Figure 27.61

(b) Refer to Fig. 27.61. $dF = IBdl\sin\phi = IBdl\cos\theta$. $dl = Rd\theta$. $F = \int_0^{\pi/2} IB\cos\theta R d\theta = IBR$. Using the numbers gives F = (5.00 A)(0.800 T)(0.200 m) = 0.800 N. By the right-hand rule, the force is in the +z-direction.

EVALUATE: Just by changing the direction of the field, the force can change direction *and* magnitude.

27.62. **IDENTIFY:** This problem involves the torque on a current-carrying coil in a magnetic field.

SET UP and **EXECUTE:** **(a)** Estimate: 15 cm in diameter.

(b) We want the rotor diameter. 1/3 of the hub circumference is (1/3)(π)(15 cm) = 15.7 cm. 15.7 cm = (12)(diameter of one rotor) = 12D, so D = 1.3 cm.

(c) We want the magnetic moment. $\tau = \mu B\sin\phi$ for each rotor. Thus $\frac{1.4\ \text{N}\cdot\text{m}}{12} = \mu(1.0\ \text{T})\sin 90°$ which gives $\mu = 0.12\ \text{A}\cdot\text{m}^2$.

(d) We want N. $\mu = NIA = NI\pi r^2$. Using $\mu = 0.12\ \text{A}\cdot\text{m}^2$, r = 0.0065 m, and I = (0.75 A)/12 gives N = 14,000 turns.

EVALUATE: This wire must be extremely thin to fit 14,000 turns into the small volume of the central hub.

27.63. **IDENTIFY:** This problem involves the magnetic force on a current-carrying wire.

SET UP and **EXECUTE:** **(a)** Estimate the current. $F_{mag} = F_{grav}$, so $ILB_{horiz} = mg = \rho\pi r^2 Lg$.

$I = \frac{\rho\pi r^2 g}{B\cos 45°}$ = 48,000 A using the given quantities.

(b) 48,000 A > 900 A so this is *not feasible.*

(c) We want the minimum magnetic field. For B to be a minimum, I would have to have its maximum possible value of 900 A. Using our analysis in (a) but with the bar perpendicular to the field, we get

$B_{min} = \frac{\rho\pi r^2 g}{I}$ = 1.9 mT = 19 G.

(d) We want the mass we could support. $F_{mag} = (m_{bar} + M)g$. $ILB = \rho\pi r^2 Lg + Mg$. Solving for M gives $M = L\left(\frac{IB}{g} - \rho\pi r^2\right)$. Using I = 10 A, B =1.0 T, and the usual quantities for the other variables, we get M = 0.085 kg, so w = 0.83 N.

EVALUATE: Magnetic levitation the earth's magnetic field is obviously not feasible in most cases.

27.64. IDENTIFY: The torque exerted by the magnetic field is $\vec{\tau} = \vec{\mu} \times \vec{B}$. The torque required to hold the loop in place is $-\vec{\tau}$.

SET UP: $\mu = IA$. $\vec{\mu}$ is normal to the plane of the loop, with a direction given by the right-hand rule that is illustrated in Figure 27.32 in the textbook. $\tau = IAB\sin\phi$, where ϕ is the angle between the normal to the loop and the direction of $\vec{B}$.

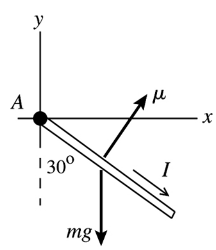
EXECUTE: (a) $\tau = IAB \sin 60° = (15.0\text{ A})(0.060\text{ m})(0.080\text{ m})(0.48\text{ T})\sin 60° = 0.030\text{ N}\cdot\text{m}$, in the $-\hat{j}$-direction. To keep the loop in place, you must provide a torque in the $+\hat{j}$-direction.

(b) $\tau = IAB \sin 30° = (15.0\text{ A})(0.60\text{ m})(0.080\text{ m})(0.48\text{ T})\sin 30° = 0.017\text{ N}\cdot\text{m}$, in the $+\hat{j}$-direction. You must provide a torque in the $-\hat{j}$-direction to keep the loop in place.

EVALUATE: (c) If the loop was pivoted through its center, then there would be a torque on both sides of the loop parallel to the rotation axis. However, the lever arm is only half as large, so the total torque in each case is identical to the values found in parts (a) and (b).

27.65. IDENTIFY: For the loop to be in equilibrium the net torque on it must be zero. Use $\vec{\tau} = \vec{\mu} \times \vec{B}$ to calculate the torque due to the magnetic field and $\tau_{mg} = mgr\sin\phi$ for the torque due to gravity.

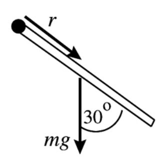
SET UP: See Figure 27.65a.



Use $\sum \tau_A = 0$, where point A is at the origin.

Figure 27.65a

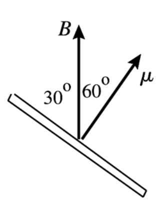
EXECUTE: See Figure 27.65b.



$\tau_{mg} = mgr\sin\phi = mg(0.400\text{ m})\sin 30.0°$.
The torque is clockwise; $\vec{\tau}_{mg}$ is directed into the paper.

Figure 27.65b

For the loop to be in equilibrium the torque due to $\vec{B}$ must be counterclockwise (opposite to $\vec{\tau}_{mg}$) and it must be that $\tau_B = \tau_{mg}$. See Figure 27.65c.



$\vec{\tau}_B = \vec{\mu} \times \vec{B}$. For this torque to be counter-clockwise ($\vec{\tau}_B$ directed out of the paper), $\vec{B}$ must be in the $+y$-direction.

Figure 27.65c

$\tau_B = \mu B \sin\phi = IAB\sin 60.0°$.

$\tau_B = \tau_{mg}$ gives $IAB\sin 60.0° = mg(0.0400\text{ m})\sin 30.0°$.

$m = (0.15\text{ g/cm})2(8.00\text{ cm} + 6.00\text{ cm}) = 4.2\text{ g} = 4.2\times 10^{-3}\text{ kg}$.

$A = (0.0800\text{ m})(0.0600\text{ m}) = 4.80\times 10^{-3}\text{ m}^2$.

$$B = \frac{mg(0.0400\text{ m})(\sin 30.0°)}{IA\sin 60.0°}.$$

$$B = \frac{(4.2\times 10^{-3}\text{ kg})(9.80\text{ m/s}^2)(0.0400\text{ m})\sin 30.0°}{(8.2\text{ A})(4.80\times 10^{-3}\text{ m}^2)\sin 60.0°} = 0.024\text{ T}.$$

EVALUATE: As the loop swings up the torque due to $\vec{B}$ decreases to zero and the torque due to mg increases from zero, so there must be an orientation of the loop where the net torque is zero.

27.66. **IDENTIFY** and **SET UP:** The force on a current-carrying bar of length l is $F = IlB$ if the field is perpendicular to the bar. The torque is $\tau_z = \mu B\sin\phi$.

EXECUTE: **(a)** The force on the infinitesimal segment is $dF = IBdl = IBdx$. The torque about point a is $d\tau_z = xdF\sin\phi = xIBdx$. In this case, $\sin\phi = 1$ because the force is perpendicular to the bar.

(b) We integrate to get the total torque: $\tau_z = \int_0^L xIBdx = \frac{1}{2}IBL^2$.

(c) For $F = ILB$ at the center of the bar, the torque is $\tau_z = F\left(\frac{L}{2}\right) = ILB\left(\frac{L}{2}\right) = \frac{1}{2}IBL^2$, which is the same result we got by integrating.

EVALUATE: We can think of the magnetic force as all acting at the center of the bar because the magnetic field is uniform. This is the same reason we can think of gravity acting at the center of a uniform bar.

27.67. **IDENTIFY:** Apply $\vec{F} = I\vec{l}\times\vec{B}$ to calculate the force on each side of the loop.

SET UP: The net force is the vector sum of the forces on each side of the loop.

EXECUTE: **(a)** $F_{PQ} = (5.00\text{ A})(0.600\text{ m})(3.00\text{ T})\sin(0°) = 0\text{ N}$.

$F_{RP} = (5.00\text{ A})(0.800\text{ m})(3.00\text{ T})\sin(90°) = 12.0\text{ N}$, into the page.

$F_{QR} = (5.00\text{ A})(1.00\text{ m})(3.00\text{ T})(0.800/1.00) = 12.0\text{ N}$, out of the page.

(b) The net force on the triangular loop of wire is zero.

(c) For calculating torque on a straight wire we can assume that the force on a wire is applied at the wire's center. Also, note that we are finding the torque with respect to the PR-axis (not about a point), and consequently the lever arm will be the distance from the wire's center to the x-axis. $\tau = rF\sin\phi$ gives $\tau_{PQ} = r(0\text{ N}) = 0$, $\tau_{RP} = (0\text{ m})F\sin\phi = 0$ and $\tau_{QR} = (0.300\text{ m})(12.0\text{ N})\sin(90°) = 3.60\text{ N}\cdot\text{m}$. The net torque is $3.60\text{ N}\cdot\text{m}$.

(d) Using $\tau = NIAB\sin\phi$ gives

$\tau = NIAB\sin\phi = (1)(5.00\text{ A})\left(\frac{1}{2}\right)(0.600\text{ m})(0.800\text{ m})(3.00\text{ T})\sin(90°) = 3.60\text{ N}\cdot\text{m}$, which agrees with our result in part (c).

(e) Since F_{QR} is out of the page and since this is the force that produces the net torque, the point Q will be rotated out of the plane of the figure.

EVALUATE: In the expression $\tau = NIAB\sin\phi$, ϕ is the angle between the plane of the loop and the direction of $\vec{B}$. In this problem, $\phi = 90°$.

27.68. **IDENTIFY:** We are dealing with magnetic force and torque.

SET UP and EXECUTE: We want the force and torque. $F = IlB\sin\phi$ and $\tau = \mu B\sin\phi$.

(a) We want for force on each segment. PQ: $F = IlB\sin\phi$ = (5.00 A)(0.600 m)(3.00 T)(1) = 9.00 N. By the right-hand rule, the direction is to the *left*.

QR: F = (5.00 A)(1.00 m)(3.00 T)(1) = 15.0 N. The direction is perpendicular to *QR* pointing upward and to the right, making a 53.1° angle with *PR*.

RP: F = (5.00 A)(0.800 m)(3.00 T)(1) = 12.0 N, downward perpendicular to *PR*.

(b) We want the net force. F_x = –9.00 N + (15.0 N) cos(53.1°) = 0. F_y = –12.0 N + (15.0 N) sin 53.1° = 0. The net force is zero.

(c) We want the torque about *PR*. $\tau_{PR} = 0$, $\tau_{PQ} = 0$, and $\tau_{QR} = 0$. The net torque is zero.

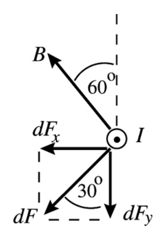
(d) From (c), the net torque is zero. Use $\tau = \mu B\sin\phi$. $\vec{\mu}$ and $\vec{B}$ both point into the page, so ϕ = 0, so the torque is zero. Both methods agree.

(e) The torque is zero, so the field would cause no rotation.

EVALUATE: The magnetic field does exert torque on the wire segments, but not about the *PR* axis.

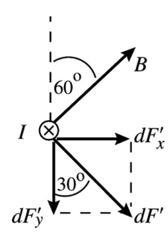
27.69. **IDENTIFY:** Use $dF = Idl\,B\sin\phi$ to calculate the force on a short segment of the coil and integrate over the entire coil to find the total force.

SET UP: See Figures 27.69a and 27.69b. The two sketches show that the *x*-components cancel and that the *y*-components add. This is true for all pairs of short segments on opposite sides of the coil. The net magnetic force on the coil is in the *y* direction and its magnitude is given by $F = \int dF_y$.



Consider the force $d\vec{F}$ on a short segment *dl* at the left-hand side of the coil, as viewed in the figure with the problem in the textbook. The current at this point is directed out of the page. $d\vec{F}$ is perpendicular both to $\vec{B}$ and to the direction of *I*.

Figure 27.69a



Consider also the force $d\vec{F}'$ on a short segment on the opposite side of the coil, at the right-hand side of the coil in the figure with the problem in the textbook. The current at this point is directed into the page.

Figure 27.69b

EXECUTE: $dF = Idl\,B\sin\phi$. But $\vec{B}$ is perpendicular to the current direction so $\phi = 90°$.

$dF_y = dF\cos 30.0 = IB\cos 30.0°dl.$

$F = \int dF_y = IB\cos 30.0° \int dl.$

But $\int dl = N(2\pi r)$, the total length of wire in the coil.

$F = IB\cos 30.0° N(2\pi r) = (0.950\text{ A})(0.220\text{ T})(\cos 30.0°)(50)2\pi(0.0078\text{ m}) = 0.444\text{ N}$ and

$\vec{F} = -(0.444\text{ N})\hat{j}$

EVALUATE: The magnetic field makes a constant angle with the plane of the coil but has a different direction at different points around the circumference of the coil so is not uniform. The net force is proportional to the magnitude of the current and reverses direction when the current reverses direction.

27.70. IDENTIFY: For rotational equilibrium, the torques due to gravity and the magnetic field must balance around point a.

SET UP: From Problem 27.66 we have $\tau_z = \frac{1}{2}IBL^2$.

EXECUTE: **(a)** Balancing the two torques gives: $mg\frac{L}{2}\cos\theta = \frac{1}{2}IBL^2$. Simplifying gives Putting in the numbers gives

$I(0.150\text{ T})(0.300\text{ m}) = (0.0120\text{ kg})(9.80\text{ m/s}^2)\cos(30.0°)$, so $I = 2.26$ A.

(b) Gravity tends to rotate the bar clockwise about point a, so the magnetic force must be upward and to the left to tend to rotate the bar clockwise. Therefore the current must flow from a to b.

EVALUATE: If the current were from b to a, the bar could not balance.

27.71. IDENTIFY: Apply $d\vec{F} = Id\vec{l} \times \vec{B}$ to each side of the loop.

SET UP: For each side of the loop, $d\vec{l}$ is parallel to that side of the loop and is in the direction of I. Since the loop is in the xy-plane, $z = 0$ at the loop and $B_y = 0$ at the loop.

EXECUTE: **(a)** The magnetic field lines in the yz-plane are sketched in Figure 27.71.

(b) Side 1, that runs from (0,0) to (0,L): $\vec{F} = \int_0^L Id\vec{l} \times \vec{B} = I\int_0^L \frac{B_0 y\, dy}{L}\hat{i} = \frac{1}{2}B_0 LI\hat{i}$.

Side 2, that runs from (0,L) to (L,L): $\vec{F} = \int_{0,y=L}^{L} Id\vec{l} \times \vec{B} = I\int_{0,y=L}^{L} \frac{B_0 y\, dx}{L}\hat{j} = -IB_0 L\hat{j}$.

Side 3, that runs from (L,L) to (L,0): $\vec{F} = \int_{L,x=L}^{0} Id\vec{l} \times \vec{B} = I\int_{L,x=L}^{0} \frac{B_0 y\, dy}{L}(-\hat{i}) = -\frac{1}{2}IB_0 L\hat{i}$.

Side 4, that runs from (L,0) to (0,0): $\vec{F} = \int_{L,y=0}^{0} Id\vec{l} \times \vec{B} = I\int_{L,y=0}^{0} \frac{B_0 y\, dx}{L}\hat{j} = 0$.

(c) The sum of all forces is $\vec{F}_{\text{total}} = -IB_0 L\hat{j}$.

EVALUATE: The net force on sides 1 and 3 is zero. The force on side 4 is zero, since $y = 0$ and $z = 0$ at that side and therefore $B = 0$ there. The net force on the loop equals the force on side 2.

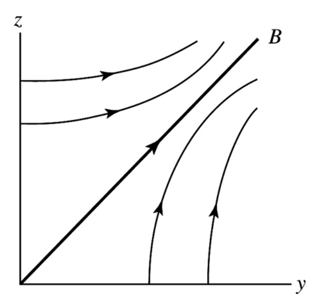


Figure 27.71

27.72. IDENTIFY and SET UP: The rod is in rotational equilibrium, so the torques must balance. Take torques about point P and use $\tau_z = \frac{1}{2}IBL^2$ from Problem 27.66.

EXECUTE: Balancing torques gives $mg\frac{L}{2}\cos\theta + \frac{1}{2}IBL^2 = T\sin\theta L$, where L is the length of the bar and T is the tension in the string. Solving for T and putting in the numbers gives

$T = [(0.0840\text{ kg})(9.80\text{ m/s}^2)\cos(53.0°) + (12.0\text{ A})(0.120\text{ T})(0.180\text{ m})]/[2\sin(53.0°)] = 0.472$ N.

Evaluate: If the current were reversed, the tension would be less than 0.472 N.

27.73. **Identify:** This problem involves the torque on a current loop due to a magnetic field.
Set Up: $\tau = \mu B \sin\phi$.

Execute: **(a)** We want the minimum current so that $h > 0$. Refer to the figure included with the problem in the textbook. The torques balance, so $\tau_{\text{tension}} = \tau_{\text{gravity}}$. $\mu B \sin\phi = MgR$. $IANB \sin\phi = MgR$.

Using $A = 2RW$ and solving for I gives $I = \dfrac{Mg}{2WNB \sin\phi}$. The minimum I occurs for maximum $\sin\phi$, which is 1 when $\phi = 90°$. So $I_{\text{min}} = \dfrac{Mg}{2WNB}$.

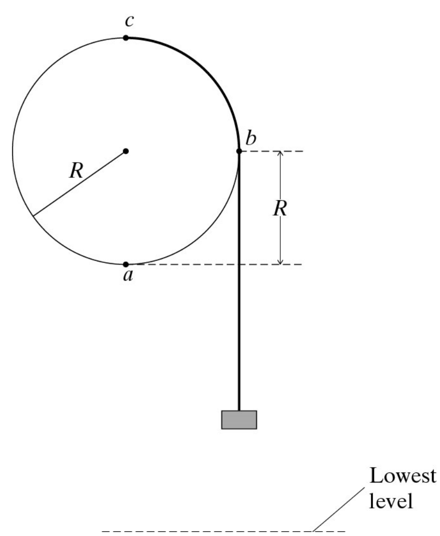

Figure 27.73a

(b) Refer to Fig. 27.73a. In one-half turn, the mass first rises a distance R from a to b. In going from b to c, the length of cable that is pulled up is ¼ of a circumference because after b the cable wraps around the rim. So the total rise is $R + (2\pi R)/4 = R(1 + \pi/2) = h_{\text{top}}$.

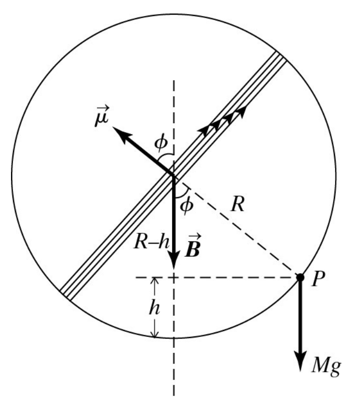

Figure 27.73b

(c) We want the net torque if $0 \le h \le R$. Refer to Fig. 27.73b. $\tau_{\text{net}} = \tau_{\text{mag}} + \tau_{\text{grav}}$. $\tau_{\text{grav}} = MgR \sin\phi$.
$\tau_{\text{mag}} = \mu B \sin\phi = 2IWRNB \sin\phi$. So $\tau_{\text{net}} = (2IWRNB - MgR)\sin\phi$. Since the cable is attached to the rim

of the cylinder at point P on the axis of the coil, $\vec{\mu}$ as shown in Fig. 27.73 in the text always points directly away from P. To find $\sin\phi$, look at Fig. 27.73a which shows that

$\sin\phi = \dfrac{\sqrt{R^2-(R-h)^2}}{R} = \dfrac{\sqrt{h(2R-h)}}{R}$. Therefore $\tau_{\text{net}} = (2IWNB - Mg)\sqrt{h(2R-h)}$. Using $\sigma = \dfrac{2NIWB}{Mg}$ as defined in the problem, we can write the net torque as

$$\tau_{\text{net}} = Mg\left(\frac{2IWNB}{Mg} - 1\right)\sqrt{h(2R-h)} = Mg(\sigma-1)\sqrt{h(2R-h)}.$$

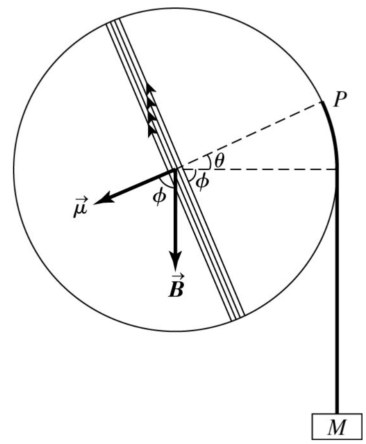

Figure 27.73c

(d) We want the net torque for $R \le h \le h_{\text{top}}$. Refer to Fig. 27.73c. Use an approach similar to that in part (a). h is equal to R plus the length of cable turned through θ. With θ in radians, this gives $h = R + R\theta$, so $\theta = \dfrac{h}{R} - 1$. From Fig. 27.73c, $\sin\phi = \cos\theta$. Therefore

$\tau_{\text{net}} = \tau_{\text{mag}} + \tau_{\text{grav}} = \mu B\sin\phi - MgR = 2INWRB\cos\theta - MgR$. Regrouping gives

$$\tau_{\text{net}} = \left(\frac{2INWB}{Mg}\cos\theta - 1\right)MgR = \left[\sigma\cos\left(\frac{h}{R} - 1\right) - 1\right]MgR.$$

(e) We want the potential energy for $0 \le h \le R$. $U = U_{\text{grav}} + U_{\text{mag}} + U_0$. $U_{\text{grav}} = Mgh$.
$U_{\text{mag}} = -\vec{\mu}\cdot\vec{B} = -\mu B\cos(180° - \phi) = \mu B\sin\phi$. Define $U(h)$ so that $U(0) = 0$. When $h = 0$, $\phi = 0$ and $\cos\phi = 1$, so U_0 must be $-\mu B$. Thus $U(h) = \mu B\cos\phi + Mgh - \mu B\cos 0° = \mu B(\cos\phi - 1) + Mgh$. Using our expression for μ, we can write this as $U(h) = 2INRWB(\cos\phi - 1) + Mgh$. From Fig. 27.73b, we see that $\cos\phi = \dfrac{R-h}{R} = 1 - \dfrac{h}{R}$, so $U(h)$ becomes

$$U(h) = 2INRWB(1 - h/R - 1) + Mgh = -2INWBh + Mgh = \left(-\frac{2INWB}{Mg} + 1\right)Mgh = (1-\sigma)Mgh.$$

(f) We want U when $R \le h \le h_{\text{top}}$. As we have seen, $U(h) = U_{\text{mag}} + U_{\text{grav}} - \mu B$. See Fig. 27.73c and the procedure for part (d). We have shown: $h = R(1+\theta)$, $\theta = \dfrac{h}{R} - 1$, $\cos\phi = \sin\theta = \sin\left(\dfrac{h}{R} - 1\right)$. Therefore $U(h) = -\mu B\cos\phi + Mgh - \mu B = -\mu B(\cos\phi + 1) + Mgh$. Continuing we get

$U(h) = -\mu B\left[\sin\left(\frac{h}{R}-1\right)+1\right]+Mgh.$ Putting in for μ and expressing in terms of σ finally gives

$U(h) = \left\{\frac{h}{R}-\sigma\left[\sin\left(\frac{h}{R}-1\right)+1\right]\right\}(MgR).$

(g) If $\sigma > 1$, what h will suspend M motionless? The net torque will be zero. There are two possibilities: $0 \le h \le R$ and $R \le h \le h_{\text{top}}$. Consider each one separately.

$\underline{0 \le h \le R}$: $\tau_{\text{net}} = Mg(\sigma-1)\sqrt{h(2R-h)} = 0.$ Either h = 0 or h = 2R. If h = 0, the object just hangs down from the rim at point P so it is not really suspended. Since h cannot be greater than 2R, neither of these answers is possible.

$\underline{R \le h \le h_{\text{top}}}$: $\tau_{\text{net}} = \left[\sigma\cos\left(\frac{h}{R}-1\right)-1\right]MgR = 0.$ $\sigma\cos\left(\frac{h}{R}-1\right)-1=0.$ $\cos(h/R-1) = 1/\sigma.$

$\frac{h}{R}-1 = \arccos(1/\sigma)$, which gives $h = R[1+\arccos(1/\sigma)].$

(h) What is σ such that $U(h_{\text{top}}) > 0$? For $R \le h \le h_{\text{top}}$ we have from part (f)

$U(h) = \left\{\frac{h}{R}-\sigma\left[\sin\left(\frac{h}{R}-1\right)+1\right]\right\}(MgR).$ From (b) we have $h_{\text{top}} = R(1 + \pi/2)$. Combining these gives

$U(h_{\text{top}}) = \frac{R(1+\pi/2)}{R} - \sigma\left[\sin(1+\pi/2-1)+1\right]MgR = 1+\pi/2-2\sigma > 0.$ This gives $\sigma < \frac{1}{2}\left(1+\frac{\pi}{2}\right).$

EVALUATE: When in doubt, check units!

27.74. **IDENTIFY:** We have a positive particle moving in a magnetic field.

SET UP and **EXECUTE:** $\vec{F} = q\vec{v}\times\vec{B}$. **(a)** We want a_x and a_y at time t. $F_x = qBv_y$,

so $a_x = \frac{qv_yB}{m} = \left(\frac{qB}{m}\right)v_y.$ $F_y = mg - qv_xB$, so $a_y = g - \left(\frac{qB}{m}\right)v_x.$

(b) $\frac{da_y}{dt} = -\left(\frac{qB}{m}\right)\frac{dv_x}{dt} = -\left(\frac{qB}{m}\right)a_x.$ Using $a_x = \left(\frac{qB}{m}\right)v_y$ and $\frac{da_y}{dt} = \frac{d^2v_y}{dt^2}$ gives

$\frac{d^2v_y}{dt^2} = -\left(\frac{qB}{m}\right)\left(\frac{qB}{m}\right)v_y = -\left(\frac{qB}{m}\right)^2 v_y.$

(c) The result in (b) is of the form $\frac{d^2x}{dt^2} = -\frac{k}{m}x,$ which has solution $x = A\cos(\omega t+\phi),$ where $\omega = \sqrt{k/m}.$ Applying this here we have $k/m \to (qB/m)^2$, so $\omega = qB/m.$ The equation for $v_y(t)$ is $v_y(t) = A\cos(\omega t+\phi).$ We need to determine A and ϕ. The initial conditions are: at t =0, v_y = 0 and a_y = g. $v_y(0) = A\cos\phi = 0$, so $\phi = \pi/2$. Thus $v_y(t) = A\cos(\omega t+\pi/2) = -A\sin\omega t.$

$a_y = \frac{dv_y}{dt} = -A\omega\cos\omega t.$ At t = 0, we have $-A\omega = g,$ so $-A = g/\omega.$ Thus $v_y(t) = \frac{g}{\omega}\sin\omega t,$ where $\omega = qB/m.$

(d) $a_x = \frac{dv_x}{dt} = \frac{qB}{m}v_y$ and $\frac{dv_x}{dt} = \frac{qB}{m}\left(\frac{g}{\omega}\right)\sin\omega t = \frac{qB}{m}\left(\frac{g}{qB/m}\right)\sin\omega t = g\sin\omega t.$

$v_x(t) = \int g\sin\omega t\,dt = -\frac{g}{\omega}\cos\omega t + C.$ When t = 0, v_x = 0, so $C = g/\omega.$ This gives $v_x(t) = \frac{g}{\omega}(1-\cos\omega t).$

(e) $x(t) = \int\frac{g}{\omega}(1-\cos\omega t)\,dt = \frac{g}{\omega}\left(t-\frac{1}{\omega}\sin\omega t\right)+C.$ When t = 0, x = 0, so C = 0. Thus

$x(t) = \frac{gt}{\omega} - \frac{g}{\omega^2}\sin\omega t.$ Now find $y(t)$.

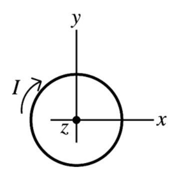
$y(t) = \int \frac{g}{\omega}\sin\omega t = -\frac{g}{\omega^2}\cos\omega t + C$. When $t = 0$, $y = 0$, so $C = g/\omega^2$. Thus $y(t) = \frac{g}{\omega^2}(1-\cos\omega t)$.

(f) We want the maximum vertical distance. From (e) we have $y(t) = \frac{g}{\omega^2}(1-\cos\omega t)$. y is a maximum when $\cos\omega t = -1$. $\omega = qB/m = (19.6\ \mu\text{C})(10.0\ \text{T})/(1.00\ \text{mg}) = 196$ rad/s. So $y_{\max} = 2g/\omega^2 = 2g/(196\ \text{rad/s})^2 = 0.510$ mm.

EVALUATE: The complete motion is quite complicated so it is easiest to deal with components as we did here.

27.75. **IDENTIFY:** Use $U = -\vec{\mu}\cdot\vec{B}$ to relate $U, \mu,$ and $\vec{B}$ and use $\vec{\tau} = \vec{\mu}\times\vec{B}$ to relate $\vec{\tau}, \vec{\mu},$ and $\vec{B}$. We also know that $B_0^2 = B_x^2 + B_y^2 + B_z^2$. This gives three equations for the three components of $\vec{B}$.

SET UP: The loop and current are shown in Figure 27.75.



$\vec{\mu}$ is into the plane of the paper, in the $-z$-direction.

Figure 27.75

EXECUTE: **(a)** $\vec{\mu} = -\mu\hat{k} = -IA\hat{k}$.

(b) $\vec{\tau} = D(+4\hat{i} - 3\hat{j})$, where $D > 0$.

$\vec{\mu} = -IA\hat{k}, \vec{B} = B_x\hat{i} + B_y\hat{j} + B_y\hat{k}$.

$\vec{\tau} = \vec{\mu}\times\vec{B} = (-IA)(B_x\hat{k}\times\hat{i} + B_y\hat{k}\times\hat{j} + B_z\hat{k}\times\hat{k}) = IAB_y\hat{i} - IAB_x\hat{j}$.

Compare this to the expression given for $\vec{\tau}$: $IAB_y = 4D$ so $B_y = 4D/IA$ and $-IAB_x = -3D$ so $B_x = 3D/IA$. B_z doesn't contribute to the torque since $\vec{\mu}$ is along the z direction. But $B = B_0$ and $B_x^2 + B_y^2 + B_z^2 = B_0^2$; with $B_0 = 13D/IA$. Thus

$B_z = \pm\sqrt{B_0^2 - B_x^2 - B_y^2} = \pm(D/IA)\sqrt{169 - 9 - 16} = \pm 12(D/IA)$.

That $U = -\vec{\mu}\,.\,\vec{B}$ is negative determines the sign of

B_z: $U = -\vec{\mu}\cdot\vec{B} = -(-IA\hat{k})\cdot(B_x\hat{i} + B_y\hat{j} + B_z\hat{k}) = +IAB_z$.

So U negative says that B_z is negative, and thus $B_z = -12D/IA$.

EVALUATE: $\vec{\mu}$ is along the z-axis so only B_x and B_y contribute to the torque. B_x produces a y-component of $\vec{\tau}$ and B_y produces an x-component of $\vec{\tau}$. Only B_z affects U, and U is negative when $\vec{\mu}$ and $\vec{B}_z$ are parallel.

27.76. **IDENTIFY:** The ions are accelerated from rest. When they enter the magnetic field, they are bent into a circular path. Newton's second law applies to the ions in the magnetic field.

SET UP: $K = \frac{1}{2}mv^2 = qV$. $R = \frac{mv}{qB}$, where q is the magnitude of the charge.

EXECUTE: **(a)** As the ions are accelerated through the potential difference V, we have $K = \frac{1}{2}mv^2 = qV$, which gives $v = \sqrt{\frac{2qV}{m}}$. In the magnetic field, $R = \frac{mv}{qB}$. Using the v we just found gives

$R = \dfrac{mv}{qB} = \dfrac{m}{qB}\sqrt{\dfrac{2qV}{m}} = \sqrt{\dfrac{m}{q}}\dfrac{\sqrt{2V}}{B} = \dfrac{1}{B}\sqrt{\dfrac{2m}{q}}\sqrt{V}$. From this result we see that a graph of R versus $\sqrt{V}$ should be a straight line with a slope equal to $\dfrac{1}{B}\sqrt{\dfrac{2m}{q}}$.

(b) The graph of R versus $\sqrt{V}$ is shown in Figure 27.76. The slope of the best-fit line is $(6.355\text{ cm})/\sqrt{\text{kV}} = (0.06355\text{ m})/\sqrt{1000\text{ V}} = 0.00201\text{ m}\cdot\text{V}^{-1/2}$. We know that $\dfrac{1}{B}\sqrt{\dfrac{2m}{q}}$ = slope, so

$\dfrac{q}{m} = \dfrac{2}{[B(\text{slope})]^2} = \dfrac{2}{[(0.250\text{ T})(0.00201\text{ m}\cdot\text{V}^{-1/2}]^2} = 7.924\times10^{-6}\text{ C/kg}$, which rounds to $7.92\times10^{6}\text{ C/kg}$.

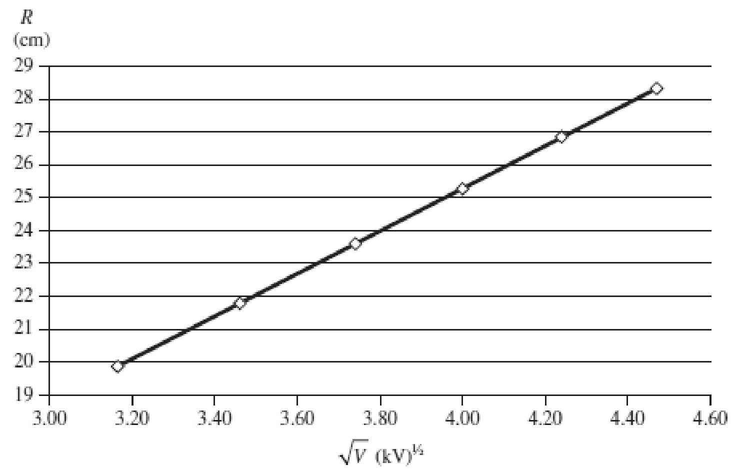


Figure 27.76

(c) Use our result for q/m: $v = \sqrt{\dfrac{2qV}{m}} = \sqrt{2(20.0\times10^{3}\text{ V})(7.924\times10^{6}\text{ C/kg})} = 5.63\times10^{5}\text{ m/s}$.

(d) Since $R = \dfrac{1}{B}\sqrt{\dfrac{2m}{q}}\sqrt{V}$, doubling q means that R is smaller by a factor of $\sqrt{2}$. Therefore $R = (21.1\text{ cm})/\sqrt{2} = 15.0\text{ cm}$.

EVALUATE: Besides the approach we have taken, the equation $R = \dfrac{1}{B}\sqrt{\dfrac{2m}{q}}\sqrt{V}$ can be graphed in other ways to obtain a straight line. For example, we could graph R^2 versus V, or even $\log R$ versus $\log V$. Ideally they should all give the same result for q/m. But differences can arise because we are dealing with less-than-ideal data points.

27.77. **IDENTIFY and SET UP:** The analysis in the text of the Thomson e/m experiment gives $\dfrac{e}{m} = \dfrac{E^2}{2VB^2}$. For a particle of charge e and mass m accelered through a potential V, $eV = \frac{1}{2}mv^2$.

EXECUTE: **(a)** Solving the equation $\dfrac{e}{m} = \dfrac{E^2}{2VB^2}$ for E^2 gives $E^2 = 2\left(\dfrac{e}{m}\right)B^2V$. Therefore a graph of E^2 versus V should be a straight line with slope equal to $2(e/m)B^2$.

(b) We can find the slope using two easily-read points on the graph. Using (100, 200) and (300, 600), we get $\dfrac{600\times10^{8}\text{ V}^2/\text{m}^2 - 200\times10^{8}\text{ V}^2/\text{m}^2}{300\text{ V} - 100\text{ V}} = 2.00\times10^{8}\text{ V/m}^2$ for the slope. This gives

e/m = (slope)/$2B^2$ = $(2.00\times10^8\ \text{V/m}^2)/[2(0.340\ \text{T})^2] = 8.65\times10^8$ C/kg, which gives

$m = 1.85\times10^{-28}$ kg.

(c) $V = Ed = (2.00\times10^5\ \text{V/m})\,(0.00600\ \text{m}) = 1.20$ kV.

(d) Using $eV = \frac{1}{2}mv^2$ to find the muon speed gives

$$v = \sqrt{\frac{2eV}{m}} = \sqrt{2(8.65\times10^8\ \text{C/kg})(400\ \text{V})} = 8.32\times10^5\ \text{m/s}.$$

EVALUATE: Results may vary due to inaccuracies in determining the slope of the graph.

27.78. IDENTIFY and SET UP: If q is the magnitude of the charge, the cyclotron frequency is $\omega = \frac{qB}{m}$, where $\omega = 2\pi f$, and $R = mv/qB$.

EXECUTE: (a) Combining $\omega = \frac{qB}{m}$ and $\omega = 2\pi f$ gives $f = \left(\frac{1}{2\pi}\frac{q}{m}\right)B$. Therefore a graph of f versus B should be a straight line having slope equal to $q/2\pi m = (2e)/2\pi m = e/\pi m$. Solving for m gives $m = \frac{e}{\pi(\text{slope})}$. We use two points on the graph to calculate the slope, giving 7.667×10^6 Hz/T.

Therefore $m = \frac{e}{\pi(\text{slope})} = e/[\pi(7.667\times10^6\ \text{Hz/T})] = 6.65\times10^{-27}$ kg.

(b) Apply $f = \left(\frac{1}{2\pi}\frac{q}{m}\right)B = qB/2\pi m$ to the electron and the proton.

Electron: $f_e = (1.602\times10^{-19}\ \text{C})(0.300\ \text{T})/[2\pi(9.11\times10^{-31}\ \text{kg})] = 8.40\times10^9\ \text{Hz} = 8.40$ GHz.

Proton: $f_p = (1.602\times10^{-19}\ \text{C})(0.300\ \text{T})/[2\pi(1.67\times10^{-27}\ \text{kg})] = 4.58\times10^6\ \text{Hz} = 4.58$ MHz.

For an alpha particle, $q = 2e$ and $m \approx 4m_p$, so q/m for an alpha particle is $(2e)/(4m_p) = \frac{1}{2}$ of what it is for a proton. Therefore $f_\alpha = \frac{1}{2}f_p = 2.3$ MHz.

For an alpha particle, $q = 2e$ and $m = 4(1836)m_e$, so q/m for an alpha particle is $2/[4(1836)] = 1/[2(1836)]$ what it is for an electron. Therefore $f_\alpha = \frac{1}{2(1836)}f_e = \frac{1}{3672}f_e = 2.3$ MHz.

(c) $R = mv/qB$ gives $v = RqB/m = (0.120\ \text{m})\,(3.2\times10^{-19}\ \text{C})(0.300\ \text{T})/(6.65\times10^{-27}\ \text{kg}) = 1.73\times10^6$ m/s.

$K = \frac{1}{2}mv^2 = (1/2)(6.65\times10^{-27}\ \text{kg})(1.73\times10^6\ \text{m/s})^2 = 1.0\times10^{-14}\ \text{J} = 6.25\times10^5\ \text{eV} = 625\ \text{keV} = 0.625$ MeV.

EVALUATE: We could use $v = R\omega$ to find v in part (c), where $\omega = 2\pi f$.

27.79. IDENTIFY: We want the magnetic moment of a spinning spherical shell.

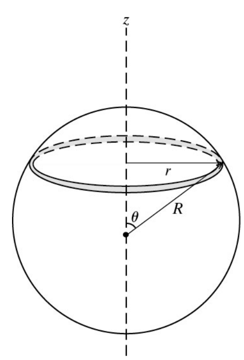

Figure 27.79

SET UP and **EXECUTE:** **(a)** See Fig. 27.79. Note that $r = R\sin\theta$.

(b) $dI = \sigma v dW = \sigma v R d\theta$. $v = r\omega$ so $dI = \sigma v R d\theta = \sigma(R\sin\theta)\omega R d\theta = \sigma\omega R^2 \sin\theta d\theta$.

(c) $d\mu = AdI$, where $A = \pi r^2 = \pi(R\sin\theta)^2$ and dI is what we found in part (b). The result is $d\mu = AdI = \pi(R\sin\theta)^2\left(\sigma\omega R^2 \sin\theta d\theta\right) = \pi R^4 \sigma\omega \sin^3\theta d\theta$.

(d) $\mu = \int_0^\pi \pi\sigma\omega R^4 \sin^3\theta d\theta = \pi\sigma\omega R^4 \int_0^\pi \sin\theta(1-\cos^2\theta)d\theta$. The integrals are fairly straightforward. The result is $\mu = \frac{4}{3}\pi\sigma\omega R^4$. Substituting $\sigma = Q/4\pi R^2$ gives $\mu = \frac{Q\omega R^2}{3}$. The right-hand rule tells us that it points in the $+z$-direction, so $\vec{\boldsymbol{\mu}} = \frac{Q\omega R^2}{3}\hat{\boldsymbol{k}}$.

(e) $\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{\mu}} \times \vec{B} = \frac{Q\omega R^2}{3}\hat{\boldsymbol{k}} \times \left(\sin\alpha\hat{\boldsymbol{i}} + \cos\alpha\hat{\boldsymbol{j}}\right)B = \frac{Q\omega BR^2}{3}\left(\sin\alpha\hat{\boldsymbol{j}} - \cos\alpha\hat{\boldsymbol{i}}\right)B$.

EVALUATE It helps to visualize a spinning spherical shell as a series of parallel concentric current loops of different sizes.

27.80. **IDENTIFY:** This problem involves the magnetic force on an electron moving in the earth's magnetic field.

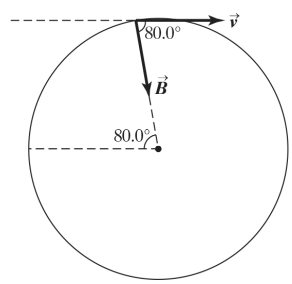

Figure 27.80a

SET UP: Fig. 27.80a shows the geometry of the motion and magnetic field.

EXECUTE: **(a)** We want the radius of the helix. The circular motion is due to the component of the velocity perpendicular to the magnetic field, which is $v_\perp = v\sin\phi$ with $\phi = 80.0°$. Therefore $R = \frac{mv_\perp}{|q|B} = \frac{mv\sin\phi}{eB} =$ 15.0 cm using the given numbers.

(b) We want the speed at which the electron approaches the surface of the earth. This is $v\cos\phi =$ (400 km/s)(cos 80.0°) = 69.5 km/s.

(c) By the right-hand rule, a positive charge would deflect clockwise, but electrons are negative so they deflect in a *counterclockwise* direction, as shown in Fig. 27.80b.

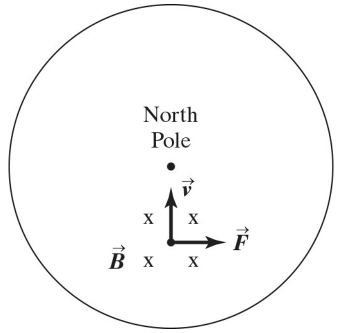

Figure 27.80b

(d) We want the frequency. Using the given numbers we get $f = \dfrac{qB}{2\pi m} = 419$ kHz.

(e) We want the new speed. Energy conservation gives $K_1 + W_{\text{E-field}} = K_2$. This gives $\frac{1}{2}mv_1^2 + eEd = \frac{1}{2}mv_2^2$. Solving for v_2 and using $E = 0.020$ V/m, $d = 100$ km, and $v_1 = 400$ km/s, we get $v_2 = \sqrt{v_1^2 + \dfrac{2eEd}{m}} = 2.65\times10^4$ km/s.

(f) $\dfrac{K_2}{K_1} = \dfrac{1/2\,mv_2^2}{1/2\,mv_1^2} = \left(\dfrac{v_2}{v_1}\right)^2 = \left(\dfrac{26{,}500 \text{ km/s}}{4000 \text{ km/s}}\right)^2 = 4390.$

EVALUATE: The electrons and protons trapped by Earth's magnetic field form the Van Allen radiation belts.

27.81. **IDENTIFY** and **SET UP:** In the magnetic field, $R = \dfrac{mv}{qB}$. Once the particle exits the field it travels in a straight line. Throughout the motion the speed of the particle is constant.

EXECUTE: **(a)** $R = \dfrac{mv}{qB} = \dfrac{(3.20\times10^{-11}\text{ kg})(1.45\times10^5\text{ m/s})}{(2.15\times10^{-6}\text{ C})(0.420\text{ T})} = 5.14$ m.

(b) See Figure 27.81. The distance along the curve, d, is given by $d = R\theta$. $\sin\theta = \dfrac{0.25\text{ m}}{5.14\text{ m}}$, so $\theta = 2.79° = 0.0486$ rad. $d = R\theta = (5.14\text{ m})(0.0486\text{ rad}) = 0.25$ m. And $t = \dfrac{d}{v} = \dfrac{0.25\text{ m}}{1.45\times10^5\text{ m/s}} = 1.72\times10^{-6}$s.

(c) $\Delta x_1 = d\tan(\theta/2) = (0.25\text{ m})\tan(2.79°/2) = 6.08\times10^{-3}$ m.

(d) $\Delta x = \Delta x_1 + \Delta x_2$, where Δx_2 is the horizontal displacement of the particle from where it exits the field region to where it hits the wall. $\Delta x_2 = (0.50\text{ m})\tan 2.79° = 0.0244$ m. Therefore, $\Delta x = 6.08\times10^{-3}\text{ m} + 0.0244\text{ m} = 0.0305$ m.

EVALUATE: d is much less than R, so the horizontal deflection of the particle is much smaller than the distance it travels in the y direction.

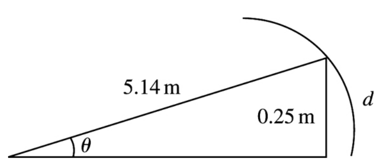

Figure 27.81

27.82. **IDENTIFY:** The electric and magnetic fields exert forces on the moving charge. The work done by the electric field equals the change in kinetic energy. At the top point, $a_y = \frac{v^2}{R}$ and this acceleration must correspond to the net force.

SET UP: The electric field is uniform so the work it does for a displacement y in the y direction is $W = Fy = qEy$. At the top point, $\vec{F}_B$ is in the $-y$-direction and $\vec{F}_E$ is in the $+y$-direction.

EXECUTE: **(a)** The maximum speed occurs at the top of the cycloidal path, and hence the radius of curvature is greatest there. Once the motion is beyond the top, the particle is being slowed by the electric field. As it returns to $y = 0$, the speed decreases, leading to a smaller magnetic force, until the particle stops completely. Then the electric field again provides the acceleration in the y-direction of the particle, leading to the repeated motion.

(b) $W = qEy = \frac{1}{2}mv^2$ and $v = \sqrt{\frac{2qEy}{m}}$.

(c) At the top, $F_y = qE - qvB = -\frac{mv^2}{R} = -\frac{m}{2y}\frac{2qEy}{m} = -qE$. $2qE = qvB$ and $v = \frac{2E}{B}$.

EVALUATE: The speed at the top depends on B because B determines the y-displacement and the work done by the electric force depends on the y-displacement.

27.83. **IDENTIFY** and **SET UP:** The torque on a magnetic moment is $\tau = \mu B \sin\phi$.

EXECUTE: $\tau = \mu B \sin\phi = (1.4\times10^{-26}\text{ J/T})(2\text{ T})(\sin 90°) = 2.8\times10^{-26}\text{ N}\cdot\text{m}$, which is choice (c).

EVALUATE: The value we have found is the maximum torque. It could be less, depending on the orientation of the proton relative to the magnetic field.

27.84. **IDENTIFY** and **SET UP:** For the nucleus to have a net magnetic moment, it must have an odd number of protons and neutrons.

EXECUTE: Only $^{31}\text{P}_{15}$ has an odd number of protons and neutrons, so choice (d) is correct.

EVALUATE: All the other choices have an even number of protons and an even number of neutrons.

27.85. **IDENTIFY** and **SET UP:** Model the nerve as a current-carrying bar in a magnetic field. The resistance of the nerve is $R = \frac{\rho L}{A}$, the current through it is $I = V/R$ (by Ohm's law), and the maximum magnetic force on it is $F = ILB$.

EXECUTE: The resistance is $R = \frac{\rho L}{A} = (0.6\ \Omega\cdot\text{m})(0.001\text{ m})/[\pi(0.0015/2\text{ m})^2] = 340\ \Omega$.

The current is $I = V/R = (0.1\text{ V})/(340\ \Omega) = 2.9\times10^{-4}\text{ A}$.

The maximum force is $F = ILB = (2.9\times10^{-4}\text{ A})(0.001\text{ m})(2\text{ T}) = 5.9\times10^{-7}\text{ N} \approx 6\times10^{-7}\text{ N}$, which is choice (a).

EVALUATE: This is the force on a 1-mm segment of nerve. The force on the entire nerve would be somewhat larger, depending on the length of the nerve.

28

SOURCES OF MAGNETIC FIELD

VP28.2.1. **IDENTIFY:** We want to calculate the magnetic field due to a moving charged particle.

SET UP: $\vec{B} = \dfrac{\mu_0}{4\pi}\dfrac{q\vec{v}\times\hat{r}}{r^2}$, $B = \dfrac{\mu_0}{4\pi}\dfrac{qv\sin\phi}{r^2}$. Our target variable is the magnetic field at various points.

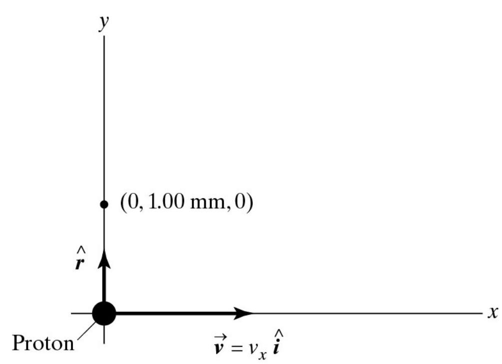

Figure VP28.2.1a

EXECUTE: **(a)** At (0, 1.00 mm, 0). See Fig. 28.2.1a. Use $B = \dfrac{\mu_0}{4\pi}\dfrac{qv\sin\phi}{r^2}$ with $q = e$, $\phi = 90°$, and the given values for v and r. By the right-hand rule, the direction is along the $+z$ axis. The result is $\vec{B} = 3.20\times10^{-15}\ \text{T}\ \hat{i}$.

(b) At (0, 0, 2.00 mm). The approach is the same as in (a) except r = 2.00 mm. The cross product is in the $-y$-direction, so we get $\vec{B} = -8.00\times10^{-16}\ \text{T}\ \hat{j}$.

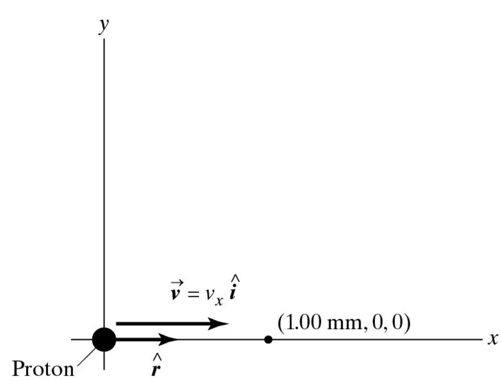

Figure VP28.2.1b

(c) At (1.00 mm, 0, 0). As Fig. VP28.2.1b shows, $\phi = 0$, so $B = 0$.

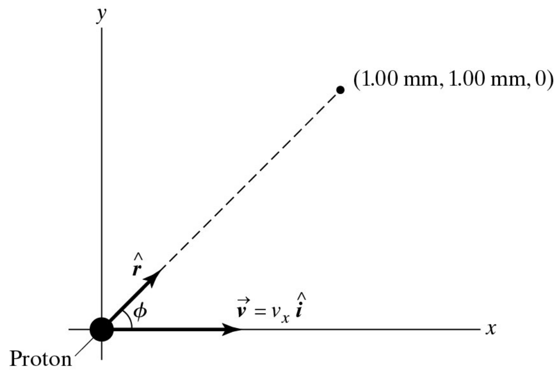

Figure VP28.2.1c

(d) At (1.00 mm, 1.00 mm, 0). See Fig. VP28.2.1c. Use $B = \dfrac{\mu_0}{4\pi}\dfrac{qv\sin\phi}{r^2}$ with $\phi = 45.0°$ and $r = \sqrt{2}$ mm. The direction is along the $+z$-axis, so $\vec{B} = 1.13\times10^{-15}\ \text{T}\ \hat{k}$.

EVALUATE: As we see, the magnetic fields produced by individual charges are very small.

VP28.2.2. **IDENTIFY:** We want to find the magnetic force between two moving charged particles.

SET UP: Our target variable is the force that the proton exerts on the electron and that the electron exerts on the proton. $\vec{B} = \dfrac{\mu_0}{4\pi}\dfrac{q\vec{v}\times\hat{r}}{r^2}$, $B = \dfrac{\mu_0}{4\pi}\dfrac{qv\sin\phi}{r^2}$, $\vec{F} = q\vec{v}\times\vec{B}$, $F = |q|vB\sin\phi$.

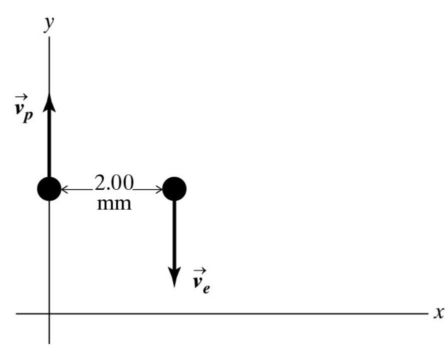

Figure VP28.2.2

EXECUTE: **(a)** We want the force that the proton exerts on the electron. See Fig. VP28.2.2. $\vec{F}_{\text{on e}} = q_e\vec{v}_e\times\vec{B}_p$, where $\vec{B}_p = \dfrac{\mu_0}{4\pi}\dfrac{q_p\vec{v}_p\times\hat{r}}{r^2}$. Putting these quantities together gives $F_{\text{on e}} = (ev)\left(\dfrac{\mu_0 ve}{4\pi r^2}\right) = \dfrac{\mu_0}{4\pi}\dfrac{v^2e^2}{r^2}$. The field due to the proton points in the $-z$-direction by the right-hand rule. The velocity of the electron is in the $-y$-direction, so the force on the electron (which is *negatively charged*) is in the $-x$-direction. Using $r = 2.00$ mm, $\phi = 90°$, and $v_e = 420$ km/s gives $F_{\text{on e}} = 1.13\times10^{-28}$ N in the $-x$-direction, or $-\hat{i}$ direction.

(b) We want the force that the electron exerts on the proton. Follow exactly the same approach as in part (a). The force on the proton has the same magnitude as the force on the electron but it points in the opposite direction. So $F_{\text{on p}} = 1.13\times10^{-28}$ N in the $+\hat{i}$ direction.

EVALUATE: The two forces are equal but opposite, which agrees with Newton's third law (action-reaction). Also note that the two charges attract each other, but this is *not* the same as the Coulomb force. That force would be $F = \dfrac{1}{4\pi \epsilon_0}\dfrac{e^2}{r^2} = \; = 2.30\times 10^{-22}$ N, which is roughly 2 million times stronger than the magnetic attraction.

VP28.2.3. **IDENTIFY:** We are looking at the magnetic field due to a very small wire segment.

SET UP: $d\vec{B} = \dfrac{\mu_0}{4\pi}\dfrac{Id\hat{l}\times\hat{r}}{r^2}$.

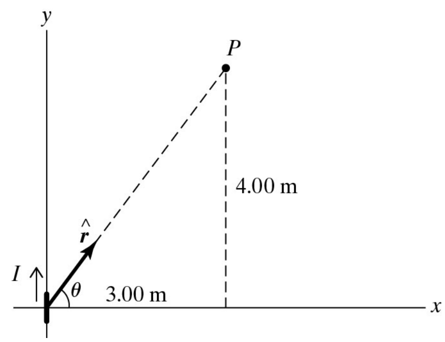

Figure VP28.2.3

EXECUTE: **(a)** We want $\hat{r}$. See Fig. VP28.2.3. We see that $\theta = \arctan(4.00/3.00) = 53.13°$. Also $|\hat{r}| = 1$. So $\hat{r} = r\cos\theta\,\hat{i} + r\sin\theta\,\hat{j} = \; = \cos 53.13°\,\hat{i} + \sin 53.13°\,\hat{j} = \; 0.600\,\hat{i} + 0.800\,\hat{j}$.

(b) We want $\vec{B}$. Use $d\vec{B} = \dfrac{\mu_0}{4\pi}\dfrac{Id\hat{l}\times\hat{r}}{r^2}$. $d\vec{l} = dl\hat{j} = (0.00200\text{ m})\hat{j}$. Using $\hat{r}$ and $d\vec{l}$ and taking the cross product with the given numbers, we get $d\vec{B} = -2.88\times 10^{-11}\text{ T}\,\hat{k}$.

EVALUATE: This is a very small field, but the wire segment is also very small.

VP28.2.4. **IDENTIFY:** We want to find the magnetic force on a moving charged particle due to a tiny current-carrying wire segment.

SET UP: $d\vec{B} = \dfrac{\mu_0}{4\pi}\dfrac{Id\hat{l}\times\hat{r}}{r^2}$, $\vec{F} = q\vec{v}\times\vec{B}$, $F = |q|vB\sin\phi$. Sketch the situation as in Fig. VP28.2.4.

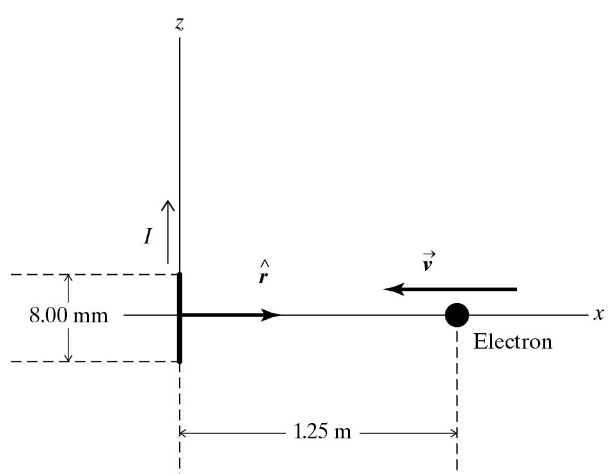

Figure VP28.2.4

EXECUTE: $\vec{F}_{\text{one}} = q_e \vec{v}_e \times \vec{B}_{\text{wire}}$. At the location of the electron, the field due to the wire points into the paper, which is in the –y-direction. Therefore the magnetic force on the electron is in the +z-direction by the right-hand rule (remember that the electron is *negative*). Combining $F = |q|vB\sin\phi$ and $d\vec{B} = \dfrac{\mu_0}{4\pi}\dfrac{Id\vec{l}\times\hat{r}}{r^2}$ gives $\vec{F}_{\text{one}} = \dfrac{\mu_0}{4\pi}\dfrac{evdl}{r^2}\hat{k}$. Using the given numbers, we have $\vec{F} = 9.83\times 10^{-23}\text{ N }\hat{k}$.

EVALUATE: Magnetic forces are typically very small compared to electrostatic forces, but not always.

VP28.5.1. IDENTIFY and **SET UP:** We want to find the magnetic field due to a long current-carrying wire. $B = \dfrac{\mu_0}{2\pi}\dfrac{I}{r}$.

EXECUTE: Solve for I and use the given numbers. $I = \dfrac{2\pi rB}{\mu_0} = 2.24\text{ A}$.

EVALUATE: This result is typical of many household currents, so it is clear that they produce small magnetic fields. This one is about 30 μT.

VP28.5.2. IDENTIFY: We want the net magnetic field $\vec{B}$ produced at various points by two long current-carrying wires.

SET UP: $B = \dfrac{\mu_0}{2\pi}\dfrac{I}{r}$. The net field is the vector sum of the two individual fields $\vec{B}_1$ and $\vec{B}_4$. Let the paper be the xy-plane with the currents coming out of the paper, as shown in Fig. VP28.5.2.

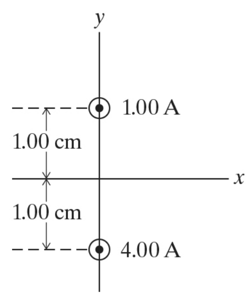

Figure VP28.5.2

EXECUTE: **(a)** At (0, 0, 0). This point is midway between the wires. $\vec{B}_1$ points in the +x-direction and $\vec{B}_4$ points in the –x-direction. $B = B_1 - B_4$. Using $B = \dfrac{\mu_0}{2\pi}\dfrac{I}{r}$ we get $B = \dfrac{\mu_0}{2\pi r}(I_1 - I_4)$. Using the given numbers gives $\vec{B} = -6.00\times 10^{-5}\text{ T }\hat{i}$.

(b) At (0, 2.00 cm, 0). This point is on the y-axis 1.00 cm above the 1.00 A wire. Both fields point in the –x-direction. $B = B_1 + B_4$. Using $B = \dfrac{\mu_0}{2\pi}\dfrac{I}{r}$ for each wire gives $B = \dfrac{\mu_0}{2\pi}\left(\dfrac{I_1}{r_1} + \dfrac{I_4}{r_4}\right)$ which gives $\vec{B} = -4.67\times 10^{-5}\text{ T }\hat{i}$.

(c) At (0, –2.00 cm, 0). This point is 1.00 cm below the 4.00 A wire. Both fields point in the +x-direction, so $B = B_1 + B_4$ and $B = \dfrac{\mu_0}{2\pi}\left(\dfrac{I_1}{r_1} + \dfrac{I_4}{r_4}\right)$. Using the numbers gives $\vec{B} = 8.67\times 10^{-5}\text{ T }\hat{i}$.

EVALUATE: The net field in (c) is the greatest of the three since this point is closer to the larger current, so this is a reasonable result.

VP28.5.3. **IDENTIFY:** We use the magnetic field due to a very long current-carrying wire.

SET UP: $B = \dfrac{\mu_0}{2\pi}\dfrac{I}{r}$. The net field $\vec{B}$ is the vector sum of the two individual fields $\vec{B}_1$ and $\vec{B}_2$. We know $I_1 = 2.00$ A and the net field, and we want to find I_2. See Fig. VP28.5.3.

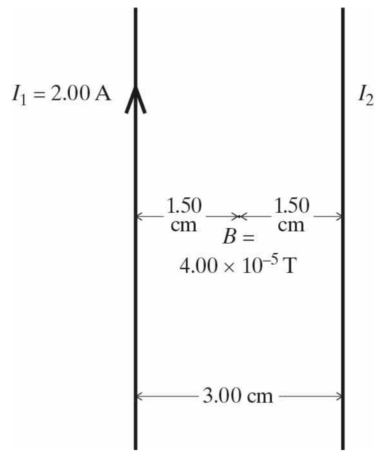

Figure VP28.5.3

EXECUTE: **(a)** Both currents are in the same direction. Their magnetic fields point in opposite directions in the region between the wires, so $B = B_2 - B_1$. Using $B = \dfrac{\mu_0}{2\pi}\dfrac{I}{r}$ for each field and solving for I_2 gives $I_2 = \dfrac{Br}{\mu_0/2\pi} + I_1$. Using $r = 1.50$ cm and the other given numbers, we get $I_2 = 5.00$ A.

(b) The currents are in opposite directions. Now both fields point into the paper, so $B = B_2 + B_1$. Using $B = \dfrac{\mu_0}{2\pi}\dfrac{I}{r}$ for each field and solving for I_2 gives $I_2 = \dfrac{Br}{\mu_0/2\pi} - I_1$. Using $r = 1.50$ cm and the other given numbers, gives $I_2 = 1.00$ A.

EVALUATE: A clear sketch is important to help decided which way the fields point and if their magnitudes should be added or subtracted.

VP28.5.4. **IDENTIFY:** This problem involves the magnetic force between two long current-carrying wires.

SET UP: $F/L = \dfrac{\mu_0}{2\pi}\dfrac{I_1 I_2}{r}$. The target variable is I_2.

EXECUTE: The wires attract each other so their currents must be in the *same* direction, which is *upward*. Solving $F/L = \dfrac{\mu_0}{2\pi}\dfrac{I_1 I_2}{r}$ for I_2 gives $I_2 = \dfrac{r(F/L)}{I_1(\mu_0/2\pi)}$. Using the given quantities with $r = 0.900$ m gives $I_2 = 3.29\times 10^4$ A.

EVALUATE: Like currents (i.e. in the same direction) attract while unlike currents (opposite direction) repel.

VP28.10.1. **IDENTIFY:** This problem deals with the magnetic field inside a current-carrying conductor.

SET UP: The target variable is the magnetic field at various distances from the axis. Inside $B = \dfrac{\mu_0 I}{2\pi}\dfrac{r}{R^2}$ and outside $B = \dfrac{\mu_0}{2\pi}\dfrac{I}{r}$.

EXECUTE: **(a)** Inside: Use $B=\frac{\mu_0 I}{2\pi}\frac{r}{R^2}$ with the given quantities, giving I = 4.94 μT.

(b) At the surface: Use either formula with $r = R$. $B=\frac{\mu_0}{2\pi}\frac{I}{R}$ = 8.89 μT.

(c) Outside: Use $B=\frac{\mu_0}{2\pi}\frac{I}{r}$ = 6.67 μT.

EVALUATE: Using $B=\frac{\mu_0 I}{2\pi}\frac{r}{R^2}$ at the surface gives $B=\frac{\mu_0 I}{2\pi}\frac{R}{R^2}=\frac{\mu_0 I}{2\pi R}$, which is the equation for outside the cylinder evaluated when $r = R$. Note that B is largest at the *surface* of the cylinder.

VP28.10.2. **IDENTIFY:** We are dealing with the magnetic field produced by a hollow cylindrical conductor. We will need to use Ampere's law to find the field.

SET UP: Ampere's law is $\oint \vec{B}\cdot d\hat{l}=\mu_0 I_{\text{encl}}$, $J = I/A$. We want to find B at several locations.

EXECUTE: **(a)** For $r < R_1$: Use $\oint \vec{B}\cdot d\hat{l}=\mu_0 I_{\text{encl}}$ and as an integration path use a circle of radius $r < R_1$. From Ampere's law this gives $B(2\pi r)=\mu_0 I_{\text{encl}}=0$, which means that $B = 0$

For $R_1 < r < R_2$: Use the same path as above except $R_1 < r < R_2$. $I_{\text{encl}} = JA_{\text{encl}} =$ $J\left(\pi r^2-\pi R_1^2\right)=J\pi\left(r^2-R_1^2\right)$. Ampere's law becomes $B(2\pi r)=\mu_0 J\pi\left(r^2-R_1^2\right)$. This gives

$B=\frac{\mu_0 J}{2r}\left(r^2-R_1^2\right)$.

For $r > R_2$: Use the same path as before except $r > R_2$. $I_{\text{encl}}=J\pi\left(R_2^2-R_1^2\right)$, so

$B(2\pi r)=\mu_0 J\pi\left(R_2^2-R_1^2\right)$. This gives $B=\frac{\mu_0 J\left(R_2^2-R_1^2\right)}{2r}$.

(b) Where is B a maximum? For $r < R_1$, $B = 0$ so it can't be in that region. For $r > R_2$, B decreases as r increases so it cannot be outside. Investigate $R_1 < r < R_2$. For a maximum, $dB/dr = 0$. Using $B=\frac{\mu_0 J}{2r}\left(r^2-R_1^2\right)$, $\frac{dB}{dr}=\frac{\mu_0 J}{2}\left(1+\frac{R_1^2}{r^2}\right)=0$. There are no real solutions to this equation, so there is no *relative* maximum in this region. But at $r = 0$, $B = 0$ and at $r = R_2$, $B=\frac{\mu_0 J}{2}\left(R_2-\frac{R_1^2}{R_2}\right)$ which is greater than zero. So in this region B keeps increasing as r increases and reaches its maximum value at $r = R_2$. For $r > R_2$, B decreases with r, so B_{max} occurs at $r = R_2$.

EVALUATE: Our result is physically reasonable. As r increases from R_1 to R_2, more and more current contributes to the field, so B increases.

VP28.10.3. **IDENTIFY** and **SET UP:** We have the magnetic field inside a solenoid. $B=\mu_0 nI$. The current is the target variable.

EXECUTE: Solve for I and use the given numbers. $I=\frac{B}{\mu_0 n}$ = 3.18 A.

EVALUATE: This is a reasonable amount of current.

VP28.10.4. **IDENTIFY** and **SET UP:** We have a toroidal solenoid. $B=\frac{\mu_0 NI}{2\pi r}$.

EXECUTE: **(a)** We want N. Solve for N and use the given values. $N=\frac{Br}{I(\mu_0/2\pi)}$ = 833 turns.

(b) We want to find the maximum and minimum field inside the toroidal solenoid. $B_{\max}$ occurs at $r = 6.00$ cm. Evaluate $B = \dfrac{\mu_0 NI}{2\pi r}$ when $r = 6.00$ cm, giving $B_{\max} = 2.33$ mT. $B_{\min}$ occurs when $r = 8.00$ cm. Using this value gives $B_{\min} = 1.75$ mT.

EVALUATE: For an ideal toroidal solenoid, $B = 0$ outisde of it ($r > 8.00$ cm) and inside the opening ($r < 6.00$ cm). For a *real* toroidal solenoid this is not quite true.

28.1. IDENTIFY and **SET UP:** Use $\vec{B} = \dfrac{\mu_0}{4\pi}\dfrac{q\vec{v}\times\hat{r}}{r^2}$ to calculate $\vec{B}$ at each point.

$\vec{B} = \dfrac{\mu_0}{4\pi}\dfrac{q\vec{v}\times\hat{r}}{r^2} = \dfrac{\mu_0}{4\pi}\dfrac{q\vec{v}\times\vec{r}}{r^3}$, since $\hat{r} = \dfrac{\vec{r}}{r}$.

$\vec{v} = (8.00\times 10^6\ \text{m/s})\hat{j}$ and $\vec{r}$ is the vector from the charge to the point where the field is calculated.

EXECUTE: (a) $\vec{r} = (0.500\ \text{m})\hat{i},\ r = 0.500\ \text{m}$.

$\vec{v}\times\vec{r} = vr\hat{j}\times\hat{i} = -vr\hat{k}$.

$\vec{B} = -\dfrac{\mu_0}{4\pi}\dfrac{qv}{r^2}\hat{k} = -(1\times 10^{-7}\ \text{T}\cdot\text{m/A})\dfrac{(6.00\times 10^{-6}\ \text{C})(8.00\times 10^6\ \text{m/s})}{(0.500\ \text{m})^2}\hat{k}$.

$\vec{B} = -(1.92\times 10^{-5}\ \text{T})\hat{k}$.

(b) $\vec{r} = -(0.500\ \text{m})\hat{j},\ r = 0.500\ \text{m}$.

$\vec{v}\times\vec{r} = -vr\hat{j}\times\hat{j} = 0$ and $\vec{B} = 0$.

(c) $\vec{r} = (0.500\ \text{m})\hat{k},\ r = 0.500\ \text{m}$.

$\vec{v}\times\vec{r} = vr\hat{j}\times\hat{k} = vr\hat{i}$.

$\vec{B} = (1\times 10^{-7}\ \text{T}\cdot\text{m/A})\dfrac{(6.00\times 10^{-6}\ \text{C})(8.00\times 10^6\ \text{m/s})}{(0.500\ \text{m})^2}\hat{i} = +(1.92\times 10^{-5}\ \text{T})\hat{i}$.

(d) $\vec{r} = -(0.500\ \text{m})\hat{j} + (0.500\ \text{m})\hat{k},\ r = \sqrt{(0.500\ \text{m})^2 + (0.500\ \text{m})^2} = 0.7071\ \text{m}$.

$\vec{v}\times\vec{r} = v(0.500\ \text{m})(-\hat{j}\times\hat{j} + \hat{j}\times\hat{k}) = (4.00\times 10^6\ \text{m}^2/\text{s})\hat{i}$.

$\vec{B} = (1\times 10^{-7}\ \text{T}\cdot\text{m/A})\dfrac{(6.00\times 10^{-6}\ \text{C})(4.00\times 10^6\ \text{m}^2/\text{s})}{(0.7071\ \text{m})^3}\hat{i} = +(6.79\times 10^{-6}\ \text{T})\hat{i}$.

EVALUATE: At each point $\vec{B}$ is perpendicular to both $\vec{v}$ and $\vec{r}$. $B = 0$ along the direction of $\vec{v}$.

28.2. IDENTIFY: A moving charge creates a magnetic field as well as an electric field.

SET UP: The magnetic field caused by a moving charge is $B = \dfrac{\mu_0}{4\pi}\dfrac{qv\sin\phi}{r^2}$, and its electric field is

$E = \dfrac{1}{4\pi\epsilon_0}\dfrac{e}{r^2}$ since $q = e$.

EXECUTE: Substitute the appropriate numbers into the above equations.

$$B = \frac{\mu_0}{4\pi}\frac{qv\sin\phi}{r^2} = \frac{4\pi\times 10^{-7}\ \text{T}\cdot\text{m/A}}{4\pi}\frac{(1.60\times 10^{-19}\text{C})(2.2\times 10^6\text{m/s})\sin 90^\circ}{(5.3\times 10^{-11}\text{m})^2} = 13\ \text{T},\ \text{out of the page.}$$

$$E = \frac{1}{4\pi_0}\frac{e}{r^2} = \frac{(9.00\times 10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)(1.60\times 10^{-19}\,\text{C})}{(5.3\times 10^{-11}\text{m})^2} = 5.1\times 10^{11}\,\text{N/C},\ \text{toward the electron.}$$

EVALUATE: There are enormous fields within the atom!

28.3. IDENTIFY: A moving charge creates a magnetic field.

SET UP: The magnetic field due to a moving charge is $B = \dfrac{\mu_0}{4\pi}\dfrac{qv\sin\phi}{r^2}$.

EXECUTE: Substituting numbers into the above equation gives

(a) $B = \dfrac{\mu_0}{4\pi}\dfrac{qv\sin\phi}{r^2} = \dfrac{4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}}{4\pi}\dfrac{(1.6\times10^{-19}\text{C})(3.0\times10^7\,\text{m/s})\sin30°}{(2.00\times10^{-6}\text{m})^2}.$

$B = 6.00\times10^{-8}$ T, out of the paper, and it is the same at point B.

(b) $B = (1.00\times10^{-7}\ \text{T}\cdot\text{m/A})(1.60\times10^{-19}\ \text{C})(3.00\times10^7\ \text{m/s})/(2.00\times10^{-6}\ \text{m})^2.$

$B = 1.20\times10^{-7}$ T, out of the page.

(c) $B = 0$ T since $\sin(180°) = 0$.

EVALUATE: Even at high speeds, these charges produce magnetic fields much less than the earth's magnetic field.

28.4. **IDENTIFY:** Both moving charges produce magnetic fields, and the net field is the vector sum of the two fields.

SET UP: Both fields point out of the paper, so their magnitudes add, giving

$$B = B_{\text{alpha}} + B_{\text{el}} = \frac{\mu_0 v}{4\pi r^2}(e\sin40° + 2e\sin140°).$$

EXECUTE: Factoring out an e and putting in the numbers gives

$$B = \frac{4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}}{4\pi}\frac{(1.60\times10^{-19}\ \text{C})(2.50\times10^5\ \text{m/s})}{(8.65\times10^{-9}\ \text{m})^2}(\sin40° + 2\sin140°).$$

$B = 1.03\times10^{-4}\ \text{T} = 0.103$ mT, out of the page.

EVALUATE: At distances very close to the charges, the magnetic field is strong enough to be important.

28.5. **IDENTIFY:** Apply $\vec{B} = \dfrac{\mu_0}{4\pi}\dfrac{q\vec{v}\times\vec{r}}{r^3}$.

SET UP: Since the charge is at the origin, $\vec{r} = x\hat{i} + y\hat{j} + z\hat{k}$.

EXECUTE: **(a)** $\vec{v} = v\vec{i}$, $\vec{r} = r\hat{i}$; $\vec{v}\times\vec{r} = 0$, $B = 0$.

(b) $\vec{v} = v\hat{i}$, $\vec{r} = r\hat{j}$; $\vec{v}\times\vec{r} = vr\hat{k}$, $r = 0.500$ m.

$$B = \left(\frac{\mu_0}{4\pi}\right)\frac{|q|v}{r^2} = \frac{(1.0\times10^{-7}\ \text{N}\cdot\text{s}^2/\text{C}^2)(4.80\times10^{-6}\ \text{C})(6.80\times10^5\ \text{m/s})}{(0.500\ \text{m})^2} = 1.31\times10^{-6}\ \text{T}.$$

q is negative, so $\vec{B} = -(1.31\times10^{-6}\ \text{T})\hat{k}$.

(c) $\vec{v} = v\hat{i}$, $\vec{r} = (0.500\ \text{m})(\hat{i} + \hat{j})$; $\vec{v}\times\vec{r} = (0.500\ \text{m})v\hat{k}$, $r = 0.7071$ m.

$$B = \left(\frac{\mu_0}{4\pi}\right)\left(|q||\vec{v}\times\vec{r}|/r^3\right) = \frac{(1.0\times10^{-7}\ \text{N}\cdot\text{s}^2/\text{C}^2)(4.80\times10^{-6}\ \text{C})(0.500\ \text{m})(6.80\times10^5\ \text{m/s})}{(0.7071\ \text{m})^3}.$$

$B = 4.62\times10^{-7}$ T. $\vec{B} = -(4.62\times10^{-7}\ \text{T})\hat{k}$.

(d) $\vec{v} = v\hat{i}$, $\vec{r} = r\hat{k}$; $\vec{v}\times\vec{r} = -vr\hat{j}$, $r = 0.500$ m.

$$B = \left(\frac{\mu_0}{4\pi}\right)\frac{|q|v}{r^2} = \frac{(1.0\times10^{-7}\ \text{N}\cdot\text{s}^2/\text{C}^2)(4.80\times10^{-6}\ \text{C})(6.80\times10^5\ \text{m/s})}{(0.500\ \text{m})^2} = 1.31\times10^{-6}\ \text{T}.$$

$\vec{B} = (1.31\times10^{-6}\ \text{T})\hat{j}$.

EVALUATE: In each case, $\vec{B}$ is perpendicular to both $\vec{r}$ and $\vec{v}$.

28.6. IDENTIFY: Apply $\vec{B} = \dfrac{\mu_0}{4\pi}\dfrac{q\vec{v}\times\vec{r}}{r^3}$. For the magnetic force, apply the results of Example 28.1, except here the two charges and velocities are different.

SET UP: In part (a), $r = d$ and $\vec{r}$ is perpendicular to $\vec{v}$ in each case, so $\dfrac{|\vec{v}\times\vec{r}|}{r^3} = \dfrac{v}{d^2}$. For calculating the force between the charges, $r = 2d$.

EXECUTE: **(a)** $B_{\text{total}} = B + B' = \dfrac{\mu_0}{4\pi}\left(\dfrac{qv}{d^2} + \dfrac{q'v'}{d^2}\right)$.

$$B = \frac{\mu_0}{4\pi}\left(\frac{(8.0\times10^{-6}\ \text{C})(4.5\times10^6\ \text{m/s})}{(0.120\ \text{m})^2} + \frac{(3.0\times10^{-6}\ \text{C})(9.0\times10^6\ \text{m/s})}{(0.120\ \text{m})^2}\right) = 4.38\times10^{-4}\ \text{T}.$$

The direction of $\vec{B}$ is into the page.

(b) Following Example 28.1 we can find the magnetic force between the charges:

$$F_B = \frac{\mu_0}{4\pi}\frac{qq'vv'}{r^2} = (10^{-7}\ \text{T}\cdot\text{m/A})\frac{(8.00\times10^{-6}\ \text{C})(3.00\times10^{-6}\ \text{C})(4.50\times10^6\ \text{m/s})(9.00\times10^6\ \text{m/s})}{(0.240\ \text{m})^2}.$$

$F_B = 1.69\times10^{-3}$ N. The force on the upper charge points up and the force on the lower charge points down. The Coulomb force between the charges is

$F_C = k\dfrac{q_1q_2}{r^2} = (8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)\dfrac{(8.0\times10^{-6}\ \text{C})(3.0\times10^{-6}\ \text{C})}{(0.240\ \text{m})^2} = 3.75\ \text{N}$. The force on the upper charge points up and the force on the lower charge points down. The ratio of the Coulomb force to the magnetic force is $\dfrac{F_C}{F_B} = \dfrac{c^2}{v_1v_2} = \dfrac{3.75\ \text{N}}{1.69\times10^{-3}\ \text{N}} = 2.22\times10^3$; the Coulomb force is much larger.

(c) The magnetic forces are reversed in direction when the direction of only one velocity is reversed but the magnitude of the force is unchanged.

EVALUATE: When two charges have the same sign and move in opposite directions, the force between them is repulsive. When two charges of the same sign move in the same direction, the force between them is attractive.

28.7. IDENTIFY: We want the magnetic field due to a moving charge.

SET UP: $\vec{B} = \dfrac{\mu_0}{4\pi}\dfrac{q\vec{v}\times\hat{r}}{r^2}$, $B = \dfrac{\mu_0}{4\pi}\dfrac{qv\sin\phi}{r^2}$.

EXECUTE: **(a)** The unit vector points from the proton to point *P*, which is to the left.

(b) We want *B*. $B = \dfrac{\mu_0}{4\pi}\dfrac{qv\sin\phi}{r^2}$ and ϕ is either 0 or 180°. In either case $\sin\phi = 0$, so $B = 0$.

(c) We want $\vec{B}$. $\phi = 90°$ and $q = e$. Using the given quantities $B = \dfrac{\mu_0}{4\pi}\dfrac{ev}{r^2} = 1.21$ pT. By the right-hand rule, the cross product in $\vec{B} = \dfrac{\mu_0}{4\pi}\dfrac{q\vec{v}\times\hat{r}}{r^2}$ is out of the page, so $\vec{B}$ is out of the page.

(d) For an electron, only the charge and mass are different, so *B* would be the same but the direction would be reversed. So $B = 1.21$ pT, into the page.

EVALUATE: The magnetic field due to a negative charge is opposite to the direction of $\vec{v}\times\hat{r}$.

28.8. IDENTIFY: Both moving charges create magnetic fields, and the net field is the vector sum of the two. The magnetic force on a moving charge is $F_{\text{mag}} = qvB\sin\phi$ and the electrical force obeys Coulomb's law.

SET UP: The magnetic field due to a moving charge is $B = \dfrac{\mu_0}{4\pi}\dfrac{qv\sin\phi}{r^2}$.

EXECUTE: **(a)** Both fields are into the page, so their magnitudes add,

giving $B = B_e + B_p = \dfrac{\mu_0}{4\pi}\left(\dfrac{ev}{r_e^2} + \dfrac{ev}{r_p^2}\right)\sin 90°.$

$$B = \frac{\mu_0}{4\pi}(1.60\times10^{-19}\,\text{C})(735{,}000\ \text{m/s})\left[\frac{1}{(5.00\times10^{-9}\,\text{m})^2} + \frac{1}{(4.00\times10^{-9}\,\text{m})^2}\right].$$

$$B = 1.21\times10^{-3}\ \text{T} = 1.21\ \text{mT, into the page.}$$

(b) Using $B = \dfrac{\mu_0}{4\pi}\dfrac{qv\sin\phi}{r^2}$, where $r = \sqrt{41}$ nm and $\phi = 180° - \arctan(5/4) = 128.7°$, we get

$$B = \frac{4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}}{4\pi}\frac{(1.6\times10^{-19}\,\text{C})(735{,}000\ \text{m/s})\sin128.7°}{(\sqrt{41}\times10^{-9}\,\text{m})^2} = 2.24\times10^{-4}\ \text{T, into the page.}$$

(c) $F_{\text{mag}} = qvB\sin90° = (1.60\times10^{-19}\ \text{C})(735{,}000\ \text{m/s})(2.24\times10^{-4}\ \text{T}) = 2.63\times10^{-17}\ \text{N}$, in the $+x$-direction.

$$F_{\text{elec}} = (1/4\pi\epsilon_0)e^2/r^2 = \frac{(9.00\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)(1.60\times10^{-19}\,\text{C})^2}{(\sqrt{41}\times10^{-9}\,\text{m})^2} = 5.62\times10^{-12}\ \text{N, at } 129°$$

counterclockwise from the $+x$-axis.

EVALUATE: The electric force is over 200,000 times as strong as the magnetic force.

28.9. **IDENTIFY:** A current segment creates a magnetic field.

SET UP: The law of Biot and Savart gives $dB = \dfrac{\mu_0}{4\pi}\dfrac{Idl\sin\phi}{r^2}$.

EXECUTE: Applying the law of Biot and Savart gives

(a) $dB = \dfrac{4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}}{4\pi}\dfrac{(10.0\ \text{A})(0.00110\ \text{m})\sin90°}{(0.0500\ \text{m})^2} = 4.40\times10^{-7}\ \text{T}$, out of the paper.

(b) The same as above, except $r = \sqrt{(5.00\ \text{cm})^2 + (14.0\ \text{cm})^2}$ and $\phi = \arctan(5/14) = 19.65°$, giving $dB = 1.67\times10^{-8}\ \text{T}$, out of the page.

(c) $dB = 0$ since $\phi = 0°$.

EVALUATE: This is a very small field, but it comes from a very small segment of current.

28.10. **IDENTIFY:** Apply the Biot-Savart law.

SET UP: Apply $d\vec{B} = \dfrac{\mu_0}{4\pi}\dfrac{q\,d\vec{l}\times\vec{r}}{r^3}$. $r = \sqrt{(-0.730\ \text{m})^2 + (0.390\ \text{m})^2} = 0.8276\ \text{m}$.

EXECUTE:

$d\vec{l}\times\vec{r} = [0.500\times10^{-3}\ \text{m}]\hat{j}\times[(-0.730\ \text{m})\hat{i} + (0.390\ \text{m})\hat{k}] = (+3.65\times10^{-4}\ \text{m}^2)\hat{k} + (+1.95\times10^{-4}\ \text{m}^2)\hat{i}.$

$$d\vec{B} = (1.00\times10^{-7}\ \text{T}\cdot\text{m/A})\frac{5.40\ \text{A}}{(0.8276\ \text{m})^3}[(3.65\times10^{-4}\ \text{m}^2)\hat{k} + (1.95\times10^{-4}\ \text{m}^2)\hat{i}].$$

$$d\vec{B} = (1.86\times10^{-10}\ \text{T})\hat{i} + (3.48\times10^{-10}\ \text{T})\hat{k}.$$

EVALUATE: The magnetic field lies in the xz-plane.

28.11. **IDENTIFY and SET UP:** The magnetic field produced by an infinitesimal current element is given by $d\vec{B} = \dfrac{\mu_0}{4\pi}\dfrac{I\vec{l}\times\hat{r}}{r^2}$.

As in Example 28.2, use $d\vec{B} = \dfrac{\mu_0}{4\pi}\dfrac{I\vec{l}\times\hat{r}}{r^2}$ for the finite 0.500-mm segment of wire since the $\Delta l = 0.500\text{-mm}$ length is much smaller than the distances to the field points.

$$\vec{B} = \frac{\mu_0}{4\pi}\frac{I\Delta\vec{l} \times \hat{r}}{r^2} = \frac{\mu_0}{4\pi}\frac{I\Delta\vec{l} \times \vec{r}}{r^3}$$

I is in the $+z$-direction, so $\Delta\vec{l} = (0.500\times10^{-3}\ \text{m})\hat{k}$.

EXECUTE: **(a)** The field point is at $x = 2.00$ m, $y = 0$, $z = 0$ so the vector $\vec{r}$ from the source point (at the origin) to the field point is $\vec{r} = (2.00\ \text{m})\hat{i}$.

$\Delta\vec{l} \times \vec{r} = (0.500\times10^{-3}\ \text{m})(2.00\ \text{m})\hat{k}\times\hat{i} = +(1.00\times10^{-3}\ \text{m}^2)\hat{j}$.

$$\vec{B} = \frac{(1\times10^{-7}\ \text{T}\cdot\text{m/A})(4.00\ \text{A})(1.00\times10^{-3}\ \text{m}^2)}{(2.00\ \text{m})^3}\hat{j} = (5.00\times10^{-11}\ \text{T})\hat{j}.$$

(b) $\vec{r} = (2.00\ \text{m})\hat{j}$, $r = 2.00$ m.

$\Delta\vec{l} \times \vec{r} = (0.500\times10^{-3}\ \text{m})(2.00\ \text{m})\hat{k}\times\hat{j} = -(1.00\times10^{-3}\ \text{m}^2)\hat{i}$.

$$\vec{B} = \frac{(1\times10^{-7}\ \text{T}\cdot\text{m/A})(4.00\ \text{A})(-1.00\times10^{-3}\ \text{m}^2)}{(2.00\ \text{m})^3}\hat{i} = -(5.00\times10^{-11}\ \text{T})\hat{i}.$$

(c) $\vec{r} = (2.00\ \text{m})(\hat{i}+\hat{j})$, $r = \sqrt{2}(2.00\ \text{m})$.

$\Delta\vec{l} \times \vec{r} = (0.500\times10^{-3}\ \text{m})(2.00\ \text{m})\hat{k}\times(\hat{i}+\hat{j}) = (1.00\times10^{-3}\ \text{m}^2)(\hat{j}-\hat{i})$.

$$\vec{B} = \frac{(1\times10^{-7}\ \text{T}\cdot\text{m/A})(4.00\ \text{A})(1.00\times10^{-3}\ \text{m}^2)}{\left[\sqrt{2}(2.00\ \text{m})\right]^3}(\hat{j}-\hat{i}) = (-1.77\times10^{-11}\ \text{T})(\hat{i}-\hat{j}).$$

(d) $\vec{r} = (2.00\ \text{m})\hat{k}$, $r = 2.00$ m.

$\Delta\vec{l} \times \vec{r} = (0.500\times10^{-3}\ \text{m})(2.00\ \text{m})\hat{k}\times\hat{k} = 0$; $\vec{B} = 0$.

EVALUATE: At each point $\vec{B}$ is perpendicular to both $\vec{r}$ and $\Delta\vec{l}$. $B = 0$ along the length of the wire.

28.12. **IDENTIFY:** A current segment creates a magnetic field.

SET UP: The law of Biot and Savart gives $dB = \dfrac{\mu_0}{4\pi}\dfrac{Idl\sin\phi}{r^2}$.

Both fields are into the page, so their magnitudes add.

EXECUTE: Applying the law of Biot and Savart for the 12.0-A current

gives $dB = \dfrac{4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}}{4\pi}\dfrac{(12.0\ \text{A})(0.00150\ \text{m})\left(\dfrac{2.50\ \text{cm}}{8.00\ \text{cm}}\right)}{(0.0800\ \text{m})^2} = 8.79\times10^{-8}\ \text{T}.$

The field from the 24.0-A segment is twice this value, so the total field is 2.64×10^{-7} T, into the page.

EVALUATE: The rest of each wire also produces field at P. We have calculated just the field from the two segments that are indicated in the problem.

28.13. **IDENTIFY:** A current segment creates a magnetic field.

SET UP: The law of Biot and Savart gives $dB = \dfrac{\mu_0}{4\pi}\dfrac{Idl\sin\phi}{r^2}$. Both fields are into the page, so their magnitudes add.

EXECUTE: Applying the Biot and Savart law, where $r = \frac{1}{2}\sqrt{(3.00\ \text{cm})^2 + (3.00\ \text{cm})^2} = 2.121\ \text{cm}$, we have $dB = 2\dfrac{4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}}{4\pi}\dfrac{(28.0\ \text{A})(0.00200\ \text{m})\sin 45.0^\circ}{(0.02121\ \text{m})^2} = 1.76\times10^{-5}\ \text{T}$, into the paper.

EVALUATE: Even though the two wire segments are at right angles, the magnetic fields they create are in the same direction.

28.14. **IDENTIFY:** This problem involves the magnetic field due to a long wire and the force on a charge moving in that field.

SET UP: $B = \frac{\mu_0}{2\pi}\frac{I}{r}$, $\vec{F} = q\vec{v}\times\vec{B}$, $\sum F_x = ma_x$, $\sum F_y = ma_y$. We want the velocity components of the particle. The given acceleration is so large that we can neglect the effects of gravity.

EXECUTE: The magnetic field at the location of the particle (call this point P) points in the $+z$-direction. At that point we use the given quantities and $B = \frac{\mu_0}{2\pi}\frac{I}{r}$ to find $B = 0.150$ mT.

Applying $\sum F_x = ma_x$ gives $qv_yB = ma_x$, so $v_y = \frac{ma_x}{qB}$. Using the given values we get $v_y = -12.5$ km/s. Now apply $\sum F_y = ma_y$. $qv_xB = ma_y$, which gives $v_x = \frac{ma_y}{qB}$. Using the given values gives $v_x = -22.5$ km/s.

EVALUATE: Notice that the x component of the velocity affects the y component of the acceleration and likewise v_y affects a_x.

28.15. **IDENTIFY:** We can model the lightning bolt and the household current as very long current-carrying wires.

SET UP: The magnetic field produced by a long wire is $B = \frac{\mu_0 I}{2\pi r}$.

EXECUTE: Substituting the numerical values gives

(a) $B = \frac{(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})(20{,}000\ \text{A})}{2\pi(5.0\ \text{m})} = 8\times10^{-4}\ \text{T}$.

(b) $B = \frac{(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})(10\ \text{A})}{2\pi(0.050\ \text{m})} = 4.0\times10^{-5}\ \text{T}$.

EVALUATE: The field from the lightning bolt is about 20 times as strong as the field from the household current.

28.16. **IDENTIFY:** The long current-carrying wire produces a magnetic field.

SET UP: The magnetic field due to a long wire is $B = \frac{\mu_0 I}{2\pi r}$.

EXECUTE: First find the current: $I = (8.20\times10^{18}\ \text{el/s})(1.60\times10^{-19}\ \text{C/el}) = 1.312\ \text{A}$.

Now find the magnetic field: $\frac{(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})(1.312\ \text{A})}{2\pi(0.0400\ \text{m})} = 6.56\times10^{-6}\ \text{T} = 6.56\ \mu\text{T}$.

Since electrons are negative, the conventional current runs from east to west, so the magnetic field above the wire points toward the north.

EVALUATE: This magnetic field is much less than that of the earth, so any experiments involving such a current would have to be shielded from the earth's magnetic field, or at least would have to take it into consideration.

28.17. **IDENTIFY:** We can model the current in the heart as that of a long straight wire. It produces a magnetic field around it.

SET UP: For a long straight wire, $B = \frac{\mu_0 I}{2\pi r}$. $\mu_0 = 4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}$. $1\ \text{gauss} = 10^{-4}\ \text{T}$.

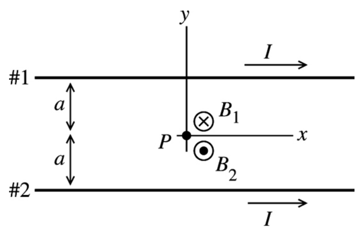
EXECUTE: Solving for the current gives

$$I = \frac{2\pi rB}{\mu_0} = \frac{2\pi(0.050\ \text{m})(1.0\times10^{-9}\ \text{T})}{4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}} = 25\times10^{-5}\ \text{A} = 250\ \mu\text{A}.$$

EVALUATE: By household standards, this is a very small current. But the magnetic field around the heart $(\approx 10\ \mu\text{G})$ is also very small.

28.18. **IDENTIFY:** For each wire $B = \dfrac{\mu_0 I}{2\pi r}$, and the direction of $\vec{B}$ is given by the right-hand rule (Figure 28.6 in the textbook). Add the field vectors for each wire to calculate the total field.

(a) SET UP: The two fields at this point have the directions shown in Figure 28.18a.

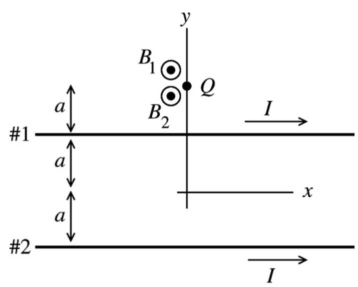


EXECUTE: At point P midway between the two wires the fields $\vec{B}_1$ and $\vec{B}_2$ due to the two currents are in opposite directions, so $B = B_2 - B_1$.

Figure 28.18a

But $B_1 = B_2 = \dfrac{\mu_0 I}{2\pi a}$, so $B = 0$.

(b) SET UP: The two fields at this point have the directions shown in Figure 28.18b.



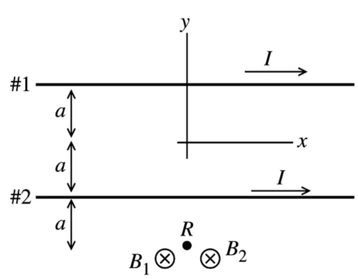
EXECUTE: At point Q above the upper wire $\vec{B}_1$ and $\vec{B}_2$ are both directed out of the page (+z-direction), so $B = B_1 + B_2$.

Figure 28.18b

$$B_1 = \frac{\mu_0 I}{2\pi a},\ B_2 = \frac{\mu_0 I}{2\pi(3a)}.$$

$$B = \frac{\mu_0 I}{2\pi a}\left(1 + \tfrac{1}{3}\right) = \frac{2\mu_0 I}{3\pi a};\ \vec{B} = \frac{2\mu_0 I}{3\pi a}\hat{k}.$$

(c) SET UP: The two fields at this point have the directions shown in Figure 28.18c.



EXECUTE: At point R below the lower wire $\vec{B}_1$ and $\vec{B}_2$ are both directed into the page ($-z$-direction), so $B = B_1 + B_2$.

Figure 28.18c

$$B_1 = \frac{\mu_0 I}{2\pi(3a)},\ B_2 = \frac{\mu_0 I}{2\pi a}.$$

$B_1 = \dfrac{\mu_0 I}{2\pi a}\left(1+\tfrac{1}{3}\right) = \dfrac{2\mu_0 I}{3\pi a}$; $\vec{\boldsymbol{B}} = -\dfrac{2\mu_0 I}{3\pi a}\hat{\boldsymbol{k}}$.

EVALUATE: In the figures we have drawn, $\vec{\boldsymbol{B}}$ due to each wire is out of the page at points above the wire and into the page at points below the wire. If the two field vectors are in opposite directions the magnitudes subtract.

28.19. **IDENTIFY:** The total magnetic field is the vector sum of the constant magnetic field and the wire's magnetic field.

SET UP: For the wire, $B_{\text{wire}} = \dfrac{\mu_0 I}{2\pi r}$ and the direction of B_{wire} is given by the right-hand rule that is illustrated in Figure 28.6 in the textbook. $\vec{\boldsymbol{B}}_0 = (1.50\times 10^{-6}\ \text{T})\hat{\boldsymbol{i}}$.

EXECUTE: **(a)** At (0, 0, 1 m), $\vec{\boldsymbol{B}} = \vec{\boldsymbol{B}}_0 - \dfrac{\mu_0 I}{2\pi r}\hat{\boldsymbol{i}} = (1.50\times 10^{-6}\ \text{T})\hat{\boldsymbol{i}} - \dfrac{\mu_0(8.00\ \text{A})}{2\pi(1.00\ \text{m})}\hat{\boldsymbol{i}} = -(1.0\times 10^{-7}\ \text{T})\hat{\boldsymbol{i}}$.

(b) At (1 m, 0, 0), $\vec{\boldsymbol{B}} = \vec{\boldsymbol{B}}_0 + \dfrac{\mu_0 I}{2\pi r}\hat{\boldsymbol{k}} = (1.50\times 10^{-6}\ \text{T})\hat{\boldsymbol{i}} + \dfrac{\mu_0(8.00\ \text{A})}{2\pi(1.00\ \text{m})}\hat{\boldsymbol{k}}$.

$\vec{\boldsymbol{B}} = (1.50\times 10^{-6}\ \text{T})\hat{\boldsymbol{i}} + (1.6\times 10^{-6}\ \text{T})\hat{\boldsymbol{k}} = 2.19\times 10^{-6}\ \text{T}$, at $\theta = 46.8°$ from x to z.

(c) At $(0, 0, -0.25\ \text{m})$, $\vec{\boldsymbol{B}} = \vec{\boldsymbol{B}}_0 + \dfrac{\mu_0 I}{2\pi r}\hat{\boldsymbol{i}} = (1.50\times 10^{-6}\ \text{T})\hat{\boldsymbol{i}} + \dfrac{\mu_0(8.00\ \text{A})}{2\pi(0.25\ \text{m})}\hat{\boldsymbol{i}} = (7.9\times 10^{-6}\ \text{T})\hat{\boldsymbol{i}}$.

EVALUATE: At point c the two fields are in the same direction and their magnitudes add. At point a they are in opposite directions and their magnitudes subtract. At point b the two fields are perpendicular.

28.20. **IDENTIFY:** The magnetic field is that of a long current-carrying wire.

SET UP: $B = \dfrac{\mu_0 I}{2\pi r}$.

EXECUTE: $B = \dfrac{\mu_0 I}{2\pi r} = \dfrac{(2.0\times 10^{-7}\ \text{T}\cdot\text{m/A})(150\ \text{A})}{8.0\ \text{m}} = 3.8\times 10^{-6}\ \text{T}$. This is 7.5% of the earth's field.

EVALUATE: Since this field is much smaller than the earth's magnetic field, it would be expected to have less effect than the earth's field.

28.21. **IDENTIFY:** $B = \dfrac{\mu_0 I}{2\pi r}$. The direction of $\vec{\boldsymbol{B}}$ is given by the right-hand rule.

SET UP: Call the wires a and b, as indicated in Figure 28.21. The magnetic fields of each wire at points P_1 and P_2 are shown in Figure 28.21a. The fields at point 3 are shown in Figure 28.21b.

EXECUTE: **(a)** At P_1, $B_a = B_b$ and the two fields are in opposite directions, so the net field is zero.

(b) $B_a = \dfrac{\mu_0 I}{2\pi r_a}$. $B_b = \dfrac{\mu_0 I}{2\pi r_b}$. $\vec{\boldsymbol{B}}_a$ and $\vec{\boldsymbol{B}}_b$ are in the same direction so

$$B = B_a + B_b = \frac{\mu_0 I}{2\pi}\left(\frac{1}{r_a} + \frac{1}{r_b}\right) = \frac{(4\pi\times 10^{-7}\ \text{T}\cdot\text{m/A})(4.00\ \text{A})}{2\pi}\left[\frac{1}{0.300\ \text{m}} + \frac{1}{0.200\ \text{m}}\right] = 6.67\times 10^{-6}\ \text{T}.$$

$\vec{\boldsymbol{B}}$ has magnitude $6.67\ \mu\text{T}$ and is directed toward the top of the page.

(c) In Figure 28.21b, $\vec{\boldsymbol{B}}_a$ is perpendicular to $\vec{\boldsymbol{r}}_a$ and $\vec{\boldsymbol{B}}_b$ is perpendicular to $\vec{\boldsymbol{r}}_b$. $\tan\theta = \dfrac{5\ \text{cm}}{20\ \text{cm}}$ and $\theta = 14.04°$. $r_a = r_b = \sqrt{(0.200\ \text{m})^2 + (0.050\ \text{m})^2} = 0.206\ \text{m}$ and $B_a = B_b$.

$$B = B_a\cos\theta + B_b\cos\theta = 2B_a\cos\theta = 2\left(\frac{\mu_0 I}{2\pi r_a}\right)\cos\theta = \frac{2(4\pi\times 10^{-7}\ \text{T}\cdot\text{m/A})(4.0\ \text{A})\cos 14.04°}{2\pi(0.206\ \text{m})} = 7.54\ \mu\text{T}$$

B has magnitude $7.53\ \mu\text{T}$ and is directed to the left.

EVALUATE: At points directly to the left of both wires the net field is directed toward the bottom of the page.

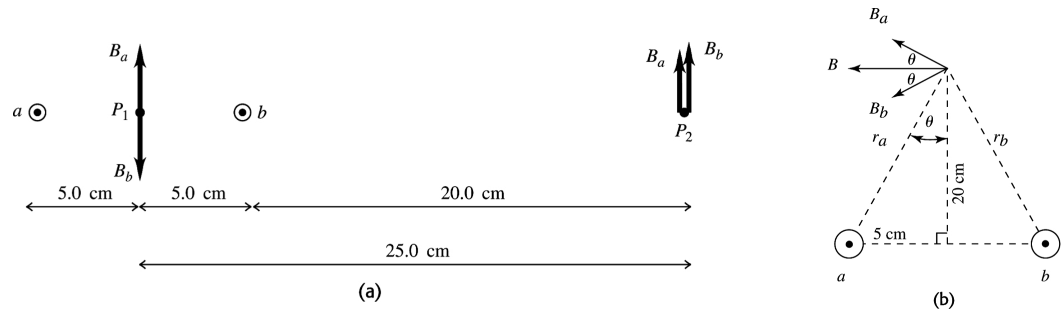


Figure 28.21

28.22. **IDENTIFY:** Each segment of the rectangular loop creates a magnetic field at the center of the loop, and all these fields are in the same direction.

SET UP: The field due to each segment is $B = \dfrac{\mu_0 I}{4\pi}\dfrac{2a}{x\sqrt{x^2+a^2}}$. $\vec{B}$ is into paper so I is clockwise around the loop.

EXECUTE: <u>Long sides:</u> $a = 4.75$ cm. $x = 2.10$ cm. For the two long sides,

$$B = 2(1.00\times10^{-7}\ \text{T}\cdot\text{m/A})I\frac{2(4.75\times10^{-2}\ \text{m})}{(2.10\times10^{-2}\ \text{m})\sqrt{(0.0210\ \text{m})^2+(0.0475\ \text{m})^2}} = (1.742\times10^{-5}\ \text{T/A})I.$$

<u>Short sides</u>: $a = 2.10$ cm. $x = 4.75$ cm. For the two short sides,

$$B = 2(1.00\times10^{-7}\ \text{T}\cdot\text{m/A})I\frac{2(2.10\times10^{-2}\ \text{m})}{(4.75\times10^{-2}\ \text{m})\sqrt{(0.0475\ \text{m})^2+(0.0210\ \text{m})^2}} = (3.405\times10^{-6}\ \text{T/A})I.$$

Using the known field, we have $B = (2.082\times10^{-5}\ \text{T/A})I = 5.50\times10^{-5}$ T, which gives $I = 2.64$ A.

EVALUATE: This is a typical household current, yet it produces a magnetic field which is about the same as the earth's magnetic field.

28.23. **IDENTIFY:** The net magnetic field at the center of the square is the vector sum of the fields due to each wire.

SET UP: For each wire, $B = \dfrac{\mu_0 I}{2\pi r}$ and the direction of $\vec{B}$ is given by the right-hand rule that is illustrated in Figure 28.6 in the textbook.

EXECUTE: **(a)** and **(b)** $B = 0$ since the magnetic fields due to currents at opposite corners of the square cancel.

(c) The fields due to each wire are sketched in Figure 28.23.

$$B = B_a\cos45° + B_b\cos45° + B_c\cos45° + B_d\cos45° = 4B_a\cos45° = 4\left(\frac{\mu_0 I}{2\pi r}\right)\cos45°.$$

$r = \sqrt{(10\ \text{cm})^2+(10\ \text{cm})^2} = 10\sqrt{2}\ \text{cm} = 0.10\sqrt{2}$ m, so

$$B = 4\frac{(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})(100\ \text{A})}{2\pi(0.10\sqrt{2}\ \text{m})}\cos45° = 4.0\times10^{-4}\ \text{T, to the left.}$$

EVALUATE: In part (c), if all four currents are reversed in direction, the net field at the center of the square would be to the right.

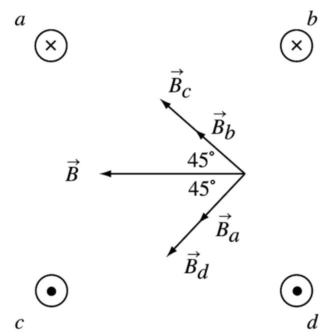

Figure 28.23

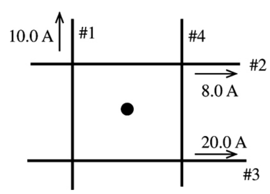
28.24. **IDENTIFY:** Use $B = \dfrac{\mu_0 I}{2\pi r}$ and the right-hand rule to determine the field due to each wire. Set the sum of the four fields equal to zero and use that equation to solve for the field and the current of the fourth wire.

SET UP: The three known currents are shown in Figure 28.24.



$\vec{B}_1 \otimes, \vec{B}_2 \otimes, \vec{B}_3 \odot$

$B = \dfrac{\mu_0 I}{2\pi r}$; $r = 0.200$ m for each wire.

Figure 28.24

EXECUTE: Let $\odot$ be the positive z-direction. $I_1 = 10.0\text{ A}, I_2 = 8.0\text{ A}, I_3 = 20.0\text{ A}$. Then

$B_1 = 1.00\times10^{-5}\text{ T},\ B_2 = 0.80\times10^{-5}\text{ T},\ \text{and}\ B_3 = 2.00\times10^{-5}\text{ T}.$

$B_{1z} = -1.00\times10^{-5}\text{ T}, B_{2z} = -0.80\times10^{-5}\text{ T}, B_{3z} = +2.00\times10^{-5}\text{ T}.$

$B_{1z} + B_{2z} + B_{3z} + B_{4z} = 0.$

$B_{4z} = -(B_{1z} + B_{2z} + B_{3z}) = -2.0\times10^{-6}\text{ T}.$

To give $\vec{B}_4$ in the $\otimes$ direction the current in wire 4 must be toward the bottom of the page.

$$B_4 = \frac{\mu_0 I}{2\pi r} \text{ so } I_4 = \frac{rB_4}{(\mu_0/2\pi)} = \frac{(0.200\text{ m})(2.0\times10^{-6}\text{ T})}{(2\times10^{-7}\text{ T}\cdot\text{m/A})} = 2.0\text{ A}.$$

EVALUATE: The fields of wires #2 and #3 are in opposite directions and their net field is the same as due to a current $20.0\text{ A} - 8.0\text{ A} = 12.0\text{ A}$ in one wire. The field of wire #4 must be in the same direction as that of wire #1, and $10.0\text{ A} + I_4 = 12.0\text{ A}$.

28.25. **IDENTIFY:** The net magnetic field at any point is the vector sum of the magnetic fields of the two wires.

SET UP: For each wire $B = \dfrac{\mu_0 I}{2\pi r}$ and the direction of $\vec{B}$ is determined by the right-hand rule described in the text. Let the wire with 12.0 A be wire 1 and the wire with 10.0 A be wire 2.

EXECUTE: **(a)** Point Q: $B_1 = \dfrac{\mu_0 I_1}{2\pi r_1} = \dfrac{(4\pi\times10^{-7}\text{T}\cdot\text{m/A})(12.0\text{ A})}{2\pi(0.15\text{ m})} = 1.6\times10^{-5}\text{ T}.$

The direction of $\vec{B}_1$ is out of the page. $B_2 = \dfrac{\mu_0 I_2}{2\pi r_2} = \dfrac{(4\pi\times10^{-7}\text{T}\cdot\text{m/A})(10.0\text{ A})}{2\pi(0.080\text{ m})} = 2.5\times10^{-5}\text{ T}.$

The direction of $\vec{B}_2$ is out of the page. Since $\vec{B}_1$ and $\vec{B}_2$ are in the same direction,

$B = B_1 + B_2 = 4.1\times10^{-5}\text{ T}$ and $\vec{B}$ is directed out of the page.

Point P: $B_1 = 1.6\times10^{-5}$ T, directed into the page. $B_2 = 2.5\times10^{-5}$ T, directed into the page.

$B = B_1 + B_2 = 4.1\times10^{-5}$ T and $\vec{B}$ is directed into the page.

(b) $\vec{B}_1$ is the same as in part (a), out of the page at Q and into the page at P. The direction of $\vec{B}_2$ is reversed from what it was in (a) so is into the page at Q and out of the page at P.

Point Q: $\vec{B}_1$ and $\vec{B}_2$ are in opposite directions so $B = B_2 - B_1 = 2.5\times10^{-5}\text{ T} - 1.6\times10^{-5}\text{ T} = 9.0\times10^{-6}$ T and $\vec{B}$ is directed into the page.

Point P: $\vec{B}_1$ and $\vec{B}_2$ are in opposite directions so $B = B_2 - B_1 = 9.0\times10^{-6}$ T and $\vec{B}$ is directed out of the page.

EVALUATE: Points P and Q are the same distances from the two wires. The only difference is that the fields point in either the same direction or in opposite directions.

28.26. **IDENTIFY:** This problem involves the magnetic field of a short current-carrying wire.

SET UP: $B = \dfrac{\mu_0}{2\pi}\dfrac{I}{r}$ (infinite wire), $B = \dfrac{\mu_0 I}{2\pi}\dfrac{2a}{x\sqrt{x^2+a^2}}$ (finite wire). We want the magnetic field this wire produces at point P(0, 5.00 cm).

EXECUTE: **(a)** Finite length: Use $B = \dfrac{\mu_0 I}{2\pi}\dfrac{2a}{x\sqrt{x^2+a^2}}$ with x = 5.00 cm and a = 10.0 cm. This gives $B = 28.6\ \mu$T.

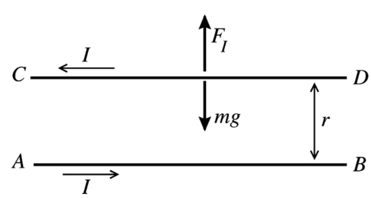
(b) Infinite length: Use $B = \dfrac{\mu_0}{2\pi}\dfrac{I}{r}$ with r = 5.00 cm, giving $B = 32.0\ \mu$T.

$$\frac{\Delta B}{B} = \frac{32.0\ \mu\text{T} - 28.6\ \mu\text{T}}{28.6\ \mu\text{T}} = 0.119 = 11.9\%.$$

EVALUATE: Using the less accurate infinite-length approximation gives an easier calculation but a less accurate answer.

28.27. **IDENTIFY:** The wire CD rises until the upward force F_I due to the currents balances the downward force of gravity.

SET UP: The forces on wire CD are shown in Figure 28.27.



Currents in opposite directions so the force is repulsive and F_I is upward, as shown.

Figure 28.27

$\dfrac{F}{L} = \dfrac{\mu_0 I'I}{2\pi r}$ says $F_I = \dfrac{\mu_0 I^2 L}{2\pi h}$ where L is the length of wire CD and h is the distance between the wires.

EXECUTE: $mg = \lambda L g$.

Thus $F_I - mg = 0$ says $\dfrac{\mu_0 I^2 L}{2\pi h} = \lambda L g$ and $h = \dfrac{\mu_0 I^2}{2\pi g \lambda}$.

EVALUATE: The larger I is or the smaller λ is, the larger h will be.

28.28. **IDENTIFY:** Apply $\dfrac{F}{L} = \dfrac{\mu_0 I'I}{2\pi r}$ for the force from each wire.

SET UP: Two parallel conductors carrying current in the same direction attract each other. Parallel conductors carrying currents in opposite directions repel each other.

EXECUTE: On the top wire $\frac{F}{L}=\frac{\mu_0 I^2}{2\pi}\left(\frac{1}{d}-\frac{1}{2d}\right)=\frac{\mu_0 I^2}{4\pi d}$, upward. On the middle wire, the magnetic forces cancel so the net force is zero. On the bottom wire $\frac{F}{L}=\frac{\mu_0 I^2}{2\pi}\left(\frac{1}{d}-\frac{1}{2d}\right)=\frac{\mu_0 I^2}{4\pi d}$, downward.

EVALUATE: The net force on the middle wire is zero because at the location of the middle wire the net magnetic field due to the other two wires is zero.

28.29. IDENTIFY: Apply $\frac{F}{L}=\frac{\mu_0 I'I}{2\pi r}$.

SET UP: Two parallel conductors carrying current in the same direction attract each other. Parallel conductors carrying currents in opposite directions repel each other.

EXECUTE: **(a)** $F=\frac{\mu_0 I_1 I_2 L}{2\pi r}=\frac{\mu_0(5.00\text{ A})(2.00\text{ A})(1.20\text{ m})}{2\pi(0.400\text{ m})}=6.00\times10^{-6}\text{ N}$, and the force is repulsive since the currents are in opposite directions.

(b) Doubling the currents makes the force increase by a factor of four to w

EVALUATE: Doubling the current in a wire doubles the magnetic field of that wire. For fixed magnetic field, doubling the current in a wire doubles the force that the magnetic field exerts on the wire.

28.30. IDENTIFY: Apply $\frac{F}{L}=\frac{\mu_0 I'I}{2\pi r}$.

SET UP: Two parallel conductors carrying current in the same direction attract each other. Parallel conductors carrying currents in opposite directions repel each other.

EXECUTE: **(a)** $\frac{F}{L}=\frac{\mu_0 I_1 I_2}{2\pi r}$ gives $I_2=\frac{F}{L}\frac{2\pi r}{\mu_0 I_1}=(4.0\times10^{-5}\text{ N/m})\frac{2\pi(0.0250\text{ m})}{\mu_0(0.60\text{ A})}=8.33\text{ A}$.

(b) The two wires repel so the currents are in opposite directions.

EVALUATE: The force between the two wires is proportional to the product of the currents in the wires.

28.31. IDENTIFY: We can model the current in the brain as a ring. Since we know the magnetic field at the center of the ring, we can calculate the current.

SET UP: At the center of a ring, $B=\frac{\mu_0 I}{2R}$. In this case, t.

EXECUTE: Solving for I gives $I=\frac{2RB}{\mu_0}=\frac{2(8\times10^{-2}\text{ m})(3.0\times10^{-12}\text{ T})}{4\times10^{-7}\text{ T}\cdot\text{m/A}}=3.8\times10^{-7}\text{ A}$.

EVALUATE: This current is about a third of a microamp, which is a very small current by household standards. However, the magnetic field in the brain is a very weak field, about a hundreth of the earth's magnetic field.

28.32. IDENTIFY: The magnetic field at the center of a circular loop is $B=\frac{\mu_0 I}{2R}$. By symmetry each segment of the loop that has length Δl contributes equally to the field, so the field at the center of a semicircle is $\frac{1}{2}$ that of a full loop.

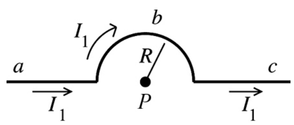
SET UP: Since the straight sections produce no field at P, the field at P is $B=\frac{\mu_0 I}{4R}$.

EXECUTE: $B=\frac{\mu_0 I}{4R}$. The direction of $\vec{B}$ is given by the right-hand rule: $\vec{B}$ is directed into the page.

EVALUATE: For a quarter-circle section of wire the magnetic field at its center of curvature is $B=\frac{\mu_0 I}{8R}$.

28.33. **IDENTIFY:** Calculate the magnetic field vector produced by each wire and add these fields to get the total field.

SET UP: First consider the field at P produced by the current I_1 in the upper semicircle of wire. See Figure 28.33a.

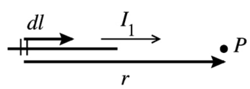


Consider the three parts of this wire:
a: long straight section
b: semicircle
c: long, straight section

Figure 28.33a

Apply the Biot-Savart law $d\vec{B} = \frac{\mu_0}{4\pi}\frac{Id\vec{l}\times\hat{r}}{r^2} = \frac{\mu_0}{4\pi}\frac{Id\vec{l}\times\vec{r}}{r^3}$ to each piece.

EXECUTE: <u>Part a</u>: See Figure 28.33b.

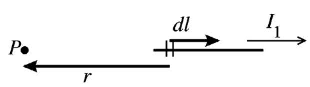


$d\vec{l}\times\vec{r} = 0$,
so $dB = 0$.

Figure 28.33b

The same is true for all the infinitesimal segments that make up this piece of the wire, so $B = 0$ for this piece.

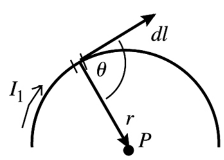
<u>Part c</u>: See Figure 28.33c.



$d\vec{l}\times\vec{r} = 0$,
so $dB = 0$ and $B = 0$ for this piece.

Figure 28.33c

<u>Part b</u>: See Figure 28.33d.



$d\vec{l}\times\vec{r}$ is directed into the paper for all infinitesimal segments that make up this semicircular piece, so $\vec{B}$ is directed into the paper and $B = \int dB$ (the vector sum of the $d\vec{B}$ is obtained by adding their magnitudes since they are in the same direction).

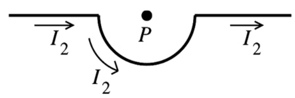
Figure 28.33d

$\left|d\vec{l}\times\vec{r}\right| = rdl\sin\theta$. The angle θ between $d\vec{l}$ and $\vec{r}$ is 90° and $r = R$, the radius of the semicircle. Thus $\left|d\vec{l}\times\vec{r}\right| = R\,dl$.

$$dB = \frac{\mu_0}{4\pi}\frac{I\left|d\vec{l}\times\vec{r}\right|}{r^3} = \frac{\mu_0 I_1}{4\pi}\frac{R}{R^3}dl = \left(\frac{\mu_0 I_1}{4\pi R^2}\right)dl.$$

$$B = \int dB = \left(\frac{\mu_0 I_1}{4\pi R^2}\right)\int dl = \left(\frac{\mu_0 I_1}{4\pi R^2}\right)(\pi R) = \frac{\mu_0 I_1}{4R}.$$

(We used that $\int dl$ is equal to πR, the length of wire in the semicircle.) We have shown that the two straight sections make zero contribution to $\vec{B}$, so $B_1 = \mu_0 I_1/4R$ and is directed into the page.



For current in the direction shown in Figure 28.33e, a similar analysis gives $B_2 = \mu_0 I_2/4R$, out of the paper.

Figure 28.33e

$\vec{B}_1$ and $\vec{B}_2$ are in opposite directions, so the magnitude of the net field at P is $B = |B_1 - B_2| = \dfrac{\mu_0 |I_1 - I_2|}{4R}$.

EVALUATE: When $I_1 = I_2, B = 0$.

28.34. **IDENTIFY:** Apply $B_x = \dfrac{\mu_0 N I a^2}{2(x^2 + a^2)^{3/2}}$.

SET UP: At the center of the coil, $x = 0$. a is the radius of the coil, 0.0240 m.

EXECUTE: **(a)** $B_x = \mu_0 NI/2a$, so $I = \dfrac{2aB_x}{\mu_0 N} = \dfrac{2(0.024\text{ m})(0.0770\text{ T})}{(4\pi \times 10^{-7}\text{ T}\cdot\text{m/A})(800)} = 3.68\text{ A}$.

(b) At the center, $B_c = \mu_0 NI/2a$. At a distance x from the center,

$B_x = \dfrac{\mu_0 N I a^2}{2(x^2 + a^2)^{3/2}} = \left(\dfrac{\mu_0 NI}{2a}\right)\left(\dfrac{a^3}{(x^2 + a^2)^{3/2}}\right) = B_c\left(\dfrac{a^3}{(x^2 + a^2)^{3/2}}\right)$. $B_x = \frac{1}{2}B_c$ says $\dfrac{a^3}{(x^2 + a^2)^{3/2}} = \frac{1}{2}$, and

$(x^2 + a^2)^3 = 4a^6$. Since $a = 0.024$ m, $x = 0.0184\text{ m} = 1.84\text{ cm}$.

EVALUATE: As shown in Figure 28.14 in the textbook, the field has its largest magnitude at the center of the coil and decreases with distance along the axis from the center.

28.35. **IDENTIFY:** The field at the center of the loops is the vector sum of the field due to each loop. They must be in opposite directions in order to add to zero.

SET UP: Let wire 1 be the inner wire with diameter 20.0 cm and let wire 2 be the outer wire with diameter 30.0 cm. To produce zero net field, the fields $\vec{B}_1$ and $\vec{B}_2$ of the two wires must have equal magnitudes and opposite directions. At the center of a wire loop $B = \dfrac{\mu_0 I}{2R}$. The direction of $\vec{B}$ is given by the right-hand rule applied to the current direction.

EXECUTE: $B_1 = \dfrac{\mu_0 I}{2R_1}$, $B_2 = \dfrac{\mu_0 I}{2R_2}$. $B_1 = B_2$ gives $\dfrac{\mu_0 I_1}{2R_1} = \dfrac{\mu_0 I_2}{2R_2}$. Solving for I_2 gives

$I_2 = \left(\dfrac{R_2}{R_1}\right)I_1 = \left(\dfrac{15.0\text{ cm}}{10.0\text{ cm}}\right)(12.0\text{ A}) = 18.0\text{ A}$. The directions of I_1 and of its field are shown in Figure 28.35. Since $\vec{B}_1$ is directed into the page, $\vec{B}_2$ must be directed out of the page and I_2 is counterclockwise.

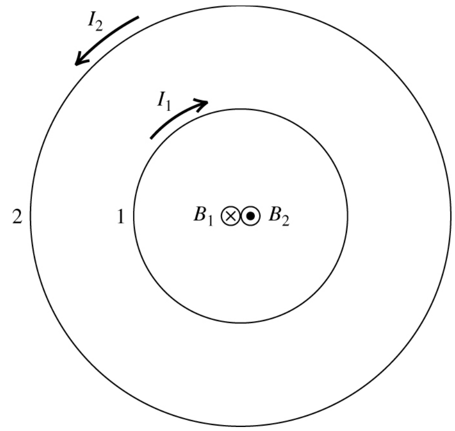


Figure 28.35

EVALUATE: The outer current, I_2, must be larger than the inner current, I_1, because the outer ring is larger than the inner ring, which makes the outer current farther from the center than the inner current is.

28.36. **IDENTIFY** and **SET UP:** The magnetic field at a point on the axis of N circular loops is given by $B_x = \dfrac{\mu_0 N I a^2}{2(x^2+a^2)^{3/2}}$. Solve for N and set $x = 0.0600$ m.

EXECUTE: $N = \dfrac{2B_x(x^2+a^2)^{3/2}}{\mu_0 I a^2} = \dfrac{2(6.39\times10^{-4}\ \text{T})\left[(0.0600\ \text{m})^2+(0.0600\ \text{m})^2\right]^{3/2}}{(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})(2.50\ \text{A})(0.0600\ \text{m})^2} = 69.$

EVALUATE: At the center of the coil the field is $B_x = \dfrac{\mu_0 N I}{2a} = 1.8\times10^{-3}$ T. The field 6.00 cm from the center is a factor of $1/2^{3/2}$ times smaller.

28.37. **IDENTIFY:** Apply Ampere's law.

SET UP: $\mu_0 = 4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}$.

EXECUTE: **(a)** $\oint \vec{B}\cdot d\vec{l} = \mu_0 I_{\text{encl}} = 3.83\times10^{-4}\ \text{T}\cdot\text{m}$ and $I_{\text{encl}} = 305$ A.

(b) $-3.83\times10^{-4}\ \text{T}\cdot\text{m}$ since at each point on the curve the direction of $d\vec{l}$ is reversed.

EVALUATE: The line integral $\oint \vec{B}\cdot d\vec{l}$ around a closed path is proportional to the net current that is enclosed by the path.

28.38. **IDENTIFY:** Apply Ampere's law.

SET UP: From the right-hand rule, when going around the path in a counterclockwise direction currents out of the page are positive and currents into the page are negative.

EXECUTE: Path a: $I_{\text{encl}} = 0 \Rightarrow \oint \vec{B}\cdot d\vec{l} = 0.$

Path b: $I_{\text{encl}} = -I_1 = -4.0\ \text{A} \Rightarrow \oint \vec{B}\cdot d\vec{l} = -\mu_0(4.0\ \text{A}) = -5.03\times10^{-6}\ \text{T}\cdot\text{m}.$

Path c: $I_{\text{encl}} = -I_1 + I_2 = -4.0\ \text{A} + 6.0\ \text{A} = 2.0\ \text{A} \Rightarrow \oint \vec{B}\cdot d\vec{l} = \mu_0(2.0\ \text{A}) = 2.51\times10^{-6}\ \text{T}\cdot\text{m}$

Path d: $I_{\text{encl}} = -I_1 + I_2 + I_3 = 4.0\ \text{A} \Rightarrow \oint \vec{B}\cdot d\vec{l} = +\mu_0(4.0\ \text{A}) = 5.03\times10^{-6}\ \text{T}\cdot\text{m}.$

EVALUATE: If we instead went around each path in the clockwise direction, the sign of the line integral would be reversed.

28.39. **IDENTIFY:** Apply Ampere's law.

SET UP: To calculate the magnetic field at a distance r from the center of the cable, apply Ampere's law to a circular path of radius r. By symmetry, $\oint \vec{B} \cdot d\vec{l} = B(2\pi r)$ for such a path.

EXECUTE: **(a)** For $a < r < b, I_{\text{encl}} = I \Rightarrow \oint \vec{B} \cdot d\vec{l} = \mu_0 I \Rightarrow B2\pi r = \mu_0 I \Rightarrow B = \dfrac{\mu_0 I}{2\pi r}.$

(b) For $r > c,$ the enclosed current is zero, so the magnetic field is also zero.

EVALUATE: A useful property of coaxial cables for many applications is that the current carried by the cable doesn't produce a magnetic field outside the cable.

28.40. **IDENTIFY** and **SET UP:** At the center of a long solenoid $B = \mu_0 n I = \mu_0 \dfrac{N}{L} I.$

EXECUTE: $I = \dfrac{BL}{\mu_0 N} = \dfrac{(0.150\text{ T})(0.550\text{ m})}{(4\pi \times 10^{-7}\text{ T}\cdot\text{m/A})(4000)} = 16.4\text{ A}.$

EVALUATE: The magnetic field inside the solenoid is independent of the radius of the solenoid, if the radius is much less than the length, as is the case here.

28.41. **IDENTIFY:** Apply Ampere's law to calculate $\vec{B}$.

(a) SET UP: For $a < r < b$ the end view is shown in Figure 28.41a.

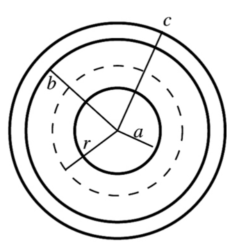

Figure 28.41a

Apply Ampere's law to a circle of radius r, where $a < r < b.$ Take currents I_1 and I_2 to be directed into the page. Take this direction to be positive, so go around the integration path in the clockwise direction.

EXECUTE: $\oint \vec{B} \cdot d\vec{l} = \mu_0 I_{\text{encl}}.$

$\oint \vec{B} \cdot d\vec{l} = B(2\pi r), I_{\text{encl}} = I_1.$

Thus $B(2\pi r) = \mu_0 I_1$ and $B = \dfrac{\mu_0 I_1}{2\pi r}.$

(b) SET UP: $\underline{r > c}$: See Figure 28.41b.

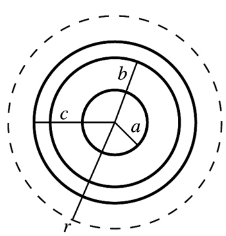

Figure 28.41b

Apply Ampere's law to a circle of radius r, where $r > c.$ Both currents are in the positive direction.

EXECUTE: $\oint \vec{B} \cdot d\vec{l} = \mu_0 I_{\text{encl}}.$

$\oint \vec{B} \cdot d\vec{l} = B(2\pi r), I_{\text{encl}} = I_1 + I_2.$

Thus $B(2\pi r) = \mu_0 (I_1 + I_2)$ and $B = \dfrac{\mu_0 (I_1 + I_2)}{2\pi r}.$

EVALUATE: For $a < r < b$ the field is due only to the current in the central conductor. For $r > c$ both currents contribute to the total field.

28.42. **IDENTIFY:** $B = \mu_0 nI = \dfrac{\mu_0 NI}{L}.$

SET UP: $L = 0.150$ m.

EXECUTE: $B = \dfrac{\mu_0\,(600)(8.00\text{ A})}{(0.150\text{ m})} = 0.0402\text{ T}.$

EVALUATE: The field near the center of the solenoid is independent of the radius of the solenoid, as long as the radius is much less than the length, as it is here.

28.43. **IDENTIFY** and **SET UP:** The magnetic field near the center of a long solenoid is given by $B = \mu_0 nI$.

EXECUTE: **(a)** Turns per unit length $n = \dfrac{B}{\mu_0 I} = \dfrac{0.0270\text{ T}}{(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})(12.0\text{ A})} = 1790\text{ turns/m}.$

(b) $N = nL = (1790\text{ turns/m})(0.400\text{ m}) = 716\text{ turns}.$

Each turn of radius R has a length $2\pi R$ of wire. The total length of wire required is

$N(2\pi R) = (716)(2\pi)(1.40\times10^{-2}\text{ m}) = 63.0\text{ m}.$

EVALUATE: A large length of wire is required. Due to the length of wire the solenoid will have appreciable resistance.

28.44. **IDENTIFY:** Outside an ideal toroidal solenoid there is no magnetic field and inside it the magnetic field is given by $B = \dfrac{\mu_0 NI}{2\pi r}.$

SET UP: The torus extends from $r_1 = 15.0$ cm to $r_2 = 18.0$ cm.

EXECUTE: **(a)** $r = 0.12$ m, which is outside the torus, so $B = 0$.

(b) $r = 0.16$ m, so $B = \dfrac{\mu_0 NI}{2\pi r} = \dfrac{\mu_0(250)(8.50\text{ A})}{2\pi(0.160\text{ m})} = 2.66\times10^{-3}\text{ T}.$

(c) $r = 0.20$ m, which is outside the torus, so $B = 0$.

EVALUATE: The magnetic field inside the torus is proportional to $1/r$, so it varies somewhat over the cross-section of the torus.

28.45. **IDENTIFY** and **SET UP:** Use the appropriate expression for the magnetic field produced by each current configuration.

EXECUTE: **(a)** $B = \dfrac{\mu_0 I}{2\pi r}$ so $I = \dfrac{2\pi rB}{\mu_0} = \dfrac{2\pi(2.00\times10^{-2}\text{ m})(37.2\text{ T})}{4\pi\times10^{-7}\text{ T}\cdot\text{m/A}} = 3.72\times10^{6}\text{ A} = 3.72\text{ MA}.$

(b) $B = \dfrac{N\mu_0 I}{2R}$ so $I = \dfrac{2RB}{N\mu_0} = \dfrac{2(0.420\text{ m})(37.2\text{ T})}{(100)(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})} = 2.49\times10^{5}\text{ A} = 249\text{ kA}.$

(c) $B = \mu_0\dfrac{N}{L}I$ so $I = \dfrac{BL}{\mu_0 N} = \dfrac{(37.2\text{ T})(0.320\text{ m})}{(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})(40{,}000)} = 237\text{ A}.$

EVALUATE: Much less current is needed for the solenoid, because of its large number of turns per unit length.

28.46. **IDENTIFY:** Use $B = \dfrac{\mu_0 NI}{2\pi r}$, with μ_0 replaced by $\mu = K_m\mu_0$, with $K_m = 80$.

SET UP: The contribution from atomic currents is the difference between B calculated with μ and B calculated with μ_0.

EXECUTE: **(a)** $B = \dfrac{\mu NI}{2\pi r} = \dfrac{K_m\mu_0 NI}{2\pi r} = \dfrac{\mu_0(80)(400)(0.25\text{ A})}{2\pi(0.060\text{ m})} = 0.0267\text{ T}.$

(b) The amount due to atomic currents is $B' = \frac{79}{80}B = \frac{79}{80}(0.0267\text{ T}) = 0.0263\text{ T}.$

EVALUATE: The presence of the core greatly enhances the magnetic field produced by the solenoid.

28.47. IDENTIFY: The magnetic field from the solenoid alone is $B_0 = \mu_0 nI$. The total magnetic field is $B = K_m B_0$. M is given by $\vec{B} = \vec{B}_0 + \mu_0 \vec{M}$.

SET UP: $n = 6000$ turns/m.

EXECUTE: **(a)** (i) $B_0 = \mu_0 nI = \mu_0(6000\text{ m}^{-1})(0.15\text{ A}) = 1.13\times10^{-3}\text{ T}.$

(ii) $M = \frac{K_m - 1}{\mu_0}B_0 = \frac{5199}{\mu_0}(1.13\times10^{-3}\text{ T}) = 4.68\times10^6\text{ A/m}.$

(iii) $B = K_m B_0 = (5200)(1.13\times10^{-3}\text{ T}) = 5.88\text{ T}.$

(b) The directions of $\vec{B}$, $\vec{B}_0$ and $\vec{M}$ are shown in Figure 28.47. Silicon steel is paramagnetic and $\vec{B}_0$ and $\vec{M}$ are in the same direction.

EVALUATE: The total magnetic field is much larger than the field due to the solenoid current alone.

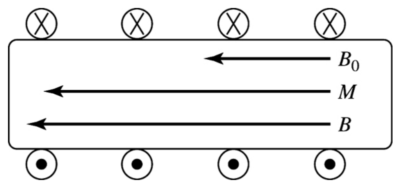

Figure 28.47

28.48. IDENTIFY: Apply $B = \frac{K_m \mu_0 NI}{2\pi r}$.

SET UP: K_m is the relative permeability and $\chi_m = K_m - 1$ is the magnetic susceptibility.

EXECUTE: **(a)** $K_m = \frac{2\pi rB}{\mu_0 NI} = \frac{2\pi(0.2500\text{ m})(1.940\text{ T})}{\mu_0(500)(2.400\text{ A})} = 2021.$

(b) $\chi_m = K_m - 1 = 2020.$

EVALUATE: Without the magnetic material the magnetic field inside the windings would be $B/2021 = 9.6\times10^{-4}\text{ T}$. The presence of the magnetic material greatly enhances the magnetic field inside the windings.

28.49. IDENTIFY: Moving charges create magnetic fields. The net field is the vector sum of the two fields. A charge moving in an external magnetic field feels a force.

(a) SET UP: The magnitude of the magnetic field due to a moving charge is $B = \frac{\mu_0}{4\pi}\frac{|q|v\sin\phi}{r^2}$. Both fields are into the paper, so their magnitudes add, giving $B_{net} = B + B' = \frac{\mu_0}{4\pi}\left(\frac{|q|v\sin\phi}{r^2} + \frac{|q'|v'\sin\phi'}{r'^2}\right)$.

EXECUTE: Substituting numbers gives

$$B_{net} = \frac{\mu_0}{4\pi}\left[\frac{(8.00\ \mu\text{C})(9.00\times10^4\text{ m/s})\sin 90^\circ}{(0.300\text{ m})^2} + \frac{(5.00\ \mu\text{C})(6.50\times10^4\text{ m/s})\sin 90^\circ}{(0.400\text{ m})^2}\right].$$

$B_{net} = 1.00\times10^{-6}\text{ T} = 1.00\mu\text{T}$, into the paper.

(b) SET UP: The magnetic force on a moving charge is $\vec{F} = q\vec{v}\times\vec{B}$, and the magnetic field of charge q' at the location of charge q is into the page. The force on q is

$$\vec{F} = q\vec{v}\times\vec{B}' = (qv)\hat{i}\times\frac{\mu_0}{4\pi}\frac{q\vec{v}'\times\hat{r}}{r^2} = (qv)\hat{i}\times\left(\frac{\mu_0}{4\pi}\frac{qv'\sin\phi}{r^2}\right)(-\hat{k}) = \left(\frac{\mu_0}{4\pi}\frac{qq'vv'\sin\phi}{r^2}\right)\hat{j}$$

where ϕ is the angle between $\vec{v}'$ and $\hat{r}'$.

EXECUTE: Substituting numbers gives

$$\vec{F} = \frac{\mu_0}{4\pi}\left[\frac{(8.00\times10^{-6}\ \text{C})(5.00\times10^{-6}\ \text{C})(9.00\times10^{4}\ \text{m/s})(6.50\times10^{4}\ \text{m/s})}{(0.500\ \text{m})^2}\left(\frac{0.400}{0.500}\right)\right]\hat{j}.$$

$\vec{F} = (7.49\times10^{-8}\,\text{N})\hat{j}.$

EVALUATE: These are small fields and small forces, but if the charge has small mass, the force can affect its motion.

28.50. **IDENTIFY:** Charge q_1 creates a magnetic field due to its motion. This field exerts a magnetic force on q_2, which is moving in that field.

SET UP: Find $\vec{B}_1$, the field produced by q_1 at the location of q_2. $\vec{B}_1 = \dfrac{\mu_0}{4\pi}\dfrac{q_1\vec{v}_1\times\vec{r}_{1\to2}}{r_{1\to2}^3}$, since $\hat{r} = \vec{r}/r$.

EXECUTE: $\vec{r}_{1\to2} = (0.150\ \text{m})\hat{i} + (-0.250\ \text{m})\hat{j}$, so $r_{1\to2} = 0.2915$ m.

$\vec{v}_1\times\vec{r}_{1\to2} = [(9.20\times10^5\ \text{m/s})\hat{i}]\times[(0.150\ \text{m})\hat{i} + (-0.250\ \text{m})\hat{j}] = (9.20\times10^5\ \text{m/s})(-0.250\ \text{m})\hat{k}$.

$$\vec{B}_1 = (1.00\times10^{-7}\ \text{T}\cdot\text{m/A})\frac{(4.80\times10^{-6}\ \text{C})(9.20\times10^5\ \text{m/s})(-0.250\ \text{m})}{(0.2915\ \text{m})^3}\hat{k} = -(4.457\times10^{-6}\ \text{T})\hat{k}.$$

The force that $\vec{B}_1$ exerts on q_2 is

$F_2 = q_2\vec{v}_2\times\vec{B}_1 = (-2.90\times10^{-6}\ \text{C})(-5.30\times10^5\ \text{m/s})(-4.457\times10^{-6}\ \text{T})\hat{j}\times\hat{k} = -(6.85\times10^{-6}\ \text{N})\hat{i}$.

EVALUATE: If we think of the moving charge q_1 as a current, we can use the right-hand rule for the direction of the magnetic field due to a current to find the direction of the magnetic field it creates in the vicinity of q_2. Then we can use the cross product right-hand rule to find the direction of the force this field exerts on q_2, which is in the $-x$-direction, in agreement with our result.

28.51. **IDENTIFY:** This problem involves the magnetic field due to two long wires. We want to know where the fields cancel completely.

SET UP: $B = \dfrac{\mu_0}{2\pi}\dfrac{I}{r}$. The fields completely cancel only if they are in opposite directions and of the same magnitude. Both conditions can be met only in the region between the wires.

EXECUTE: Call y the coordinate of the point where $B = 0$. At that point $B_1 = B_2$. This gives $\dfrac{\mu_0}{2\pi}\dfrac{I_1}{r_1} = \dfrac{\mu_0}{2\pi}\dfrac{I_2}{r_2}$, so $\dfrac{2}{r_1} = \dfrac{6}{r_2}$. $r_1 = y$ and $r_2 = 0.800\ \text{m} - y$, so $\dfrac{1}{y} = \dfrac{3}{0.800\ \text{m} - y}$. Solving for y gives us $y = 0.200$ m.

EVALUATE: The point where $B = 0$ must be closer to the smaller current than to the larger one. $y_1 = 0.200$ m and $y_2 = 0.600$ m, which agrees with this condition.

28.52. **IDENTIFY:** This problem involves the magnetic field due to two long wires. We want to know where the fields cancel completely.

SET UP: $B = \dfrac{\mu_0}{2\pi}\dfrac{I}{r}$. The fields completely cancel only if they are in opposite directions and of the same magnitude. Both conditions can be met only in the region below the 2.00 A current wire.

EXECUTE: Call y the coordinate of the point where $B = 0$. At that point $B_1 = B_2$. This gives $\dfrac{\mu_0}{2\pi}\dfrac{I_1}{r_1} = \dfrac{\mu_0}{2\pi}\dfrac{I_2}{r_2}$, so $\dfrac{2}{r_1} = \dfrac{6}{r_2}$. $r_1 = y$ and $r_2 = 0.800\ \text{m} + y$, so $\dfrac{1}{y} = \dfrac{3}{0.800\ \text{m} + y}$. Solving for y gives us $y = -0.400$ m.

EVALUATE: The point where $B = 0$ must be closer to the smaller current than to the larger one. $y_1 = 0.400$ m and $y_2 = 1.20$ m, which agrees with this condition.

28.53. **IDENTIFY:** In this problem, we are dealing with the magnetic force on a current-carrying wire.

SET UP: $F = IlB\sin\phi$, $B = \dfrac{\mu_0}{2\pi}\dfrac{I}{r}$ (long wire), $B = \dfrac{\mu_0 I}{2a}$ (center of circular loop).

EXECUTE: **(a)** We want the force. Combine $F = IlB\sin\phi$ and $B = \dfrac{\mu_0}{2\pi}\dfrac{I}{r}$ with ϕ = 90°. This gives

$F = IlB = I(2\pi R)\left(\dfrac{\mu_0 I}{2\pi d}\right) = \mu_0 I^2 R/d.$

(b) We want the force. At the center of the loop we use $B = \dfrac{\mu_0 I}{2a}$. In this case, $a = R$. Solve for I:

$I = \dfrac{2RB}{\mu_0}$. Express the area A in terms of R: $A = \pi R^2 \rightarrow R = \sqrt{A/\pi}$. Use the result from (a):

$F = \dfrac{\mu_0 I^2 R}{d} = \dfrac{\mu_0 (2RB/\mu_0)^2 \sqrt{A/\pi}}{d}$, which reduces to $F = \dfrac{4B^2}{\mu_0 d}\left(\dfrac{A}{\pi}\right)^{3/2}$.

(c) Solve for B: $B = \dfrac{1}{2}\sqrt{\mu_0 F d}\left(\dfrac{\pi}{A}\right)^{3/4}$.

(d) Estimate: F = 5 N.

(e) Estimate: A = 2 cm by 4 cm = 8 cm^2.

(f) $B = \dfrac{1}{2}\sqrt{\mu_0 F d}\left(\dfrac{\pi}{A}\right)^{3/4}$. Using the estimates and d = 25 μm, we get 3 mT.

EVALUATE: This field is about 3 mT and the earth's magnetic field is about 0.05 mT, so the magnet's field is roughly 60 times that of the earth.

28.54. **IDENTIFY:** The wire creates a magnetic field near it, and the moving electron feels a force due to this field.

SET UP: The magnetic field due to the wire is $B = \dfrac{\mu_0 I}{2\pi r}$, and the force on a moving charge is $F = |q| vB\sin\phi$.

EXECUTE: $F = |q| vB\sin\phi = (ev\mu_0 I \sin\phi)/2\pi r$. Substituting numbers gives

$F = (1.60\times10^{-19}\text{ C})(6.00\times10^4\text{ m/s})(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})(8.60\text{ A})(\sin 90°)/[2\pi(0.0450\text{ m})]$.

$F = 3.67\times10^{-19}$ N. From the right-hand rule for the cross product, the direction of $\vec{v}\times\vec{B}$ is opposite to the current, but since the electron is negative, the force is in the same direction as the current.

EVALUATE: This force is small at an everyday level, but it would give the electron an acceleration of over 10^{11} m/s^2.

28.55. **IDENTIFY:** Find the force that the magnetic field of the wire exerts on the electron.

SET UP: The force on a moving charge has magnitude $F = |q| vB\sin\phi$ and direction given by the right-hand rule. For a long straight wire, $B = \dfrac{\mu_0 I}{2\pi r}$ and the direction of $\vec{B}$ is given by the right-hand rule.

EXECUTE: **(a)** $a = \dfrac{F}{m} = \dfrac{|q| vB\sin\phi}{m} = \dfrac{ev}{m}\left(\dfrac{\mu_0 I}{2\pi r}\right)$. Substituting numbers gives

$a = \dfrac{(1.6\times10^{-19}\text{C})(2.50\times10^5\text{ m/s})(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})(13.0\text{ A})}{(9.11\times10^{-31}\text{ kg})(2\pi)(0.0200\text{ m})} = 5.7\times10^{12}\text{ m/s}^2$, away from the wire.

(b) The electric force must balance the magnetic force. $eE = evB$, and

$E = vB = v\dfrac{\mu_0 I}{2\pi r} = \dfrac{(250{,}000\text{ m/s})(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})(13.0\text{ A})}{2\pi(0.0200\text{ m})} = 32.5\text{ N/C}$. The magnetic force is directed away from the wire so the force from the electric field must be toward the wire. Since the charge of the electron is negative, the electric field must be directed away from the wire to produce a force in the desired direction.

EVALUATE: **(c)** $mg = (9.11\times10^{-31}\text{ kg})(9.8\text{ m/s}^2) \approx 10^{-29}\text{ N}.$

$F_{\text{el}} = eE = (1.6\times10^{-19}\text{ C})(32.5\text{ N/C}) \approx 5\times10^{-18}\text{ N}.$ $F_{\text{el}} \approx 5\times10^{11}\,F_{\text{grav}},$ so we can neglect gravity.

28.56. **IDENTIFY:** The current in the wire creates a magnetic field, and that field exerts a force on the moving electron.

SET UP: The magnetic field due to the current in the wire is $B = \dfrac{\mu_0 I}{2\pi r}$. The force the field exerts on the electron is $\vec{F} = q\vec{v}\times\vec{B},$ where $q = -e$. The magnitude of a vector is $A = \sqrt{A_x^2 + A_y^2 + A_z^2}$. The electron is on the $+y$-axis. The current is in the $-x$-direction so, by the right-hand rule, the magnetic field it produces at the location of the electron is in the $-z$-direction, so $\vec{B} = -\dfrac{\mu_0 I}{2\pi r}\,\hat{k}.$

EXECUTE: The magnitude of the magnetic field is $B = \dfrac{\mu_0 I}{2\pi r} = \dfrac{\mu_0(9.00\text{ A})}{2\pi(0.200\text{ m})} = 9.00\times10^{-6}\text{ T},$ so

$\vec{B} = -9.00\times10^{-6}\text{ T}\,\hat{k}$. The force on the electron is $\vec{F} = q\vec{v}\times\vec{B},$ so

$\vec{F} = q\vec{v}\times\vec{B} = -e(5.00\times10^4\text{ m/s}\,\hat{i} - 3.00\times10^4\text{ m/s}\,\hat{j})\times(-9.00\times10^{-6}\text{ T}\,\hat{k}).$

Taking out common factors gives $\vec{F} = (9\times10^{-2}e\text{ T}\cdot\text{m/s})(5\hat{i} - 3\hat{j})\times\hat{k}.$ Using the fact that $\boldsymbol{i}\times\boldsymbol{k} = -\boldsymbol{j}$ and $\boldsymbol{j}\times\boldsymbol{k} = \boldsymbol{i},$ we get $\vec{F} = (9\times10^{-2}e\text{ T}\cdot\text{m/s})(-5\hat{j} - 3\hat{i}).$ Using $e = 1.60\times10^{-19}\text{ C}$ gives

$\vec{F} = -4.32\times10^{-20}\text{ N}\,\hat{i} - 7.20\times10^{-20}\text{ N}\,\hat{j}.$

The magnitude of this force is

$F = \sqrt{F_x^2 + F_y^2 + F_z^2} = \sqrt{(-4.32\times10^{-20}\text{ N})^2 + (-7.20\times10^{-20}\text{ N})^2} = 8.40\times10^{-20}\text{ N}.$

EVALUATE: This is a small force on an everyday scale, but it would give the electron an acceleration of $a = F/m = (8.40\times10^{-20}\text{ N})/(9.11\times10^{-31}\text{ kg}) \approx 9\times10^{10}\text{ m/s}^2.$

28.57. **IDENTIFY:** This problem deals with the magnetic field in a cell phone.

SET UP and **EXECUTE:** **(a)** $P = 1.5$ W.

(b) $I = P/V = (1.5\text{ W})/(1.5\text{ V}) = 1.0$ A.

(c) Width = 20 cm.

(d) Estimate: Diameter = 3.0 cm. Treat the phone as a circular current loop. The field is given by $B = \dfrac{\mu_0 I a^2}{2(x^2 + a^2)^{3/2}}$, where a is the radius of the loop and x is the distance from its center along its axis. The estimated diameter is 3.0 cm, so $a = 1.5$ cm, and x is the distance from the phone to the middle of your head, which is 10 cm from our estimate in (c). Using these values,

$B = \dfrac{\mu_0 I a^2}{2(x^2 + a^2)^{3/2}} = 0.14\ \mu\text{T}.$

(e) $\dfrac{B_{\text{phone}}}{B_{\text{earth}}} = \dfrac{0.14\ \mu\text{T}}{50\ \mu\text{T}} \approx 3\times10^{-3} \approx 0.3\%.$ The magnetic field of the cell phone at the location of your brain is about 0.3% of the earth's magnetic field.

EVALUATE: This magnetic field is extremely weak compared to the earth's field which we experience all day every day.

28.58. **IDENTIFY:** Find the vector sum of the magnetic fields due to each wire.

SET UP: For a long straight wire $B = \dfrac{\mu_0 I}{2\pi r}$. The direction of $\vec{B}$ is given by the right-hand rule and is perpendicular to the line from the wire to the point where the field is calculated.

EXECUTE: **(a)** The magnetic field vectors are shown in Figure 28.58a.

(b) At a position on the x-axis $B_{\text{net}} = 2\dfrac{\mu_0 I}{2\pi r}\sin\theta = \dfrac{\mu_0 I}{\pi\sqrt{x^2+a^2}}\dfrac{a}{\sqrt{x^2+a^2}} = \dfrac{\mu_0 I a}{\pi(x^2+a^2)}$, in the positive x-direction.

(c) The graph of B versus x/a is given in Figure 28.58b.

EVALUATE: **(d)** The magnetic field is a maximum at the origin, $x = 0$.

(e) When $x \gg a$, $B \approx \dfrac{\mu_0 I a}{\pi x^2}$.

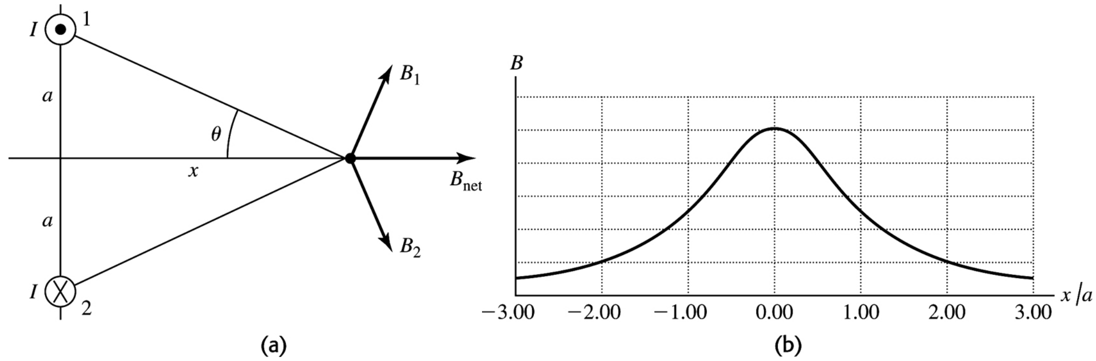

Figure 28.58

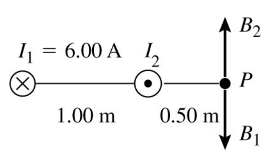
28.59. **IDENTIFY:** Use $B = \dfrac{\mu_0 I}{2\pi r}$ and the right-hand rule to calculate the magnitude and direction of the magnetic field at P produced by each wire. Add these two field vectors to find the net field.

(a) SET UP: The directions of the fields at point P due to the two wires are sketched in Figure 28.59a.



EXECUTE: $\vec{B}_1$ and $\vec{B}_2$ must be equal and opposite for the resultant field at P to be zero. $\vec{B}_2$ is to the upward so I_2 is out of the page.

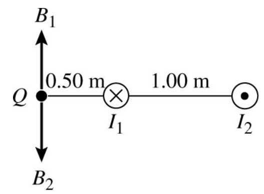
Figure 28.59a

$$B_1 = \frac{\mu_0 I_1}{2\pi r_1} = \frac{\mu_0}{2\pi}\left(\frac{6.00\ \text{A}}{1.50\ \text{m}}\right) \qquad B_2 = \frac{\mu_0 I_2}{2\pi r_2} = \frac{\mu_0}{2\pi}\left(\frac{I_2}{0.50\ \text{m}}\right).$$

$$B_1 = B_2 \text{ says } \frac{\mu_0}{2\pi}\left(\frac{6.00\ \text{A}}{1.50\ \text{m}}\right) = \frac{\mu_0}{2\pi}\left(\frac{I_2}{0.50\ \text{m}}\right).$$

$$I_2 = \left(\frac{0.50\ \text{m}}{1.50\ \text{m}}\right)(6.00\ \text{A}) = 2.00\ \text{A}.$$

(b) SET UP: The directions of the fields at point Q are sketched in Figure 28.59b.



EXECUTE: $B_1 = \dfrac{\mu_0 I_1}{2\pi r_1}$.

$$B_1 = (2\times10^{-7}\ \text{T}\cdot\text{m/A})\left(\frac{6.00\ \text{A}}{0.50\ \text{m}}\right) = 2.40\times10^{-6}\ \text{T}.$$

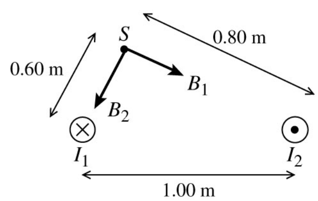
$$B_2 = \frac{\mu_0 I_2}{2\pi r_2}.$$

$$B_2 = (2\times10^{-7}\ \text{T}\cdot\text{m/A})\left(\frac{2.00\ \text{A}}{1.50\ \text{m}}\right) = 2.67\times10^{-7}\ \text{T}.$$

Figure 28.59b

$\vec{B}_1$ and $\vec{B}_2$ are in opposite directions and $B_1 > B_2$ so $B = B_1 - B_2 = 2.40\times10^{-6}\ \text{T} - 2.67\times10^{-7}\ \text{T} = 2.13\times10^{-6}\ \text{T}$, and $\vec{B}$ is upward.

(c) SET UP: The directions of the fields at point *S* are sketched in Figure 28.59c.



EXECUTE: $B_1 = \dfrac{\mu_0 I_1}{2\pi r_1}$.

$$B_1 = (2\times10^{-7}\ \text{T}\cdot\text{m/A})\left(\frac{6.00\ \text{A}}{0.60\ \text{m}}\right) = 2.00\times10^{-6}\ \text{T}.$$

$$B_2 = \frac{\mu_0 I_2}{2\pi r_2}.$$

$$B_2 = (2\times10^{-7}\ \text{T}\cdot\text{m/A})\left(\frac{2.00\ \text{A}}{0.80\ \text{m}}\right) = 5.00\times10^{-7}\ \text{T}.$$

Figure 28.59c

$\vec{B}_1$ and $\vec{B}_2$ are right angles to each other, so the magnitude of their resultant is given by

$$B = \sqrt{B_1^2 + B_2^2} = \sqrt{(2.00\times10^{-6}\ \text{T})^2 + (5.00\times10^{-7}\ \text{T})^2} = 2.06\times10^{-6}\ \text{T}.$$

EVALUATE: The magnetic field lines for a long, straight wire are concentric circles with the wire at the center. The magnetic field at each point is tangent to the field line, so $\vec{B}$ is perpendicular to the line from the wire to the point where the field is calculated.

28.60. IDENTIFY: Consider the forces on each side of the loop.

SET UP: The forces on the left and right sides cancel. The forces on the top and bottom segments of the loop are in opposite directions, so the magnitudes subtract.

EXECUTE: $F = F_\text{t} - F_\text{b} = \left(\dfrac{\mu_0 I_\text{wire}}{2\pi}\right)\left(\dfrac{Il}{r_\text{t}} - \dfrac{Il}{r_\text{b}}\right) = \dfrac{\mu_0 I l I_\text{wire}}{2\pi}\left(\dfrac{1}{r_\text{t}} - \dfrac{1}{r_\text{b}}\right)$.

$F = \dfrac{\mu_0 (5.00\ \text{A})(0.200\ \text{m})(14.0\ \text{A})}{2\pi}\left(-\dfrac{1}{0.100\ \text{m}} + \dfrac{1}{0.026\ \text{m}}\right) = 7.97\times10^{-5}\ \text{N}$. The force on the top segment is toward the wire, so the net force is toward the wire.

EVALUATE: The net force on a current loop in a uniform magnetic field is zero, but the magnetic field of the wire is not uniform; it is stronger closer to the wire.

28.61. **IDENTIFY:** Apply $\sum \vec{F} = 0$ to one of the wires. The force one wire exerts on the other depends on I so $\sum \vec{F} = 0$ gives two equations for the two unknowns T and I.

SET UP: The force diagram for one of the wires is given in Figure 28.61.

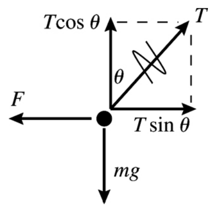


Figure 28.61

The force one wire exerts on the other is $F = \left(\dfrac{\mu_0 I^2}{2\pi r}\right)L,$ where $r = 2(0.040\ \text{m})\sin\theta = 8.362\times10^{-3}\ \text{m}$ is the distance between the two wires.

EXECUTE: $\sum F_y = 0$ gives $T\cos\theta = mg$ and $T = mg/\cos\theta$.

$\sum F_x = 0$ gives $F = T\sin\theta = (mg/\cos\theta)\sin\theta = mg\tan\theta$.

And $m = \lambda L$, so $F = \lambda Lg\tan\theta$.

$$\left(\frac{\mu_0 I^2}{2\pi r}\right)L = \lambda Lg\tan\theta.$$

$$I = \sqrt{\frac{\lambda gr\tan\theta}{(\mu_0/2\pi)}}.$$

$$I = \sqrt{\frac{(0.0125\ \text{kg/m})(9.80\ \text{m/s}^2)(\tan 6.00°)(8.362\times10^{-3}\ \text{m})}{2\times10^{-7}\ \text{T}\cdot\text{m/A}}} = 23.2\ \text{A}.$$

EVALUATE: Since the currents are in opposite directions the wires repel. When I is increased, the angle θ from the vertical increases; a large current is required even for the small displacement specified in this problem.

28.62. **IDENTIFY:** Apply $d\vec{B} = \dfrac{\mu_0}{4\pi}\dfrac{Id\vec{l}\times\hat{r}}{r^2}$.

SET UP: The two straight segments produce zero field at P. The field at the center of a circular loop of radius R is $B = \dfrac{\mu_0 I}{2R}$, so the field at the center of curvature of a semicircular loop is $B = \dfrac{\mu_0 I}{4R}$.

EXECUTE: The semicircular loop of radius a produces field out of the page at P and the semicircular loop of radius b produces field into the page. Therefore, $B = B_a - B_b = \dfrac{1}{2}\left(\dfrac{\mu_0 I}{2}\right)\left(\dfrac{1}{a} - \dfrac{1}{b}\right) = \dfrac{\mu_0 I}{4a}\left(1 - \dfrac{a}{b}\right)$, out of page.

EVALUATE: If $a = b$, $B = 0$.

28.63. **IDENTIFY:** Apply Ampere's law to a circle of radius r.

SET UP: The current within a radius r is $I = \int \vec{J}\cdot d\vec{A}$, where the integration is over a disk of radius r.

EXECUTE: **(a)** $I_0 = \int \vec{J}\cdot d\vec{A} = \int\left(\dfrac{b}{r}e^{(r-a)/\delta}\right)rdrd\theta = 2\pi b\int_0^a e^{(r-a)/\delta}dr = 2\pi b\delta\, e^{(r-a)/\delta}\Big|_0^a = 2\pi b\delta(1 - e^{-a/\delta})$.

$I_0 = 2\pi(600\ \text{A/m})(0.025\ \text{m})(1 - e^{(0.050/0.025)}) = 81.5\ \text{A}.$

(b) For $r \ge a$, r$\vec{B}\cdot d\vec{l} = B2\pi r = \mu_0 I_{\text{encl}} = \mu_0 I_0$ and $B = \dfrac{\mu_0 I_0}{2\pi r}$.

(c) For $r \le a$, $I(r) = \int \vec{J}\cdot d\vec{A} = \int\left(\dfrac{b}{r'}e^{(r'-a)/\delta}\right)r'dr'd\theta = 2\pi b\int_0^r e^{(r-a)/\delta}dr = 2\pi b\delta e^{(r'-a)/\delta}\Big|_0^r$.

$I(r)=2\pi b\delta(e^{(r-a)/\delta}-e^{-a/\delta})=2\pi b\delta e^{-a/\delta}(e^{r/\delta}-1)$ and $I(r)=I_0\dfrac{(e^{r/\delta}-1)}{(e^{a/\delta}-1)}$.

(d) For $r\le a$, $\oint \vec{B}\cdot d\vec{l}=B(r)2\pi r=\mu_0 I_{\text{encl}}=\mu_0 I_0\dfrac{(e^{r/\delta}-1)}{(e^{a/\delta}-1)}$ and $B=\dfrac{\mu_0 I_0(e^{r/\delta}-1)}{2\pi r(e^{a/\delta}-1)}$.

(e) At $r=\delta=0.025$ m, $B=\dfrac{\mu_0 I_0(e-1)}{2\pi\delta(e^{a/\delta}-1)}=\dfrac{\mu_0(81.5\text{ A})}{2\pi(0.025\text{ m})}\dfrac{(e-1)}{(e^{0.050/0.025}-1)}=1.75\times10^{-4}$ T.

At $r=a=0.050$ m, $B=\dfrac{\mu_0 I_0}{2\pi a}\dfrac{(e^{a/\delta}-1)}{(e^{a/\delta}-1)}=\dfrac{\mu_0(81.5\text{ A})}{2\pi(0.050\text{ m})}=3.26\times10^{-4}$ T.

At $r=2a=0.100$ m, $B=\dfrac{\mu_0 I_0}{2\pi r}=\dfrac{\mu_0(81.5\text{ A})}{2\pi(0.100\text{ m})}=1.63\times10^{-4}$ T.

EVALUATE: At points outside the cylinder, the magnetic field is the same as that due to a long wire running along the axis of the cylinder.

28.64. IDENTIFY: Both arcs produce magnetic fields at point *P* perpendicular to the plane of the page. The field due to arc *DA* points into the page, and the field due to arc *BC* points out of the page. The field due to *DA* has a greater magnitude than the field due to arc *BC*. The net field is the sum of these two fields.

SET UP: The magnitude field at the center of a circular loop of radius a is $B=\dfrac{\mu_0 I}{2\pi a}$. Each arc is 120°/360° = 1/3 of a complete loop, so the field due to each of them is $B=\dfrac{1}{3}\dfrac{\mu_0 I}{2\pi a}=\dfrac{\mu_0 I}{6\pi a}$.

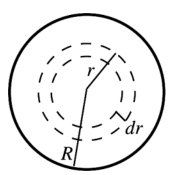
EXECUTE: The net field is

$B_{\text{net}}=B_{20}-B_{30}=\dfrac{\mu_0(12.0\text{ A})}{6\pi}\left(\dfrac{1}{0.200\text{ m}}-\dfrac{1}{0.300\text{ m}}\right)=4.19\times10^{-6}\text{ T}=4.19\ \mu\text{T}$. Since $B_{20}>B_{30}$, the net field points into the page at *P*.

EVALUATE: The current in segments *CD* and *AB* produces no magnetic field at *P* because its direction is directly toward (or away from) point *P*.

28.65. (a) IDENTIFY: Consider current density *J* for a small concentric ring and integrate to find the total current in terms of α and *R*.

SET UP: We can't say $I=JA=J\pi R^2$, since *J* varies across the cross section.



To integrate *J* over the cross section of the wire, divide the wire cross section up into thin concentric rings of radius *r* and width *dr*, as shown in Figure 28.65.

Figure 28.65

EXECUTE: The area of such a ring is *dA*, and the current through it is $dI=J\,dA$; $dA=2\pi r dr$ and $dI=J\,dA=\alpha r(2\pi r\,dr)=2\pi\alpha r^2 dr$.

$I=\int dI=2\pi\alpha\int_0^R r^2 dr=2\pi\alpha(R^3/3)$ so $\alpha=\dfrac{3I}{2\pi R^3}$.

(b) IDENTIFY and **SET UP:** (i) $r\le R$.

Apply Ampere's law to a circle of radius $r<R$. Use the method of part (a) to find the current enclosed by Ampere's law path.

EXECUTE: $\oint \vec{B}\cdot d\vec{l}=\oint B\,dl=B\oint dl=B(2\pi r)$, by the symmetry and direction of $\vec{B}$. The current passing through the path is $I_{\text{encl}}=\int dl$, where the integration is from 0 to *r*.

$I_{\text{encl}} = 2\pi\alpha\int_0^r r^2 dr = \dfrac{2\pi\alpha r^3}{3} = \dfrac{2\pi}{3}\left(\dfrac{3I}{2\pi R^3}\right)r^3 = \dfrac{Ir^3}{R^3}$. Thus $\oint \vec{B}\cdot d\vec{l} = \mu_0 I_{\text{encl}}$ gives

$B(2\pi r) = \mu_0\left(\dfrac{Ir^3}{R^3}\right)$ and $B = \dfrac{\mu_0 I r^2}{2\pi R^3}$.

(ii) **IDENTIFY** and **SET UP:** $r \ge R$.

Apply Ampere's law to a circle of radius $r > R$.

EXECUTE: $\oint \vec{B}\cdot d\vec{l} = \oint B\,dl = B\oint dl = B(2\pi r)$.

$I_{\text{encl}} = I$; all the current in the wire passes through this path. Thus $\oint \vec{B}\cdot d\vec{l} = \mu_0 I_{\text{encl}}$ gives

$B(2\pi r) = \mu_0 I$ and $B = \dfrac{\mu_0 I}{2\pi r}$.

EVALUATE: Note that at $r = R$ the expression in (i) (for $r \le R$) gives $B = \dfrac{\mu_0 I}{2\pi R}$. At $r = R$ the expression in (ii) (for $r \ge R$) gives $B = \dfrac{\mu_0 I}{2\pi R}$, which is the same.

28.66. **IDENTIFY:** Apply $d\vec{B} = \dfrac{\mu_0}{4\pi}\dfrac{I d\vec{l}\times\hat{r}}{r^2}$.

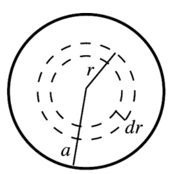
SET UP: The horizontal wire yields zero magnetic field since $d\vec{l}\times\vec{r} = 0$. The vertical current provides the magnetic field of half of an infinite wire. (The contributions from all infinitesimal pieces of the wire point in the same direction, so there is no vector addition or components to worry about.)

EXECUTE: $B = \frac{1}{2}\left(\dfrac{\mu_0 I}{2\pi a}\right) = \dfrac{\mu_0 I}{4\pi a}$ and is directed out of the page.

EVALUATE: In the equation preceding Eq. (28.8) the limits on the integration are 0 to a rather than $-a$ to a and this introduces a factor of $\frac{1}{2}$ into the expression for B.

28.67. **IDENTIFY:** Use the current density J to find dI through a concentric ring and integrate over the appropriate cross section to find the current through that cross section. Then use Ampere's law to find $\vec{B}$ at the specified distance from the center of the wire.

(a) SET UP:

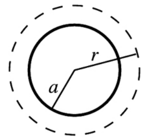


Divide the cross section of the cylinder into thin concentric rings of radius r and width dr, as shown in Figure 28.67a. The current through each ring is $dI = J\,dA = J2\pi r\,dr$.

Figure 28.67a

EXECUTE: $dI = \dfrac{2I_0}{\pi a^2}\left[1-(r/a)^2\right]2\pi r\,dr = \dfrac{4I_0}{a^2}\left[1-(r/a)^2\right]r\,dr$. The total current I is obtained by integrating dI over the cross section $I = \int_0^a dI = \left(\dfrac{4I_0}{a^2}\right)\int_0^a (1-r^2/a^2)r\,dr = \left(\dfrac{4I_0}{a^2}\right)\left[\dfrac{1}{2}r^2 - \dfrac{1}{4}r^4/a^2\right]_0^a = I_0$, as was to be shown.

(b) SET UP: Apply Ampere's law to a path that is a circle of radius $r > a$, as shown in Figure 28.67b.



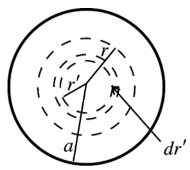
$\oint \vec{B} \cdot d\vec{l} = B(2\pi r)$.

$I_{\text{encl}} = I_0$ (the path encloses the entire cylinder).

Figure 28.67b

EXECUTE: $\oint \vec{B} \cdot d\vec{l} = \mu_0 I_{\text{encl}}$ says $B(2\pi r) = \mu_0 I_0$ and $B = \dfrac{\mu_0 I_0}{2\pi r}$.

(c) SET UP:



Divide the cross section of the cylinder into concentric rings of radius r' and width dr', as was done in part (a). See Figure 28.67c. The current dI through each ring is

$$dI = \frac{4I_0}{a^2}\left[1 - \left(\frac{r'}{a}\right)^2\right] r'\,dr'.$$

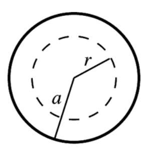
Figure 28.67c

EXECUTE: The current I is obtained by integrating dI from $r' = 0$ to $r' = r$:

$$I = \int dI = \frac{4I_0}{a^2}\int_0^r \left[1 - \left(\frac{r'}{a}\right)^2\right] r'\,dr' = \frac{4I_0}{a^2}\left[\tfrac{1}{2}(r')^2 - \tfrac{1}{4}(r')^4/a^2\right]_0^r.$$

$$I = \frac{4I_0}{a^2}(r^2/2 - r^4/4a^2) = \frac{I_0 r^2}{a^2}\left(2 - \frac{r^2}{a^2}\right).$$

(d) SET UP: Apply Ampere's law to a path that is a circle of radius $r < a$, as shown in Figure 28.67d.



$\oint \vec{B} \cdot d\vec{l} = B(2\pi r)$.

$I_{\text{encl}} = \dfrac{I_0 r^2}{a^2}\left(2 - \dfrac{r^2}{a^2}\right)$ (from part (c)).

Figure 28.67d

EXECUTE: $\oint \vec{B} \cdot d\vec{l} = \mu_0 I_{\text{encl}}$ says $B(2\pi r) = \mu_0 \dfrac{I_0 r^2}{a^2}(2 - r^2/a^2)$ and $B = \dfrac{\mu_0 I_0}{2\pi}\dfrac{r}{a^2}(2 - r^2/a^2)$.

EVALUATE: Result in part (b) evaluated at $r = a$: $B = \dfrac{\mu_0 I_0}{2\pi a}$. Result in part (d) evaluated at $r = a$: $B = \dfrac{\mu_0 I_0}{2\pi}\dfrac{a}{a^2}(2 - a^2/a^2) = \dfrac{\mu_0 I_0}{2\pi a}$. The two results, one for $r > a$ and the other for $r < a$, agree at $r = a$.

28.68. IDENTIFY: The net field is the vector sum of the fields due to the circular loop and to the long straight wire.

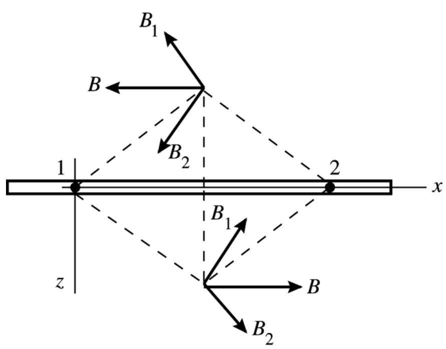
SET UP: For the long wire, $B = \dfrac{\mu_0 I_1}{2\pi D}$, and for the loop, $B = \dfrac{\mu_0 I_2}{2R}$.

EXECUTE: At the center of the circular loop the current I_2 generates a magnetic field that is into the page, so the current I_1 must point to the right. For complete cancellation the two fields must have the same magnitude: $\dfrac{\mu_0 I_1}{2\pi D} = \dfrac{\mu_0 I_2}{2R}$. Thus, $I_1 = \dfrac{\pi D}{R} I_2$.

EVALUATE: If I_1 is to the left the two fields add.

28.69. **IDENTIFY:** Use what we know about the magnetic field of a long, straight conductor to deduce the symmetry of the magnetic field. Then apply Ampere's law to calculate the magnetic field at a distance a above and below the current sheet.

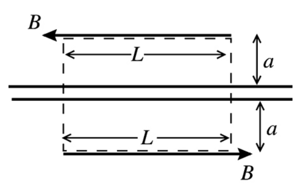
SET UP: Do parts (a) and (b) together.



Consider the individual currents in pairs, where the currents in each pair are equidistant on either side of the point where $\vec{B}$ is being calculated. Figure 28.69a shows that for each pair the z-components cancel, and that above the sheet the field is in the $-x$-direction and that below the sheet it is in the $+x$-direction.

Figure 28.69a

Also, by symmetry the magnitude of $\vec{B}$ a distance a above the sheet must equal the magnitude of $\vec{B}$ a distance a below the sheet. Now that we have deduced the symmetry of $\vec{B}$, apply Ampere's law. Use a path that is a rectangle, as shown in Figure 28.69b.



$$\oint \vec{B} \cdot d\vec{l} = \mu_0 I_{\text{encl}}.$$

Figure 28.69b

I is directed out of the page, so for I to be positive the integral around the path is taken in the counterclockwise direction.

EXECUTE: Since $\vec{B}$ is parallel to the sheet, on the sides of the rectangle that have length $2a$, $\oint \vec{B} \cdot d\vec{l} = 0.$ On the long sides of length L, $\vec{B}$ is parallel to the side, in the direction we are integrating around the path, and has the same magnitude, B, on each side. Thus $\oint \vec{B} \cdot d\vec{l} = 2BL.$ n conductors per unit length and current I out of the page in each conductor gives $I_{\text{encl}} = InL.$ Ampere's law then gives $2BL = \mu_0 InL$ and $B = \frac{1}{2}\mu_0 In.$

EVALUATE: Note that B is independent of the distance a from the sheet. Compare this result to the electric field due to an infinite sheet of charge in Chapter 22.

28.70. **IDENTIFY:** Find the vector sum of the fields due to each sheet.

SET UP: Problem 28.69 shows that for an infinite sheet $B = \frac{1}{2}\mu_0 In.$ If I is out of the page, $\vec{B}$ is to the left above the sheet and to the right below the sheet. If I is into the page, $\vec{B}$ is to the right above the sheet and to the left below the sheet. B is independent of the distance from the sheet. The directions of the two fields at points P, R and S are shown in Figure 28.70.

EXECUTE: **(a)** Above the two sheets, the fields cancel (since there is no dependence upon the distance from the sheets).

(b) In between the sheets the two fields add up to yield $B = \mu_0 nI$, to the right.

(c) Below the two sheets, their fields again cancel (since there is no dependence upon the distance from the sheets).

EVALUATE: The two sheets with currents in opposite directions produce a uniform field between the sheets and zero field outside the two sheets. This is analogous to the electric field produced by large parallel sheets of charge of opposite sign.

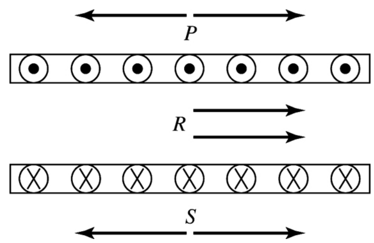


Figure 28.70

28.71. **IDENTIFY:** A charged cylindrical shell is rotating. This motion produces a magnetic field which exerts a torque on a very small disk at its midpoint.

SET UP and **EXECUTE:** **(a)** We want the current. $I = \dfrac{\Delta Q}{\Delta t}$. In one full rotation, charge Q_1 passes through in time T_1 which is the period of rotation of the cylinder. Thus $\Delta Q = Q_1$ and $\Delta T = T_1 = 2\pi/\omega_1$. So $I = \dfrac{Q_1}{(2\pi/\omega_1)} = \dfrac{Q_1\omega_1}{2\pi}$.

(b) We want B. Apply Ampere's law: $\oint \vec{B}\cdot d\hat{l} = \mu_0 I_{\text{encl}}$. The rectangular path of integration is similar to the one used in Example 28.9. The inner segment ab is on the axis of the cylinder, is equidistant from its ends, and has length $l << H$. $B = 0$ outside the cylinder, and the field is perpendicular to bc and da. Using the current from part (a), $\oint \vec{B}\cdot d\hat{l} = \mu_0 I_{\text{encl}}$ gives us $Bl = \mu_0 I \dfrac{l}{H} = \mu_0 \dfrac{Q_1\omega_1}{2\pi}\dfrac{l}{H}$. Solving for B and realizing that the field points along the $+z$-axis, we have $\vec{B} = \dfrac{\mu_0\omega_1 Q_1}{2\pi H}\hat{k}$.

(c) We want the torque on the disk. $\tau = \mu B\sin\phi$. Since the disk is very small, we can treat the magnetic field as uniform over its surface and equal to the field at the center of the cylinder. Using the given magnetic moment, our result from (b), and $\phi = \theta$, we get

$$\tau = \left(\frac{1}{4}Q_2\omega_2 R_2^2\right)\left(\frac{\mu_0 Q_1\omega_1}{2\pi H}\right)\sin\theta = \frac{\mu_0 Q_1 Q_2\omega_1\omega_2 R_2^2}{8\pi H}\sin\theta.$$

(d) We want the angular momentum of the disk. $L = I\omega = \dfrac{1}{2}MR_2^2\omega_2$.

(e) We want the precession rate. From Section 10.7 we have

$$\Omega = \frac{\tau_z}{L_z} = \frac{\dfrac{\mu_0}{8\pi H}Q_1Q_2\omega_1\omega_2 R_2^2\sin\theta}{\dfrac{1}{2}MR_2^2\omega_2} = \frac{\mu_0}{4\pi H}\frac{Q_1Q_2\omega_1\sin\theta}{M}.$$

EVALUATE: The spinning charged cylinder behaves like a solenoid.

28.72. **IDENTIFY** and **SET UP:** We assume that both solenoids are ideal, in which case the field due to each one is given by $B = \mu_0 nI = \mu_0 \dfrac{N}{L}I$. The net field inside is the sum of both the fields.

EXECUTE: **(a)** The net field is $B=\mu_0\frac{N_1}{L}I_1+\mu_0\frac{N_2}{L}I_2=\frac{\mu_0}{L}[N_1I_1+N_2I_2]$. For the numbers in this problem, we have $BL/\mu_0=(0.00200\text{ A})N_1+N_2I_2$. Therefore a graph of BL/μ_0 versus I_2 should be a straight line with slope equal to N_2 and *y*-intercept equal to (0.00200 A)N_1.

(b) Using the graph given with the problem, we calculate the slope using the points (5.00 mA, 16.00 A) and (2.00 mA, 8.00 A), which gives slope = (16.00 A – 8.00 A)/(5.00 mA – 2.00 mA) = 2667. Therefore N_2 = 2667 turns, which rounds to 2670 turns. To find the *y*-intercept, we use the point (5.00 mA, 16.00 A) and the slope to deduce the equation of the line. This gives $\frac{y-16.00\text{ A}}{x-0.00500\text{ A}}=2667$, which simplifies to y = 2667x + 2.67. When x = 0, y = 2.67 A. As we saw, the *y*-intercept is equal to (0.00200 A)N_1, so N_1 = (2.67 A)/(0.00200 A) = 1335 turns, which rounds to 1340 turns.

(c) Now the fields are in opposite directions, so $B=\mu_0\frac{N_1}{L}I_1-\mu_0\frac{N_2}{L}I_2=\frac{\mu_0}{L}[N_1I_1-N_2I_2]$.

B = [(μ_0)/(0.400 m)][(0.00200 A)(1335) – (0.00500 A)(2667)] $=-3.35\times10^{-5}$ T. The minus sign just tells us that the field due to I_2 is stronger than the field due to I_1. So the magnitude of the net field is $B=3.35\times0^{-5}\text{ T}=33.5\ \mu\text{T}$.

EVALUATE: As a check for N_1 in part (b), we could use a ruler to extrapolate the graph in the textbook back to its intersection with the *y*-axis to find the *y*-intercept. This method is not particularly accurate, but it should give reasonable agreement with the result for N_1 from part (b).

28.73. **IDENTIFY** and **SET UP:** The magnitude of the magnetic a distance r from the center of a very long current-carrying wire is $B=\frac{\mu_0 I}{2\pi r}$. In this case, the measured quantity x is the distance from the *surface* of the cable, not from the center.

EXECUTE: **(a)** Multiplying the quantities given in the table in the problem, we get the following values for Bx in units of $\text{T}\cdot\text{cm}$, starting with the first pair: 0.812, 1.00, 1.09, 1.13, 1.16. As we can see, these values are not constant. However the last three values are nearly constant. Therefore Bx is not truly constant. The reason for this is that x is the distance from the *surface* of the cable, not from the center. In the formula $B=\frac{\mu_0 I}{2\pi r}$, r is the distance from the center of the cable. In that case, we would expect Br to be constant. For the last three points, it does appear that Bx is nearly constant. The reason for this is that the proper formula for the magnetic field for this cable is $B=\frac{\mu_0 I}{2\pi(R+x)}$, where R is the radius of the cable. As x gets large compared to R, $r\approx x$ and the magnitude approaches $\frac{\mu_0 I}{2\pi r}$.

(b) Using the equation appropriate for the cable and solving for x gives $x=(\mu_0 I/2\pi)\frac{1}{B}-R$. A graph of x versus $1/B$ should have a slope equal to $\mu_0 I/2\pi$ and a *y*-intercept equal to $-R$. Figure 28.73 shows the graph of x versus $1/B$.

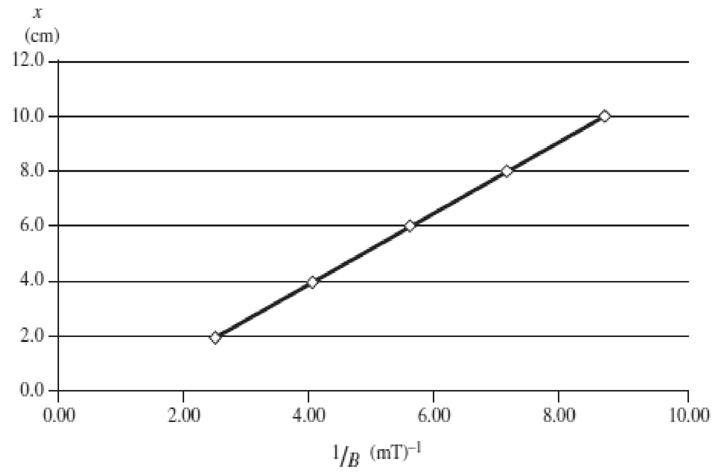

Figure 28.73

(c) The best-fit equation for this graph is $x = (1.2981\ \text{mT}\cdot\text{cm})\dfrac{1}{B} - 1.1914$ cm. The slope is $1.2981\ \text{mT}\cdot\text{cm} = 1.2981\times10^{-5}\ \text{T}\cdot\text{m}$. Since the slope is equal to $\mu_0 I/2\pi$, we have $\mu_0 I/2\pi$ = slope, which gives $I = 2\pi(\text{slope})/\mu_0 = 2\pi(1.2981\times10^{-5}\ \text{T}\cdot\text{m})/\mu_0 = 64.9\ \text{A}$, which rounds to 65 A. The *y*-intercept is $-R$, so $R = -(-1.1914\ \text{cm}) = 1.2$ cm.

EVALUATE: As we can see, the field within 2 cm or so of the surface of the cable would vary considerably from the value given by $B = \dfrac{\mu_0 I}{2\pi r}$.

28.74. **IDENTIFY** and **SET UP:** The wires repel each other since they carry currents in opposite directions, so the wires will move away from each other until the magnetic force is just balanced by the force due to the spring. The force per unit length between two parallel current-carrying wires of equal length and separation r is $\dfrac{F}{L} = \dfrac{\mu_0}{2\pi}\dfrac{I'I}{r}$. In this case, the currents are the same and the distance between the wires is $l_0 + x$, where x is the distance the spring stretches. Therefore the force is $F = \dfrac{\mu_0 I^2 L}{2\pi(l_0 + x)}$. The magnitude of the force that each spring exerts is $F = kx$, by Hooke's law. On each wire, $F_{\text{spr}} = F_{\text{mag}}$, and there are *two* spring forces on each wire. Therefore $\dfrac{\mu_0 I^2 L}{2\pi(l_0 + x)} = 2kx$.

EXECUTE: **(a)** We are given two cases with values for I and x, and each one leads to an equation involving l_0 and k. If we take the ratio of these two equations, common factors such as L will cancel. This gives us

$$\frac{(13.1\ \text{A})^2(l_0 + 0.40\ \text{m})}{(8.05\ \text{A})^2(l_0 + 0.80\ \text{m})} = \frac{0.80\ \text{cm}}{0.40\ \text{cm}} = 2.0.$$ Solving for l_0 gives $l_0 = 0.834$ cm, which rounds to 0.83 cm.

Now we can solve for k using this value for l_0 using $\dfrac{\mu_0 I^2 L}{2\pi(l_0 + x)} = 2kx$.

$$\frac{\mu_0(13.1\text{ A})^2(0.50\text{ m})}{2\pi(0.0080\text{ m}+0.00834\text{ m})}=2k(0.0080\text{ m}).$$ $k = 0.0656$ N/m, which rounds to 0.066 N/m.

(b) For a 12.0-A current, we have $\frac{\mu_0(12.0\text{ A})^2(0.50\text{ m})}{2\pi(x+0.00834\text{ m})}=2(0.0656\text{ N/m})x.$ Carrying out the multiplication and division and simplifying we get the quadratic equation
$x^2 + (0.00834\text{ m})x - 1.097\times10^{-4}\text{ m}^2 = 0.$

Using the quadratic formula and taking the positive solution gives $x = 0.0071$ m = 0.71 cm.

(c) To stretch the spring by 1.00 cm, the current must satisfy the equation

$$\frac{\mu_0 I^2(0.50\text{ m})}{2\pi(0.0100\text{ m}+0.00834\text{ m})}=2(0.0656\text{ N/m})(0.0100\text{ m}).$$ This gives $I = 15.5$ A, which rounds to 16 A.

EVALUATE: The spring force in part (c) is kx =(0.0656 N/m)(0.0100 m) = 6.56×10^{-4} N. This is a very small force resulting from a rather large 16-A current. This tells us that magnetic forces between parallel wires, such as extension cords, are not very significant for typical household currents.

28.75. **IDENTIFY:** The moving charges in the plasma cause a magnetic field.
SET UP and **EXECUTE:** **(a)** We want the charge density. There are n ions per unit volume, each with charge q, so $\rho = nq$.

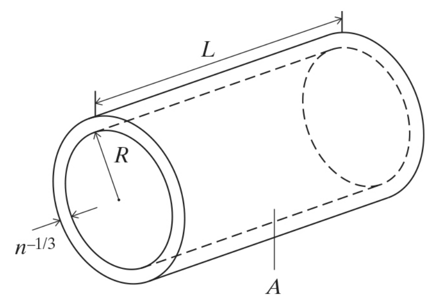

Figure 28.75a

(b) We want the surface charge density. See Fig. 28.75a. The "surface" has thickness equal to $n^{-1/3}$, so its volume is $V = 2\pi Rn^{-1/3}L.$ $\sigma A = \rho V,$ so $\sigma=\frac{\rho V}{A}=\frac{\rho 2\pi R n^{-1/3}L}{2\pi RL}=\rho n^{-1/3}=(nq)n^{-1/3}=n^{2/3}q.$

(c) We want B at the surface. Use Ampere's law, taking an integration path around the surface. The current density is $J = \rho v.$ This gives $B2\pi R=\mu_0 I=\mu_0(JA)=\mu_0\rho vA=\mu_0\rho v\pi R^2$. Solve for B and using $\rho = nq.$ $B=\frac{1}{2}\mu_0 nqvR.$ By the right-hand rule, its direction is tangent to the circle. So we can express the field as $\vec{B}=\frac{1}{2}\mu_0 nqvR\hat{\phi}.$

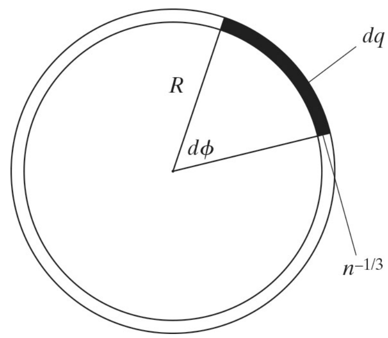

Figure 28.75b

(d) We want dI. Fig. 28.75b shows the geometric configuration. We know $\rho = nq$, $J = \rho v$, and $I = JA$. $dA = (Rd\phi)\left(n^{-1/3}\right)$. $dI = JdA = \rho v dA = \rho v\left(n^{-1/3}Rd\phi\right) = (qn)vn^{-1/3}Rd\phi = n^{2/3}qvRd\phi.$

(e) We want dF. $dF = dI(BL) = BL\left(n^{2/3}qvRd\phi\right) = \left(\frac{\mu_0}{2}nqvR\right)(L)\left(n^{2/3}qvRd\phi\right)$. This simplifies to $dF = \frac{\mu_0}{2}n^{5/3}q^2v^2R^2Ld\phi.$

(f) We want the force F and the pressure p. $F = \int_0^{2\pi} dF = \pi\mu_0 n^{5/3}q^2v^2R^2L$. The direction is inward toward the axis of the cylinder. $p = F/A$. Using F from above and $A = 2\pi RL$ gives $p = \frac{\mu_0}{2}n^{5/3}q^2v^2R.$

(g) We want the pressure. Using the numbers given in the problem, we get $p = 1.9\times10^{-5}$ Pa.

EVALUATE: This is a small pressure but it acts on very small objects (atoms).

28.76. IDENTIFY: We want to find the magnetic field inside a spinning charged cylinder.

SET UP and **EXECUTE:** **(a)** We want the surface charge density. $\sigma = \frac{Q}{A} = \frac{Q}{2\pi RW}.$

(b) We want dI. In one period T, the charge dq that passes along dx is $dq = \sigma dA = \sigma 2\pi Rdx$. The time for this charge to pass by is $T = 2\pi/\omega$, so $dI = \frac{dq}{T} = \frac{\sigma 2\pi Rdx}{2\pi/\omega} = \sigma\omega Rdx.$

(c) We want dB_x at the origin. Eq. (28.15): $B_x = \frac{\mu_0 Ia^2}{2\left(x^2+a^2\right)^{3/2}}$. Let a circular strip be at a distance x from the origin. In this case, $I \to dI, a \to R, x \to x$. Using this information and our results from parts (a) and (b), we get $dB_x = \frac{\mu_0 dI\,R^2}{2\left(x^2+R^2\right)^{3/2}} = \frac{\mu_0\sigma\omega RdxR^2}{2\left(x^2+R^2\right)^{3/2}} = \frac{\mu_0}{2}\left(\frac{Q}{2\pi RW}\right)\frac{\omega R^3dx}{\left(x^2+R^2\right)^{3/2}}$, which reduces to $dB_x = \frac{\mu_0 Q\omega R^2dx}{4\pi W\left(x^2+R^2\right)^{3/2}}$. By the right-hand rule, the direction is along the $+x$ axis.

(d) Integrate to find B_x. $B_x = 2\int_0^{W/2} dB_x = 2\int_0^{W/2}\frac{\mu_0 Q\omega R^2dx}{4\pi W\left(x^2+R^2\right)^{3/2}}$. Using the integral tables in Appendix B we find $B_x = \frac{\mu_0}{2\pi}\frac{Q\omega}{\sqrt{W^2+4R^2}}$. The full field is $\vec{B} = \frac{\mu_0}{2\pi}\frac{Q\omega}{\sqrt{W^2+4R^2}}\hat{\imath}.$

EVALUATE: The rotating cylinder is quite similar to a solenoid.

28.77. **IDENTIFY:** A spinning spherical shell produces a magnetic moment.

SET UP and **EXECUTE:** $\vec{\mu} = \gamma \vec{L}$ where γ is the gyromagnetic ratio. $\gamma = g\dfrac{Q}{2M}$ where g is the g-factor.

(a) We want dI. Refer to Fig. 28.77 with the problem in the textbook. $dI = dq/T$, where $T =$ $T = 2\pi/\omega$. dq is the charge in one complete turn in time T. $q = \sigma dA = \left(\dfrac{Q}{4\pi R^2}\right)(Rd\theta)2\pi r$.

$r = R\sin\theta$. So $dI = \dfrac{\left(\dfrac{Q}{4\pi R^2}\right)(Rd\theta)(2\pi)(R\sin\theta)}{2\pi/\omega} = \dfrac{Q\omega}{4\pi}\sin\theta d\theta.$

(b) We want $d\mu$. $d\mu = AdI = \pi r^2 dI = \pi(R\sin\theta)^2\left(\dfrac{Q\omega}{4\pi}\sin\theta d\theta\right) = \dfrac{1}{4}Q\omega R^2\sin^3\theta\, d\theta$. The direction is $+z$.

(c) We want $\vec{\mu}$. $\mu = \int d\mu = \int_0^\pi \dfrac{Q\omega R^2}{4}\sin^3\theta\, d\theta = \dfrac{Q\omega R^2}{4}\int_0^\pi \sin\theta(1-\cos^2\theta)d\theta = \dfrac{Q\omega R^2}{3}$. The direction is $+z$.

(d) We want the angular momentum. $L = I\omega = \dfrac{2}{3}MR^2\omega.$

(e) We want γ. $\gamma = \dfrac{\mu}{L} = \dfrac{Q\omega R^2/3}{2MR^2\omega/3} = \dfrac{Q}{2M}$.

(f) We want g. $\gamma = g\dfrac{Q}{2M}$, $L = \dfrac{\mu}{\gamma}$, and $L = \dfrac{2}{3}MR^2\omega$. Equate the two expressions for L and solve for g, which gives $g = 1$.

EVALUATE: If $g = 1$, $\gamma = \dfrac{Q}{2M}$ so $\mu = QL/2M$.

28.78. **IDENTIFY:** We are dealing with the magnetic field inside a rotating charged cylinder.

SET UP: $\vec{B} = \dfrac{\mu_0}{4\pi}\int \dfrac{\sigma\vec{v}\times\hat{r}}{r^2}dA$. Refer to the Fig. 28.78 with the problem in the textbook.

EXECUTE: **(a)** Find σ. $\sigma = Q/A = \dfrac{Q}{2\pi RW}$.

(b) We want $\vec{r}$. ϕ is the angle with the $+y$-axis in the yz-plane. $\vec{r}$ is the vector from point (x, y, z) to the origin (0, 0, 0). So $r_x = -x$, $r_{y-} = -R\cos\phi$, and $r_z = -R\sin\phi$. Therefore

$\vec{r} = -(x\hat{i} + R\cos\phi\hat{j} + R\sin\phi\hat{k})$.

(c) We want $\vec{v}$. The velocity is in the yz-plane. v_y is negative when $0 < \phi \le \pi$. So $v_x = 0$, $v_y = -R\omega\sin\phi$, $v_z = R\omega\cos\phi$. So $\vec{v} = -R\omega\sin\phi\hat{j} + R\omega\cos\phi\hat{k}$.

(d) We want $\vec{v}\times\hat{r}$. $\hat{r} = \dfrac{\vec{r}}{r} = \dfrac{\vec{r}}{\sqrt{x^2+R^2}}$. Use this fact, along with the results from (b) and (c), to take the cross product $\vec{v}\times\hat{r}$. Combining and simplifying gives

$\vec{v}\times\hat{r} = \dfrac{R\omega}{\sqrt{x^2+R^2}}\left[R\hat{i} - x\left(\cos\phi\hat{j} + \sin\phi\hat{k}\right)\right]$.

(e) Integrate to find $\vec{B}$. $\vec{B} = \dfrac{\mu_0}{4\pi}\int \dfrac{\sigma\vec{v}\times\hat{r}}{r^2}dA$ where $dA = R\,dx\,d\phi$. Use

$\vec{v}\times\hat{r} = \dfrac{R\omega}{\sqrt{x^2+R^2}}\left[R\hat{i} - x\left(\cos\phi\hat{j} + \sin\phi\hat{k}\right)\right]$ from part (d). The integral is

$\vec{B} = \dfrac{\mu_0 \sigma}{4\pi} \int_{-W/2}^{W/2} \int_{\phi=0}^{2\pi} \dfrac{R\omega}{(x^2+R^2)\sqrt{x^2+R^2}} \left[R\hat{i} - x(\cos\phi \hat{j} + \sin\phi \hat{k}) \right] R\,dx\,d\phi.$ Carrying out the integration

(which takes some time) yields $\vec{B} = \dfrac{\mu_0}{2\pi} \dfrac{Q\omega}{\sqrt{W^2+4R^2}} \hat{i}.$

EVALUATE: **(f)** Our answer agrees with the result of problem 28.76.

28.79. **IDENTIFY:** The current-carrying wires repel each other magnetically, causing them to accelerate horizontally. Since gravity is vertical, it plays no initial role.

SET UP: The magnetic force per unit length is $\dfrac{F}{L} = \dfrac{\mu_0}{2\pi} \dfrac{I^2}{d}$, and the acceleration obeys the equation $F/L = m/L\ a$. The rms current over a short discharge time is $I_0/\sqrt{2}$.

EXECUTE: **(a)** First get the force per unit length: $\dfrac{F}{L} = \dfrac{\mu_0}{2\pi} \dfrac{I^2}{d} = \dfrac{\mu_0}{2\pi d}\left(\dfrac{I_0}{\sqrt{2}}\right)^2 = \dfrac{\mu_0}{4\pi d}\left(\dfrac{V}{R}\right)^2 = \dfrac{\mu_0}{4\pi d}\left(\dfrac{Q_0}{RC}\right)^2.$

Now apply Newton's second law using the result above: $\dfrac{F}{L} = \dfrac{m}{L} a = \lambda a = \dfrac{\mu_0}{4\pi d}\left(\dfrac{Q_0}{RC}\right)^2$. Solving for a gives $a = \dfrac{\mu_0 Q_0^2}{4\pi\lambda R^2 C^2 d}$. From the kinematics equation $v_x = v_{0x} + a_x t$, we have $v_0 = at = aRC = \dfrac{\mu_0 Q_0^2}{4\pi\lambda RCd}.$

(b) Conservation of energy gives $\frac{1}{2}mv_0^2 = mgh$ and $h = \dfrac{v_0^2}{2g} = \dfrac{\left(\dfrac{\mu_0 Q_0^2}{4\pi\lambda RCd}\right)^2}{2g} = \dfrac{1}{2g}\left(\dfrac{\mu_0 Q_0^2}{4\pi\lambda RCd}\right)^2.$

EVALUATE: Once the wires have swung apart, we would have to consider gravity in applying Newton's second law.

28.80. **IDENTIFY:** Approximate the moving belt as an infinite current sheet.

SET UP: Problem 28.69 shows that $B = \frac{1}{2}\mu_0 In$ for an infinite current sheet. Let L be the width of the sheet, so $n = 1/L$.

EXECUTE: The amount of charge on a length Δx of the belt is $\Delta Q = L\Delta x\sigma$, so $I = \dfrac{\Delta Q}{\Delta t} = L\dfrac{\Delta x}{\Delta t}\sigma = Lv\sigma$. Approximating the belt as an infinite sheet $B = \dfrac{\mu_0 I}{2L} = \dfrac{\mu_0 v\sigma}{2}$. $\vec{B}$ is directed out of the page, as shown in Figure 28.80.

EVALUATE: The field is uniform above the sheet, for points close enough to the sheet for it to be considered infinite.

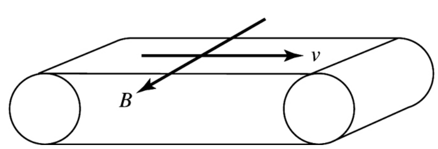

Figure 28.80

28.81. **IDENTIFY** and **SET UP:** This solenoid is not ideal since its width is fairly large compared to its length. But we can get a rough estimate using the ideal formula, $B = \mu_0 nI$.

EXECUTE: $B = \mu_0 nI = \mu_0 (1000\ \text{m}^{-1})I = 150\times10^{-6}\ \text{T}$, which gives $I = 0.12$ A, choice (b).

EVALUATE: This is a reasonable laboratory current of 120 mA.

28.82. **IDENTIFY** and **SET UP:** The magnetic field of an ideal solenoid is $B = \mu_0 nI$.

EXECUTE: Both solenoids have the same current, the same length, and the same number of turns, so the magnetic field inside both of them should be the same, which is choice (c).

EVALUATE: This answer is somewhat of an approximation. Even though both solenoids have the same current and same length and number of turns, the second (larger) solenoid is even farther from the ideal case than the first one. Therefore there would be some difference in the magnetic fields inside.

28.83. **IDENTIFY** and **SET UP:** The enclosure is no longer present to shield the solenoid from the earth's magnetic field of $50\ \mu\text{T}$, so net field inside is a sum of the solenoid field and the earth's field. Whether the earth's field adds or subtracts from the solenoid's field depends on the orientation of the solenoid. The magnetic field due to the solenoid is $150\ \mu\text{T}$.

EXECUTE: When the solenoid field is parallel to the earth's field, the net field is $150\ \mu\text{T} + 50\ \mu\text{T} = 200\ \mu\text{T}$. When the field's are antiparallel (opposite), the net field is $150\ \mu\text{T} - 50\ \mu\text{T} = 100\ \mu\text{T}$. So the field that the bacteria experience is between $100\ \mu\text{T}$ and $200\ \mu\text{T}$, which is choice (c).

EVALUATE: Since the earth's field is quite appreciable compared to the solenoid's field, it is important to shield the solenoid from external fields, such as that of the earth. The earth's field can make a difference of up to a factor of 2 in the field experienced by the bacteria.

29

ELECTROMAGNETIC INDUCTION

VP29.8.1. **IDENTIFY:** This problem is about magnetic flux and induced emfs. It requires use of Faraday's law.

SET UP: $\Phi_B = BA\cos\phi$, $\mathcal{E} = -\dfrac{d\Phi_B}{dt}$.

EXECUTE: **(a)** We want the flux. $A = \pi r^2$. $\Phi_B = BA\cos\phi$.

At $t = 0$: $\Phi_B = (0.140\text{ T})\pi(0.0240\text{ m})^2\cos 0° = 2.53\times10^{-4}\text{ T}\cdot\text{m}^2 = 2.53\times10^{-4}\text{ Wb}$.

At $t = 2.00$ s: $\Phi_B = (0.110\text{ T})\pi(0.0240\text{ m})^2\cos 180° = -1.99\times10^{-4}\text{ T}\cdot\text{m}^2 = -1.99\times10^{-4}\text{ Wb}$.

(b) We want the emf. Since this is a steady rate of change, and we only want the magnitude of the emf, we can use $\mathcal{E} = \dfrac{\Delta\Phi_B}{\Delta t} = \dfrac{\left|-1.99\times10^{-4}\text{ T}\cdot\text{m}^2 - 2.53\times10^{-4}\text{ T}\cdot\text{m}^2\right|}{2.00\text{ s}} = 0.226\text{ mV}$.

EVALUATE: Careful! Flux can be negative as well as positive.

VP29.8.2. **IDENTIFY:** This problem is about magnetic flux and induced emfs. It requires use of Faraday's law.

SET UP: $\Phi_B = BA\cos\phi$, $\mathcal{E} = -N\dfrac{d\Phi_B}{dt}$.

EXECUTE: **(a)** We want the emf. Since this is a steady rate of change, and we only want the magnitude of the emf, we can use $\mathcal{E} = N\dfrac{\Delta\Phi_B}{\Delta t}$. $\Phi_B = BA\cos\phi = B\pi r^2\cos\phi$.

$\mathcal{E} = N\dfrac{\Delta\Phi_B}{\Delta t} = N\dfrac{\Delta BA\cos\phi}{\Delta t} = NA\cos\phi\dfrac{\Delta B}{\Delta t} = N\pi r^2\cos\phi\dfrac{\Delta B}{\Delta t}$. Using $\phi = 20.0°$, $N = 455$ turns, $\dfrac{\Delta B}{\Delta t} = -3.00\times10^{-3}$ T/s, and $r = 0.0500$ m, we get for the magnitude $\mathcal{E} = 10.1$ mV.

(b) We want the current. $I = \mathcal{E}/R = (10.1\text{ mV})/(14.5\ \Omega) = 0.695$ mA.

EVALUATE: It is not the strength of the magnetic field that induces an emf. It is the *rate* at which the field changes that does it.

VP29.8.3. **IDENTIFY:** This problem is about changing flux so we need to use Faraday's law.

SET UP: $\Phi_B = \vec{B}\bullet\vec{A}$, $\mathcal{E} = N\dfrac{\Delta\Phi_B}{\Delta t}$.

EXECUTE: **(a)** We want the magnitude of the emf. $\Phi_B = \vec{B}\bullet\vec{A} = B_zA_z$, so $\mathcal{E} = N\dfrac{\Delta\Phi_B}{\Delta t}$ gives

$$\mathcal{E} = N\frac{A_z\Delta B_z}{\Delta t} = (875)\frac{\left|(0.0400\text{ m})^2(-0.200\text{ T} - 0.150\text{ T})\right|}{3.00\text{ s}} = 0.163\text{ V}.$$

(b) B_z is decreasing so the flux through the coil is decreasing. Initially B_z was positive and after 3.00 s it was negative, so the flux went from positive to negative. Therefore the induced magnetic field must be *counterclockwise* to oppose this change.

EVALUATE: It is the *change* in flux that determines the direction of the current, not the field direction alone.

VP29.8.4. **IDENTIFY:** This problem requires the use of Faraday's law.

SET UP: $\Phi_B = BA\cos\phi$, $\mathcal{E} = -N\dfrac{d\Phi_B}{dt}$.

EXECUTE: **(a)** We want the emf. $\mathcal{E} = -N\dfrac{d(BA)}{dt} = -NA\dfrac{d(B_0 \sin\omega t)}{dt} = -NA\omega B_0 \cos\omega t$.

(b) At $t = 0$, $B = 0$ but increasing in the $+z$-direction, so the induced current is in the *clockwise* direction to oppose the flux increase. At $t = \pi/\omega$, $B = 0$ but increasing in the $-z$-direction. So the induced current is *counterclockwise* to oppose the flux increase.

EVALUATE: It is not the flux that is important, but rather the *rate of change* of the flux.

VP29.9.1. **IDENTIFY:** The movement causes a motional emf.

SET UP: $\mathcal{E} = vBL$, $E = V/d$.

EXECUTE: **(a)** We want the emf. $\mathcal{E} = vBL$ = (3.90 m/s)(0.600 T)(0.0800 m) = 0.187 V.

(b) We want electric field. $E = V/d = (vBL)/L = vB$ = (3.90 m/s)(0.600 T) = 2.34 V/m. The force on a positive charge is $\vec{F} = q\vec{v}\times\vec{B}$ in the $+x$-direction, so $\vec{E} = 2.34\ \text{V/m}\,\hat{i}$.

EVALUATE: The electric field is due to the separation of charges in the conducting rod by the magnetic force.

VP29.9.2. **IDENTIFY:** The movement causes a motional emf.

SET UP: $\mathcal{E} = vBL$.

EXECUTE: $E = vBL = RI$, so $I = vBL/R$ = (2.40 m/s)(0.150 T)(0.500 m)/(0.0200 Ω) = 0.900 A. Positive charges in the rod experience a magnetic force $\vec{F} = q\vec{v}\times\vec{B}$ downward, so the current is *clockwise* around the circuit.

EVALUATE: The flux is decreasing so the current flows to increase it, which is clockwise.

VP29.9.3. **IDENTIFY:** A motional emf is caused by the movement of the rod.

SET UP: $\mathcal{E} = \left(\vec{v}\times\vec{B}\right)\cdot\vec{L}$.

EXECUTE: **(a)** We want the emf. Use the given vectors for $\vec{v}$ and $\vec{B}$ to find $\vec{v}\times\vec{B}$. Then do the dot product of that with $\vec{L}$. $\vec{v}\times\vec{B} = 0.300\ \text{T}\cdot\text{m/s}\,\hat{i} - 2.25\,\text{T}\cdot\text{m/s}\,\hat{j} + 2.40\,\text{T}\cdot\text{m/s}\,\hat{k}$ and $\vec{L} = 0.0800\ \text{m}\,\hat{i}$.

$\mathcal{E} = \left(\vec{v}\times\vec{B}\right)_x \vec{L}_x$ = (0.300 T · m/s)(0.0800 m) = 0.0240 V = 24.0 mV.

(b) The x component of $\vec{v}\times\vec{B}$ is positive, so F_x is positive, so positive charges move toward b and negative ones toward a. Therefore b is at a higher potential than a.

EVALUATE: The right-hand rule for $\vec{F} = q\vec{v}\times\vec{B}$ shows us that F_x is toward the $+x$-direction, which supports our result.

VP29.9.4. **IDENTIFY:** A motional emf is caused by the movement of the rod.

SET UP: $\mathcal{E} = vBL$ and $F = ILB$. The speed of the rod is the target variable.

EXECUTE: $\mathcal{E} = vBL = RI$. $F = ILB$, so $I = F/LB$. Combining these equations gives $vBL = RF/LB$. Solving for v gives $v = RF/(LB)^2$. Using the given numbers gives v = 4.12 m/s.

EVALUATE: Check: The current at this instant is $I = F/LB$ = 0.5742 A. $v = RI/LB$ = 4.12 m/s, which agrees with our result.

VP29.11.1. **IDENTIFY:** This problem involves an induced emf in a solenoid. We need to use Faraday's law.

SET UP: $B = \mu_0 nI$, $\mathcal{E} = -\dfrac{d\Phi_B}{dt}$, $E = V/d$. We need only magnitudes.

EXECUTE: **(a)** We want n. $\mathcal{E} = -\dfrac{d\Phi_B}{dt} = \dfrac{d(BA)}{dt} = \dfrac{d(\mu_0 InA)}{dt} = \mu_0 nA\dfrac{dI}{dt}$. Solve for n and use the given numbers. $n = \dfrac{\mathcal{E}}{\mu_0 A(dI/dt)}$ = 1810 turns/m.

(b) We want E within the loop. $E = V/d = V/2\pi r = (15.0\ \mu\text{V})/[2\pi(0.0310\ \text{m})] = 77.0\ \mu\text{V/m}$.

EVALUATE: 1810 turns/m is a reasonable turn density since wires are rather thin. The electric field is small compared to typical laboratory fields.

VP29.11.2. **IDENTIFY:** The changing magnetic field causes a changing flux which induces an emf in the loop. Faraday's law applies.

SET UP: $\mathcal{E} = Ed$, $\mathcal{E} = -\dfrac{d\Phi_B}{dt}$. The target variable is the magnitude of the induced electric field in the wire.

EXECUTE: $\mathcal{E} = Ed = E(2\pi r)$. $\mathcal{E} = \dfrac{d\Phi_B}{dt} = \dfrac{d(BA)}{dt} = A\dfrac{dB}{dt} = \pi r^2\dfrac{dB}{dt}$. Equate the two expressions for $\mathcal{E}$ and solve for E. $\mathcal{E} = \dfrac{r}{2}\dfrac{dB}{dt} = [(0.00360\ \text{m})/2](0.0150\ \text{T/s}) = 27.0\ \mu\text{V/m}$.

EVALUATE: The electric field is small compared to typical lab fields, but after all, B is changing quite slowly.

VP29.11.3. **IDENTIFY:** The changing magnetic field inside the solenoid causes a changing flux through the wire loop surrounding the solenoid. This induces an emf in the loop. Faraday's law applies.

SET UP: $\mathcal{E} = -\dfrac{d\Phi_B}{dt}$, $B = \mu_0 nI$, $E = V/d$. The target variable is dI/dt in the *solenoid*. We must be very careful to distinguish between quantities that pertain to the solenoid and those that pertain to the loop. To do so, we use subscripts L for the loop and S for the solenoid. Fig. VP29.11.3 illustrates the loop inside the solenoid. Let r be the radius of the loop. Recall that the magnetic field of the solenoid is zero outside of it.

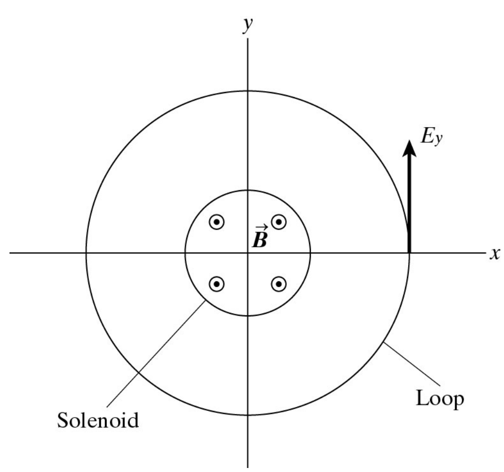

Figure VP29.11.3

EXECUTE: (a) $E_y = +1.20\times10^{-5}$ V/m. $\mathcal{E}_L = \dfrac{d\Phi_L}{dt} = \dfrac{d(B_S A_S)}{dt} = \dfrac{d(\mu_0 I_S n A_S)}{dt} = \mu_0 n A_S \dfrac{dI_S}{dt}$.

Using $E = V/d$, we have $E_y = \dfrac{\mathcal{E}_L}{2\pi r}$. This gives $E_y = \dfrac{\mathcal{E}_L}{2\pi r} = \dfrac{\mu_0 n A_S \dfrac{dI_S}{dt}}{2\pi r}$. Solving for dI_S/dt gives

$\dfrac{dI_S}{dt} = \dfrac{2\pi r E_y}{\mu_0 n A_S} = \dfrac{2\pi(0.0500\text{ m})(1.20\times10^{-5}\text{ V/m})}{\mu_0(965\text{ turns/m})(4.00\times10^{-4}\text{ m}^2)} = 7.77\text{ A/s}$. As shown in Fig. VP29.11.3, E_y is positive at the point (5.00 cm, 0, 0), so the current in the loop is *counterclockwise*. That current produces a magnetic field inside the solenoid that is in the $+z$-direction—the same as the field of the solenoid. This means that the flux through the solenoid must be decreasing, so I_S is decreasing, which means that dI_S/dt is negative, so $dI_s/dt = -7.77$ A/s.

(b) In this case, $E_y = -1.80\times10^{-5}$ V/m. Use the same approach as in part (a) except that E_y is negative and has a different numerical value. Since E_y is negative, I_S must be increasing, so dI_S/dt is positive. Using the new value for E_y, the result is $dI_S/dt = +11.7$ A/s.

EVALUATE: Only E_y changes, so it should follow that $\dfrac{dI_S/dt_{part\ a}}{dI_S/dt_{part\ b}} = \dfrac{E_a}{E_b} = \dfrac{1.20}{1.80} = 0.667$. Our result gives $\dfrac{7.77}{11.7} = 0.664$. The two results agree; the small difference is due to rounding during the numerical calculations.

VP29.11.4. IDENTIFY: The changing magnetic field inside the solenoid causes a changing flux through the wire loop surrounding the solenoid. This induces an emf in the loop. Faraday's law applies.

SET UP: $\mathcal{E} = -\dfrac{d\Phi_B}{dt}$, $B = \mu_0 n I$. The target variable is the current in the loop at $t = 13.9$ s. We must be very careful to distinguish between quantities that pertain to the solenoid and those that pertain to the loop. To do so, we use subscripts L for the loop and S for the solenoid. Let r be the radius of the loop. Recall that the magnetic field of the solenoid is zero outside of it.

EXECUTE: $\mathcal{E}_L = \dfrac{d\Phi_L}{dt} = \dfrac{d(B_S A_S)}{dt} = \dfrac{d(\mu_0 I_S n A_S)}{dt} = \mu_0 n A_S \dfrac{dI_S}{dt}$. $I_L = \dfrac{\mathcal{E}_L}{R} = \dfrac{\mu_0 n A_S \dfrac{dI_S}{dt}}{R}$. At time $t = 13.9$ s, $dI_S/dt = d\left[\left(0.600\text{ A/s}^2\right)t^2\right]/dt = (1.20\text{ A/s}^2)t = (1.20\text{ A/s}^2)(13.9\text{ s}) = 16.68$ A/s. Using this quantity and the other given quantities, we get $I_L = 5.52\ \mu$A.

EVALUATE: We use the cross-sectional area of the solenoid to find the flux through the loop because B_S is essentially zero outside the solenoid.

29.1. IDENTIFY: The changing magnetic field causes a changing magnetic flux through the loop. This induces an emf in the loop which causes a current to flow in it.

SET UP: $|\mathcal{E}| = \left|\dfrac{d\Phi_B}{dt}\right|$, $\Phi_B = BA\cos\phi$, $\phi = 0°$. A is constant and B is changing.

EXECUTE: (a) $|\mathcal{E}| = A\dfrac{dB}{dt} = (0.0900\text{ m}^2)(0.190\text{ T/s}) = 0.0171\text{ V}$.

(b) $I = \dfrac{\mathcal{E}}{R} = \dfrac{0.0171\text{V}}{0.600\,\Omega} = 0.0285\text{ A}$.

EVALUATE: These are small emfs and currents by everyday standards.

29.2. IDENTIFY: $|\mathcal{E}| = N\left|\dfrac{d\Phi_B}{dt}\right|$. $\Phi_B = BA\cos\phi$. Φ_B is the flux through each turn of the coil.

SET UP: $\phi_\text{i} = 0°$. $\phi_\text{f} = 90°$.

EXECUTE: **(a)** $\Phi_{B,\text{i}} = BA\cos 0° = (6.0\times10^{-5}\ \text{T})(12\times10^{-4}\ \text{m}^2)(1) = 7.2\times10^{-8}\ \text{Wb}$.

$\Phi_{B,\text{f}} = BA\cos 90° = 0.$ So $\Phi_B = 7.2\times10^{-8}$ Wb.

(b) $|\mathcal{E}_\text{av}| = N\left|\dfrac{\Phi_\text{i}-\Phi_\text{f}}{\Delta t}\right| = 200\left(\dfrac{7.2\times10^{-8}\ \text{Wb}}{0.040\ \text{s}}\right) = \dfrac{1.44\times10^{-5}\ \text{Wb}}{0.040\ \text{s}} = 3.6\times10^{-4}\ \text{V} = 0.36\ \text{mV}.$

EVALUATE: The average induced emf depends on how rapidly the flux changes.

29.3. IDENTIFY: The changing flux through the coil induces an emf in it. Faraday's law applies.

SET UP: $\Phi_\text{B} = BA\cos\phi$, $\mathcal{E} = -\dfrac{d\Phi_\text{B}}{dt}$.

EXECUTE: **(a)** We want the units. Magnetic flux has units of webers (Wb). Therefore α has units of Wb/s and β has units of Wb/s^3.

(b) We want to relate α and β. $\mathcal{E} = -\dfrac{d\Phi_\text{B}}{dt} = -\dfrac{d(\alpha t - \beta t^3)}{dt} = -\alpha + 3\beta t^2$. At t = 0.500 s, $\mathcal{E}$ = 0, so

$-\alpha + 3\beta(0.500\ \text{s})^2 = 0.$ So $\alpha = (0.750\ \text{s}^2)\beta$.

(c) We want the emf at t = 0.250 s. <u>At t = 0</u>: β = –1.60 V, so –1.60 V = $-\alpha + 3\beta(0)$, so $\alpha = 1.60$ V.

$\alpha = (0.750\ \text{s}^2)\beta$ so 1.60 V = $(0.750\ \text{s}^2)\beta$. β = 2.13 V/s^2.

<u>At t = 0.250 s</u>: $\mathcal{E} = -\alpha + 3\beta t^2$ = –1.60 V + 3(2.13 V/s^2)(0.250 s)^2 = –1.20 V.

EVALUATE: Comparing the units from (a) and (c) shows that Wb/s = V and Wb/s^3 = V/s^2, and these results are consistent with each other.

29.4. IDENTIFY: We are dealing with an induced emf due to changing magnetic flux.

SET UP and **EXECUTE:** **(a)** We want current. $\mathcal{E}_\text{av} = N\dfrac{\Delta\Phi_\text{B}}{\Delta t} = N\dfrac{BA}{\Delta t} = \dfrac{NAB}{\Delta t}$. $I_\text{av} = \dfrac{\mathcal{E}_\text{av}}{R} = \dfrac{NAB}{R\Delta t}$.

(b) We want the charge. $Q = I_\text{av}\Delta t = \dfrac{NAB}{R}$.

(c) We want the charge. Use $Q = \dfrac{NAB}{R}$ with the given numbers. Q = 0.450 mC.

EVALUATE: The *rate* of flux change affects the current but not the charge that flows.

29.5. IDENTIFY: Apply Faraday's law.

SET UP: Let $+z$ be the positive direction for $\vec{A}$. Therefore, the initial flux is positive and the final flux is zero.

EXECUTE: **(a)** and **(b)** $\mathcal{E} = -\dfrac{\Delta\Phi_B}{\Delta t} = -\dfrac{0-(1.5\ \text{T})\pi(0.120\ \text{m})^2}{2.0\times10^{-3}\ \text{s}} = +34\ \text{V}$. Since $\mathcal{E}$ is positive and $\vec{A}$ is toward us, the induced current is counterclockwise.

EVALUATE: The shorter the removal time, the larger the average induced emf.

29.6. IDENTIFY: Apply $\mathcal{E} = -N\dfrac{d\Phi_B}{dt}$ and $I = \mathcal{E}/R$.

SET UP: $d\Phi_B/dt = AdB/dt$.

EXECUTE: **(a)** $|\mathcal{E}| = \dfrac{Nd\Phi_B}{dt} = NA\dfrac{d}{dt}(B) = NA\dfrac{d}{dt}((0.012\ \text{T/s})t + (3.00\times10^{-5}\ \text{T/s}^4)t^4)$.

$|\mathcal{E}| = NA((0.012\ \text{T/s}) + (1.2\times10^{-4}\ \text{T/s}^4)t^3) = 0.0302\ \text{V} + (3.02\times10^{-4}\ \text{V/s}^3)t^3$.

(b) At $t = 5.00$ s, $|\mathcal{E}| = 0.0302 \text{ V} + (3.02\times10^{-4} \text{ V/s}^3)(5.00 \text{ s})^3 = 0.0680 \text{ V}$.

$I = \dfrac{\mathcal{E}}{R} = \dfrac{0.0680 \text{ V}}{600\ \Omega} = 1.13\times10^{-4} \text{ A}$.

EVALUATE: The rate of change of the flux is increasing in time, so the induced current is not constant but rather increases in time.

29.7. **IDENTIFY:** Calculate the flux through the loop and apply Faraday's law.

SET UP: To find the total flux integrate $d\Phi_B$ over the width of the loop. The magnetic field of a long straight wire, at distance *r* from the wire, is $B = \dfrac{\mu_0 I}{2\pi r}$. The direction of $\vec{B}$ is given by the right-hand rule.

EXECUTE: **(a)** $B = \dfrac{\mu_0 i}{2\pi r}$, into the page.

(b) $d\Phi_B = BdA = \dfrac{\mu_0 i}{2\pi r} Ldr$.

(c) $\Phi_B = \int_a^b d\Phi_B = \dfrac{\mu_0 iL}{2\pi}\int_a^b \dfrac{dr}{r} = \dfrac{\mu_0 iL}{2\pi}\ln(b/a)$.

(d) $|\mathcal{E}| = \dfrac{d\Phi_B}{dt} = \dfrac{\mu_0 L}{2\pi}\ln(b/a)\dfrac{di}{dt}$.

(e) $|\mathcal{E}| = \dfrac{\mu_0 (0.240 \text{ m})}{2\pi}\ln(0.360/0.120)(9.60 \text{ A/s}) = 5.06\times10^{-7} \text{ V}$.

EVALUATE: The induced emf is proportional to the rate at which the current in the long straight wire is changing

29.8. **IDENTIFY:** Apply Faraday's law.

SET UP: Let $\vec{A}$ be upward in Figure E29.8 in the textbook.

EXECUTE: **(a)** $|\mathcal{E}_{\text{ind}}| = \left|\dfrac{d\Phi_B}{dt}\right| = \left|\dfrac{d}{dt}(B_\perp A)\right|$.

$|\mathcal{E}_{\text{ind}}| = A\sin 60°\left|\dfrac{dB}{dt}\right| = A\sin 60°\left|\dfrac{d}{dt}\left((1.4 \text{ T})e^{-(0.057\text{s}^{-1})t}\right)\right| = (\pi r^2)(\sin 60°)(1.4 \text{ T})(0.057 \text{ s}^{-1})e^{-(0.057 \text{ s}^{-1})t}$.

$|\mathcal{E}_{\text{ind}}| = \pi(0.75 \text{ m})^2(\sin 60°)(1.4 \text{ T})(0.057 \text{ s}^{-1})e^{-(0.057 \text{ s}^{-1})t} = (0.12 \text{ V})\ e^{-(0.057 \text{ s}^{-1})t}$.

(b) $\mathcal{E} = \frac{1}{10}\mathcal{E}_0 = \frac{1}{10}(0.12 \text{ V})$. $\frac{1}{10}(0.12 \text{ V}) = (0.12 \text{ V})\ e^{-(0.057 \text{ s}^{-1})t}$. $\ln(1/10) = -(0.057 \text{ s}^{-1})t$ and $t = 40.4$ s.

(c) $\vec{B}$ is in the direction of $\vec{A}$ so Φ_B is positive. *B* is getting weaker, so the magnitude of the flux is decreasing and $d\Phi_B/dt < 0$. Faraday's law therefore says $\mathcal{E} > 0$. Since $\mathcal{E} > 0$, the induced current must flow *counterclockwise* as viewed from above.

EVALUATE: The flux changes because the magnitude of the magnetic field is changing.

29.9. **IDENTIFY** and **SET UP:** Use Faraday's law to calculate the emf (magnitude and direction). The direction of the induced current is the same as the direction of the emf. The flux changes because the area of the loop is changing; relate dA/dt to dc/dt, where *c* is the circumference of the loop.

(a) EXECUTE: $c = 2\pi r$ and $A = \pi r^2$ so $A = c^2/4\pi$.

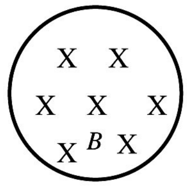
$\Phi_B = BA = (B/4\pi)c^2$.

$|\mathcal{E}| = \left|\dfrac{d\Phi_B}{dt}\right| = \left(\dfrac{B}{2\pi}\right)c\left|\dfrac{dc}{dt}\right|$.

At $t = 9.0$ s, $c = 1.650 \text{ m} - (9.0 \text{ s})(0.120 \text{ m/s}) = 0.570 \text{ m}$.

$|\mathcal{E}| = (0.500 \text{ T})(1/2\pi)(0.570 \text{ m})(0.120 \text{ m/s}) = 5.44 \text{ mV}$.

(b) SET UP: The loop and magnetic field are sketched in Figure 29.9.



Take into the page to be the positive direction for $\vec{A}$.
Then the magnetic flux is positive.

Figure 29.9

EXECUTE: The positive flux is decreasing in magnitude; $d\Phi_B/dt$ is negative and $\mathcal{E}$ is positive. By the right-hand rule, for $\vec{A}$ into the page, positive $\mathcal{E}$ is clockwise.
EVALUATE: Even though the circumference is changing at a constant rate, dA/dt is not constant and $|\mathcal{E}|$ is not constant. Flux $\otimes$ is decreasing so the flux of the induced current is $\otimes$ and this means that I is clockwise, which checks.

29.10. **IDENTIFY:** Rotating the coil changes the angle between it and the magnetic field, which changes the magnetic flux through it. This change induces an emf in the coil.
SET UP: $\mathcal{E}_{\text{av}} = N\left|\frac{\Delta\Phi_B}{\Delta t}\right|$, $\Phi_B = BA\cos\phi$. ϕ is the angle between the normal to the loop and $\vec{B}$, so $\phi_{\text{i}} = 90.0° - 37.0° = 53.0°$ and $\phi_{\text{f}} = 0°$.
EXECUTE: $\mathcal{E}_{\text{av}} = \frac{NBA|\cos\phi_{\text{f}} - \cos\phi_{\text{i}}|}{\Delta t} = \frac{(80)(1.70\text{ T})(0.250\text{ m})(0.400\text{ m})}{0.0600\text{ s}}|\cos 0° - \cos 53.0°| = 90.3\text{ V}.$
EVALUATE: The flux changes because the orientation of the coil relative to the magnetic field changes, even though the field remains constant.

29.11. **IDENTIFY:** We are dealing with an induced emf due to changing magnetic flux.
SET UP: $\mathcal{E} = -\frac{d\Phi_{\text{B}}}{dt}$, $\mathcal{E} = RI$, $B = B_0 e^{-t/\tau}$. The target variable is the current.
EXECUTE: **(a)** $\mathcal{E} = \frac{dBA}{dt} = \frac{dB_0 e^{-t/\tau} A}{dt} = -\frac{B_0 A}{\tau} e^{-t/\tau}$. $|I| = \frac{\mathcal{E}}{R} = \frac{B_0 A}{R\tau} e^{-t/\tau}$. I is a maximum when $t = 0$.
Using $A = \pi r^2$ and the given values, we get $I_{\max} = 12.6$ mA.
(b) At $t = 1.50$ s, we use the result from (a) for the emf with $t = 1.50$ s and $I_{\max} = 12.6$ mA. This gives $I = 0.626$ mA $= 626\ \mu$A.
EVALUATE: With exponential decay such as this, the current initially decreases rapidly. Note that $e^{-1.5/0.5} = e^{-3} \approx 0.05$.

29.12. **IDENTIFY:** A change in magnetic flux through a coil induces an emf in the coil.
SET UP: The flux through a coil is $\Phi_B = NBA\cos\phi$ and the induced emf is $\mathcal{E} = -d\Phi_B/dt$.
EXECUTE: The flux is constant in each case, so the induced emf is zero in all cases.
EVALUATE: Even though the coil is moving within the magnetic field and has flux through it, this flux is not *changing*, so no emf is induced in the coil.

29.13. **IDENTIFY:** Apply the results of Example 29.3.
SET UP: $\mathcal{E}_{\max} = NBA\omega$.
EXECUTE: $\omega = \frac{\mathcal{E}_{\max}}{NBA} = \frac{2.40\times10^{-2}\text{ V}}{(120)(0.0750\text{ T})(0.016\text{ m})^2} = 10.4\text{ rad/s}.$
EVALUATE: We may also express ω as 99.3 rev/min or 1.66 rev/s.

29.14. **IDENTIFY:** The changing flux through the loop due to the changing magnetic field induces a current in the wire. Energy is dissipated by the resistance of the wire due to the induced current in it.

SET UP: The magnitude of the induced emf is $|\mathcal{E}| = \left|\dfrac{d\Phi_B}{dt}\right| = \pi r^2 \left|\dfrac{dB}{dt}\right|$, $P = I^2 R$, $I = \mathcal{E}/R$.

EXECUTE: **(a)** $\vec{B}$ is out of page and Φ_B is decreasing, so the field of the induced current is directed out of the page inside the loop and the induced current is counterclockwise.

(b) $|\mathcal{E}| = \left|\dfrac{d\Phi_B}{dt}\right| = \pi r^2 \left|\dfrac{dB}{dt}\right|$. The current due to the emf is

$I = \dfrac{|\mathcal{E}|}{R} = \dfrac{\pi r^2}{R}\left|\dfrac{dB}{dt}\right| = \dfrac{\pi(0.0480\ \text{m})^2}{0.160\ \Omega}(0.680\ \text{T/s}) = 0.03076\ \text{A}$. The rate of energy dissipation is

$P = I^2 R = (0.03076\ \text{A})^2(0.160\ \Omega) = 1.51\times10^{-4}\ \text{W}$.

EVALUATE: Both the current and resistance are small, so the power is also small.

29.15. **IDENTIFY** and **SET UP:** The field of the induced current is directed to oppose the change in flux.
EXECUTE: **(a)** The field is into the page and is increasing so the flux is increasing. The field of the induced current is out of the page. To produce field out of the page the induced current is counterclockwise.
(b) The field is into the page and is decreasing so the flux is decreasing. The field of the induced current is into the page. To produce field into the page the induced current is clockwise.
(c) The field is constant so the flux is constant and there is no induced emf and no induced current.
EVALUATE: The direction of the induced current depends on the direction of the external magnetic field and whether the flux due to this field is increasing or decreasing.

29.16. **IDENTIFY** and **SET UP:** Use Lenz's law. The induced current flows so as to oppose the flux change that is inducing it. The magnetic field due to I is out of the page for loops A and C and into the page for loops B and D. The field is constant since I is constant, so any flux change is due to the motion of the loops.
EXECUTE: **(a)** *A:* The loop is moving away from the wire, so the magnetic field through the loop is getting weaker. This results in decreasing flux through the loop. Since the field is out of the page, the induced current flows in a direction so that its magnetic field inside the loop will be out of the page, which is a counterclockwise direction.
B: The flux through the loop is decreasing with the magnetic field into the page, so the induced current is clockwise.
C: The flux through the loop is constant, so there is no induced current.
D: The flux through the loop is increasing with the field into the page, so the induced current is counterclockwise.
(b) *A:* The flux is decreasing, so the loop is pulled toward the wire to increase the flux through the loop.
B: The flux is decreasing, so the loop is pulled toward the wire to increase the flux through the loop.
C: No current is induced, so there is no force.
D: The flux is increasing, so the loop is repelled by the wire to decrease the flux through the loop.
EVALUATE: In part (b), look at the direction of the force on the segment of each loop closest to the wire. For A and B, the induced current is in the same direction as I, so the wire attracts these loops. For D the induced current is opposite to I, so the wire repels the loop. For C there is no induced current, so there is no force.

29.17. **IDENTIFY** and **SET UP:** Use the right-hand rule to find the direction of the magnetic field due to the long wire at the location of each loop. Lenz's law says that the magnetic field of the induced current is directed to oppose the change in flux through the circuit. Since the current I is decreasing, the flux through each coil is decreasing, so the induced current flows to oppose this flux decrease.

EXECUTE: **(a)** The magnetic field of the long wire is directed out of the page at *C* and into the page at *A*. When the current decreases, the magnetic field decreases. Therefore, the magnetic field of the induced current in loop *C* is directed out of the page inside the loop, to oppose the decrease in flux out of the page due to the current in the long wire. To produce magnetic field in this direction, the induced current in *C* is counterclockwise. The magnetic field of the induced current in loop *A* is directed into the page inside the loop, to oppose the decrease in flux into the page due to the current in the long wire. To produce a magnetic field in this direction, the induced current in *A* is clockwise.
(b) The through both coils A and C is decreasing, so they will be pulled toward the long wire to oppose this decrease.
EVALUATE: As a check on the answer in (b), look at the current in the section of each loop that is nearest to the wire. For both loops, this induced current is in the same direction as the current *I* in the wire. When two parallel wires carry current in the same direction, they attract each other, which agrees with our answer in (b).

29.18. **IDENTIFY:** By Lenz's law, the induced current flows to oppose the flux change that caused it.
SET UP and **EXECUTE:** The magnetic field is outward through the round coil and is decreasing, so the magnetic field due to the induced current must also point outward to oppose this decrease. Therefore the induced current is counterclockwise.
EVALUATE: Careful! Lenz's law does not say that the induced current flows to oppose the magnetic flux. Instead it says that the current flows to oppose the *change* in flux.

29.19. **IDENTIFY** and **SET UP:** Apply Lenz's law, in the form that states that the flux of the induced current tends to oppose the change in flux.
EXECUTE: **(a)** With the switch closed the magnetic field of coil *A* is to the right at the location of coil *B*. When the switch is opened the magnetic field of coil *A* goes away. Hence by Lenz's law the field of the current induced in coil *B* is to the right, to oppose the decrease in the flux in this direction. To produce magnetic field that is to the right the current in the circuit with coil *B* must flow through the resistor in the direction *a* to *b*.
(b) With the switch closed the magnetic field of coil *A* is to the right at the location of coil *B*. This field is stronger at points closer to coil *A* so when coil *B* is brought closer the flux through coil *B* increases. By Lenz's law the field of the induced current in coil *B* is to the left, to oppose the increase in flux to the right. To produce magnetic field that is to the left the current in the circuit with coil *B* must flow through the resistor in the direction *b* to *a*.
(c) With the switch closed the magnetic field of coil *A* is to the right at the location of coil *B*. The current in the circuit that includes coil *A* increases when *R* is decreased and the magnetic field of coil *A* increases when the current through the coil increases. By Lenz's law the field of the induced current in coil *B* is to the left, to oppose the increase in flux to the right. To produce magnetic field that is to the left the current in the circuit with coil *B* must flow through the resistor in the direction *b* to *a*.
EVALUATE: In parts (b) and (c) the change in the circuit causes the flux through circuit *B* to increase and in part (a) it causes the flux to decrease. Therefore, the direction of the induced current is the same in parts (b) and (c) and opposite in part (a).

29.20. **IDENTIFY:** Apply Lenz's law.
SET UP: The field of the induced current is directed to oppose the change in flux in the secondary circuit.
EXECUTE: **(a)** The magnetic field in *A* is to the left and is increasing. The flux is increasing so the field due to the induced current in *B* is to the right. To produce magnetic field to the right, the induced current flows through *R* from right to left.
(b) The magnetic field in *A* is to the right and is decreasing. The flux is decreasing so the field due to the induced current in *B* is to the right. To produce magnetic field to the right the induced current flows through *R* from right to left.

(c) The magnetic field in A is to the right and is increasing. The flux is increasing so the field due to the induced current in B is to the left. To produce magnetic field to the left the induced current flows through R from left to right.

EVALUATE: The direction of the induced current depends on the direction of the external magnetic field and whether the flux due to this field is increasing or decreasing.

29.21. IDENTIFY and **SET UP:** Lenz's law requires that the flux of the induced current opposes the change in flux.

EXECUTE: **(a)** The magnetic field is out of the page and increasing, so the induced current should flow so that its field is into the page, so the induced current is clockwise.

(b) The current reaches a constant value so Φ_B is constant. $d\Phi_B/dt = 0$ and there is no induced current.

(c) The magnetic field is out of the page and is decreasing, so the induced current should flow that its magnetic field is out of the page. Thus the induced current is counterclockwise.

EVALUATE: Only a change in flux produces an induced current. The induced current is in one direction when the current in the outer ring is increasing and is in the opposite direction when that current is decreasing.

29.22. IDENTIFY: The changing flux through the loop due to the changing magnetic field induces a current in the wire.

SET UP: The magnitude of the induced emf is $|\mathcal{E}| = \left|\frac{d\Phi_B}{dt}\right| = \pi r^2 \left|\frac{dB}{dt}\right|$, $I = \mathcal{E}/R$.

EXECUTE: $\vec{B}$ is into the page and Φ_B is increasing, so the field of the induced current is directed out of the page inside the loop and the induced current is counterclockwise.

$$|\mathcal{E}| = \left|\frac{d\Phi_B}{dt}\right| = \pi r^2 \left|\frac{dB}{dt}\right| = \pi(0.0250\text{ m})^2(0.380\text{ T/s}^3)(3t^2) = (2.238\times10^{-3}\text{ V/s}^2)t^2.$$

$I = \frac{|\mathcal{E}|}{R} = (5.739\times10^{-3}\text{ A/s}^2)t^2$. When $B = 1.33\text{ T}$, we have $1.33\text{ T} = (0.380\text{ T/s}^3)t^3$, which gives $t = 1.518\text{ s}$. At this t, $I = (5.739\times10^{-3}\text{ A/s}^2)(1.518\text{ s})^2 = 0.0132\text{ A}$.

EVALUATE: As the field changes, the current will also change.

29.23. IDENTIFY: The movement of the wire causes a motional emf.

SET UP: $\mathcal{E} = \left(\vec{v}\times\vec{B}\right)\bullet\vec{L}$. We want the emf.

EXECUTE: **(a)** $\vec{v} = v_x\hat{i} + v_y\hat{j} + v_z\hat{k}$, $\vec{B} = 0.080\text{T}\,\hat{j}$ and $\vec{L} = L\hat{k}$. The result of the vector products is $\mathcal{E} = \left(\vec{v}\times\vec{B}\right)\bullet\vec{L} = Lv_xB_y$ = (0.50 m)(18 m/s)(0.080 T) = 0.72 V.

(b) $\vec{v}\times\vec{B}$ has no y component, so its dot product with $L\hat{k}$ is zero, so $\mathcal{E} = 0$.

EVALUATE: It is visualize 3-dimensional problems, but working with components makes the solutions easier to do.

29.24. IDENTIFY: The magnetic flux through the loop is decreasing, so an emf will be induced in the loop, which will induce a current in the loop. The magnetic field will exert a force on the loop due to this current.

SET UP: The motional $\mathcal{E}$ is $\mathcal{E} = vBL$, $I = \mathcal{E}/R$, and $F_B = ILB$.

EXECUTE: Use $I = \frac{\mathcal{E}}{R} = \frac{BLv}{R}$ and $F_B = ILB$.

$$F_B = ILB = v\frac{B^2L^2}{R} = \frac{3.00\text{ m/s}}{0.600\ \Omega}(2.40\text{ T})^2(0.0150\text{ m})^2 = 6.48\times10^{-3}\text{ N} = 6.48\text{ mN}.$$

$\vec{B}$ is into the page and Φ_B is decreasing, so the field of the induced current is into the page inside the loop and the induced current is clockwise. Using $\vec{F} = I\vec{l} \times \vec{B}$, we see that the force on the left-hand end of the loop to be to the left.

EVALUATE: The force is very small by everyday standards.

29.25. **IDENTIFY:** A conductor moving in a magnetic field may have a potential difference induced across it, depending on how it is moving.

SET UP: The induced emf is $\mathcal{E} = vBL \sin\phi$, where ϕ is the angle between the velocity and the magnetic field.

EXECUTE: **(a)** $\mathcal{E} = vBL \sin\phi = (5.00\text{ m/s})(0.450\text{ T})(0.300\text{ m})(\sin 90°) = 0.675\text{ V}$

(b) The positive charges are moved to end b, so b is at the higher potential.

(c) $E = V/L = (0.675\text{ V})/(0.300\text{ m}) = 2.25\text{ V/m}$. The direction of $\vec{E}$ is from b to a.

(d) The positive charges are pushed to b, so b has an excess of positive charge.

(e) (i) If the rod has no appreciable thickness, $L = 0$, so the emf is zero. (ii) The emf is zero because no magnetic force acts on the charges in the rod since it moves parallel to the magnetic field.

EVALUATE: The motional emf is large enough to have noticeable effects in some cases.

29.26. **IDENTIFY:** A change in magnetic flux through a coil induces an emf in the coil.

SET UP: The flux through a coil is $\Phi_B = NBA\cos\phi$ and the induced emf is $\mathcal{E} = -d\Phi_B/dt$.

EXECUTE: **(a)** and **(c)** The magnetic flux is constant, so the induced emf is zero.

(b) The area inside the field is changing. If we let x be the length (along the 30.0-cm side) in the field, then

$A = (0.400\text{ m})x.\ \Phi_B = BA = B(0.400\text{ m})x.$

$|\mathcal{E}| = |d\Phi_B/dt| = B\, d[(0.400\text{ m})x]/dt = B(0.400\text{ m})dx/dt = B(0.400\text{ m})v.$

$\mathcal{E} = (1.25\text{ T})(0.400\text{ m})(0.0200\text{ m/s}) = 0.0100\text{ V}.$

EVALUATE: It is not *flux* that induces an emf, but rather a *rate of change* of the flux. The induced emf in part (b) is small enough to be ignored in many instances.

29.27. **IDENTIFY** and **SET UP:** $\mathcal{E} = vBL$. Use Lenz's law to determine the direction of the induced current. The force F_{ext} required to maintain constant speed is equal and opposite to the force F_I that the magnetic field exerts on the rod because of the current in the rod.

EXECUTE: **(a)** $\mathcal{E} = vBL = (7.50\text{ m/s})(0.800\text{ T})(0.500\text{ m}) = 3.00\text{ V}.$

(b) $\vec{B}$ is into the page. The flux increases as the bar moves to the right, so the magnetic field of the induced current is out of the page inside the circuit. To produce magnetic field in this direction the induced current must be counterclockwise, so from b to a in the rod.

(c) $I = \dfrac{\mathcal{E}}{R} = \dfrac{3.00\text{ V}}{1.50\ \Omega} = 2.00\text{ A}.$ $F_I = ILB\sin\phi = (2.00\text{ A})(0.500\text{ m})(0.800\text{ T})\sin 90° = 0.800\text{ N}.$ $\vec{F}_I$ is to the left. To keep the bar moving to the right at constant speed an external force with magnitude $F_{\text{ext}} = 0.800\text{ N}$ and directed to the right must be applied to the bar.

(d) The rate at which work is done by the force F_{ext} is $F_{\text{ext}}v = (0.800\text{ N})(7.50\text{ m/s}) = 6.00\text{ W}$. The rate at which thermal energy is developed in the circuit is $I^2R = (2.00\text{ A})^2(1.50\ \Omega) = 6.00\text{ W}$. These two rates are equal, as is required by conservation of energy.

EVALUATE: The force on the rod due to the induced current is directed to oppose the motion of the rod. This agrees with Lenz's law.

29.28. **IDENTIFY:** Use the three approaches specified in the problem for determining the direction of the induced current. $I = \mathcal{E}/R$. The induced potential across a moving bar is $\mathcal{E} = vBL$.

SET UP: Let $\vec{A}$ be directed into the figure, so a clockwise emf is positive.

EXECUTE: **(a)** $\mathcal{E} = vBL = (5.0\text{ m/s})(0.750\text{ T})(0.650\text{ m}) = 2.438\text{ V}$, which rounds to 2.4 V.

(b) (i) Let q be a positive charge in the moving bar, as shown in Figure 29.28a. The magnetic force on this charge is $\vec{F} = q\vec{v} \times \vec{B}$, which points *upward*. This force pushes the current in a *counterclockwise* direction through the circuit.

(ii) Φ_B is positive and is increasing in magnitude, so $d\Phi_B/dt > 0$. Then by Faraday's law $\mathcal{E} < 0$ and the emf and induced current are counterclockwise.

(iii) The flux through the circuit is increasing, so the induced current must cause a magnetic field out of the paper to oppose this increase. Hence this current must flow in a *counterclockwise sense*, as shown in Figure 29.28b.

(c) $\mathcal{E} = RI$. $I = \dfrac{\mathcal{E}}{R} = \dfrac{2.438\ \text{V}}{25.0\ \Omega} = 0.09752\ \text{A}$, which rounds to 98 mA.

EVALUATE: All three methods agree on the direction of the induced current.

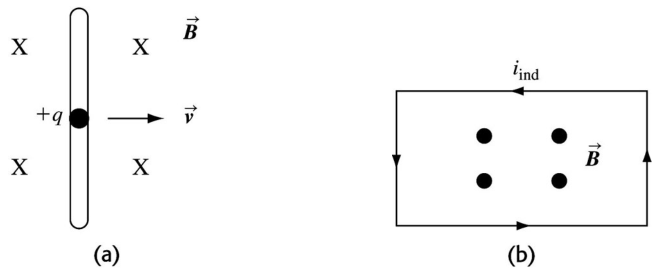


Figure 29.28

29.29. IDENTIFY: The motion of the bar due to the applied force causes a motional emf to be induced across the ends of the bar, which induces a current through the bar. The magnetic field exerts a force on the bar due to this current.

SET UP: The applied force is to the left and equal to $F_{\text{applied}} = F_B = ILB$. $\mathcal{E} = BvL$ and $I = \dfrac{\mathcal{E}}{R} = \dfrac{BvL}{R}$.

EXECUTE: **(a)** $\vec{B}$ out of page and Φ_B decreasing, so the field of the induced current is out of the page inside the loop and the induced current is counterclockwise.

(b) Combining $F_{\text{applied}} = F_B = ILB$ and $\mathcal{E} = BvL$, we have $I = \dfrac{\mathcal{E}}{R} = \dfrac{BvL}{R}$. $F_{\text{applied}} = \dfrac{vB^2L^2}{R}$. The rate at which this force does work is

$$P_{\text{applied}} = F_{\text{applied}}v = \frac{(vBL)^2}{R} = \frac{[(5.90\ \text{m/s})(0.650\ \text{T})(0.360\ \text{m})]^2}{45.0\ \Omega} = 0.0424\ \text{W}.$$

EVALUATE: The power is small because the magnetic force is usually small compared to everyday forces.

29.30. IDENTIFY: The motion of the bar due to the applied force causes a motional emf to be induced across the ends of the bar, which induces a current through the bar and through the resistor. This current dissipates energy in the resistor.

SET UP: $P_R = I^2R$, $\mathcal{E} = BvL = IR$.

EXECUTE: **(a)** $\vec{B}$ is out of the page and Φ_B is increasing, so the field of the induced current is into the page inside the loop and the induced current is clockwise.

(b) $P_R = I^2R$ so $I = \sqrt{\dfrac{P_R}{R}} = \sqrt{\dfrac{0.840\ \text{W}}{45.0\ \Omega}} = 0.1366\ \text{A}$. $I = \dfrac{\text{emf}}{R} = \dfrac{BvL}{R}$.

$$v = \frac{IR}{BL} = \frac{(0.1366\ \text{A})(45.0\ \Omega)}{(0.650\ \text{T})(0.360\ \text{m})} = 26.3\ \text{m/s}.$$

EVALUATE: This speed is around 60 mph, so it would not be very practical to generate energy this way.

29.31. IDENTIFY: The motion of the bar causes an emf to be induced across its ends, which induces a current in the circuit.
SET UP: $\mathcal{E} = BvL, I = \mathcal{E}/R.$
EXECUTE: $\vec{F}_B$ on the bar is to the left so $\vec{v}$ is to the right. Using $\mathcal{E} = BvL$ and $I = \mathcal{E}/R,$ we have
$I = \dfrac{BvL}{R}.$ $v = \dfrac{IR}{BL} = \dfrac{(1.75\text{ A})(6.00\ \Omega)}{(1.20\text{ T})(0.250\text{ m})} = 35.0\text{ m/s}.$
EVALUATE: This speed is greater than 60 mph!

29.32. IDENTIFY: A motional emf is induced across the blood vessel.
SET UP and **EXECUTE:** **(a)** Each slab of flowing blood has maximum width *d* and is moving perpendicular to the field with speed *v*. $\mathcal{E} = vBL$ becomes $\mathcal{E} = vBd$.

(b) $B = \dfrac{\mathcal{E}}{vd} = \dfrac{1.0\times10^{-3}\text{ V}}{(0.15\text{ m/s})(5.0\times10^{-3}\text{ m})} = 1.3\text{ T}.$

(c) The blood vessel has cross-sectional area $A = \pi d^2/4.$ The volume of blood that flows past a cross section of the vessel in time *t* is $\pi(d^2/4)vt.$ The volume flow rate is $\text{volume/time} = R = \pi d^2 v/4.$
$v = \dfrac{\mathcal{E}}{Bd}$
so $R = \dfrac{\pi d^2}{4}\left(\dfrac{\mathcal{E}}{Bd}\right) = \dfrac{\pi\mathcal{E}d}{4B}.$

EVALUATE: A very strong magnetic field (1.3 T) is required to produce a small potential difference of only 1 mV.

29.33. IDENTIFY: While the circuit is entering and leaving the region of the magnetic field, the flux through it will be changing. This change will induce an emf in the circuit.
SET UP: When the loop is entering or leaving the region of magnetic field the flux through it is changing and there is an induced emf. The magnitude of this induced emf is $\mathcal{E} = BLv.$ The length *L* is 0.750 m. When the loop is totally within the field the flux through the loop is not changing so there is no induced emf. The induced current has magnitude $I = \dfrac{\mathcal{E}}{R}$ and direction given by Lenz's law.

EXECUTE: **(a)** $I = \dfrac{\mathcal{E}}{R} = \dfrac{BLv}{R} = \dfrac{(1.25\text{ T})(0.750\text{ m})(3.0\text{ m/s})}{12.5\ \Omega} = 0.225\text{ A}.$ The magnetic field through the loop is directed out of the page and is increasing, so the magnetic field of the induced current is into the page inside the loop and the induced current is clockwise.
(b) The flux is not changing so $\mathcal{E}$ and *I* are zero.
(c) $I = \dfrac{\mathcal{E}}{R} = 0.225\text{ A}.$ The magnetic field through the loop is directed out of the page and is decreasing, so the magnetic field of the induced current is out of the page inside the loop and the induced current is counterclockwise.

(d) Let clockwise currents be positive. At $t = 0$ the loop is entering the field. It is totally in the field at time t_a and beginning to move out of the field at time $t_b.$ The graph of the induced current as a function of time is sketched in Figure 29.33.

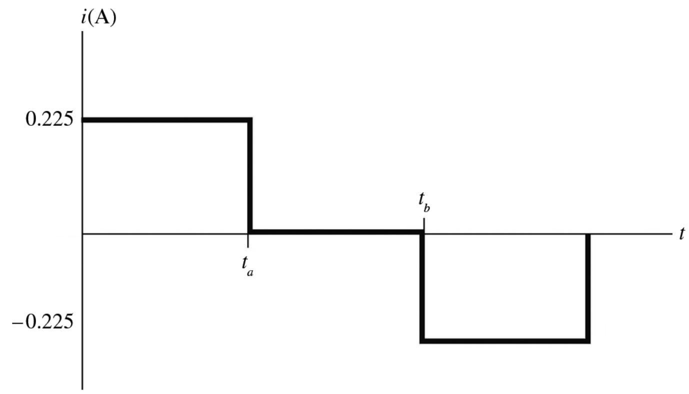

Figure 29.33

EVALUATE: Even though the circuit is moving throughout all parts of this problem, an emf is induced in it only when the flux through it is changing. While the coil is entirely within the field, the flux is constant, so no emf is induced.

29.34. **IDENTIFY:** A changing magnetic flux through a coil induces an emf in that coil, which means that an electric field is induced in the material of the coil.

SET UP: According to Faraday's law, the induced electric field obeys the equation $r\vec{E}\cdot d\vec{l} = -\dfrac{d\Phi_B}{dt}$.

EXECUTE: **(a)** For the magnitude of the induced electric field, Faraday's law gives

$$E2\pi r = d(B\pi r^2)/dt = \pi r^2\ dB/dt.$$

$$E = \frac{r}{2}\frac{dB}{dt} = \frac{0.0225\text{ m}}{2}(0.250\text{ T/s}) = 2.81\times10^{-3}\text{ V/m}.$$

(b) The field points toward the south pole of the magnet and is decreasing, so the induced current is counterclockwise.

EVALUATE: This is a very small electric field compared to most others found in laboratory equipment.

29.35. **IDENTIFY:** Apply $E = \dfrac{1}{2\pi r}\left|\dfrac{d\Phi_B}{dt}\right|$ with $\Phi_B = \mu_0 niA.$

SET UP: $A = \pi r^2$, where $r = 0.0110$ m. In $E = \dfrac{1}{2\pi r}\left|\dfrac{d\Phi_B}{dt}\right|$, $r = 0.0350$ m.

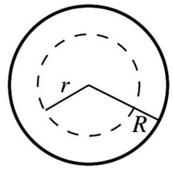
EXECUTE: $|\mathcal{E}| = \left|\dfrac{d\Phi_B}{dt}\right| = \left|\dfrac{d}{dt}(BA)\right| = \left|\dfrac{d}{dt}(\mu_0 niA)\right| = \mu_0 nA\left|\dfrac{di}{dt}\right|$ and $|\mathcal{E}| = E(2\pi r)$. Therefore, $\left|\dfrac{di}{dt}\right| = \dfrac{E2\pi r}{\mu_0 nA}$.

$$\left|\frac{di}{dt}\right| = \frac{(8.00\times10^{-6}\text{ V/m})2\pi(0.0350\text{ m})}{\mu_0(400\text{ m}^{-1})\pi(0.0110\text{ m})^2} = 9.21\text{ A/s}.$$

EVALUATE: Outside the solenoid the induced electric field decreases with increasing distance from the axis of the solenoid.

29.36. **IDENTIFY:** Use $\oint \vec{E}\cdot d\vec{l} = -\dfrac{d\Phi_B}{dt}$ to calculate the induced electric field E at a distance r from the center of the solenoid. Away from the ends of the solenoid, $B = \mu_0 nI$ inside and $B = 0$ outside.

SET UP: The end view of the solenoid is sketched in Figure 29.36.



Let R be the radius of the solenoid.

Figure 29.36

Apply $\oint \vec{E} \cdot d\vec{l} = -\dfrac{d\Phi_B}{dt}$ to an integration path that is a circle of radius r, where $r < R$. We need to calculate just the magnitude of E so we can take absolute values.

EXECUTE: **(a)** $\oint \left| \vec{E} \cdot d\vec{l} \right| = E(2\pi r)$.

$\Phi_B = B\pi r^2, \left| -\dfrac{d\Phi_B}{dt} \right| = \pi r^2 \left| \dfrac{dB}{dt} \right|$.

$\oint \left| \mathrm{r}\vec{E} \cdot d\vec{l} \right| = \left| -\dfrac{d\Phi_B}{dt} \right|$ implies $E(2\pi r) = \pi r^2 \left| \dfrac{dB}{dt} \right|$.

$E = \frac{1}{2} r \left| \dfrac{dB}{dt} \right|$.

$B = \mu_0 nI$, so $\dfrac{dB}{dt} = \mu_0 n \dfrac{dI}{dt}$.

Thus $E = \frac{1}{2} r \mu_0 n \dfrac{dI}{dt} = \frac{1}{2}(0.00500\text{ m})(4\pi \times 10^{-7}\text{ T} \cdot \text{m/A})(900\text{ m}^{-1})(36.0\text{ A/s}) = 1.02 \times 10^{-4}\text{ V/m}$.

(b) $r = 0.0100\text{ cm}$ is still inside the solenoid so the expression in part (a) applies.

$E = \frac{1}{2} r \mu_0 n \dfrac{dI}{dt} = \frac{1}{2}(0.0100\text{ m})(4\pi \times 10^{-7}\text{ T} \cdot \text{m/A})(900\text{ m}^{-1})(36.0\text{ A/s}) = 2.04 \times 10^{-4}\text{ V/m}$.

EVALUATE: Inside the solenoid E is proportional to r, so E doubles when r doubles.

29.37. **IDENTIFY:** Apply Faraday's law in the form $|\mathcal{E}_{\text{av}}| = N \left| \dfrac{\Delta\Phi_B}{\Delta t} \right|$.

SET UP: The magnetic field of a large straight solenoid is $B = \mu_0 nI$ inside the solenoid and zero outside. $\Phi_B = BA$, where A is 8.00 cm^2, the cross-sectional area of the long straight solenoid.

EXECUTE: $|\mathcal{E}_{\text{av}}| = N \left| \dfrac{\Delta\Phi_B}{\Delta t} \right| = \left| \dfrac{NA(B_\text{f} - B_\text{i})}{\Delta t} \right| = \dfrac{NA\mu_0 nI}{\Delta t}$.

$\mathcal{E}_{\text{av}} = \dfrac{\mu_0(12)(8.00 \times 10^{-4}\text{ m}^2)(9000\text{ m}^{-1})(0.350\text{ A})}{0.0400\text{ s}} = 9.50 \times 10^{-4}\text{ V}$.

EVALUATE: An emf is induced in the second winding even though the magnetic field of the solenoid is zero at the location of the second winding. The changing magnetic field induces an electric field outside the solenoid and that induced electric field produces the emf.

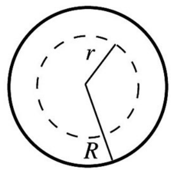
29.38. **IDENTIFY** and **SET UP:** The equations $i_\text{C} = \dfrac{dq}{dt} = \mathcal{E}\dfrac{d\Phi_E}{dt}$ and $i_\text{D} = \mathcal{E}\dfrac{d\Phi_E}{dt}$ show that $i_\text{C} = i_\text{D}$ and also relate i_D to the rate of change of the electric field flux between the plates. Use this to calculate dE/dt and apply the generalized form of Ampere's law to calculate B.

EXECUTE: **(a)** $i_\text{C} = i_\text{D}$, so $j_\text{D} = \dfrac{i_\text{D}}{A} = \dfrac{i_\text{C}}{A} = \dfrac{0.520\text{ A}}{\pi r^2} = \dfrac{0.520\text{ A}}{\pi(0.0400\text{ m})^2} = 103\text{ A/m}^2$.

(b) $j_\text{D} = \epsilon_0 \dfrac{dE}{dt}$ so $\dfrac{dE}{dt} = \dfrac{j_\text{D}}{\epsilon_0} = \dfrac{103\text{ A/m}^2}{8.854 \times 10^{-12}\text{ C}^2/\text{N} \cdot \text{m}^2} = 1.16 \times 10^{13}\text{ V/m} \cdot \text{s}$.

SET UP and EXECUTE: **(c)** Apply Ampere's law $\oint \vec{B} \cdot d\vec{l} = \mu_0 (i_C + i_D)_{encl}$ to a circular path with radius $r = 0.0200$ m.

An end view of the solenoid is given in Figure 29.38.



By symmetry the magnetic field is tangent to the path and constant around it.

Figure 29.38

Thus $\oint \vec{B} . d\vec{l} = \text{r}Bdl = B\int dl = B(2\pi r).$

$i_C = 0$ (no conduction current flows through the air space between the plates)

The displacement current enclosed by the path is $j_D \pi r^2$.

Thus $B(2\pi r) = \mu_0 (j_D \pi r^2)$ and

$B = \frac{1}{2}\mu_0 j_D r = \frac{1}{2}(4\pi \times 10^{-7} \text{ T} \cdot \text{m/A})(103 \text{ A/m}^2)(0.0200 \text{ m}) = 1.30 \times 10^{-6} \text{ T} = 1.30\ \mu\text{T}.$

(d) $B = \frac{1}{2}\mu_0 j_D r$. Now r is $\frac{1}{2}$ the value in (c), so B is also $\frac{1}{2}$ its value in (c):

$B = \frac{1}{2}(1.30 \times 10^{-6} \text{ T}) = 0.650 \times 10^{-7} \text{ T} = 0.650\ \mu\text{T}.$

EVALUATE: The definition of displacement current allows the current to be continuous at the capacitor. The magnetic field between the plates is zero on the axis $(r = 0)$ and increases as r increases.

29.39. **IDENTIFY:** $q = CV$. For a parallel-plate capacitor, $C = \dfrac{\mathcal{E}A}{d}$, where $\mathcal{E} = K\mathcal{E}_0$. $i_C = dq/dt$. $j_D = \mathcal{E}\dfrac{dE}{dt}$.

SET UP: $E = q/\mathcal{E}A$ so $dE/dt = i_C/\mathcal{E}A$.

EXECUTE: **(a)** $q = CV = \left(\dfrac{\mathcal{E}A}{d}\right)V = \dfrac{(4.70)\epsilon_0 (3.00 \times 10^{-4} \text{ m}^2)(120 \text{ V})}{2.50 \times 10^{-3} \text{ m}} = 5.99 \times 10^{-10} \text{ C}.$

(b) $\dfrac{dq}{dt} = i_C = 6.00 \times 10^{-3}$ A.

(c) $j_D = \mathcal{E}\dfrac{dE}{dt} = K\epsilon_0 \dfrac{i_C}{K\varepsilon_0 A} = \dfrac{i_C}{A} = j_C$, so $i_D = i_C = 6.00 \times 10^{-3}$ A.

EVALUATE: $i_D = i_C$, so Kirchhoff's junction rule is satisfied where the wire connects to each capacitor plate.

29.40. **IDENTIFY and SET UP:** Use $i_C = q/t$ to calculate the charge q that the current has carried to the plates in time t. The equations $V = Ed$ and $E = \dfrac{\sigma}{\epsilon_0}$ relate q to the electric field E and the potential difference between the plates. The displacement current density is $j_D = \mathcal{E}\dfrac{dE}{dt}$.

EXECUTE: **(a)** $i_C = 1.80 \times 10^{-3}$ A.

$q = 0$ at $t = 0$.

The amount of charge brought to the plates by the charging current in time t is

$q = i_C t = (1.80 \times 10^{-3} \text{ A})(0.500 \times 10^{-6} \text{ s}) = 9.00 \times 10^{-10} \text{ C}.$

$$E = \frac{\sigma}{\epsilon_0} = \frac{q}{\epsilon_0 A} = \frac{9.00 \times 10^{-10} \text{ C}}{(8.854 \times 10^{-12} \text{ C}^2/\text{N} \cdot \text{m}^2)(5.00 \times 10^{-4} \text{ m}^2)} = 2.03 \times 10^5 \text{ V/m}.$$

$V = Ed = (2.03\times10^5\ \text{V/m})(2.00\times10^{-3}\,\text{m}) = 406\ \text{V}.$

(b) $E = q/\epsilon_0 A.$

$$\frac{dE}{dt} = \frac{dq/dt}{\epsilon_0 A} = \frac{i_C}{\epsilon_0 A} = \frac{1.80\times10^{-3}\ \text{A}}{(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(5.00\times10^{-4}\ \text{m}^2)} = 4.07\times10^{11}\ \text{V/m}\cdot\text{s}.$$

Since i_C is constant dE/dt does not vary in time.

(c) $j_D = \epsilon_0 \dfrac{dE}{dt}$ (with ϵ replaced by ϵ_0 since there is vacuum between the plates).

$j_D = (8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(4.07\times10^{11}\ \text{V/m}\cdot\text{s}) = 3.60\ \text{A/m}^2.$

$i_D = j_D A = (3.60\ \text{A/m}^2)(5.00\times10^{-4}\ \text{m}^2) = 1.80\times10^{-3}\ \text{A};\ i_D = i_C.$

EVALUATE: $i_C = i_D$. The constant conduction current means the charge q on the plates and the electric field between them both increase linearly with time and i_D is constant.

29.41. **IDENTIFY:** We are dealing with displacement current.

SET UP: $I_d = \mathcal{E}\dfrac{d\Phi_E}{dt}$, $\mathcal{E} = K\epsilon_0$.

EXECUTE: **(a)** We want I_d at t = 1.5 s. $I_d = \mathcal{E}\dfrac{d\Phi_E}{dt} = \mathcal{E}\dfrac{d\left[(4.0\ \text{V}\cdot\text{m/s}^5)t^5\right]}{dt} = K\epsilon_0\,(20\ \text{V}\cdot\text{m/s}^5)t^4$. At t = 1.5 s using K = 2.5 we get I_d = 2.2 nA.

(b) We want the time when I_d = 1/16 as much. Solve the result in (a) when I_d = (1/16)(2.2 nA), giving t = 0.75 s.

EVALUATE: The displacement current is much smaller than typical household currents or even many lab currents.

29.42. **IDENTIFY:** Apply $\vec{B} = \vec{B}_0 + \mu_0\vec{M}$.

SET UP: For magnetic fields less than the critical field, there is no internal magnetic field. For fields greater than the critical field, $\vec{B}$ is very nearly equal to $\vec{B}_0$.

EXECUTE: **(a)** The external field is less than the critical field, so inside the superconductor $\vec{B} = 0$ and $\vec{M} = -\dfrac{\vec{B}_0}{\mu_0} = -\dfrac{(0.130\ \text{T})\hat{i}}{\mu_0} = -(1.03\times10^5\ \text{A/m})\hat{i}$. Outside the superconductor, $\vec{B} = \vec{B}_0 = (0.130\ \text{T})\hat{i}$ and $\vec{M} = 0$.

(b) The field is greater than the critical field and $\vec{B} = \vec{B}_0 = (0.260\ \text{T})\hat{i}$, both inside and outside the superconductor.

EVALUATE: Below the critical field the external field is expelled from the superconducting material.

29.43. **IDENTIFY:** We are dealing with induced current and Faraday's law.

SET UP and EXECUTE: $\mathcal{E}_{av} = N\dfrac{\Delta\Phi_B}{\Delta t}$. **(a)** We want the charge. Q = 70 A·h = (70 C/s)(3600 s) = 2.5×10^5 C.

(b) We want the peak current.

Headlights: 2(20 A) = 40 A

Radiator fan: 10 A

Windshield wipers (2 front, 1 back): 3(5 A) = 15 A

Peak current is 65 A.

(c) We want the magnetic field. Stator coil: 42 windings, d = 5.0 cm, f = 400 Hz, $\mathcal{E}$ = 14 V.

The magnetic field reverses once per cycle but the flux changes twice for each direction of the field, so $\Delta\Phi_B = 4\Phi_B$. The time for a cycle is $1/f$. Therefore $\Phi_B = BA$. $\dfrac{\Delta\Phi_B}{\Delta t} = \dfrac{4BA}{\Delta t}$.

$\mathcal{E}_{\text{av}} = N\dfrac{\Delta\Phi_B}{\Delta t} = N\dfrac{4AB}{1/f} = 4NABf$. Putting in the numbers: 14 V = 4(42)π(0.025 m)^2 (500 Hz)B, which gives B = 0.11 T.

EVALUATE: The field needed could be decreased by adding more windings or spinning the coils faster.

29.44. IDENTIFY: The 4.00-cm long left side of the loop is a bar moving in a magnetic field, so an emf is induced across its ends. This emf causes current to flow through the loop, and the external magnetic field exerts a force on the bar due to the current in it. Ohm's law applies to the circuit and Newton's second law applies to the loop.

SET UP: The induced potential across the left-end side is $\mathcal{E} = vBL$, the magnetic force on the bar is $F_{\text{mag}} = ILB$, and Ohm's law is $\mathcal{E} = IR$. Newton's second law is $\Sigma\vec{F} = m\vec{a}$. The flux through the loop is decreasing, so the induced current is clockwise. Alternatively, the magnetic force on positive charge in the moving left-end bar is upward, by the right-hand rule, which also gives a clockwise current. Therefore the magnetic force on the 4.00-cm segment is to the left, opposite to $\vec{F}_{\text{ext}}$.

EXECUTE: **(a)** Combining the equations discussed in the set up, the magnetic force on the 4.00-cm bar (and on the loop) is

$F_{\text{mag}} = ILB = (\mathcal{E}/R)LB = (vBL/R)LB = v(BL)^2/R.$

Newton's second law gives

$F_{\text{ext}} - F_{\text{mag}} = ma.$

$ma = F_{\text{ext}} - v(BL)^2/R.$

(0.0240 kg)a = 0.180 N – (0.0300 m/s)[(2.90 T)(0.0400 m)]^2/(0.00500 Ω).

a = 4.14 m/s^2.

(b) At terminal speed v_T, $F_{\text{mag}} = F_{\text{ext}}$.

$v_T(BL)^2/R = F_{\text{ext}}$.

$v_T = RF_{\text{ext}}/(BL)^2$ = (0.00500 Ω)(0.180 N)/[(2.90 T)(0.0400 m)]^2 = 0.0669 m/s = 6.69 cm/s. The speed is constant thereafter, so the acceleration is zero.

(c) $a = F_{\text{ext}}/m$ = (0.180 N)/(0.0240 kg) = 7.50 m/s^2.

EVALUATE: The acceleration is acceleration is constant once the loop is out of the magnetic field. But while it is partly in the field, the acceleration is not constant because the current changes as the speed changes and this causes the magnetic force to vary.

29.45. IDENTIFY: Apply Faraday's law and Lenz's law.

SET UP: For a discharging RC circuit, $i(t) = \dfrac{V_0}{R}e^{-t/RC}$, where V_0 is the initial voltage across the capacitor. The resistance of the small loop is $(25)(0.600\text{ m})(1.0\ \Omega/\text{m}) = 15.0\ \Omega$.

EXECUTE: **(a)** The large circuit is an RC circuit with a time constant of $\tau = RC = (10\ \Omega)(20\times10^{-6}\text{ F}) = 200\ \mu\text{s}$. Thus, the current as a function of time is $i = ((100\text{ V})/(10\ \Omega))\,e^{-t/200\,\mu\text{s}}$. At $t = 200\ \mu s$, we obtain $i = (10\text{ A})(e^{-1}) = 3.7$ A.

(b) Assuming that only the long wire nearest the small loop produces an appreciable magnetic flux through the small loop and referring to the solution of Exercise 29.7 we obtain

$\Phi_B = \int_c^{c+a}\dfrac{\mu_0 ib}{2\pi r}dr = \dfrac{\mu_0 ib}{2\pi}\ln\left(1+\dfrac{a}{c}\right)$. Therefore, the emf induced in the small loop at $t = 200\ \mu$s is

$\mathcal{E} = -N\dfrac{d\Phi_B}{dt} = -\dfrac{N\mu_0 b}{2\pi}\ln\left(1+\dfrac{a}{c}\right)\dfrac{di}{dt}.$

$$\mathcal{E} = -\frac{(25)(4\pi\times10^{-7}\ \text{Wb/A}\cdot\text{m}^2)(0.200\ \text{m})}{2\pi}\ln(3.0)\left(-\frac{3.7\ \text{A}}{200\times10^{-6}\ \text{s}}\right) = +20.0\ \text{mV}.$$ Thus, the induced current in the small loop is $i' = \frac{\mathcal{E}}{R} = \frac{20.0\ \text{mV}}{15.0\ \Omega} = 1.33\ \text{mA}.$

(c) The magnetic field from the large loop is directed out of the page within the small loop.The induced current will act to oppose the decrease in flux from the large loop. Thus, the induced current flows counterclockwise.

EVALUATE: **(d)** Three of the wires in the large loop are too far away to make a significant contribution to the flux in the small loop—as can be seen by comparing the distance *c* to the dimensions of the large loop.

29.46 **IDENTIFY:** The changing current in the large *RC* circuit produces a changing magnetic flux through the small circuit, which induces an emf in the small circuit. This emf causes a current in the small circuit.

SET UP: For a charging *RC* circuit, $i(t) = \frac{\mathcal{E}}{R}e^{-t/RC}$, where $\mathcal{E}$ is the emf (90.0 V) added to the large circuit. Exercise 29.7 shows that $\Phi_B = \frac{\mu_0 ib}{2\pi}\ln(1 + a/c)$ for each turn of the small circuit, and $\mathcal{E}_{\text{induced}} = -\frac{d\Phi_B}{dt}$.

EXECUTE: $\frac{d\Phi_B}{dt} = \frac{\mu_0 b}{2\pi}\ln(1 + a/c)\frac{di}{dt}$. $\frac{di}{dt} = -\frac{\mathcal{E}}{R^2C}e^{-t/RC}$ and

$\left|\mathcal{E}_{\text{induced}}\right| = N\left|\frac{d\Phi_B}{dt}\right| = \frac{N\mu_0 b}{2\pi}\ln(1 + a/c)\frac{\varepsilon}{R^2C}e^{-t/RC} = \frac{N\mu_0 b}{2\pi}\ln(1 + a/c)\frac{1}{RC}i.$ The resistance of the small loop is $(25)(0.600\ \text{m})(1.0\ \Omega/\text{m}) = 15\ \Omega.$

$$\left|\mathcal{E}_{\text{induced}}\right| = (25)(2.00\times10^{-7}\ \text{T}\cdot\text{m/A})(0.200\ \text{m})\ln(1 + 10.0/5.0)\frac{1}{(10\ \Omega)(20\times10^{-6}\ \text{F})}(5.00\ \text{A}).$$

$\left|\mathcal{E}_{\text{induced}}\right| = 0.02747\ \text{V}.$ The induced current is $\frac{\left|\mathcal{E}_{\text{induced}}\right|}{R} = \frac{0.02747\ \text{V}}{15\ \Omega} = 1.83\times10^{-3}\ \text{A} = 1.83\ \text{mA},$ which rounds to 1.8 mA. The current in the large loop is counterclockwise. The magnetic field through the small loop is into the page and the flux is decreasing, so the magnetic field due to the induced current in the small loop is into the page and the induced current in the small loop is clockwise.

EVALUATE: The answer is actually independent of *N* because the emf induced in the small coil is proportional to *N* and the resistance of that coil is also proportional to *N*. Since $I = \mathcal{E}/R$, the *N* will cancel out.

29.47. **IDENTIFY:** The changing current in the solenoid will cause a changing magnetic field (and hence changing flux) through the secondary winding, which will induce an emf in the secondary coil.

SET UP: The magnetic field of the solenoid is $B = \mu_0 ni$, and the induced emf is $\left|\mathcal{E}\right| = N\left|\frac{d\Phi_B}{dt}\right|$.

EXECUTE: $B = \mu_0 ni = (4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})(90.0\times10^2\ \text{m}^{-1})(0.160\ \text{A/s}^2)t^2 = (1.810\times10^{-3}\ \text{T/s}^2)t^2$. The total flux through secondary winding is $(5.0)B(2.00\times10^{-4}\ \text{m}^2) = (1.810\times10^{-6}\ \text{Wb/s}^2)t^2$.

$\left|\mathcal{E}\right| = N\left|\frac{d\Phi_B}{dt}\right| = (3.619\times10^{-6}\ \text{V/s})t.$ $i = 3.20\ \text{A}$ says $3.20\ \text{A} = (0.160\ \text{A/s}^2)t^2$ and $t = 4.472\ \text{s}.$ This gives $\left|\mathcal{E}\right| = (3.619\times10^{-6}\ \text{V/s})(4.472\ \text{s}) = 1.62\times10^{-5}\ \text{V}.$

EVALUATE: This a very small voltage, about $16\ \mu\text{V}$.

29.48. IDENTIFY: Apply Faraday's law.

SET UP: For rotation about the y-axis the situation is the same as in Examples 29.3 and 29.4 and we can apply the results from those examples.

EXECUTE: **(a)** Rotating about the y-axis: the flux is given by $\Phi_B = BA\cos\phi$ and

$\mathcal{E}_{\text{max}} = \omega BA = (35.0 \text{ rad/s})(0.320 \text{ T})(6.00\times10^{-2} \text{ m}^2) = 0.672 \text{ V}.$

(b) Rotating about the x-axis: $\dfrac{d\Phi_B}{dt} = 0$ and $\mathcal{E} = 0.$

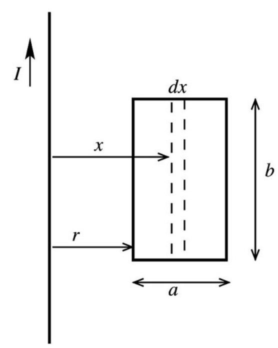
(c) Rotating about the z-axis: the flux is given by $\Phi_B = BA\cos\phi$ and

$\mathcal{E}_{\text{max}} = \omega BA = (35.0 \text{ rad/s})(0.320 \text{ T})(6.00\times10^{-2} \text{ m}^2) = 0.672 \text{ V}.$

EVALUATE: The maximum emf is the same if the loop is rotated about an edge parallel to the z-axis as it is when it is rotated about the z-axis.

29.49. (a) IDENTIFY: (i) $|\mathcal{E}| = \left|\dfrac{d\Phi_B}{dt}\right|$. The flux is changing because the magnitude of the magnetic field of the wire decreases with distance from the wire. Find the flux through a narrow strip of area and integrate over the loop to find the total flux.

SET UP:



Consider a narrow strip of width dx and a distance x from the long wire, as shown in Figure 29.49a. The magnetic field of the wire at the strip is $B = \mu_0 I/2\pi x$. The flux through the strip is $d\Phi_B = Bb\,dx = (\mu_0 Ib/2\pi)(dx/x)$.

Figure 29.49a

EXECUTE: The total flux through the loop is $\Phi_B = \int d\Phi_B = \left(\dfrac{\mu_0 Ib}{2\pi}\right)\int_r^{r+a}\dfrac{dx}{x}.$

$$\Phi_B = \left(\frac{\mu_0 Ib}{2\pi}\right)\ln\left(\frac{r+a}{r}\right).$$

$$\frac{d\Phi_B}{dt} = \frac{d\Phi_B}{dr}\frac{dr}{dt} = \frac{\mu_0 Ib}{2\pi}\left(-\frac{a}{r(r+a)}\right)v.$$

$$|\mathcal{E}| = \frac{\mu_0 Iabv}{2\pi r(r+a)}.$$

(ii) **IDENTIFY:** $\mathcal{E} = Bvl$ for a bar of length l moving at speed v perpendicular to a magnetic field B. Calculate the induced emf in each side of the loop, and combine the emfs according to their polarity.

SET UP: The four segments of the loop are shown in Figure 29.49b.

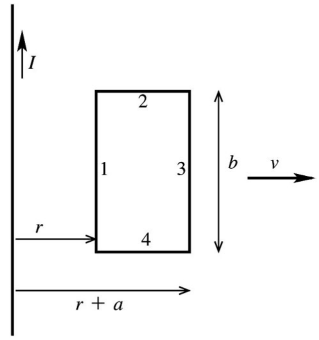


Figure 29.49b

EXECUTE: The emf in each side of the loop is

$$\mathcal{E}_1 = \left(\frac{\mu_0 I}{2\pi r}\right)vb,\quad \mathcal{E}_3 = \left(\frac{\mu_0 I}{2\pi(r+a)}\right)vb,\quad \mathcal{E}_2 = \mathcal{E}_4 = 0.$$

Both emfs $\mathcal{E}_1$ and $\mathcal{E}_3$ are directed toward the top of the loop so oppose each other. The net emf is

$$\mathcal{E} = \mathcal{E}_1 - \mathcal{E}_3 = \frac{\mu_0 Ivb}{2\pi}\left(\frac{1}{r} - \frac{1}{r+a}\right) = \frac{\mu_0 Iabv}{2\pi r(r+a)}.$$

This expression agrees with what was obtained in (i) using Faraday's law.

(b) (i) **IDENTIFY** and **SET UP:** The flux of the induced current opposes the change in flux.

EXECUTE: $\vec{B}$ is $\otimes$. Φ_B is decreasing, so the flux Φ_{ind} of the induced current is $\otimes$ and the current is clockwise.

(ii) **IDENTIFY** and **SET UP:** Use the right-hand rule to find the force on the positive charges in each side of the loop. The forces on positive charges in segments 1 and 3 of the loop are shown in Figure 29.49c.

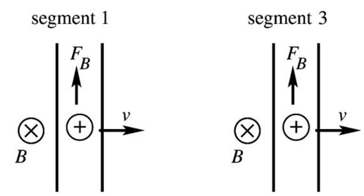

Figure 29.49c

EXECUTE: B is larger at segment 1 since it is closer to the long wire, so F_B is larger in segment 1 and the induced current in the loop is clockwise. This agrees with the direction deduced in (i) using Lenz's law.

(c) EVALUATE: When $v = 0$ the induced emf should be zero; the expression in part (a) gives this. When $a \to 0$ the flux goes to zero and the emf should approach zero; the expression in part (a) gives this. When $r \to \infty$ the magnetic field through the loop goes to zero and the emf should go to zero; the expression in part (a) gives this.

29.50. **IDENTIFY:** We are dealing with induced current and Faraday's law.

SET UP and **EXECUTE:** $\mathcal{E}_{\text{av}} = N\dfrac{\Delta\Phi_B}{\Delta t}$ s.

EXECUTE: **(a)** We want the flux. $\Phi_B = BA\cos\phi$ = (5 mT)(8 cm^2)(1) = 4 μWb.

(b) We want $\dfrac{\Delta\Phi_B}{\Delta t}$ and $\mathcal{E}$. Δt = x/v = (4 cm)/(2 cm/s) = 2 s. $\dfrac{\Delta\Phi_B}{\Delta t}$ = (4 μWb)/(2 s) = 2 μWb/s.

$\mathcal{E}_{\text{av}} = \dfrac{\Delta\Phi_B}{\Delta t}$ = 2 μV.

EVALUATE: This is a small voltage, but the motion is very slow.

29.51. **IDENTIFY:** Apply Faraday's law in the form $\mathcal{E}_{\text{av}} = -N\dfrac{\Delta\Phi_B}{\Delta t}$ to calculate the average emf. Apply Lenz's law to calculate the direction of the induced current.

SET UP: $\Phi_B = BA.$ The flux changes because the area of the loop changes.

EXECUTE: **(a)** $\mathcal{E}_{\text{av}} = \left|\dfrac{\Delta\Phi_B}{\Delta t}\right| = B\left|\dfrac{\Delta A}{\Delta t}\right| = B\dfrac{\pi r^2}{\Delta t} = (1.35\text{ T})\dfrac{\pi(0.0650/2\text{ m})^2}{0.250\text{ s}} = 0.0179\text{ V} = 17.9\text{ mV}.$

(b) Since the magnetic field is directed into the page and the magnitude of the flux through the loop is decreasing, the induced current must produce a field that goes into the page. Therefore the current flows from point *a* through the resistor to point *b*.

EVALUATE: Faraday's law can be used to find the direction of the induced current. Let $\vec{A}$ be into the page. Then Φ_B is positive and decreasing in magnitude, so $d\Phi_B/dt < 0.$ Therefore $\mathcal{E} > 0$ and the induced current is clockwise around the loop.

29.52. **IDENTIFY:** The movement of the rod causes an emf to be induced across its ends, which causes a current to flow through the circuit. The magnetic field exerts a force on this current.

SET UP: The magnetic force is $F_{\text{mag}} = ILB,$ the induced emf is $\mathcal{E} = vBL.$ $\sum F = ma$ applies to the rod, and $a = dv/dt.$

EXECUTE: The net force on the rod is $F - iLB = ma.$ $i = \dfrac{vBL}{R}.$ $F - \dfrac{vB^2L^2}{R} = ma.$ $F - \dfrac{vB^2L^2}{R} = m\dfrac{dv}{dt}.$

Integrating to find the time gives $\dfrac{F}{m}\displaystyle\int_0^t dt' = \int_0^v \dfrac{dv'}{1 - \dfrac{v'B^2L^2}{FR}},$ which gives $\dfrac{Ft}{m} = -\dfrac{FR}{B^2L^2}\ln\left(1 - \dfrac{vB^2L^2}{FR}\right).$

Solving for *t* and putting in the numbers gives

$$t = -\frac{Rm}{B^2L^2}\ln\left(1 - \frac{vB^2L^2}{FR}\right) = -(0.120\text{ kg})(888.9\text{ s/kg})\ln\left(1 - \frac{25.0\text{ m/s}}{(1.90\text{ N})(888.9\text{ s/kg})}\right) = 1.59\text{ s}.$$

EVALUATE: We cannot use the constant-acceleration kinematics formulas because as the speed *v* of the rod changes, the magnetic force on it also changes. Therefore the acceleration of the rod is not constant.

29.53. **IDENTIFY:** Find the magnetic field at a distance *r* from the center of the wire. Divide the rectangle into narrow strips of width *dr*, find the flux through each strip and integrate to find the total flux.

SET UP: Example 28.8 uses Ampere's law to show that the magnetic field inside the wire, a distance r from the axis, is $B(r) = \mu_0 Ir/2\pi R^2.$

EXECUTE: Consider a small strip of length *W* and width *dr* that is a distance *r* from the axis of the wire, as shown in Figure 29.53. The flux through the strip is $d\Phi_B = B(r)W\,dr = \dfrac{\mu_0 IW}{2\pi R^2}r\,dr.$ The total flux through the rectangle is $\Phi_B = \displaystyle\int d\Phi_B = \left(\frac{\mu_0 IW}{2\pi R^2}\right)\int_0^R r\,dr = \frac{\mu_0 IW}{4\pi}.$

EVALUATE: Note that the result is independent of the radius *R* of the wire.

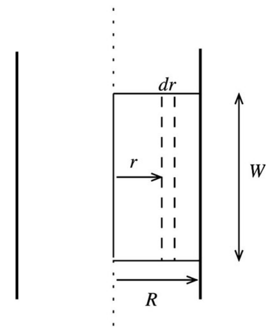

Figure 29.53

29.54. **IDENTIFY:** Apply Newton's second law to the bar. The bar will experience a magnetic force due to the induced current in the loop. Use $a = dv/dt$ to solve for v. At the terminal speed, $a = 0$.

SET UP: The induced emf in the loop has a magnitude BLv. The induced emf is counterclockwise, so it opposes the voltage of the battery, $\mathcal{E}$.

EXECUTE: **(a)** The net current in the loop is $I = \dfrac{\mathcal{E} - BLv}{R}$. The acceleration of the bar is $a = \dfrac{F}{m} = \dfrac{ILB\sin(90°)}{m} = \dfrac{(\mathcal{E} - BLv)LB}{mR}$. To find $v(t)$, set $\dfrac{dv}{dt} = a = \dfrac{(\mathcal{E} - BLv)LB}{mR}$ and solve for v using the method of separation of variables:

$\int_0^v \dfrac{dv}{(\mathcal{E} - BLv)} = \int_0^t \dfrac{LB}{mR}dt \rightarrow v = \dfrac{\mathcal{E}}{BL}(1 - e^{-B^2L^2t/mR}) = (14 \text{ m/s})(1 - e^{-t/6.0 \text{ s}})$. The graph of v versus t is sketched in Figure 29.54. Note that the graph of this function is similar in appearance to that of a charging capacitor.

(b) Just after the switch is closed, $v = 0$ and $I = \mathcal{E}/R = 2.4$ A, $F = ILB = 2.074$ N, and $a = F/m = 2.3 \text{ m/s}^2$.

(c) When $v = 2.0$ m/s, $a = \dfrac{[12 \text{ V} - (2.4 \text{ T})(0.36 \text{ m})(2.0 \text{ m/s})](0.36 \text{ m})(2.4 \text{ T})}{(0.90 \text{ kg})(5.0\ \Omega)} = 2.0 \text{ m/s}^2$.

(d) Note that as the speed increases, the acceleration decreases. The speed will asymptotically approach the terminal speed $\dfrac{\mathcal{E}}{BL} = \dfrac{12 \text{ V}}{(2.4 \text{ T})(0.36 \text{ m})} = 14$ m/s, which makes the acceleration zero.

EVALUATE: The current in the circuit is clockwise and the magnetic force on the bar is to the right. The energy that appears as kinetic energy of the moving bar is supplied by the battery.

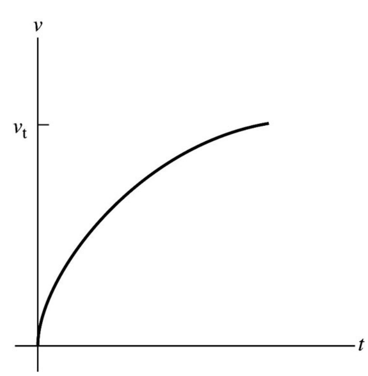

Figure 29.54

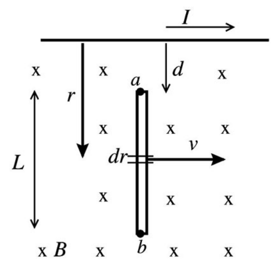
29.55. **(a)** and **(b)** **IDENTIFY** and **SET UP:**



The magnetic field of the wire is given by $B = \dfrac{\mu_0 I}{2\pi r}$ and varies along the length of the bar. At every point along the bar $\vec{B}$ has direction into the page. Divide the bar up into thin slices, as shown in Figure 29.55a.

Figure 29.55a

EXECUTE: The emf $d\mathcal{E}$ induced in each slice is given by $d\mathcal{E} = \vec{v} \times \vec{B} \cdot d\vec{l}$. $\vec{v} \times \vec{B}$ is directed toward the wire, so $d\mathcal{E} = -vB\,dr = -v\left(\dfrac{\mu_0 I}{2\pi r}\right)dr.$ The total emf induced in the bar is

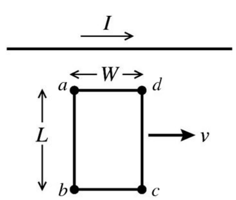
$$V_{ba} = \int_a^b d\mathcal{E} = -\int_d^{d+L}\left(\frac{\mu_0 Iv}{2\pi r}\right)dr = -\frac{\mu_0 Iv}{2\pi}\int_d^{d+L}\frac{dr}{r} = -\frac{\mu_0 Iv}{2\pi}\left[\ln(r)\right]_d^{d+L}.$$

$$V_{ba} = -\frac{\mu_0 Iv}{2\pi}(\ln(d+L) - \ln(d)) = -\frac{\mu_0 Iv}{2\pi}\ \ln(1 + L/d).$$

EVALUATE: The minus sign means that V_{ba} is negative, point *a* is at higher potential than point *b*. (The force $\vec{F} = q\vec{v} \times \vec{B}$ on positive charge carriers in the bar is towards *a*, so *a* is at higher potential.) The potential difference increases when *I* or *v* increase, or *d* decreases.

(c) **IDENTIFY:** Use Faraday's law to calculate the induced emf.

SET UP: The wire and loop are sketched in Figure 29.55b.



EXECUTE: As the loop moves to the right the magnetic flux through it doesn't change.

Thus $\mathcal{E} = -\dfrac{d\Phi_B}{dt} = 0$ and $I = 0$.

Figure 29.55b

EVALUATE: This result can also be understood as follows. The induced emf in section *ab* puts point *a* at higher potential; the induced emf in section *dc* puts point *d* at higher potential. If you travel around the loop then these two induced emf's sum to zero. There is no emf in the loop and hence no current.

29.56. **IDENTIFY:** Apply Faraday's law to calculate the magnitude and direction of the induced emf.

SET UP: Let $\vec{A}$ be directed out of the page in the figure with the problem in the textbook. This means that counterclockwise emf is positive.

EXECUTE: **(a)** $\Phi_B = BA = B_0 \pi r_0^2\left[1 - 3(t/t_0)^2 + 2(t/t_0)^3\right].$

(b) $\mathcal{E} = -\dfrac{d\Phi_B}{dt} = -B_0 \pi r_0^2 \dfrac{d}{dt}\left[1 - 3(t/t_0)^2 + 2(t/t_0)^3\right] = -\dfrac{B_0 \pi r_0^2}{t_0}\left[-6(t/t_0) + 6(t/t_0)^2\right].$

$\mathcal{E} = -\dfrac{6\, B_0 \pi r_0^2}{t_0}\left(\left(\dfrac{t}{t_0}\right)^2 - \left(\dfrac{t}{t_0}\right)\right).$ At $t = 5.0 \times 10^{-3}$ s,

$$\mathcal{E} = -\frac{6B_0\pi(0.0420\text{ m})^2}{0.010\text{ s}}\left(\left(\frac{5.0\times10^{-3}\text{ s}}{0.010\text{ s}}\right)^2 - \left(\frac{5.0\times10^{-3}\text{ s}}{0.010\text{ s}}\right)\right) = 0.0665\text{ V}.$$ $\mathcal{E}$ is positive so it is counterclockwise.

(c) $I = \dfrac{\mathcal{E}}{R_{\text{total}}} \Rightarrow R_{\text{total}} = r + R = \dfrac{\mathcal{E}}{I} \Rightarrow r = \dfrac{0.0665\text{ V}}{3.0\times10^{-3}\text{ A}} - 12\ \Omega = 10.2\ \Omega.$

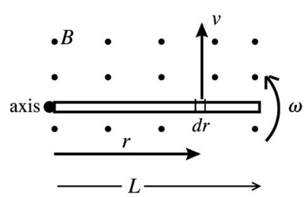
(d) Evaluating the emf at $t = 1.21\times10^{-2}$ s and using the equations of part (b), $\mathcal{E} = -0.0676$ V, and the current flows clockwise, from b to a through the resistor.

(e) $\mathcal{E} = 0$ when $0 = \left(\left(\dfrac{t}{t_0}\right)^2 - \left(\dfrac{t}{t_0}\right)\right)$. $1 = \dfrac{t}{t_0}$ and $t = t_0 = 0.010$ s.

EVALUATE: At $t = t_0$, $B = 0$. At $t = 5.00\times10^{-3}$ s, $\vec{B}$ is in the $+\hat{k}$-direction and is decreasing in magnitude. Lenz's law therefore says $\mathcal{E}$ is counterclockwise. At $t = 0.0121$ s, $\vec{B}$ is in the $+\hat{k}$-direction and is increasing in magnitude. Lenz's law therefore says $\mathcal{E}$ is clockwise. These results for the direction of $\mathcal{E}$ agree with the results we obtained from Faraday's law.

29.57. **IDENTIFY:** Use the expression for motional emf to calculate the emf induced in the rod.

SET UP: **(a)** The rotating rod is shown in Figure 29.57a.



The emf induced in a thin slice is $d\mathcal{E} = \vec{v}\times\vec{B}\cdot d\vec{l}$.

Figure 29.57a

EXECUTE: Assume that $\vec{B}$ is directed out of the page. Then $\vec{v}\times\vec{B}$ is directed radially outward and $dl = dr$, so $\vec{v}\times\vec{B}\cdot d\vec{l} = vB\,dr$.

$v = r\omega$ so $d\mathcal{E} = \omega Br\,dr$.

The $d\mathcal{E}$ for all the thin slices that make up the rod are in series so they add:

$\mathcal{E} = \int d\mathcal{E} = \int_0^L \omega Br\,dr = \frac{1}{2}\omega BL^2 = \frac{1}{2}(8.80\text{ rad/s})(0.650\text{ T})(0.240\text{ m})^2 = 0.165\text{ V}.$

EVALUATE: $\mathcal{E}$ increases with $\omega, B,$ or L^2.

(b) SET UP and **EXECUTE:** No current flows so there is no IR drop in potential. Thus the potential difference between the ends equals the emf of 0.165 V calculated in part (a).

(c) SET UP: The rotating rod is shown in Figure 29.57b.

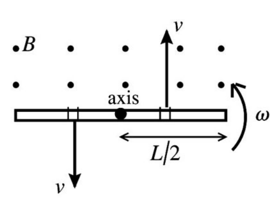


Figure 29.57b

EXECUTE: The emf between the center of the rod and each end is $\mathcal{E}=\frac{1}{2}\omega B(L/2)^2=\frac{1}{4}(0.165\text{ V})=0.0412\text{ V},$ with the direction of the emf from the center of the rod toward each end. The emfs in each half of the rod thus oppose each other and there is no net emf between the ends of the rod.

EVALUATE: ω and B are the same as in part (a) but L of each half is $\frac{1}{2}L$ for the whole rod. $\mathcal{E}$ is proportional to L^2, so is smaller by a factor of $\frac{1}{4}$.

29.58. **IDENTIFY:** Since the bar is straight and the magnetic field is uniform, integrating $d\mathcal{E}=\vec{v}\times\vec{B}\cdot d\vec{l}$ along the length of the bar gives $\mathcal{E}=(\vec{v}\times\vec{B})\cdot\vec{L}.$

SET UP: $\vec{v}=(6.80\text{ m/s})\hat{i}.$ $\vec{L}=(0.250\text{ m})(\cos 36.9°\hat{i}+\sin 36.9°\hat{j}).$

EXECUTE: **(a)** $\mathcal{E}=(\vec{v}\times\vec{B})\cdot\vec{L}=(6.80\text{ m/s})\hat{i}\times\left[(0.120\text{ T})\hat{i}-(0.220\text{ T})\hat{j}-(0.0900\text{ T})\hat{k}\right]\cdot\vec{L}.$

$\mathcal{E}=\left[(0.612\text{ V/m})\hat{j}-(1.496\text{ V/m})\hat{k}\right]\cdot\left[(0.250\text{ m})(\cos 36.9°\hat{i}+\sin 36.9°\hat{j})\right].$

$\mathcal{E}=(0.612\text{ V/m})(0.250\text{ m})\sin 36.9°=0.0919\text{ V}=91.9\text{ mV}.$

(b) The higher potential end is the end to which positive charges in the rod are pushed by the magnetic force. $\vec{v}\times\vec{B}$ has a positive y-component, so the end of the rod marked + in Figure 29.58 is at higher potential.

EVALUATE: Since $\vec{v}\times\vec{B}$ has nonzero $\hat{j}$- and $\hat{k}$-components, and $\vec{L}$- has nonzero $\hat{i}$- and $\hat{j}$-components, only the $\hat{k}$-component of $\vec{B}$ contributes to $\mathcal{E}$. In fact, $|\mathcal{E}|=|v_xB_zL_y|(6.80\text{ m/s})(0.0900\text{ T})(0.250\text{ m})\sin 36.9°=0.0919\text{ V}=91.9\text{ mV}.$

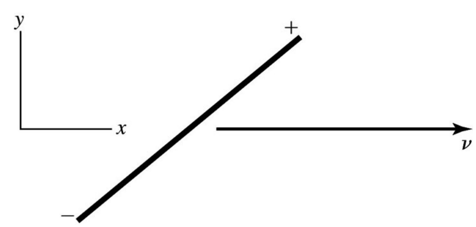

Figure 29.58

29.59. **(a) IDENTIFY:** Use Faraday's law to calculate the induced emf, Ohm's law to calculate I, and $\vec{F}=I\vec{l}\times\vec{B}$ to calculate the force on the rod due to the induced current.

SET UP: The force on the wire is shown in Figure 29.59.

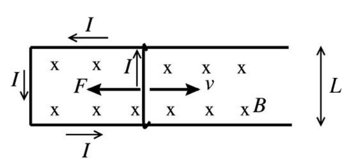

Figure 29.59

EXECUTE: When the wire has speed v the induced emf is $\mathcal{E}=BvL$ and the induced current is $I=\mathcal{E}/R=\dfrac{BvL}{R}.$

The induced current flows upward in the wire as shown, so the force $\vec{F}=I\vec{l}\times\vec{B}$ exerted by the magnetic field on the induced current is to the left. $\vec{F}$ opposes the motion of the wire, as it must by Lenz's law. The magnitude of the force is $F=ILB=B^2L^2v/R.$

(b) IDENTIFY and **SET UP:** Apply $\sum \vec{F} = m\vec{a}$ to the wire. Take $+x$ to be toward the right and let the origin be at the location of the wire at $t = 0$, so $x_0 = 0$.

EXECUTE: $\sum F_x = ma_x$ says $-F = ma_x$.

$$a_x = -\frac{F}{m} = -\frac{B^2L^2v}{mR}.$$

Use this expression to solve for $v(t)$:

$$a_x = \frac{dv}{dt} = -\frac{B^2L^2v}{mR} \text{ and } \frac{dv}{v} = -\frac{B^2L^2}{mR}dt.$$

$$\int_{v_0}^{v} \frac{dv'}{v'} = -\frac{B^2L^2}{mR}\int_0^t dt'.$$

$$\ln(v) - \ln(v_0) = -\frac{B^2L^2t}{mR}.$$

$$\ln\left(\frac{v}{v_0}\right) = -\frac{B^2L^2t}{mR} \text{ and } v = v_0 e^{-B^2L^2t/mR}.$$

Note: At $t = 0, v = v_0$ and $v \to 0$ when $t \to \infty$.

Now solve for $x(t)$:

$$v = \frac{dx}{dt} = v_0 e^{-B^2L^2t/mR} \text{ so } dx = v_0 e^{-B^2L^2t/mR}dt.$$

$$\int_0^x dx' = \int_0^t v_0 e^{-B^2L^2t'/mR}dt'.$$

$$x = v_0\left(-\frac{mR}{B^2L^2}\right)\left[e^{-B^2L^2t'/mR}\right]_0^t = \frac{mRv_0}{B^2L^2}(1 - e^{-B^2L^2t/mR}).$$

Comes to rest implies $v = 0$. This happens when $t \to \infty$.

$t \to \infty$ gives $x = \dfrac{mRv_0}{B^2L^2}$. Thus this is the distance the wire travels before coming to rest.

EVALUATE: The motion of the slide wire causes an induced emf and current. The magnetic force on the induced current opposes the motion of the wire and eventually brings it to rest. The force and acceleration depend on v and are constant. If the acceleration were constant, not changing from its initial value of $a_x = -B^2L^2v_0/mR$, then the stopping distance would be $x = -v_0^2/2a_x = mRv_0/2B^2L^2$. The actual stopping distance is twice this.

29.60. IDENTIFY: This problem involves Faraday's law, Lenz's law, and an *R-C* circuit.

SET UP: $\mathcal{E} = -\dfrac{d\Phi_B}{dt}$, $i = I_0 e^{-t/RC}$, $q = Q_0 e^{-t/RC}$, $B = \dfrac{\mu_0 I a^2 N}{2(x^2 + a^2)^{3/2}}$.

EXECUTE: **(a)** We want I_2 at $t = 0$. $I_1 = I_0 e^{-t/R_1C}$. $R_1 = (0.0100\ \Omega/\text{m})(2\pi a)(N_1) = 125.7\ \Omega$ so $I_0 = Q_0/R_1C = 79.6$ mA.

(b) We want Φ_2 at $t = 0$. Apply $B_1 = \dfrac{\mu_0 I_1 a^2 N_1}{2(x^2 + a^2)^{3/2}}$ for $x = 0$: $B_1 = \dfrac{\mu_0 I_1 N_1}{2a}$. $\Phi_2 = B_1 A_2$ which gives

$\Phi_2 = \left(\dfrac{\mu_0 I_1 N_1}{2a}\right)(\pi b^2)$. Using the given numbers we get $\Phi_2 =$ 314 μWb.

(c) We want the direction of I_2. Just after S is closed, I_1 is increasing to its maximum value and runs counterclockwise through the outer loop. This produces an increasing field in the inner circuit pointing out of the paper. I_2 flows to oppose this increase, so it flows *clockwise.*

(d) We want the direction of I_2. At this time, I_1 is decreasing, so B_1 is out of the paper but decreasing. So I_2 flows to oppose this decrease, which is *counterclockwise*.

(e) We want I_1 at $t = 1.26$ ms. $I_1 = \dfrac{Q_0}{R_1C}e^{-t/R_1C}.\ \dfrac{dI_1}{dt} = \dfrac{Q_0}{(R_1C)^2}e^{-t/R_1C}.\ \ \Phi_2 = \left(\dfrac{\mu_0 I_1 N_1}{2a}\right)(\pi b^2)$.

$B_1 = \dfrac{\mu_0 I_1 N_1}{2a}.\ \ \mathcal{E}_2 = N_2\dfrac{d\Phi_2}{dt} = \left(\dfrac{\mu_0 N_1 N_2 \pi b^2}{2a}\right)\dfrac{dI_1}{dt} = \left(\dfrac{\mu_0 N_1 N_2 \pi b^2}{2a}\right)\dfrac{Q_0}{(R_1C)^2}e^{-t/R_1C}$.

$I_2 = \dfrac{\mathcal{E}_2}{R_2} = \dfrac{\mathcal{E}_2}{N_2(0.0100\ \Omega/\text{m})(2\pi b)}$. Substituting our expression above for $\mathcal{E}_2$ into our equation for I_2 and dividing out common factors gives $I_2 = \dfrac{\mu_0 N_1 b Q_0 e^{-t/R_1C}}{4a(R_1C)^2(0.0100\ \Omega/\text{m})}$. Putting in the numbers gives $I_2 = 365$ mA.

EVALUATE: Note that N_2 does not affect the final result for I_2 because it is a factor in R_2 and in $\mathcal{E}_2$ so it cancels out.

29.61. IDENTIFY: Use $\oint \vec{E}\cdot d\vec{l} = -\dfrac{d\Phi_B}{dt}$ to calculate the induced electric field at each point and then use $\vec{F} = q\vec{E}$.

SET UP:

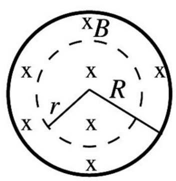

Figure 29.61a

Apply $\oint \vec{E}\cdot d\vec{l} = -\dfrac{d\Phi_B}{dt}$ to a concentric circle of radius r, as shown in Figure 29.61a. Take $\vec{A}$ to be into the page, in the direction of $\vec{B}$.

EXECUTE: B increasing then gives $\dfrac{d\Phi_B}{dt} > 0$, so $\oint \vec{E}\cdot d\vec{l}$ is negative. This means that E is tangent to the circle in the counterclockwise direction, as shown in Figure 29.61b.

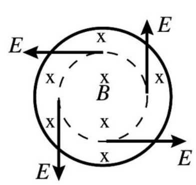

Figure 29.61b

$$\oint \vec{E}\cdot d\vec{l} = -E(2\pi r)$$

$$\frac{d\Phi_B}{dt} = \pi r^2\frac{dB}{dt}$$

$-E(2\pi r) = -\pi r^2\dfrac{dB}{dt}$ so $E = \frac{1}{2}r\dfrac{dB}{dt}$.

Point *a*: The induced electric field and the force on q are shown in Figure 29.61c.

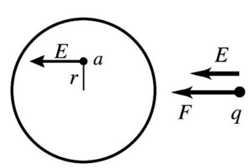

Figure 29.61c

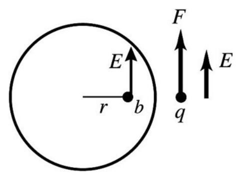
$F = qE = \frac{1}{2}qr\dfrac{dB}{dt}$.

$\vec{F}$ is to the left ($\vec{F}$ is in the same direction as $\vec{E}$ since q is positive).

Point *b*: The induced electric field and the force on *q* are shown in Figure 29.61d.



$$F = qE = \tfrac{1}{2}qr\frac{dB}{dt}.$$

$\vec{F}$ is toward the top of the page.

Figure 29.61d

Point *c*: $r = 0$ here, so $E = 0$ and $F = 0$.

EVALUATE: If there were a concentric conducting ring of radius *r* in the magnetic field region, Lenz's law tells us that the increasing magnetic field would induce a counterclockwise current in the ring. This agrees with the direction of the force we calculated for the individual positive point charges.

29.62. **IDENTIFY:** This problem involves motional emf and damped harmonic motion.
SET UP: Eq. (14.41): $-kx - bv_x = ma_x$ (or $-kx - bdx/dt = m\, d^2x/dt^2$). $\mathcal{E} = vBL = BL\, dx/dt$. $F = ILB$. $\mathcal{E} = RI$.
EXECUTE: **(a)** We want the damping constant. Apply Newton's second law to the bar when it is a distance *x* beyond the equilibrium position and released, as shown in Fig. P29.62 in the textbook. This gives $F_{\text{spr}} + F_{\text{mag}} = m\dfrac{d^2x}{dt^2}$. $F_{\text{spr}} = -kx$. $F_{\text{mag}} = ILB = \dfrac{\mathcal{E}}{R}LB = \left(\dfrac{vBL}{R}\right)LB = \dfrac{(BL)^2}{R}v = \dfrac{(BL)^2}{R}\dfrac{dx}{dt}$. When released the bar moves to the left, which forces a downward current in the bar. The magnetic force on the bar is in the +*x*-direction, which is opposite to the velocity, so $F_{\text{mag}} = -\dfrac{(BL)^2}{R}\dfrac{dx}{dt}$. Newton's second law now becomes $-kx - \dfrac{(BL)^2}{R}\dfrac{dx}{dt} = m\dfrac{d^2x}{dt^2}$. Comparing with Eq. (14.41) tells us that

$$b = \frac{(BL)^2}{R} = \frac{[(1.00\text{ T})(0.400\text{ m})]^2}{0.500\ \Omega} = 0.320\text{ kg/s}.$$

(b) We want the frequency. For damped harmonic motion $f' = \dfrac{\omega'}{2\pi} = \dfrac{1}{2\pi}\sqrt{\dfrac{k}{m} - \dfrac{b^2}{4m^2}}$. Putting in the given values we get $f' = 1.38$ Hz. (This also gives $\omega' = 8.67$ rad/s.)

(c) We want the amplitude at $t = 5.00$ s. For damped harmonic motion, the amplitude is $A(t) = A_0 e^{-(b/2m)t}$. $A_0 = x_0 = 10.0$ cm, so using the numbers we get $A(5.00\text{ s}) = 5.13$ cm.

(d) We want the current when the bar passes its equilibrium position. For damped harmonic motion we have $x(t) = A(t)\cos(\omega' t + \phi)$. If the bar starts from rest, $v = 0$ when $x = x_0$, which makes $\phi = 0$. When $x = 0$ for the first time, $x = 0$ so $\cos(\omega' t) = 0$, which means that $\omega' t = \pi/2$.

$\mathcal{E} = vBL = BL\dfrac{dx}{dt} = BL\dfrac{d[A(t)\cos(\omega' t)]}{dt}$. Carry out this derivative of a product using the fact that $\omega' t = \pi/2$. The result is $\mathcal{E} = A\omega' BL$. Now evaluate $A(t) = A_0 e^{-(b/2m)t}$ using $t = \pi/2\omega'$ and $\omega' = 8.67$ rad/s from part (b). The result is $A = 9.76$ cm. The current is $I = \dfrac{\mathcal{E}}{R} = \dfrac{A\omega' BL}{R}$. Using these known quantities gives $I = 0.677$ A.

(e) The bar is moving to the left so the magnetic force on a positive charge in the bar is downward in Fig. P29.62, so the current is *counterclockwise* in the circuit.

EVALUATE: The amplitude of the motion of the bar decreases with time, so the motional emf and the induced current also decrease in amplitude with time.

29.63. **IDENTIFY:** Apply $i_D = \mathcal{E}\dfrac{d\Phi_E}{dt}$.

SET UP: $\mathcal{E} = 3.5\times10^{-11}$ F/m.

EXECUTE: $i_D = \mathcal{E}\dfrac{d\Phi_E}{dt} = (3.5\times10^{-11}\text{ F/m})(24.0\times10^3\text{ V}\cdot\text{m/s}^3)t^2$. $i_D = 21\times10^{-6}$ A gives $t = 5.0$ s.

EVALUATE: i_D depends on the rate at which Φ_E is changing.

29.64. **IDENTIFY:** Faraday's law and Ohm's law both apply. The flux change is due to the changing magnetic field.

SET UP: $\mathcal{E} = \left|\dfrac{d\Phi_B}{dt}\right|$ and $V = IR$, where $V = \mathcal{E}$ since it is caused by the changing flux. Since the flux change is due only to the change in B, we have $\mathcal{E} = \left|\dfrac{d\Phi_B}{dt}\right| = AN\left|\dfrac{dB}{dt}\right|$, where N is the number of turns.

EXECUTE: **(a)** Combining Ohm's law and Faraday's law and dropping the absolute value signs gives
$\dfrac{dB}{dt} = \dfrac{\varepsilon}{AN} = \dfrac{RI}{AN} \quad \rightarrow dB = \dfrac{RI}{AN}dt.$

Integrating gives $\Delta B_{0\rightarrow2} = \dfrac{R}{AN}\int_0^{2.00\text{ s}} Idt$. The integral is the area under the curve in the i-versus-t graph shown with the problem. We can get that using simple geometry on the graph.
area = integral = (1/2)(2.00 s)(3.00 mA) = 0.00300 A·s.
The field starts out with zero magnitude, so at 2.00 s it is
$B = R(\text{integral})/AN = (0.250\ \Omega)(0.00300\text{ A}\cdot\text{s})/[\pi(0.00800\text{ m})^2(4)] = 0.9325$ T, which rounds to 0.933 T.
(b) We use the same geometric approach as in part (a).
$\Delta B_{2\rightarrow5} = R(\text{area from 2.00 s to 5.00 s})/AN = (0.250\ \Omega)(3.00\text{ mA})(3.0\text{ s})/[\pi(0.00800\text{ m})^2(4)] = 2.798$ T.
$B_5 = B_2 + \Delta B_{2\rightarrow5} = 0.9325\text{ T} + 2.798\text{ T} = 3.73$ T.
(c) The area under the curve from 5.00 s to 6.00 s is half the area from 0.00 s to 2.00 s, so
$\Delta B_{5\rightarrow6} = \tfrac{1}{2}\,\Delta B_{0\rightarrow2} = (0.9325\text{ T})/2 = 0.46625$ T.
$B_6 = B_5 + \Delta B_{5\rightarrow6} = 3.73\text{ T} + 0.46625\text{ T} = 4.20$ T.

EVALUATE: Careful! Just because the current i is constant between 2.0 s and 5.0 s does *not* mean that B is constant since i is induced by a changing B. A constant i just means that B is changing at a constant rate.

29.65. **IDENTIFY:** An emf is induced across the moving metal bar, which causes current to flow in the circuit. The magnetic field exerts a force on the moving bar due to the current in it, which causes acceleration of the bar. Newton's second law applies to the accelerating bar. Ohm's law applies to the resistor in the circuit.
SET UP: The induced potential across the moving bar is $\mathcal{E} = vBL$, the magnetic force on the bar is $F_{mag} = ILB$, and Ohm's law is $\mathcal{E} = IR$. Newton's second law is $\Sigma\vec{F} = m\vec{a}$, and $a_x = dv_x/dt$. The flux through the loop is increasing, so the induced current is counterclockwise. Alternatively, the magnetic force $\vec{F} = q\vec{v}\times\vec{B}$ on positive charge in the moving bar is upward, by the right-hand rule, which also gives a counterclockwise current. So the magnetic force on the bar is to the left, opposite to the velocity of the bar.
EXECUTE: **(a)** Combining the equations discussed in the set up, the magnetic force on the moving bar is $F_{mag} = ILB = (\mathcal{E}/R)LB = (vBL/R)LB = v(BL)^2/R$. Newton's second law gives

$F_{mag} = ma.$
$ma = v(BL)^2/R.$
$$a = \frac{(BL)^2}{mR}v.$$
A graph of a versus v should be a straight line having slope equal to $(BL)^2/mR$. The graph of a versus v is shown in Figure 29.65. The best-fit slope of this graph is $0.3071\ \text{s}^{-1}$.

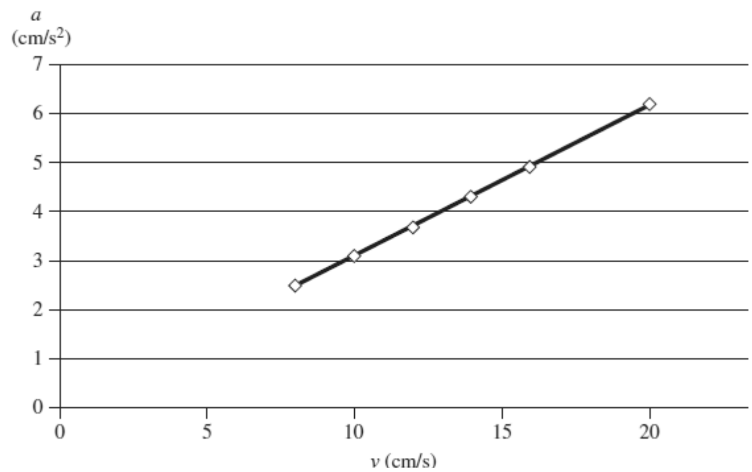


Figure 29.65

(b) $(BL)^2/mR$ = slope, so $B = \sqrt{\frac{(\text{slope})mR}{L^2}} = \sqrt{\frac{(0.3071\ \text{s}^{-1})(0.200\ \text{kg})(0.800\ \Omega)}{(0.0600\ \text{m})^2}} = 3.69\ \text{T}.$

(c) The current flows in a counterclockwise direction in the circuit. Therefore the charges lose potential energy as they pass through the resistor R from a to b, which makes point a at a higher potential than b.
(d) We know that $a_x = dv_x/dt$, and in part (a) we found that the magnitude of the acceleration is $a = \frac{(BL)^2}{mR}v.$ We also saw that a is opposite to v, so $a_x = -\frac{(BL)^2}{mR}v.$ Therefore $\frac{dv}{dt} = -\frac{(BL)^2}{mR}v.$
Separating variables and integrating gives
$$\int_{20.0\ \text{cm/s}}^{10.0\ \text{cm/s}} \frac{dv}{v} = -\int_0^t \frac{(BL)^2}{mR}dt'.$$
$$\ln\left(\frac{10}{20}\right) = -\frac{(BL)^2}{mR}t.$$
$$t = -\frac{mR}{(BL)^2}\ln(1/2) = -(0.200\ \text{kg})(0.800\ \Omega)(\ln ½)/[(3.69\ \text{T})(0.0600\ \text{m})]^2 = 2.26\ \text{s}.$$
EVALUATE: We cannot use the standard kinematics formulas because the acceleration is not constant.

29.66. **IDENTIFY:** The 8.00-cm long left side of the loop is a bar moving in a magnetic field, so an emf is induced across its ends. This emf causes current to flow through the loop, and the external magnetic field exerts a force on this bar due to the current in it. Ohm's law applies to the circuit and Newton's second law applies to the loop.
SET UP: The induced potential across the left-end side is $\mathcal{E} = vBL,$ the magnetic force on the 8.00-cm bar is $F_{mag} = ILB$, and Ohm's law is $\mathcal{E} = IR$. Newton's second law is $\Sigma\vec{F} = m\vec{a}.$ The flux through the loop is decreasing, so the induced current is counterclockwise to oppose this decrease. Alternatively, the magnetic force on positive charge in the moving left-end segment is downward, by the right-hand rule, which also gives a counterclockwise current. Therefore the magnetic force on the 8.00-cm segment is to

the left, opposite to the velocity and the external $\vec{F}$. Since the speed of the loop is constant, the external force is equal in magnitude to the magnetic force, so $F_{mag} = F$.

EXECUTE: **(a)** Combining the equations discussed in the set up, the magnetic force on the 8.00-cm bar (and on the loop) is $F = F_{mag} = ILB = (\mathcal{E}/R)LB = (vBL/R)LB = v(BL)^2/R$, so $F = v(BL)^2/R$. Therefore a graph of F versus v should be a straight line having slope equal to $(BL)^2/R$. Figure 29.66 shows a graph of F versus v. The best-fit slope of the line in this graph is 0.0520 N/(cm/s) = 5.20 N·s/m.

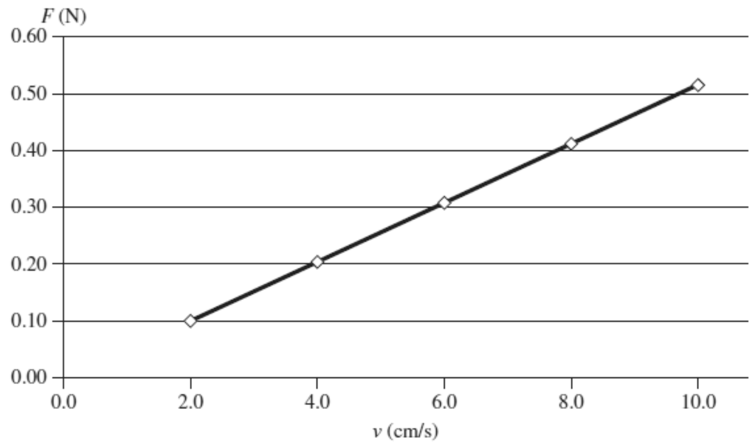

Figure 29.66

(b) Since $(BL)^2/R$ = slope, we solve for B and have

$$B = \sqrt{\frac{R(\text{slope})}{L^2}} = \sqrt{\frac{(0.00400\ \Omega)(5.20\ \text{N}\cdot\text{s/m})}{(0.0800\ \text{m})^2}} = 1.80\ \text{T}.$$

(c) The magnetic flux is decreasing through the loop, so the induced current must flow counterclockwise to oppose the decrease.

(d) $P = Fv = \dfrac{(BL)^2 v}{R}v = \dfrac{(BLv)^2}{R}$ = [(1.80 T)(0.0800 m)(0.0500 m/s)]^2/(0.00400 Ω) = 0.0130 W = 13.0 mW.

EVALUATE: For (d) we could use $P = I^2R = (vBL/R)^2/R = (vBL)^2/R$, the same result we got.

29.67. **IDENTIFY:** We are dealing with induced emf and Faraday's law.

SET UP: Refer to Fig. P29.67 with the problem in the textbook.

EXECUTE: **(a)** We want the velocity of a point on the sphere. As it is described, the particle is moving in the $-x$-direction with speed $v = r\omega$, where $r = R\sin\theta$. So $\vec{v} = R\omega\sin\theta\,\hat{i}$. Using $\omega = 2\pi f$ gives $\vec{v} = -(1.26\ \text{m/s})\sin\theta\,\hat{i}$.

(b) We want $\vec{v}\times\vec{B}$. $\vec{B}$ is in the $-z$-direction and $\vec{v}$ is in the $-x$-direction, so $\vec{v}\times\vec{B} = -(-1.26\ \text{m/s}\ \sin\theta)(-1.00\ \text{T})\,\hat{j} = -1.26\sin\theta\ \text{T}\cdot\text{m/s}\,\hat{j}$.

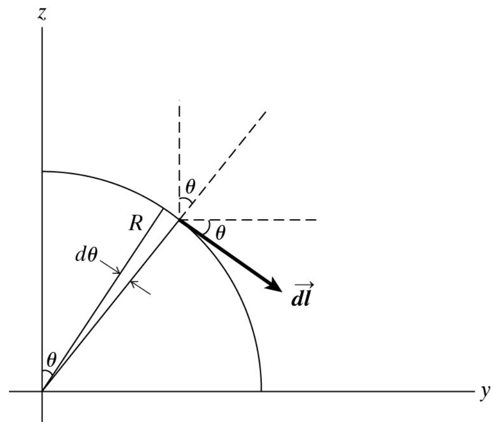

Figure 29.67

(c) We want $d\hat{l}$. See Fig. 29.67. We see that $dl = Rd\theta$ and $d\hat{l} = dl\cos\theta\,\hat{j} - dl\sin\theta\,\hat{k}$ $= Rd\theta(\cos\theta\,\hat{j} - \sin\theta\,\hat{k}) = (10.0\text{ cm})(\cos\theta\,\hat{j} - \sin\theta\,\hat{k})d\theta.$

(d) We want the current in the wire. Using our results in (b) and (c) gives $\mathcal{E} = \int(\vec{v}\times\vec{B})\bullet d\vec{L}$ $= \int_0^{60.0°}(-1.26\sin\theta\text{ T}\cdot\text{m/s}\,\hat{j})\bullet(10.0\text{ cm})(\cos\theta\,\hat{j} - \sin\theta\,\hat{k})d\theta.$ Doing the integration gives $\mathcal{E} = 4.73$ mA.

The current is $I = \dfrac{\mathcal{E}}{R} = \dfrac{4.73\text{ mA}}{10.0\ \Omega} = 4.73$ mA.

EVALUATE: (e) The segment of spherical surface from the upper rod to the lower rod behaves like a rotating curved bar and develops motional emf between its ends. The magnetic force on charges in this section of the surface forces positive charges to flow *upward* in the vertical bar.

29.68. IDENTIFY: This problem involves displacement current and Faraday's law.

SET UP: $I_d = \epsilon_0\dfrac{d\Phi_E}{dt}$, $\oint\vec{B}\cdot d\hat{l} = \mu_0(I + I_d)$, $\Phi_B = \int\vec{B}\bullet d\vec{A}$, $E = \eta t^2$.

EXECUTE: (a) We want the displacement current. $I_d = \epsilon_0\dfrac{d\Phi_E}{dt} = \epsilon_0\dfrac{d(E\pi r^2)}{dt} = \epsilon_0\pi r^2\dfrac{dE}{dt}$. Using $E = \eta t^2$ we get $dE/dt = 2\eta t$, so $I_d = 2\pi\epsilon_0\eta r^2 t.$

(b) We want $B(r)$. $\oint\vec{B}\cdot d\hat{l} = \mu_0(I + I_d)$. $I = 0$ and we have I_d from (a). Using a path or radius r we get $B2\pi r = 2\mu_0\pi\epsilon_0\eta r^2 t.$ Solving for B gives $B = \mu_0\epsilon_0\eta rt.$

(c) We want the magnetic flux. $\Phi_B = \int\vec{B}\bullet d\vec{A}$. Use $dA = bdr$. $\Phi_B = \int_0^a\mu_0\epsilon_0\eta rtbdr = \dfrac{1}{2}\mu_0\epsilon_0\eta bta^2.$

(d) We want the current. $I = \dfrac{\mathcal{E}}{R} = \dfrac{1}{R}\dfrac{d\Phi_B}{dt} = \dfrac{1}{R}\dfrac{d(\mu_0\epsilon_0\eta bta^2/2)}{dt} = \dfrac{\mu_0\epsilon_0\eta ba^2}{2R}.$

(e) The magnetic flux through the circuit is increasing. This means that the induced current flows to oppose this increase, so the current is *counterclockwise*.

EVALUATE: A changing magnetic field induces an electric field and a changing electric field induces a magnetic field.

29.69. IDENTIFY: The motion of the bar produces an induced current and that results in a magnetic force on the bar.

SET UP: $\vec{F}_B$ is perpendicular to $\vec{B}$, so is horizontal. The vertical component of the normal force equals $mg\cos\phi$, so the horizontal component of the normal force equals $mg\tan\phi$.

EXECUTE: **(a)** As the bar starts to slide, the flux is decreasing, so the current flows to increase the flux, which means it flows from a to b.

$$F_B = iLB = \frac{LB}{R}\mathcal{E} = \frac{LB}{R}\frac{d\Phi_B}{dt} = \frac{LB}{R}(B\cos\phi)\frac{dA}{dt} = \frac{LB^2}{R}(vL\cos\phi) = \frac{vL^2B^2}{R}\cos\phi.$$

(b) At the terminal speed the horizontal forces balance, so $mg\tan\phi = \frac{v_t L^2B^2}{R}\cos\phi$ and $v_t = \frac{Rmg\tan\phi}{L^2B^2\cos\phi}$.

(c) $i = \frac{\mathcal{E}}{R} = \frac{1}{R}\frac{d\Phi_B}{dt} = \frac{1}{R}(B\cos\phi)\frac{dA}{dt} = \frac{B}{R}(v_t L\cos\phi) = \frac{v_t LB\cos\phi}{R} = \frac{mg\tan\phi}{LB}$.

(d) $P = i^2R = \frac{Rm^2g^2\tan^2\phi}{L^2B^2}$.

(e) $P_g = Fv_t\cos(90° - \phi) = mg\left(\frac{Rmg\tan\phi}{L^2B^2\cos\phi}\right)\sin\phi$ and $P_g = \frac{Rm^2g^2\tan^2\phi}{L^2B^2}$.

EVALUATE: The power in part (e) equals that in part (d), as is required by conservation of energy.

29.70. **IDENTIFY:** A current is induced in the loop because of its motion and because of this current the magnetic field exerts a torque on the loop.

SET UP: Each side of the loop has mass $m/4$ and the center of mass of each side is at the center of each side. The flux through the loop is $\Phi_B = BA\cos\phi$.

EXECUTE: **(a)** $\vec{\boldsymbol{\tau}}_g = \sum \vec{\boldsymbol{r}}_{cm} \times m\vec{\boldsymbol{g}}$ summed over each leg.

$$\tau_g = \left(\frac{L}{2}\right)\left(\frac{m}{4}\right)g\sin(90° - \phi) + \left(\frac{L}{2}\right)\left(\frac{m}{4}\right)g\sin(90° - \phi) + (L)\left(\frac{m}{4}\right)g\sin(90° - \phi).$$

$$\tau_g = \frac{mgL}{2}\cos\phi \text{ (clockwise).}$$

$$\tau_B = \left|\vec{\boldsymbol{\tau}} \times \vec{\boldsymbol{B}}\right| = IAB\sin\phi \text{ (counterclockwise).}$$

$I = \frac{\mathcal{E}}{R} = -\frac{BA}{R}\frac{d}{dt}\cos\phi = \frac{BA}{R}\frac{d\phi}{dt}\sin\phi = \frac{BA\omega}{R}\sin\phi$. The current is going counterclockwise looking to the $-\hat{\boldsymbol{k}}$-direction. Therefore, $\tau_B = \frac{B^2A^2\omega}{R}\sin^2\phi = \frac{B^2L^4\omega}{R}\sin^2\phi$. The net torque is

$\tau = \frac{mgL}{2}\cos\phi - \frac{B^2L^4\omega}{R}\sin^2\phi$, opposite to the direction of the rotation.

(b) $\tau = I\alpha$ (I being the moment of inertia). About this axis $I = \frac{5}{12}mL^2$. Therefore,

$$\alpha = \frac{12}{5}\frac{1}{mL^2}\left[\frac{mgL}{2}\cos\phi - \frac{B^2L^4\omega}{R}\sin^2\phi\right] = \frac{6g}{5L}\cos\phi - \frac{12B^2L^2\omega}{5mR}\sin^2\phi.$$

EVALUATE: **(c)** The magnetic torque slows down the fall (since it opposes the gravitational torque). **(d)** Some energy is lost through heat from the resistance of the loop.

29.71. **IDENTIFY** and **SET UP:** Apply Lenz's law to determine the direction of the induced current. The figure shows the current pulse in the coil is in the counterclockwise direction as viewed from above. Also, the figure shows that direction-1 for the induced current is clockwise and direction-2 is counterclockwise.

EXECUTE: As the current pulse increases, it produces an increasing upward magnetic field in the brain. To oppose the increasing flux, the induced current must flow clockwise (direction-1). As the current pulse decreases its upward magnetic field decreases and the induced current must flow counterclockwise (direction-2) to oppose this. The correct choice is (c).

EVALUATE: Although the brain is made up of tissue, in some ways it behaves like a resistor and allows current to flow in it.

29.72. **IDENTIFY** and **SET UP:** Apply Faraday's law, $\mathcal{E} = \left|\frac{d\Phi_B}{dt}\right|$.

EXECUTE: $\mathcal{E} = \left|\frac{d\Phi_B}{dt}\right|$ $= d(BA)/dt = A\ dB/dt$. The greater the area, the greater the flux and hence the greater the rate of change of the flux in a given time. Therefore the largest area will have the greatest induced emf, and this is the periphery of the dashed line, which is choice (b).

EVALUATE: Only the field is changing, but the flux depends on the field *and* the area.

29.73. **IDENTIFY** and **SET UP:** Faraday's law gives $\mathcal{E} = \left|\frac{d\Phi_B}{dt}\right| = \frac{d(B_{\text{av}}A)}{dt} = A\frac{dB_{\text{av}}}{dt}$. $d(B_{\text{av}}A)/dt = A\ dB_{\text{av}}/dt$.

The quantity dB_{av}/dt is the slope in a B-versus-t graph, so the induced emf is greatest when the slope is steepest. Ohm's law gives $\mathcal{E} = IR$, so the current will be greatest when $\mathcal{E}$ is the greatest, which is where the slope of the B-versus-t graph is the greatest.

EXECUTE: We need to compare the slopes of graphs A and B with the slope of the graph in part (b) of the introduction to this set of passage problems. The graph in part (b) rises to 4 T in about 0.15 ms. In Figure P29.73, graph A rises to 4 T in less than 0.1 ms, and graph B also reaches 4 T in less than 0.1 ms. Therefore both graphs A and B have steeper slopes than the graph in part (b), so both of them would achieve a larger current than the process shown by the graph in part (b). This makes choice (c) correct.

EVALUATE: It is not the magnitude of the magnetic field that induces potential, but rather the *rate* at which the field changes.

29.74. **IDENTIFY** and **SET UP:** Faraday's law gives $\mathcal{E} = -\frac{d\Phi_B}{dt} - \frac{d(B_{\text{av}}A)}{dt} = -A\frac{dB_{\text{av}}}{dt}$. Ohm's law gives $\mathcal{E} = IR$, so the current is proportional to the rate at which the magnetic field is changing. That is, the current is proportional to the slope of the B-t graph.

EXECUTE: From the graph in part (b) of the figure shown with the introduction to the passage problems, we see that the magnetic field first increases rapidly as the graph has a positive slope. It then reaches a maximum value at around 0.15 ms, and then gradually decreases and the graph has a negative slope that approaches zero. Since the current is proportional to the slope of the B-t graph, the current is initially positive, then curves down to zero when the B-t graph is a maximum and becomes negative as the slope becomes negative, and it then gradually approaches zero as the slope approaches zero. Graph C most closely describes this behavior, so (c) it is the best choice.

EVALUATE: From Faraday's law, we see that the current depends on the rate at which B changes, not on the magnitude of B.

30

INDUCTANCE

VP30.4.1. **IDENTIFY:** This problem is about mutual inductance.

SET UP: $M = -\dfrac{N_2\Phi_2}{i_1}$, $\mathcal{E}_2 = -M\dfrac{di_1}{dt}$.

EXECUTE: **(a)** We want the mutual inductance. $\mathcal{E}_2 = -M\dfrac{di_1}{dt}$. Solve for M, giving $M = \dfrac{\mathcal{E}_2}{di_1/dt}$ = (0.130 mV)/(2.00 A/s) = 65.0 μH.

(b) We want the flux due to i_1. $M = -\dfrac{N_2\Phi_2}{i_1}$. Using the answer to (a) and the given quantities gives $\Phi_2 = 1.56\times10^{-3}$ Wb.

EVALUATE: Each coil induces an emf in the other one. That's why it's called *mutual* inductance.

VP30.4.2. **IDENTIFY:** This problem is about mutual inductance.

SET UP: $M = -\dfrac{N_2\Phi_2}{i_1}$, $\mathcal{E}_2 = -M\dfrac{di_1}{dt}$. We want the magnitude of $\mathcal{E}_2$.

EXECUTE: **(a)** $\mathcal{E}_2 = M\dfrac{di_1}{dt}$ = (48.0 μH)(7.00 A/s) = 0.336 mV.

(b) Since di/dt = 0, $\mathcal{E}_2$ = 0.

(c) $\mathcal{E}_2 = -M\dfrac{di_1}{dt}$ = (48.0 μH)(3.00 A/s) = 0.144 mV.

EVALUATE: The signs of $\mathcal{E}_2$ would be reversed in (a) and (c) because di/dt has opposite signs.

VP30.4.3. **IDENTIFY:** This problem involves the self-inductance of a toroidal solenoid.

SET UP: $L = N\dfrac{\Phi_B}{I}$, $\mathcal{E} = L\dfrac{di}{dt}$.

EXECUTE: **(a)** We want the flux when i = 12.0 A. Solve $L = N\dfrac{\Phi_B}{I}$ for Φ_B. This gives $\Phi_B = Li/N$ = (76.0 μH)(12.0 A)/465 = 1.96 μWb.

(b) We want the magnitude of the emf. $\mathcal{E} = L\dfrac{di}{dt}$ = (76.0 μH)(55.0 A/s) = 4.18 mV.

EVALUATE: It is not the amount of flux that causes an induced emf, but rather the *rate of change* of the flux.

VP30.4.4. **IDENTIFY:** This problem is about self-inductance.

SET UP: $\mathcal{E} = -L\dfrac{di}{dt}$.

EXECUTE: **(a)** We want L. $\mathcal{E} = L\frac{di}{dt}$. $L = \frac{\mathcal{E}}{di/dt} =$ (3.70 mV)/(145 A/s) = 25.5 μH.

(b) We want $\mathcal{E}$ at t = 2.00 s. i = (225 A/s^2)t^2, so di/dt = (450 A/s)t. Now evaluate $\mathcal{E} = -L\frac{di}{dt}$ at t = 2.00 s. $\mathcal{E} = -L\frac{di}{dt}$ = –(25.5 μH)[(450 A/s)(2.00 s)] = –23.0 mV. The minus sign means that its direction is opposite that of the current.

EVALUATE: The current is increasing, so the induced emf opposes this increase, which means that it opposes the current.

VP30.7.1. **IDENTIFY:** This is about an R-L circuit.

SET UP: $i = \frac{\mathcal{E}}{R}\left(1 - e^{-(R/L)t}\right)$.

EXECUTE: **(a)** Resistance is the target variable. When t = 80.0 μs, i = 0.750i_{max}. $i = \frac{\mathcal{E}}{R}\left(1 - e^{-(R/L)t}\right)$:

0.750i_{max} = $i_{max}\left(1 - e^{-(R/L)(80.0\ \mu s)}\right)$. Use logarithms to solve for R giving

$R = -\frac{L\ln(0.250)}{t} = -\frac{(4.90\text{ mH})\ln(0.250)}{80.0\mu\text{s}}$ = 84.9 Ω.

(b) We want the current 80.0 μs after closing the switch. At 80.0 μs the current is 75.0% of its maximum value, so $i = (0.750)\frac{\mathcal{E}}{R} = (0.750)\frac{24.0\text{ V}}{84.9\ \Omega} = 0.212$ A.

EVALUATE: As a check we can use the equation for the current. Putting all these values into $i = \frac{\mathcal{E}}{R}\left(1 - e^{-(R/L)t}\right)$, we get i = 0.212. which is in agreement with our result in (b).

VP30.7.2. **IDENTIFY:** This problem is about an R-L circuit.

SET UP: $i = \frac{\mathcal{E}}{R}\left(1 - e^{-(R/L)t}\right)$, $U_L = \frac{1}{2}Li^2$. We want the current, di/dt, and stored energy in the inductor at time t = 0.700 ms.

EXECUTE: **(a)** Current: Use $i = \frac{\mathcal{E}}{R}\left(1 - e^{-(R/L)t}\right)$ with the given quantities and t = 0.700 ms. The result is i = 0.190 A.

(b) di/dt: Take the derivative of $i = \frac{\mathcal{E}}{R}\left(1 - e^{-(R/L)t}\right)$. $di/dt = \frac{\mathcal{E}}{L}e^{-(R/L)t}$. Now evaluate it at t = 0.700 ms, giving di/dt = +229 A/s.

(c) Energy: Evaluate $U_L = \frac{1}{2}Li^2 = \frac{1}{2}$(37.5 μH)(0.190 A)^2 = 0.679 mJ.

EVALUATE: The energy does not remain in the inductor if the current decreases. Unlike a capacitor, an inductor cannot store energy if you remove it from a circuit.

VP30.7.3. **IDENTIFY:** This is an R-L circuit.

SET UP: $i = I_0 e^{-(R/L)t}$, $U_L = \frac{1}{2}Li^2$. We want the current, di/dt, and the energy in the inductor at t = 0.700 ms.

EXECUTE: **(a)** Current: Evaluate $i = I_0 e^{-(R/L)t}$ at t = 0.700 ms, giving i = 0.476 A.

(b) di/dt: Take the derivative of $i = I_0 e^{-(R/L)t}$ and evaluate it at t = 0.700 ms. This gives $di/dt = -\frac{\mathcal{E}}{L}e^{-(R/L)t}$ = –229 A/s.

(c) Energy: Evaluate $U_L = \frac{1}{2}Li^2 = \frac{1}{2}(37.5\ \mu\text{H})(0.476\ \text{A})^2 = 4.26\ \text{mJ}$.

EVALUATE: *di/dt* is negative because the current is decreasing with time. U_L decreases as the current decreases.

VP30.7.4. **IDENTIFY:** We have an *R-L* circuit.

SET UP: $i = \frac{\mathcal{E}}{R}\left(1 - e^{-(R/L)t}\right)$, $\mathcal{E} = -L\frac{di}{dt}$, $V_R = Ri$.

EXECUTE: **(a)** We want the time when $V_L = V_R$. $V_L = L\frac{di}{dt}$ and $V_R = Ri$. Equate these potentials and solve for *t*. Take *di/dt* to get V_L, giving $L\frac{di}{dt} = \mathcal{E}e^{-(R/L)t}$. Equating potentials gives $R\left(\frac{\mathcal{E}}{R}\right)\left(1 - e^{-(R/L)t}\right) = \mathcal{E}e^{-(R/L)t}$. Use logarithms to solve for *t*, giving $t = (L/R)\ln 2$.

(b) We want the current at the time in (a). $i = \frac{\mathcal{E}}{R}\left(1 - e^{-(R/L)t}\right)$. During the solution in (a), we found that $e^{-(R/L)t} = \frac{1}{2}$. Therefore $i = \frac{\mathcal{E}}{2R}$.

(c) We want *di/dt* at this time. When $V_{-L} = V_R$, each is $\mathcal{E}/2$, so $L\frac{di}{dt} = \frac{\mathcal{E}}{2}$. Thus $\frac{di}{dt} = \frac{\mathcal{E}}{2L}$.

EVALUATE: Check for (b): When $V_L = V_R$, $V_R = \mathcal{E}/2 = Ri$, so $i = \frac{\mathcal{E}}{2R}$ as we found.

VP30.10.1. **IDENTIFY:** This is an *L-C* circuit.

SET UP: $\omega = 1/\sqrt{LC}$, $U_L = \frac{1}{2}Li^2$, $U_C = \frac{Q^2}{2C}$.

EXECUTE: **(a)** We want *C*. $2\pi f = \omega = 1/\sqrt{LC}$. Solve for *C* and use the given values. $C = \frac{1}{L(2\pi f)^2}$ $= 5.12\ \text{mF}$.

(b) We want the maximum current. By energy conservation $U_{L,\max} = U_{C,\max}$. $\frac{1}{2}Li_{\max}^2 = \frac{Q_{\max}^2}{2C}$. Solve for $i_{\max}$ and use the given quantities. $i_{\max} = \frac{Q_{\max}}{\sqrt{LC}} = 14.0\ \text{A}$.

EVALUATE: The maximum charge occurs when there is no current in the circuit because there is no energy in the inductor at that instant.

VP30.10.2. **IDENTIFY:** This is an *L-C* circuit.

SET UP: $2\pi f = \omega = 1/\sqrt{LC}$, $T = 1/f$, $U_L = \frac{1}{2}Li^2$, $U_C = \frac{Q^2}{2C}$.

EXECUTE: **(a)** We want the time when the capacitor first discharges. This time is $\frac{1}{4}$ of a period. $T = 1/f = 2\pi/\omega$. Using $\omega = 1/\sqrt{LC}$, we get $t = \frac{1}{4}T = \frac{1}{4}\left(\frac{2\pi}{\omega}\right) = \frac{\pi}{2}\sqrt{LC}$. Using the values for *L* and *C* gives $t = 0.220\ \text{ms}$.

(b) We want the current when the capacitor is uncharged. By energy conservation $U_{L,\max} = U_{C,\max}$. $\frac{1}{2}Li_{\max}^2 = \frac{Q_{\max}^2}{2C}$. Solve for $i_{\max}$ and use the given quantities. $i_{\max} = \frac{Q_{\max}}{\sqrt{LC}} = 2.85\ \text{A}$.

EVALUATE: The current in (b) is the maximum current.

VP30.10.3. IDENTIFY: This is an L-C circuit.

SET UP: $U_L = \frac{1}{2}Li^2,\ U_C = \frac{Q^2}{2C},\ \omega = 1/\sqrt{LC}$. $U_L + U_C = 0.800$ J. When $U_L = U_C$, $Q = 5.30$ mC and $i = 8.00$ A.

EXECUTE: **(a)** We want C. Solve $U_C = \frac{Q^2}{2C}$ for C. $C = \frac{Q^2}{2U_C} = \frac{(5.30\text{ mC})^2}{2(0.400\text{ J})} = 35.1\,\mu\text{F}$.

(b) We want L. Solve $U_L = \frac{1}{2}Li^2$ for L. $L = \frac{2U_L}{i^2} = \frac{2(0.400\text{ mC})}{(8.00\text{ A})^2} = 12.5\text{ mH}$.

(c) We want ω. Use $\omega = 1/\sqrt{LC}$ = 1510 rad/s using the values of L and C from parts (a) and (b).

EVALUATE: If this circuit has absolutely no resistance, the sum $U_L + U_C$ will always be 0.800 J.

VP30.10.4. IDENTIFY: This is an L-R-C circuit, so we have damped oscillations.

SET UP: $\omega_0 = 1/\sqrt{LC},\ \omega' = \sqrt{\frac{1}{LC} - \frac{R^2}{4L^2}}$.

EXECUTE: **(a)** We want C. Use $\omega_0 = 1/\sqrt{LC}$ and solve for C, giving

$$C = \frac{1}{L\omega_0^2} = \frac{1}{(42.0\text{ mH})(624\text{ rad/s})^2} = 61.1\,\mu\text{F}.$$

(b) We want R. For damped oscillations, $\omega' = \sqrt{\frac{1}{LC} - \frac{R^2}{4L^2}} = \sqrt{\omega_0^2 - \frac{R^2}{4L^2}}$. Solve for R:

$R = 2L\sqrt{\omega_0^2 - \omega'^2}$. Using $\omega' = 208$ rad/s, $\omega_0 = 624$ rad/s, and $L = 42.0$ mH, we get $R = 49.4\ \Omega$.

EVALUATE: As we see, the resistance makes a very large difference in the angular frequency.

30.1. IDENTIFY and SET UP: Apply $|\mathcal{E}_2| = M\left|\frac{di_1}{dt}\right|$ and $|\mathcal{E}_1| = M\left|\frac{di_2}{dt}\right|$.

EXECUTE: **(a)** $|\mathcal{E}_2| = M\left|\frac{di_1}{dt}\right| = (3.25\times10^{-4}\text{ H})(830\text{ A/s}) = 0.270\text{ V}$; yes, it is constant.

(b) $|\mathcal{E}_1| = M\left|\frac{di_2}{dt}\right|$; M is a property of the pair of coils so is the same as in part (a). Thus $|\mathcal{E}_1| = 0.270$ V.

EVALUATE: The induced emf is the same in either case. A constant di/dt produces a constant emf.

30.2. IDENTIFY: $\mathcal{E}_1 = M\left|\frac{\Delta i_2}{\Delta t}\right|$ and $\mathcal{E}_2 = M\left|\frac{\Delta i_1}{\Delta t}\right|$. $M = \left|\frac{N_2\Phi_{B2}}{i_1}\right|$, where Φ_{B2} is the flux through one turn of the second coil.

SET UP: M is the same whether we consider an emf induced in coil 1 or in coil 2.

EXECUTE: **(a)** $M = \frac{\mathcal{E}_2}{|\Delta i_1/\Delta t|} = \frac{1.65\times10^{-3}\text{ V}}{0.242\text{ A/s}} = 6.82\times10^{-3}\text{ H} = 6.82\text{ mH}$.

(b) $\Phi_{B2} = \frac{Mi_1}{N_2} = \frac{(6.82\times10^{-3}\text{ H})(1.20\text{ A})}{25} = 3.27\times10^{-4}\text{ Wb}$.

(c) $\mathcal{E}_1 = M\left|\frac{\Delta i_2}{\Delta t}\right| = (6.82\times10^{-3}\text{ H})(0.360\text{ A/s}) = 2.46\times10^{-3}\text{ V} = 2.46\text{ mV}$.

EVALUATE: We can express M either in terms of the total flux through one coil produced by a current in the other coil, or in terms of the emf induced in one coil by a changing current in the other coil.

30.3. **IDENTIFY** and **SET UP:** Apply $M = \dfrac{N_2\Phi_{B2}}{i_1}$.

EXECUTE: **(a)** $M = \dfrac{N_2\Phi_{B2}}{i_1} = \dfrac{400(0.0320 \text{ Wb})}{6.52 \text{ A}} = 1.96 \text{ H}.$

(b) $M = \dfrac{N_1\Phi_{B1}}{i_2}$ so $\Phi_{B1} = \dfrac{Mi_2}{N_1} = \dfrac{(1.96 \text{ H})(2.54 \text{ A})}{700} = 7.11\times10^{-3} \text{ Wb}.$

EVALUATE: M relates the current in one coil to the flux through the other coil. Eq. (30.5) shows that M is the same for a pair of coils, no matter which one has the current and which one has the flux.

30.4. **IDENTIFY:** Changing flux from one object induces an emf in another object.

(a) SET UP: The magnetic field due to a solenoid is $B = \mu_0 nI$.

EXECUTE: The above formula gives

$$B_1 = \frac{(4\pi\times10^{-7} \text{ T}\cdot\text{m/A})(300)(0.120 \text{ A})}{0.250 \text{ m}} = 1.81\times10^{-4} \text{ T}.$$

The average flux through each turn of the inner solenoid is therefore

$$\Phi_B = B_1 A = (1.81\times10^{-4} \text{ T})\pi(0.0100 \text{ m})^2 = 5.68\times10^{-8} \text{ Wb}.$$

(b) SET UP: The flux is the same through each turn of both solenoids due to the geometry, so

$$M = \frac{N_2\Phi_{B,2}}{i_1} = \frac{N_2\Phi_{B,1}}{i_1}.$$

EXECUTE: $M = \dfrac{(25)(5.68\times10^{-8} \text{ Wb})}{0.120 \text{ A}} = 1.18\times10^{-5} \text{ H}.$

(c) SET UP: The induced emf is $\mathcal{E}_2 = -M\dfrac{di_1}{dt}$.

EXECUTE: $\mathcal{E}_2 = -(1.18\times10^{-5} \text{ H})(1750 \text{ A/s}) = -0.0207 \text{ V}.$

EVALUATE: A mutual inductance around 10^{-5} H is not unreasonable.

30.5. **IDENTIFY:** We can relate the known self-inductance of the toroidal solenoid to its geometry to calculate the number of coils it has. Knowing the induced emf, we can find the rate of change of the current.

SET UP: Example 30.3 shows that the self-inductance of a toroidal solenoid is $L = \dfrac{\mu_0 N^2 A}{2\pi r}$. The voltage across the coil is related to the rate at which the current in it is changing by $\mathcal{E} = L\left|\dfrac{di}{dt}\right|$.

EXECUTE: **(a)** Solving $L = \dfrac{\mu_0 N^2 A}{2\pi r}$ for N gives

$$N = \sqrt{\frac{2\pi rL}{\mu_0 A}} = \sqrt{\frac{2\pi(0.0600 \text{ m})(2.50\times10^{-3} \text{ H})}{(4\pi\times10^{-7} \text{ T}\cdot\text{m/A})(2.00\times10^{-4} \text{ m}^2)}} = 1940 \text{ turns}.$$

(b) $\left|\dfrac{di}{dt}\right| = \dfrac{\mathcal{E}}{L} = \dfrac{2.00 \text{ V}}{2.50\times10^{-3} \text{ H}} = 800 \text{ A/s}.$

EVALUATE: The inductance is determined solely by how the coil is constructed. The induced emf depends on the rate at which the current through the coil is changing.

30.6. **IDENTIFY:** A changing current in an inductor induces an emf in it.

(a) SET UP: The self-inductance of a toroidal solenoid is $L = \dfrac{\mu_0 N^2 A}{2\pi r}$.

EXECUTE: $L = \dfrac{(4\pi \times 10^{-7}\ \text{T} \cdot \text{m/A})(500)^2 (6.25 \times 10^{-4}\ \text{m}^2)}{2\pi (0.0400\ \text{m})} = 7.81 \times 10^{-4}\ \text{H}.$

(b) SET UP: The magnitude of the induced emf is $\mathcal{E} = L\left|\dfrac{di}{dt}\right|$.

EXECUTE: $\mathcal{E} = (7.81 \times 10^{-4}\ \text{H})\left(\dfrac{5.00\ \text{A} - 2.00\ \text{A}}{3.00 \times 10^{-3}\ \text{s}}\right) = 0.781\ \text{V}.$

(c) The current is decreasing, so the induced emf will be in the same direction as the current, which is from a to b, making b at a higher potential than a.

EVALUATE: This is a reasonable value for self-inductance, in the range of a mH.

30.7. **IDENTIFY:** $\mathcal{E} = L\left|\dfrac{\Delta i}{\Delta t}\right|$ and $L = \dfrac{N\Phi_B}{i}$.

SET UP: $\dfrac{\Delta i}{\Delta t} = 0.0640\ \text{A/s}.$

EXECUTE: **(a)** $L = \dfrac{\mathcal{E}}{|\Delta i/\Delta t|} = \dfrac{0.0160\ \text{V}}{0.0640\ \text{A/s}} = 0.250\ \text{H}.$

(b) The average flux through each turn is $\Phi_B = \dfrac{Li}{N} = \dfrac{(0.250\ \text{H})(0.720\ \text{A})}{400} = 4.50 \times 10^{-4}\ \text{Wb}.$

EVALUATE: The self-induced emf depends on the rate of change of flux and therefore on the rate of change of the current, not on the value of the current.

30.8. **IDENTIFY:** Combine the two expressions for L: $L = N\Phi_B/i$ and $L = \mathcal{E}/|di/dt|$.

SET UP: Φ_B is the average flux through one turn of the solenoid.

EXECUTE: Solving for N we have $N = \mathcal{E}i/\Phi_B|di/dt| = \dfrac{(12.6 \times 10^{-3}\ \text{V})(1.40\ \text{A})}{(0.00285\ \text{Wb})(0.0260\ \text{A/s})} = 238$ turns.

EVALUATE: The induced emf depends on the time rate of change of the total flux through the solenoid.

30.9. **IDENTIFY** and **SET UP:** Apply $|\mathcal{E}| = L|di/dt|$. Apply Lenz's law to determine the direction of the induced emf in the coil.

EXECUTE: **(a)** $|\mathcal{E}| = L|di/dt| = (0.260\ \text{H})(0.0180\ \text{A/s}) = 4.68 \times 10^{-3}\ \text{V}.$

(b) Terminal a is at a higher potential since the coil pushes current through from b to a and if replaced by a battery it would have the $+$ terminal at a.

EVALUATE: The induced emf is directed so as to oppose the decrease in the current.

30.10. **IDENTIFY:** Apply $\mathcal{E} = -L\dfrac{di}{dt}$.

SET UP: The induced emf points from low potential to high potential across the inductor.

EXECUTE: **(a)** The induced emf points from b to a, in the direction of the current. Therefore, the current is decreasing and the induced emf is directed to oppose this decrease.

(b) $|\mathcal{E}| = L|di/dt|$, so $|di/dt| = V_{ab}/L = (1.04\ \text{V})/(0.260\ \text{H}) = 4.00\ \text{A/s}.$ In 2.00 s the decrease in i is 8.00 A and the current at 2.00 s is 12.0 A − 8.0 A = 4.0 A.

EVALUATE: When the current is decreasing the end of the inductor where the current enters is at the lower potential. This agrees with our result and with Figure 30.6d in the textbook.

30.11. IDENTIFY: Use the definition of inductance and the geometry of a solenoid to derive its self-inductance.

SET UP: The magnetic field inside a solenoid is $B = \mu_0 \frac{N}{l} i$, and the definition of self-inductance is

$L = \frac{N\Phi_B}{i}$.

EXECUTE: **(a)** $B = \mu_0 \frac{N}{l} i$, $L = \frac{N\Phi_B}{i}$, and $\Phi_B = \frac{\mu_0 NAi}{l}$. Combining these expressions gives

$L = \frac{N\Phi_B}{i} = \frac{\mu_0 N^2 A}{l}$.

(b) $L = \frac{\mu_0 N^2 A}{l}$. $A = \pi r^2 = \pi(0.0750\times10^{-2}\text{ m})^2 = 1.767\times10^{-6}\text{ m}^2$.

$$L = \frac{(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})(50)^2(1.767\times10^{-6}\text{ m}^2)}{5.00\times10^{-2}\text{ m}} = 1.11\times10^{-7}\text{ H} = 0.111\ \mu\text{H}.$$

EVALUATE: This is a physically reasonable value for self-inductance.

30.12. IDENTIFY: The changing current induces an emf in the solenoid.

SET UP: By definition of self-inductance, $L = \frac{N\Phi_B}{i}$. The magnitude of the induced emf is $|\mathcal{E}| = L\left|\frac{di}{dt}\right|$.

EXECUTE: $L = \frac{N\Phi_B}{i} = \frac{(800)(3.25\times10^{-3}\text{ Wb})}{2.90\text{ A}} = 0.8966\text{ H}.$

$$\left|\frac{di}{dt}\right| = \frac{|\mathcal{E}|}{L} = \frac{6.20\times10^{-3}\text{ V}}{0.8966\text{ H}} = 6.92\times10^{-3}\text{ A/s} = 6.92\text{ mA/s}.$$

EVALUATE: An inductance of nearly a henry is rather large. For ordinary laboratory inductors, which are around a few millihenries, the current would have to be changing much faster to induce 6.2 mV.

30.13. IDENTIFY: This problem deals with a solenoid and Faraday's law.

SET UP: $B = \mu_0 nI$, $L = \mu_0 AN^2/l$, $\mathcal{E} = -L\frac{di}{dt}$. We want B. Use the given information to find n, and then use that result to find B. We only need to deal with magnitudes.

EXECUTE: $\mathcal{E}_L = L\frac{di}{dt} = \left(\mu_0 AN^2/l\right)\frac{di}{dt} = \left(\mu_0 ANn\right)\frac{di}{dt}$. Using the given numbers for $\mathcal{E}$, A, N, and di/dt gives $n = 0.0100/\mu_0$ turns/m. $B = \mu_0 nI = \mu_0\left(\frac{0.0100\text{ turns/m}}{\mu_0}\right)(3.00\text{ A}) = 0.0300\text{ T}$.

EVALUATE: By planning a solution, one can sometimes avoid unnecessary arithmetic. In this case, we did not need to calculate with μ_0 because it cancels in the final step.

30.14. IDENTIFY and SET UP: The stored energy is $U = \frac{1}{2}LI^2$. The rate at which thermal energy is developed is $P = I^2 R$.

EXECUTE: **(a)** $U = \frac{1}{2}LI^2 = \frac{1}{2}(12.0\text{ H})(0.500\text{ A})^2 = 1.50\text{ J}$.

(b) $P = I^2 R = (0.500\text{ A})^2(180\ \Omega) = 45.0\text{ W} = 45.0\text{ J/s}$.

EVALUATE: **(c)** No. If I is constant then the stored energy U is constant. The energy being consumed by the resistance of the inductor comes from the emf source that maintains the current; it does not come from the energy stored in the inductor.

30.15. IDENTIFY and SET UP: Use $U_L = \frac{1}{2}LI^2$ to relate the energy stored to the inductance. Example 30.3 gives the inductance of a toroidal solenoid to be $L = \dfrac{\mu_0 N^2 A}{2\pi r}$, so once we know L we can solve for N.

EXECUTE: $U = \frac{1}{2}LI^2$ so $L = \dfrac{2U}{I^2} = \dfrac{2(0.390\text{ J})}{(12.0\text{ A})^2} = 5.417\times 10^{-3}\text{ H}.$

$$N = \sqrt{\frac{2\pi r L}{\mu_0 A}} = \sqrt{\frac{2\pi(0.150\text{ m})(5.417\times 10^{-3}\text{ H})}{(4\pi\times 10^{-7}\text{ T}\cdot\text{m/A})(5.00\times 10^{-4}\text{ m}^2)}} = 2850.$$

EVALUATE: L and hence U increase according to the square of N.

30.16. IDENTIFY: A current-carrying inductor has a magnetic field inside of itself and hence stores magnetic energy.

(a) SET UP: The magnetic field inside a toroidal solenoid is $B = \dfrac{\mu_0 NI}{2\pi r}$.

EXECUTE: $B = \dfrac{\mu_0(300)(5.00\text{ A})}{2\pi(0.120\text{ m})} = 2.50\times 10^{-3}\text{ T} = 2.50\text{ mT}.$

(b) SET UP: The self-inductance of a toroidal solenoid is $L = \dfrac{\mu_0 N^2 A}{2\pi r}$.

EXECUTE: $L = \dfrac{(4\pi\times 10^{-7}\text{ T}\cdot\text{m/A})(300)^2(4.00\times 10^{-4}\text{ m}^2)}{2\pi(0.120\text{ m})} = 6.00\times 10^{-5}\text{ H}.$

(c) SET UP: The energy stored in an inductor is $U_L = \frac{1}{2}LI^2$.

EXECUTE: $U_L = \frac{1}{2}(6.00\times 10^{-5}\text{ H})(5.00\text{ A})^2 = 7.50\times 10^{-4}\text{ J}.$

(d) SET UP: The energy density in a magnetic field is $u = \dfrac{B^2}{2\mu_0}$.

EXECUTE: $u = \dfrac{(2.50\times 10^{-3}\text{ T})^2}{2(4\pi\times 10^{-7}\text{ T}\cdot\text{m/A})} = 2.49\text{ J/m}^3.$

EVALUATE: **(e)** $u = \dfrac{\text{energy}}{\text{volume}} = \dfrac{\text{energy}}{2\pi r A} = \dfrac{7.50\times 10^{-4}\text{ J}}{2\pi(0.120\text{ m})(4.00\times 10^{-4}\text{ m}^2)} = 2.49\text{ J/m}^3.$

An inductor stores its energy in the magnetic field inside of it.

30.17. IDENTIFY: A current-carrying inductor has a magnetic field inside of itself and hence stores magnetic energy.

(a) SET UP: The magnetic field inside a solenoid is $B = \mu_0 nI$.

EXECUTE: $B = \dfrac{(4\pi\times 10^{-7}\text{ T}\cdot\text{m/A})(400)(80.0\text{ A})}{0.250\text{ m}} = 0.161\text{ T}.$

(b) SET UP: The energy density in a magnetic field is $u = \dfrac{B^2}{2\mu_0}$.

EXECUTE: $u = \dfrac{(0.161\text{ T})^2}{2(4\pi\times 10^{-7}\text{ T}\cdot\text{m/A})} = 1.03\times 10^4\text{ J/m}^3.$

(c) SET UP: The total stored energy is $U = uV$.

EXECUTE: $U = uV = u(lA) = (1.03\times 10^4\text{ J/m}^3)(0.250\text{ m})(0.500\times 10^{-4}\text{ m}^2) = 0.129\text{ J}.$

(d) SET UP: The energy stored in an inductor is $U = \frac{1}{2}LI^2$.

EXECUTE: Solving for L and putting in the numbers gives

$$L = \frac{2U}{I^2} = \frac{2(0.129\ \text{J})}{(80.0\ \text{A})^2} = 4.02\times10^{-5}\ \text{H}.$$

EVALUATE: An inductor stores its energy in the magnetic field inside of it.

30.18. **IDENTIFY:** Energy $= Pt$. $U = \frac{1}{2}LI^2$.

SET UP: $P = 150\ \text{W} = 150\ \text{J/s}$.

EXECUTE: **(a)** Energy $= (150\ \text{W})(24\ \text{h})(3600\ \text{s/h}) = 1.296\times10^7\ \text{J}$, which rounds to $1.30\times10^7\ \text{J} = 13.0\ \text{MJ}$.

(b) $L = \dfrac{2U}{I^2} = \dfrac{2(1.296\times10^7\ \text{J})}{(80.0\ \text{A})^2} = 4.05\times10^3\ \text{H} = 4.05\ \text{kH}$.

EVALUATE: A large value of L and a large current would be required, just for one light bulb. Also, the resistance of the inductor would have to be very small, to avoid a large $P = I^2R$ rate of electrical energy loss.

30.19. **IDENTIFY:** The energy density depends on the strength of the magnetic field, and the energy depends on the volume in which the magnetic field exists.

SET UP: The energy density is $u = \dfrac{B^2}{2\mu_0}$.

EXECUTE: First find the energy density: $u = \dfrac{B^2}{2\mu_0} = \dfrac{(4.80\ \text{T})^2}{2(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})} = 9.167\times10^6\ \text{J/m}^3$. The energy U in a volume V is $U = uV = (9.167\times10^6\ \text{J/m}^3)(10.0\times10^{-6}\ \text{m}^3) = 91.7\ \text{J}$.

EVALUATE: A field of 4.8 T is very strong, so this is a high energy density for a magnetic field.

30.20. **IDENTIFY:** This problem is about the energy density in electric and magnetic fields.

SET UP: $u_E = \dfrac{\epsilon_0 E^2}{2}$, $u_B = \dfrac{B^2}{2\mu_0}$.

EXECUTE: **(a)** We want E/B when $u_E = u_B$. Equate the energy densities. $\dfrac{\epsilon_0 E^2}{2} = \dfrac{B^2}{2\mu_0}$.

$$\frac{E}{B} = \frac{1}{\sqrt{\mu_0 \epsilon_0}} = 3.00\times10^8\ \text{V/m}\cdot\text{T}.$$

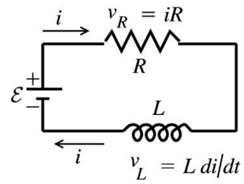
(b) We want B. Use the result from (a) giving $B = 1.67\ \mu\text{T}$.

EVALUATE: Note the units of E/B: $\dfrac{\text{V}}{\text{m}\cdot\text{T}} = \dfrac{\text{J/C}}{\text{m}\left(\dfrac{\text{N}}{\text{C}\cdot\text{m/s}}\right)} =$ m/s. Therefore,

$$\frac{E}{B} = \frac{1}{\sqrt{\mu_0 \epsilon_0}} = 3.00\times10^8\ \text{V/m}\cdot\text{T} = 3.00\times10^8\ \text{m/s},$$ which is the speed of light in vacuum.

30.21. **IDENTIFY:** Apply Kirchhoff's loop rule to the circuit. $i(t)$ is given by $i = \dfrac{\mathcal{E}}{R}(1 - e^{-(R/L)t})$.

SET UP: The circuit is sketched in Figure 30.21.



$\frac{di}{dt}$ is positive as the current increases from its initial value of zero.

Figure 30.21

EXECUTE: $\mathcal{E} - v_R - v_L = 0.$

$\mathcal{E} - iR - L\frac{di}{dt} = 0$ so $i = \frac{\mathcal{E}}{R}(1 - e^{-(R/L)t}).$

(a) Initially $(t = 0)$, $i = 0$ so $\mathcal{E} - L\frac{di}{dt} = 0.$

$$\frac{di}{dt} = \frac{\mathcal{E}}{L} = \frac{6.00\text{ V}}{2.50\text{ H}} = 2.40\text{ A/s}.$$

(b) $\mathcal{E} - iR - L\frac{di}{dt} = 0.$ (Use this equation rather than $\frac{di}{dt} = \frac{\mathcal{E}}{L}e^{-(R/L)t}$ since i rather than t is given.)

Thus $\frac{di}{dt} = \frac{\mathcal{E} - iR}{L} = \frac{6.00\text{ V} - (0.500\text{ A})(8.00\ \Omega)}{2.50\text{ H}} = 0.800\text{ A/s}.$

(c) $i = \frac{\mathcal{E}}{R}(1 - e^{-(R/L)t}) = \left(\frac{6.00\text{ V}}{8.00\ \Omega}\right)(1 - e^{-(8.00\ \Omega/2.50\text{ H})(0.250\text{ s})}) = 0.750\text{ A}(1 - e^{-0.800}) = 0.413\text{ A}.$

(d) Final steady state means $t \to \infty$ and $\frac{di}{dt} \to 0$, so $\mathcal{E} - iR = 0.$

$$i = \frac{\mathcal{E}}{R} = \frac{6.00\text{ V}}{8.00\ \Omega} = 0.750\text{ A}.$$

EVALUATE: Our results agree with Figure 30.12 in the textbook. The current is initially zero and increases to its final value of $\mathcal{E}/R$. The slope of the current in the figure, which is *di/dt*, decreases with *t*.

30.22. IDENTIFY: With S_1 closed and S_2 open, the current builds up to a steady value. Then with S_1 open and S_2 closed, the current decreases exponentially.

SET UP: The decreasing current is $i = I_0 e^{-(R/L)t}$.

EXECUTE: **(a)** $i = I_0 e^{-(R/L)t} = \frac{\mathcal{E}}{R}e^{-(R/L)t}$. $e^{-(R/L)t} = \frac{iR}{\mathcal{E}} = \frac{(0.280\text{ A})(15.0\ \Omega)}{6.30\text{ V}} = 0.6667.$

$$\frac{Rt}{L} = -\ln(0.6667).\quad L = -\frac{Rt}{\ln(0.6667)} = -\frac{(15.0\ \Omega)(2.00\times10^{-3}\text{ s})}{\ln(0.6667)} = 0.0740\text{ H} = 74.0\text{ mH}.$$

(b) $\frac{i}{I_0} = e^{-(R/L)t}$. $e^{-(R/L)t} = 0.0100.$ $\frac{Rt}{L} = -\ln(0.0100).$

$$t = -\frac{\ln(0.0100)L}{R} = -\frac{\ln(0.0100)(0.0740\text{ H})}{15.0\ \Omega} = 0.0227\text{ s} = 22.7\text{ ms}.$$

EVALUATE: Typical *LR* circuits change rapidly compared to human time scales, so 22.7 ms is not unusual.

30.23. IDENTIFY: $i = \mathcal{E}/R(1 - e^{-t/\tau})$, with $\tau = L/R$. The energy stored in the inductor is $U = \frac{1}{2}Li^2$.

SET UP: The maximum current occurs after a long time and is equal to $\mathcal{E}/R$.

EXECUTE: **(a)** $i_{max} = \mathcal{E}/R$ so $i = i_{max}/2$ when $(1 - e^{-t/\tau}) = \frac{1}{2}$ and $e^{-t/\tau} = \frac{1}{2}$. $-t/\tau = \ln(\frac{1}{2})$.

$$t = \frac{L\ln 2}{R} = \frac{(\ln 2)(1.25\times10^{-3}\text{ H})}{50.0\ \Omega} = 17.3\ \mu\text{s}.$$

(b) $U = \frac{1}{2}U_{\max}$ when $i = i_{\max}/\sqrt{2}$. $1 - e^{-t/\tau} = 1/\sqrt{2}$, so $e^{-t/\tau} = 1 - 1/\sqrt{2} = 0.2929$.
$t = -L\ln(0.2929)/R = 30.7\ \mu\text{s}$.

EVALUATE: $\tau = L/R = 2.50 \times 10^{-5}\ \text{s} = 25.0\ \mu s$. The time in part (a) is 0.692τ and the time in part (b) is 1.23τ.

30.24. **IDENTIFY:** We have an *R*-*L* circuit.

SET UP: $\mathcal{E}_L = -L\dfrac{di}{dt}$, $i = I_{\max}\left(1 - e^{-(R/L)t}\right)$. We want the time *T* when *i* = 5.00 A. First find *R* and *L*.

EXECUTE: After a long time, $i = I_{\max}$ = 15.0 A, so $R = \mathcal{E}/I_{\max}$ = (240 V)/(15.0 A) = 16.0 Ω. At time *T*, $V_R = Ri$ = (16.0 Ω)(5.00 A) = 80.0 V, so $\mathcal{E}_L$ = 240 V – 80.0 V = 160 V, so $L\dfrac{di}{dt}$ = 160 V. This gives *L*(20.0 A/s) = 160 V, so *L* = 8.00 H. Now find the current. Use $i = I_{\max}\left(1 - e^{-(R/L)t}\right)$, and solve for *T* using the known quantities. Using logarithms gives *T* = –(*L/R*) ln(2/3) = 0.203 s.

EVALUATE: $\tau = L/R$ = (8.00 H)/(16.0 Ω) = 0.500 s, so *T* is *not* the time constant for this circuit.

30.25. **IDENTIFY:** We have an *R*-*L* circuit.

SET UP: $U_L = \dfrac{1}{2}Li^2$. We want the voltage across the inductor when it contains 0.400 J of energy.

EXECUTE: Solve $U_L = \dfrac{1}{2}Li^2$ for *i*, giving $i = \sqrt{2U_L/L}$. $V_L = \mathcal{E} - V_R = \mathcal{E} - RI = \mathcal{E} - R\sqrt{2U_L/L}$. Using the given quantities gives V_L = 15.4 V.

EVALUATE: As time increases, *i* increases so U_L increases to a maximum value when $i = \mathcal{E}/R$ = 1.67 A.

30.26. **IDENTIFY:** This is an *R*-*L* circuit.

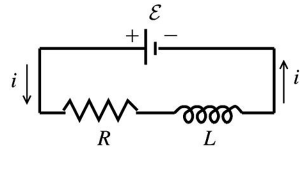
SET UP: We want the time *T* for the current to decrease from 12.0 A to 6.00 A. $i = I_0 e^{-(R/L)t}$, $\mathcal{E}_L = -L\dfrac{di}{dt}$.

EXECUTE: After we close S_2 the current is $i = I_0 e^{-(R/L)t}$. At time *T* the current is half its initial value, so $\dfrac{1}{2}I_0 = I_0 e^{-(R/L)T}$. Use logarithms to solve for *T*, giving *T* = (*L/R*) ln 2. We see that we need to find *L/R*. At *t* = 0, $V_L = V_R$, so $-L\dfrac{di}{dt} = -Ri_0$. $L/R = i_0/(di/dt)$ = (12.0 A)/(36.0 A/s) = 0.333 s. Therefore *T* = (0.333 s) ln 2 = 0.231 s.

EVALUATE: The time constant *L/R* is the same with S_1 closed and S_2 open as it is with S_1 open and S_2 closed. But in the first case, the current increases with time but in the second case it decreases with time.

30.27. **IDENTIFY:** Apply the concepts of current decay in an *R*-*L* circuit. Apply the loop rule to the circuit. $i(t)$ is given by $i = I_0 e^{-(R/L)t}$. The voltage across the resistor depends on *i* and the voltage across the inductor depends on di/dt.

SET UP: The circuit with S_1 closed and S_2 open is sketched in Figure 30.27a.



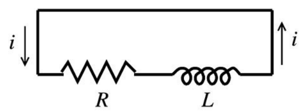
$$\mathcal{E} - iR - L\frac{di}{dt} = 0.$$

Figure 30.27a

Constant current established means $\frac{di}{dt} = 0.$

$$i = \frac{\mathcal{E}}{R} = \frac{60.0\ \text{V}}{240\ \Omega} = 0.250\ \text{A}.$$

EXECUTE: **(a)** The circuit with S_2 closed and S_1 open is shown in Figure 30.27b.



$i = I_0 e^{-(R/L)t}$.

At $t = 0, i = I_0 = 0.250$ A.

Figure 30.27b

The inductor prevents an instantaneous change in the current; the current in the inductor just after S_2 is closed and S_1 is opened equals the current in the inductor just before this is done.

(b) $i = I_0 e^{-(R/L)t} = (0.250\ \text{A})e^{-(240\,\Omega/0.160\,\text{H})(4.00\times10^{-4}\,\text{s})} = (0.250\ \text{A})e^{-0.600} = 0.137\ \text{A}.$

(c) See Figure 30.27c.

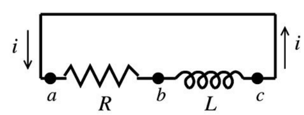


Figure 30.27c

If we trace around the loop in the direction of the current the potential falls as we travel through the resistor so it must rise as we pass through the inductor: $v_{ab} > 0$ and $v_{bc} < 0$. So point *c* is at a higher potential than point *b*.

$v_{ab} + v_{bc} = 0$ and $v_{bc} = -v_{ab}$.

Or, $v_{cb} = v_{ab} = iR = (0.137\ \text{A})(240\ \Omega) = 32.9\ \text{V}.$

(d) $i = I_0 e^{-(R/L)t}$.

$i = \frac{1}{2}I_0$ says $\frac{1}{2}I_0 = I_0 e^{-(R/L)t}$ and $\frac{1}{2} = e^{-(R/L)t}$.

Taking natural logs of both sides of this equation gives $\ln(\frac{1}{2}) = -Rt/L$.

$$t = \left(\frac{0.160\ \text{H}}{240\ \Omega}\right)\ln 2 = 4.62\times10^{-4}\ \text{s}.$$

EVALUATE: The current decays, as shown in Figure 30.13 in the textbook. The time constant is $\tau = L/R = 6.67\times10^{-4}$ s. The values of *t* in the problem are less than one time constant. At any instant the potential drop across the resistor (in the direction of the current) equals the potential rise across the inductor.

30.28. **IDENTIFY:** Apply $i = \frac{\mathcal{E}}{R}(1 - e^{-(R/L)t})$.

SET UP: $v_{ab} = iR$. $v_{bc} = L\frac{di}{dt}$. The current is increasing, so di/dt is positive.

EXECUTE: **(a)** At $t = 0$, $i = 0$. $v_{ab} = 0$ and $v_{bc} = 60$ V.

(b) As $t \to \infty$, $i \to \mathcal{E}/R$ and $di/dt \to 0$. $v_{ab} \to 60$ V and $v_{bc} \to 0$.

(c) When $i = 0.150$ A, $v_{ab} = iR = 36.0$ V and $v_{bc} = 60.0\ \text{V} - 36.0\ \text{V} = 24.0$ V.

EVALUATE: At all times, $\mathcal{E} = v_{ab} + v_{bc}$, as required by the loop rule.

30.29. **IDENTIFY:** With S_1 closed and S_2 open, the current builds up to a steady value.

SET UP: Applying Kirchhoff's loop rule gives $\mathcal{E} - iR - L\dfrac{di}{dt} = 0.$

EXECUTE: $v_R = \mathcal{E} - L\dfrac{di}{dt} = 18.0\text{ V} - (0.380\text{ H})(7.20\text{ A/s}) = 15.3\text{ V}.$

EVALUATE: The rest of the 18.0 V of the emf is across the inductor.

30.30. **IDENTIFY and SET UP:** The inductor opposes changes in current through it. $P = iV$, $P_R = i^2R$, $V = Ri$, $U_L = \frac{1}{2}Li^2$.

EXECUTE: **(a)** The inductor prevents an instantaneous build up of current, so the initial current is zero. The power supplied by the battery is $P = i\mathcal{E} = 0$ since $i_0 = 0$.

(b) The energy stored in the inductor is $U_L = \frac{1}{2}Li^2$ and $i = \mathcal{E}/R$, so

$U_L = (1/2)(2.50\text{ H})[(6.00\text{ V})/(8.00\ \Omega)]^2 = 0.703\text{ J}.$
$P_R = i^2R = [(6.00\text{ V})/(8.00\ \Omega)]^2(8.00\ \Omega) = 4.50\text{ W}.$
The power supplied by the battery is
$P_{\mathcal{E}} = i\mathcal{E} = (\mathcal{E}/R)\mathcal{E} = (6.00\text{ V})^2/(8.00\ \Omega) = 4.50\text{ W}.$

EVALUATE: At steady-state the current is not changing so the potential difference across the inductor is zero. Therefore the power supplied by the battery is all consumed in the resistor, as we found.

30.31. **IDENTIFY:** This is an *R-L* circuit.
SET UP: $P = iV$. We want the power in the inductor.
EXECUTE: **(a)** At $t = 0$: $P_L = iV_L = 0$ because $i = 0$.
(b) As $t \to \infty$: The current is not changing, so $V_L = 0$. Therefore $P_L = iV_L = 0$.
(c) When $i = \mathcal{E}/2R$: $V_R = Ri = R\left(\dfrac{\mathcal{E}}{2R}\right) = \dfrac{\mathcal{E}}{2}$, so $V_L = \dfrac{\mathcal{E}}{2}$. $P_L = iV_L = \left(\dfrac{\mathcal{E}}{2R}\right)\left(\dfrac{\mathcal{E}}{2}\right) = \dfrac{\mathcal{E}^2}{4R}.$

EVALUATE: As $t \to \infty$, P_L becomes a maximum but its rate of change approaches zero.

30.32. **IDENTIFY:** An L-C circuit oscillates, with the energy going back and forth between the inductor and capacitor.

(a) SET UP: The frequency is $f = \dfrac{\omega}{2\pi}$ and $\omega = \dfrac{1}{\sqrt{LC}}$, giving $f = \dfrac{1}{2\pi\sqrt{LC}}$.

EXECUTE: $f = \dfrac{1}{2\pi\sqrt{(0.280\times10^{-3}\text{ H})(15.0\times10^{-6}\text{ F})}} = 2.456\times10^3\text{ Hz},$ which rounds to 2.46 kHz.

(b) SET UP: The energy stored in a capacitor is $U = \frac{1}{2}CV^2$.

EXECUTE: $U = \frac{1}{2}(15.0\times10^{-6}\text{ F})(150.0\text{ V})^2 = 0.169\text{ J}.$

(c) SET UP: The current in the circuit is $i = -\omega Q\sin\omega t$, and the energy stored in the inductor is $U = \frac{1}{2}Li^2$.

EXECUTE: First find ω and Q. $\omega = 2\pi f = 2\pi(2456\text{ Hz}) = 1.543\times10^4\text{ rad/s}.$

$Q = CV = (15.0\times10^{-6}\text{ F})(150.0\text{ V}) = 2.25\times10^{-3}\text{ C}.$ Now calculate the current:

$i = -(1.543\times10^4\text{ rad/s})(2.25\times10^{-3}\text{ C})\sin[(1.543\times10^4\text{ rad/s})(1.30\times10^{-3}\text{ s})].$ Notice that the argument of the sine is in *radians*, so convert it to degrees if necessary. The result is $i = -32.48$ A.
Now find the energy in the inductor: $U = \frac{1}{2}Li^2 = \frac{1}{2}(0.280\times10^{-3}\text{ H})(-32.48\text{ A})^2 = 0.148\text{ J}.$

EVALUATE: At the end of 1.30 ms, more of the energy is now in the inductor than in the capacitor.

30.33. **IDENTIFY:** Apply $\frac{1}{2}Li^2 + \frac{q^2}{2C} = \frac{Q^2}{2C}$.

SET UP: $q = Q$ when $i = 0$. $i = i_{\text{max}}$ when $q = 0$. $1/\sqrt{LC} = 1917\ \text{s}^{-1}$.

EXECUTE: **(a)** $\frac{1}{2}Li_{\text{max}}^2 = \frac{Q^2}{2C}$.

$Q = i_{\text{max}}\sqrt{LC} = (0.850\times10^{-3}\ \text{A})\sqrt{(0.0850\ \text{H})(3.20\times10^{-6}\ \text{F})} = 4.43\times10^{-7}\ \text{C}$.

(b) $q = \sqrt{Q^2 - LCi^2} = \sqrt{(4.43\times10^{-7}\ \text{C})^2 - \left(\frac{5.00\times10^{-4}\,\text{A}}{1917\ \text{s}^{-1}}\right)^2} = 3.58\times10^{-7}\ \text{C}$.

EVALUATE: The value of q calculated in part (b) is less than the maximum value Q calculated in part (a).

30.34. **IDENTIFY:** The energy moves back and forth between the inductor and capacitor.

(a) SET UP: The period is $T = \frac{1}{f} = \frac{1}{\omega/2\pi} = \frac{2\pi}{\omega} = 2\pi\sqrt{LC}$.

EXECUTE: Solving for L gives

$$L = \frac{T^2}{4\pi^2 C} = \frac{(8.60\times10^{-5}\ \text{s})^2}{4\pi^2(7.50\times10^{-9}\ \text{F})} = 2.50\times10^{-2}\ \text{H} = 25.0\ \text{mH}.$$

(b) SET UP: The charge on a capacitor is $Q = CV$.

EXECUTE: $Q = CV = (7.50\times10^{-9}\ \text{F})(12.0\ \text{V}) = 9.00\times10^{-8}\ \text{C}$.

(c) SET UP: The stored energy is $U = Q^2/2C$.

EXECUTE: $U = \frac{(9.00\times10^{-8}\ \text{C})^2}{2(7.50\times10^{-9}\ \text{F})} = 5.40\times10^{-7}\ \text{J}$.

(d) SET UP: The maximum current occurs when the capacitor is discharged, so the inductor has all the initial energy. $U_L + U_C = U_{\text{Total}}$. $\frac{1}{2}LI^2 + 0 = U_{\text{Total}}$.

EXECUTE: Solve for the current:

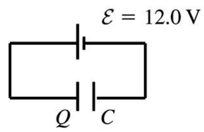
$$I = \sqrt{\frac{2U_{\text{Total}}}{L}} = \sqrt{\frac{2(5.40\times10^{-7}\ \text{J})}{2.50\times10^{-2}\ \text{H}}} = 6.58\times10^{-3}\ \text{A} = 6.58\ \text{mA}.$$

EVALUATE: The energy oscillates back and forth forever. However, if there is any resistance in the circuit, no matter how small, all this energy will eventually be dissipated as thermal energy in the resistor.

30.35. **IDENTIFY and SET UP:** The angular frequency is given by $\omega = \frac{1}{\sqrt{LC}}$. $q(t)$ and $i(t)$ are given by $q = Q\cos(\omega t + \phi)$ and $i = -\omega Q\sin(\omega t + \phi)$. The energy stored in the capacitor is $U_C = \frac{1}{2}CV^2 = q^2/2C$. The energy stored in the inductor is $U_L = \frac{1}{2}Li^2$.

EXECUTE: **(a)** $\omega = \frac{1}{\sqrt{LC}} = \frac{1}{\sqrt{(1.50\ \text{H})(6.00\times10^{-5}\ \text{F})}} = 105.4\ \text{rad/s}$, which rounds to $105\ \text{rad/s}$. The period is given by $T = \frac{2\pi}{\omega} = \frac{2\pi}{105.4\ \text{rad/s}} = 0.0596\ \text{s}$.

(b) The circuit containing the battery and capacitor is sketched in Figure 30.35.



$\mathcal{E} - \dfrac{Q}{C} = 0.$

$Q = \mathcal{E}C = (12.0\text{ V})(6.00\times10^{-5}\text{ F}) = 7.20\times10^{-4}\text{ C}.$

Figure 30.35

(c) $U = \tfrac{1}{2}CV^2 = \tfrac{1}{2}(6.00\times10^{-5}\text{ F})(12.0\text{ V})^2 = 4.32\times10^{-3}\text{ J}.$

(d) $q = Q\cos(\omega t + \phi)$ (Eq. 30.21).

$q = Q$ at $t = 0$ so $\phi = 0$.

$q = Q\cos\omega t = (7.20\times10^{-4}\text{ C})\cos([105.4\text{ rad/s}][0.0230\text{ s}]) = -5.42\times10^{-4}\text{ C}.$

The minus sign means that the capacitor has discharged fully and then partially charged again by the current maintained by the inductor; the plate that initially had positive charge now has negative charge and the plate that initially had negative charge now has positive charge.

(e) The current is $i = -\omega Q\sin(\omega t + \phi)$.

$i = -(105\text{ rad/s})(7.20\times10^{-4}\text{ C})\sin[(105.4\text{ rad/s})(0.0230\text{ s})] = -0.050\text{ A}.$

The negative sign means the current is counterclockwise in Figure 30.15 in the textbook.

or

$\tfrac{1}{2}Li^2 + \dfrac{q^2}{2C} = \dfrac{Q^2}{2C}$ gives $i = \pm\sqrt{\dfrac{1}{LC}}\sqrt{Q^2 - q^2}$ (Eq. 30.26).

$i = \pm(105\text{ rad/s})\sqrt{(7.20\times10^{-4}\text{ C})^2 - (-5.42\times10^{-4}\text{ C})^2} = \pm0.050\text{ A},$ which checks.

(f) $U_C = \dfrac{q^2}{2C} = \dfrac{(-5.42\times10^{-4}\text{ C})^2}{2(6.00\times10^{-5}\text{ F})} = 2.45\times10^{-3}\text{ J}.$

$U_L = \tfrac{1}{2}Li^2 = \tfrac{1}{2}(1.50\text{ H})(0.050\text{ A})^2 = 1.87\times10^{-3}\text{ J}.$

Evaluate: Note that $U_C + U_L = 2.45\times10^{-3}\text{ J} + 1.87\times10^{-3}\text{ J} = 4.32\times10^{-3}\text{ J}.$

This agrees with the total energy initially stored in the capacitor,

$U = \dfrac{Q^2}{2C} = \dfrac{(7.20\times10^{-4}\text{ C})^2}{2(6.00\times10^{-5}\text{ F})} = 4.32\times10^{-3}\text{ J}.$

Energy is conserved. At some times there is energy stored in both the capacitor and the inductor. When $i = 0$ all the energy is stored in the capacitor and when $q = 0$ all the energy is stored in the inductor. But at all times the total energy stored is the same.

30.36. Identify: $\omega = \dfrac{1}{\sqrt{LC}} = 2\pi f.$

Set Up: ω is the angular frequency in rad/s and *f* is the corresponding frequency in Hz.

Execute: **(a)** $L = \dfrac{1}{4\pi^2 f^2 C} = \dfrac{1}{4\pi^2(1.6\times10^6\text{ Hz})^2(4.18\times10^{-12}\text{ F})} = 2.37\times10^{-3}\text{ H}.$

(b) The maximum capacitance corresponds to the minimum frequency.

$C_{\max} = \dfrac{1}{4\pi^2 f_{\min}^2 L} = \dfrac{1}{4\pi^2(5.40\times10^5\text{ Hz})^2(2.37\times10^{-3}\text{ H})} = 3.67\times10^{-11}\text{ F} = 36.7\text{ pF}.$

Evaluate: To vary *f* by a factor of three (approximately the range in this problem), *C* must be varied by a factor of nine.

30.37. Identify: Apply energy conservation and $\omega = \dfrac{1}{\sqrt{LC}}$ and $i = -\omega Q\sin(\omega t + \phi)$.

Set Up: If *I* is the maximum current, $\tfrac{1}{2}LI^2 = \dfrac{Q^2}{2C}$. For the inductor, $U_L = \tfrac{1}{2}Li^2$.

EXECUTE: (a) $\frac{1}{2}LI^2 = \dfrac{Q^2}{2C}$ gives $Q = I\sqrt{LC} = (0.750\text{ A})\sqrt{(0.0800\text{ H})(1.25\times10^{-9}\text{ F})} = 7.50\times10^{-6}\text{ C}.$

(b) $\omega = \dfrac{1}{\sqrt{LC}} = \dfrac{1}{\sqrt{(0.0800\text{ H})(1.25\times10^{-9}\text{ F})}} = 1.00\times10^5\text{ rad/s}.$ $f = \dfrac{\omega}{2\pi} = 1.59\times10^4\text{ Hz}.$

(c) $q = Q$ at $t = 0$ means $\phi = 0$. $i = -\omega Q\sin(\omega t)$, so

$i = -(1.00\times10^5\text{ rad/s})(7.50\times10^{-6}\text{ C})\sin[(1.00\times10^5\text{ rad/s})(2.50\times10^{-3}\text{ s})] = 0.7279\text{ A}.$

$U_L = \frac{1}{2}Li^2 = \frac{1}{2}(0.0800\text{ H})(0.7279\text{ A})^2 = 0.0212\text{ J}.$

EVALUATE: The total energy of the system is $\frac{1}{2}LI^2 = 0.0225\text{ J}$. At $t = 2.50\text{ ms}$, the current is close to its maximum value and most of the system's energy is stored in the inductor.

30.38. IDENTIFY: The presence of resistance in an *L-R-C* circuit affects the frequency of oscillation and causes the amplitude of the oscillations to decrease over time.

(a) SET UP: The frequency of damped oscillations is $\omega' = \sqrt{\dfrac{1}{LC} - \dfrac{R^2}{4L^2}}.$

EXECUTE: $\omega' = \sqrt{\dfrac{1}{(22\times10^{-3}\text{ H})(15.0\times10^{-9}\text{ F})} - \dfrac{(75.0\ \Omega)^2}{4(22\times10^{-3}\text{ H})^2}} = 5.5\times10^4\text{ rad/s}.$

The frequency *f* is $f = \dfrac{\omega}{2\pi} = \dfrac{5.50\times10^4\text{ rad/s}}{2\pi} = 8.76\times10^3\text{ Hz} = 8.76\text{ kHz}.$

(b) SET UP: The amplitude decreases as $A(t) = A_0\, e^{-(R/2L)t}$.

EXECUTE: Solving for *t* and putting in the numbers gives:

$$t = \frac{-2L\ln(A/A_0)}{R} = \frac{-2(22.0\times10^{-3}\text{ H})\ln(0.100)}{75.0\ \Omega} = 1.35\times10^{-3}\text{ s} = 1.35\text{ ms}.$$

(c) SET UP: At critical damping, $R = \sqrt{4L/C}$.

EXECUTE: $R = \sqrt{\dfrac{4(22.0\times10^{-3}\text{ H})}{15.0\times10^{-9}\text{ F}}} = 2420\ \Omega.$

EVALUATE: The frequency with damping is almost the same as the resonance frequency of this circuit $(1/\sqrt{LC})$, which is plausible because the $75\text{-}\Omega$ resistance is considerably less than the $2420\ \Omega$ required for critical damping.

30.39. IDENTIFY: Evaluate $\omega' = \sqrt{\dfrac{1}{LC} - \dfrac{R^2}{4L^2}}.$

SET UP: The angular frequency of the circuit is ω'.

EXECUTE: (a) When $R = 0$, $\omega_0 = \dfrac{1}{\sqrt{LC}} = \dfrac{1}{\sqrt{(0.450\text{ H})(2.50\times10^{-5}\text{ F})}} = 298\text{ rad/s}.$

(b) We want $\dfrac{\omega'}{\omega_0} = 0.95$, so $\dfrac{(1/LC - R^2/4L^2)}{1/LC} = 1 - \dfrac{R^2C}{4L} = (0.95)^2$. This gives

$R = \sqrt{\dfrac{4L}{C}(1-(0.95)^2)} = \sqrt{\dfrac{4(0.450\text{ H})(0.0975)}{(2.50\times10^{-5}\text{ F})}} = 83.8\ \Omega.$

EVALUATE: When *R* increases, the angular frequency decreases and approaches zero as $R \to 2\sqrt{L/C}$.

30.40. IDENTIFY and SET UP: Eq. (30.28) is $q = Ae^{-(R/2L)t}\cos\left(\sqrt{\dfrac{1}{LC} - \dfrac{R^2}{4L^2}}t + \phi\right)$. We first find *A* and ϕ using the given information.

EXECUTE: **(a)** The charge is a maximum at $t = 0$, so $A = q_0 = 2.80\times10^{-4}$ C and $\phi = 0$.

(b) At the end of the first oscillation, $\sqrt{\dfrac{1}{LC}-\dfrac{R^2}{4L^2}}\,t = 2\pi$. Solving for t gives

$$t=\frac{2\pi}{\sqrt{\dfrac{1}{LC}-\dfrac{R^2}{4L^2}}}=\frac{2\pi}{\sqrt{\dfrac{1}{(0.400\text{ H})(7.00\ \mu\text{F})}-\dfrac{(320\ \Omega)^2}{4(0.400\text{ H})^2}}}=0.0142\text{ s}=14.2\text{ ms}.$$

(c) In Eq. (30.28), at the end of the first oscillation, the cosine factor is equal to 1, so the charge is $q = q_0 e^{-(R/2L)t} = (2.80\times10^{-4}\text{ C})\,e^{-(320\,\Omega)(0.0142\text{ s})/[2(0.400\text{ H})]} = 9.75\times10^{-7}\text{ C}$.

EVALUATE: The charge on the capacitor is only 0.35% of its initial value.

30.41. **IDENTIFY:** This problem is about a solenoid inductor.

SET UP and **EXECUTE:** **(a)** Estimate: Diameter = 7.0 mm.

(b) Estimate: With no overlap of the wires, $N(0.812\text{ mm}) = 4.0$ cm. $N = (40\text{ mm})/(0.812\text{ mm}) = 49$, which we round to 50 turns.

(c) If B is constant, $L = \mu_0 AN^2/l = \mu_0\,[\pi(0.406\text{ mm})^2](50^2)/(4.0\text{ cm}) = 3.0\ \mu\text{H}$.

(d) $U_L = \dfrac{1}{2}Li^2 = (1/2)(3.0\ \mu\text{H})(1.0\text{ A})^2 = 1.5\ \mu\text{J}$.

EVALUATE: Some lab inductors have an inductance of a few microhenries.

30.42. **IDENTIFY:** This is an R-L circuit and $i(t)$ is given by $i = \dfrac{\mathcal{E}}{R}(1-e^{-(R/L)t})$.

SET UP: When $t\to\infty$, $i \to i_f = V/R$.

EXECUTE: **(a)** $R = \dfrac{V}{i_f} = \dfrac{16.0\text{ V}}{6.45\times10^{-3}\text{ A}} = 2481\ \Omega$, which rounds to 2480 Ω.

(b) $i = i_f(1-e^{-(R/L)t})$ so $\dfrac{Rt}{L} = -\ln(1-i/i_f)$ and $L = \dfrac{-Rt}{\ln(1-i/i_f)} = \dfrac{-(2481\ \Omega)(9.40\times10^{-4}\text{ s})}{\ln(1-(4.86/6.45))} = 1.67$ H.

EVALUATE: The current after a long time depends only on R and is independent of L. The value of R/L determines how rapidly the final value of i is reached.

30.43. **IDENTIFY:** This problem involves electromagnetic induction and self-inductance.

SET UP and **EXECUTE:** $L = \dfrac{\Phi_B}{i}$, $B = \dfrac{\mu_0 I}{2r}$, $\mathcal{E} = -\dfrac{d\Phi_B}{dt}$.. **(a)** We want the self-inductance.

$$\Phi_B = BA = \left(\frac{\mu_0 I}{2r}\right)(\pi r^2) = \frac{\mu_0\pi ri}{2}.\quad L = \frac{\Phi_B}{i} = \frac{\mu_0\pi ri/2}{i} = \frac{\mu_0\pi r}{2} = \frac{\mu_0\pi(3.0\text{ cm})}{2} = 59\text{ nH}.$$

(b) We want the maximum emf. $|\mathcal{E}| = \dfrac{d\Phi_B}{dt} = \dfrac{d}{dt}\left(\dfrac{\mu_0\pi ri}{2}\right) = \dfrac{\mu_0\pi r}{2}\dfrac{di}{dt}$. $i(t) = I_0\sin(2\pi ft)$ gives

$\mathcal{E} = \mu_0\pi^2 rI_0 f\cos(2\pi ft)$. $\mathcal{E}_{\text{max}} = \mu_0\pi^2 rI_0 f = \ = \mu_0\pi^2(0300\text{ m})(1.20\text{ A})(60.0\text{ Hz}) = 26.8\ \mu\text{V}$.

EVALUATE: This only an estimate but it suggests a rather small induced voltage.

30.44. **IDENTIFY:** Apply $\mathcal{E} = -L\dfrac{di}{dt}$ and $Li = N\Phi_B$.

SET UP: Φ_B is the flux through one turn.

EXECUTE: **(a)** $\mathcal{E} = -L\dfrac{di}{dt} = -(7.50\times10^{-3}\text{ H})\dfrac{d}{dt}\{(0.680\text{ A})\cos[\pi t/(0.0250\text{ s})]\}.$

$\mathcal{E} = (7.50\times10^{-3}\text{ H})(0.680\text{ A})\dfrac{\pi}{0.0250\text{ s}}\sin[\pi t/(0.0250\text{ s})].$ Therefore,

$\mathcal{E}_{\text{max}} = (7.50\times10^{-3}\text{ H})(0.680\text{ A})\dfrac{\pi}{0.0250\text{ s}} = 0.641\text{ V}.$

(b) $\Phi_{B\max} = \dfrac{Li_{\text{max}}}{N} = \dfrac{(7.50\times10^{-3}\text{ H})(0.680\text{ A})}{400} = 1.28\times10^{-5}\text{ Wb} = 12.8\ \mu\text{Wb}.$

(c) $\mathcal{E}(t) = -L\dfrac{di}{dt} = (7.50\times10^{-3}\text{ H})(0.680\text{ A})(\pi/0.0250\text{ s})\sin[\pi t/(0.0250\text{ s})].$

$\mathcal{E}(t) = (0.641\text{ V})\sin[(125.6\text{ s}^{-1})t].$ Therefore, at $t = 0.0180$ s,

$\mathcal{E}(0.0180\text{ s}) = (0.641\text{ V})\sin[(125.6\text{ s}^{-1})(0.0180\text{ s})] = 0.494\text{ V}.$ The magnitude of the induced emf is 0.494 V.

EVALUATE: The maximum emf is when $i = 0$ and at this instant $\Phi_B = 0$.

30.45. **IDENTIFY:** Set $U_B = K$, where $K = \frac{1}{2}mv^2$.

SET UP: The energy density in the magnetic field is $u_B = B^2/2\mu_0$. Consider volume $V = 1\text{ m}^3$ of sunspot material.

EXECUTE: The energy density in the sunspot is $u_B = B^2/2\mu_0 = 6.366\times10^4\text{ J/m}^3$. The total energy stored in volume *V* of the sunspot is $U_B = u_B V$. The mass of the material in volume *V* of the sunspot is $m = \rho V$. $K = U_B$ so $\frac{1}{2}mv^2 = U_B$. $\frac{1}{2}\rho V v^2 = u_B V$. The volume divides out, and $v = \sqrt{2u_B/\rho} = 2\times10^4$ m/s.

EVALUATE: The speed we calculated is about 30 times smaller than the escape speed.

30.46. **IDENTIFY:** Follow the steps outlined in the problem.

SET UP: The energy stored is $U = \frac{1}{2}Li^2$.

EXECUTE: **(a)** $\oint \vec{B}\cdot d\vec{l} = \mu_0 I_{\text{encl}} \Rightarrow B2\pi r = \mu_0 i \Rightarrow B = \dfrac{\mu_0 i}{2\pi r}.$

(b) $d\Phi_B = BdA = \dfrac{\mu_0 i}{2\pi r}ldr.$

(c) $\Phi_B = \displaystyle\int_a^b d\Phi_B = \frac{\mu_0 il}{2\pi}\int_a^b \frac{dr}{r} = \frac{\mu_0 il}{2\pi}\ln(b/a).$

(d) $L = \dfrac{N\Phi_B}{i} = l\dfrac{\mu_0}{2\pi}\ln(b/a).$

(e) $U = \dfrac{1}{2}Li^2 = \dfrac{1}{2}l\dfrac{\mu_0}{2\pi}\ln(b/a)i^2 = \dfrac{\mu_0 li^2}{4\pi}\ln(b/a).$

EVALUATE: The magnetic field between the conductors is due only to the current in the inner conductor.

30.47. **IDENTIFY:** $U = \frac{1}{2}LI^2$. The self-inductance of a solenoid is found in Exercise 30.15 to be $L = \dfrac{\mu_0 AN^2}{l}$.

SET UP: The length *l* of the solenoid is the number of turns divided by the turns per unit length.

EXECUTE: **(a)** $L = \dfrac{2U}{I^2} = \dfrac{2(10.0\text{ J})}{(2.00\text{ A})^2} = 5.00\text{ H}.$

(b) $L = \dfrac{\mu_0 AN^2}{l}$. If α is the number of turns per unit length, then $N = \alpha l$ and $L = \mu_0 A\alpha^2 l$. For this coil $\alpha = 10$ coils/mm $= 10\times10^3$ coils/m. Solving for l gives

$$l = \frac{L}{\mu_0 A\alpha^2} = \frac{5.00\text{ H}}{(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})\pi(0.0200\text{ m})^2(10\times10^3\text{ coils/m})^2} = 31.7\text{ m}.$$ This is not a practical length for laboratory use.

EVALUATE: The number of turns is $N = (31.7\text{ m})(10\times10^3\text{ coils/m}) = 3.17\times10^5$ turns. The length of wire in the solenoid is the circumference C of one turn times the number of turns. $C = \pi d = \pi(4.00\times10^{-2}\text{ m}) = 0.126$ m. The length of wire is $(0.126\text{ m})(3.17\times10^5) = 4.0\times10^4\text{ m} = 40$ km. This length of wire will have a large resistance and I^2R electrical energy loses will be very large.

30.48. IDENTIFY and **SET UP:** Eq. (30.14) is $i = \dfrac{\mathcal{E}}{R}(1-e^{-Rt/L})$, $P_R = i^2R$, $\mathcal{E}_L = -L\dfrac{di}{dt}$.

EXECUTE: **(a)** Using Eq. (30.14) in the power consumed in the resistor gives

$$P_R = i^2R = \left[\frac{\mathcal{E}}{R}(1-e^{-Rt/L})\right]^2 R = \frac{\mathcal{E}^2}{R}(1-2e^{-Rt/L}+e^{-2Rt/L}).$$

After a long time, that is $t\to\infty$, the exponential terms all go to zero and the power approaches its maximum value of $\dfrac{\mathcal{E}^2}{R}$.

(b) The power in the inductor is

$$P_L = i\mathcal{E}_L = i\left(L\frac{di}{dt}\right) = \left[\frac{\mathcal{E}}{R}(1-e^{-Rt/L})\right]L\frac{d}{dt}\left[\frac{\mathcal{E}}{R}(1-e^{-Rt/L})\right] = \left[\frac{\mathcal{E}}{R}(1-e^{-Rt/L})\right]L\left(\frac{\mathcal{E}}{L}\right)e^{-Rt/L}.$$

$$P_L = \frac{\mathcal{E}^2}{R}(1-e^{-Rt/L})e^{-Rt/L}.$$

(c) $P_L(0) = 0$ since $1-e^0 = 0$. $P_L(t\to\infty) = 0$ since $e^{-Rt/L}\to 0$ as $t\to\infty$.

(d) P_L is a maximum when $dP_L/dt = 0$. Taking the time derivative of P_L from (b), we have

$$\frac{\mathcal{E}^2}{R}\left[\left(\frac{R}{L}e^{-Rt/L}\right)(e^{-Rt/L}) - \frac{R}{L}(1-e^{-Rt/L})(e^{-Rt/L})\right] = \frac{\mathcal{E}^2}{L}e^{-Rt/L}(e^{-Rt/L}-1+e^{-Rt/L}) = 0.$$

$2e^{-Rt/L} = 1.$

$t = -(L/R)\ln(1/2) = (L/R)\ln 2.$

At this instant, $e^{-Rt/L} = \frac{1}{2}$. Using the result from (b), we have

$$P_L = \frac{\mathcal{E}^2}{R}(1-e^{-Rt/L})e^{-Rt/L} = \frac{\mathcal{E}^2}{R}\left(1-\frac{1}{2}\right)\left(\frac{1}{2}\right) = \frac{1}{4}\frac{\mathcal{E}^2}{R}.$$

(e) $P_{\varepsilon} = i\mathcal{E} = \dfrac{\mathcal{E}^2}{R}(1-e^{-Rt/L})$. The maximum power is $\dfrac{\mathcal{E}^2}{R}$ as $t\to\infty$.

EVALUATE: As time gets very large, current approaches a steady-state value, so the potential across an inductor approaches zero since the current through it is not changing.

30.49. IDENTIFY and **SET UP:** Use $U_C = \frac{1}{2}CV_C^2$ (energy stored in a capacitor) to solve for C. Then use $\omega = \dfrac{1}{\sqrt{LC}}$ and $\omega = 2\pi f$ to solve for the L that gives the desired current oscillation frequency.

EXECUTE: $V_C = 12.0$ V; $U_C = \frac{1}{2}CV_C^2$ so $C = 2U_C/V_C^2 = 2(0.0160\text{ J})/(12.0\text{ V})^2 = 222\ \mu$F.

$f = \dfrac{1}{2\pi\sqrt{LC}}$ so $L = \dfrac{1}{(2\pi f)^2 C}$.

$f = 3500$ Hz gives $L = 9.31\ \mu$H.

EVALUATE: f is in Hz and ω is in rad/s; we must be careful not to confuse the two.

30.50. IDENTIFY and SET UP: Apply $\mathcal{E}_L = -L\dfrac{di}{dt}$ and $V_R = Ri$. An inductor opposes a change in current through it. Kirchhoff's rules apply.

EXECUTE: **(a)** At the instant the switch is closed, the inductor will not allow any current through it, so all the current goes through R_1. So $i_1 = i_2 = \mathcal{E}/R_1 = (96.0\text{ V})/(12.0\ \Omega) = 8.00$ A. $i_3 = 0$.

(b) After a long time, steady-state is reached, so $di_3/dt = 0$ and $\mathcal{E}_L = -L\dfrac{di_3}{dt} = 0$. In this case, the potential across R_1 and across R_2 is 96.0 V. Therefore

$i_2 = (96.0\text{ V})/(12.0\ \Omega) = 8.00$ A.

$i_3 = (96.0\text{ V})/(16.0\ \Omega) = 6.00$ A.

$i_1 = i_2 + i_3 = 8.00\text{ A} + 6.00\text{ A} = 14.00$ A.

(c) Apply Kirchhoff's loop rule, giving

$$\mathcal{E} - i_3R_2 - L\frac{di_3}{dt} = 0.$$

Separating variables and integrating gives

$$\int_0^t -\frac{R_2}{L}dt' = \int_0^{i_3}\frac{1}{i_3' - \mathcal{E}/R_2}di_3'.$$

Carrying out the integration and solving for t gives

$$-\frac{R_2}{L}t = \ln\left(\frac{i_3 - \mathcal{E}/R_2}{-\mathcal{E}/R_2}\right).$$

$$t = \frac{L}{R_2}\ln\left(\frac{\mathcal{E}/R_2}{\mathcal{E}/R_2 - i_3}\right) = \frac{0.300\text{ H}}{16.0\ \Omega}\ln\left(\frac{96.0\text{ V}}{96.0\text{ V} - (3.00\text{ A})(16.0\ \Omega)}\right) = 0.0130\text{ s} = 13.0\text{ ms}.$$

(d) $i_2 = \mathcal{E}/R_1 = (96.0\text{ V})/(12.0\ \Omega) = 8.00$ A. $i_1 = i_2 + i_3 = 8.00\text{ A} + 3.00\text{ A} = 11.0$ A.

EVALUATE: At steady-state, the potential drop across an inductor is zero if it has no resistance. Initially the inductor acts like an open circuit because it will not allow current to flow through it.

30.51. IDENTIFY: This problem involves induction and magnetic torque.

SET UP and EXECUTE: **(a)** We want the force the bar exerts on the spool. The torques due to the force of the bar and the magnetic force balance so $Fa = \mu B\sin\theta = i(\pi a^2)NB\sin\theta$. This gives $F = \pi aiNB\sin\theta = \pi(0.0500\text{ m})(1.00\text{ A})(500)(2.00\text{ T})(\sin 45°) = 111$ N.

(b) We want the time when the force is zero. At this time, the magnetic torque equals the counter torque, so $i\pi a^2NB\sin\theta = \tau$. The current is $i = i_0e^{-(R/L)t}$, so $i_0e^{-(R/L)t}\ \pi a^2NB\sin\theta = \tau$. Isolate the exponential: $e^{-(R/L)t} = \dfrac{\tau}{i_0\pi a^2NB\sin\theta}$. Using the given numerical values gives $e^{-(R/L)t} = 0.09005$. Solving using logarithms gives $t = -(L/R)\ln(0.09005) = 37.1$ ms.

(c) We want the angular acceleration after a long time. Using $\Sigma\tau = I\alpha$, we have $\tau_{\text{mag}} = I\alpha$. $\tau_{\text{mag}} = \mu BN\sin\theta = i\pi a^2BN\sin\theta$. $I = \dfrac{1}{2}Ma^2$. So $\tau_{\text{mag}} = I\alpha$ gives $i\pi a^2BN\sin\theta = \dfrac{1}{2}Ma^2\alpha$.

$\alpha = \dfrac{2i\pi BN\sin\theta}{M}$. After a long time, $i = 1.00$ A, as in part (a). Using the given quantities we have $\alpha = 4000\text{ rad/s}^2$.

EVALUATE: Be careful not to confuse μ (the magnetic moment) with μ_0 (the magnetic constant).

30.52. **IDENTIFY** and **SET UP:** Apply Kirchhoff's rules. $V_R = Ri$ and $\mathcal{E}_L = -L\dfrac{di}{dt}$.

EXECUTE: **(a)** Immediately after the switch is closed, the inductor will not allow any current in it, so all the current flows through R_2. At that instant, the equivalent circuit consists of R_1 and R_2 in series with each other and connected across the terminals of the battery. Ohm's law gives
$i_1 = i_2 = \mathcal{E}/(R_1 + R_2) = (48.0\text{ V})/(14\ \Omega) = 3.43\text{ A}$.

The current through the inductor is zero, so $i_3 = 0$.
(b) After a long time, steady-state has been achieved, so the potential across the inductor is zero. Therefore it acts like a short circuit, so no current flows through R_2. The equivalent circuit consists of R_3 connected across the terminals of the battery. By Ohm's law
$i_1 = i_3 = \mathcal{E}/R_1 = (48.0\text{ V})/(8.00\ \Omega) = 6.00\text{ A}$. $i_2 = 0$.
(c) Use Kirchhoff's loop rule. A loop around the left-hand section of the circuit gives
$\mathcal{E} - i_1R_1 - i_2R = 0$ (Eq. 1).
A loop around the right-hand section of the circuit gives
$-i_2R_2 + L\,di_3/dt = 0$ (Eq. 2).
Kirchhoff's junction rule gives
$i_1 = i_2 + i_3$ (Eq. 3).

Combining Eq. 1 and Eq. 3 and rearranging gives $i_2 = \dfrac{\mathcal{E} - i_3R_1}{R_1 + R_2}$. Putting this result into Eq. 2 gives

$-\left(\dfrac{\mathcal{E} - i_3R_1}{R_1 + R_2}\right)R_2 + L\dfrac{di_3}{dt} = 0$. Separating variables and integrating gives

$$\int_0^{i_3} \frac{di_3'}{i_3' - \mathcal{E}/R_1} = -\int_0^t \frac{R_1R_2}{L(R_1 + R_2)}\,dt'.$$

$$\ln\left(\frac{i_3 - \mathcal{E}/R_1}{-\mathcal{E}/R_1}\right) = -\frac{R_1R_2}{L(R_1 + R_2)}t.$$

$$i_3 = \frac{\mathcal{E}}{R_1}(1 - e^{-R_1R_2t/L(R_1+R_2)}).$$

(d) Solve for t when $i_3 = (\mathcal{E}/R_1)/2$.

$$t = \frac{L(R_1 + R_2)}{R_1R_2}\ln\left(\frac{\mathcal{E}/R_1}{\mathcal{E}/R_1 - \mathcal{E}/2R_1}\right) = \frac{L(R_1 + R_2)}{R_1R_2}\ln 2 = \frac{(0.200\text{ H})(14.00\ \Omega)}{(8.00\ \Omega)(6.00\ \Omega)}\ln 2 = 0.0404\text{ s}.$$

(e) $i_2 = \dfrac{\mathcal{E} - i_3R_1}{R_1 + R_2} = \dfrac{48.0\text{ V} - (3.00\text{ A})(8.00\ \Omega)}{14.00\ \Omega} = 1.71\text{ A}$.

$i_1 = i_2 + i_3 = 1.71\text{ A} + 3.00\text{ A} = 4.71\text{ A}$.
EVALUATE: The inductor initially acted like an open circuit, but at steady-state it acted like a short circuit. If it had resistance, it would not have behaved like a short circuit at steady-state.

30.53. **IDENTIFY:** In this problem we treat damping in an L-R-C circuit.

SET UP and **EXECUTE:** **(a)** We want the charge that flows onto the capacitor. Apply $\mathcal{E}_{\text{av}} = N\dfrac{\Delta\Phi_B}{\Delta t}$.

$\Delta B = B - 0 = B$, so $\dfrac{\Delta\Phi_B}{\Delta t} = \dfrac{BA}{\Delta t}$. $\mathcal{E}_{\text{av}} = N\dfrac{BA}{\Delta t} = IR$. $I = \dfrac{NBA}{R\Delta t}$. $Q = I\Delta t = \left(\dfrac{NBA}{R\Delta t}\right)\Delta t = \dfrac{NBA}{R}$. $A = \pi r^2$. R $= (0.0333\ \Omega/\text{m})(2\pi r)N = 0.6277\ \Omega$. Using the area, this R, and the other given quantities, we get $Q =$ 15.0 mC.
(b) We want the time for the capacitor to fully discharge for the first time. Apply Kirchhoff's loop rule, giving $L\dfrac{di}{dt} + Ri + \dfrac{q}{C} = 0$, which we can express as $\dfrac{d^2q}{dt^2} + \dfrac{R}{L}\dfrac{dq}{dt} + \dfrac{q}{LC} = 0$. The solution to this

differential equation is $q(t) = Ae^{-(R/2L)t}\cos\left(\sqrt{\frac{1}{LC}-\frac{R^2}{4L^2}}\,t+\phi\right)$. At $t = 0$, $q = Q_0$ and $i = 0$, so $A = Q_0$ and $\phi = \pi/2$. When the capacitor discharges for the first time, $q = 0$, which occurs when $\sqrt{\frac{1}{LC}-\frac{R^2}{4L^2}}\,t$ $= \pi/2$. Therefore $t = \dfrac{\pi}{2\sqrt{\frac{1}{LC}-\frac{R^2}{4L^2}}}$. We know that $R = 0.6277\ \Omega$ and $C = 10.0\ \mu\text{F}$, so we need L. Using $L = \mu_0 AN^2/l$ with the given quantities we get $L = 355.3\ \mu\text{H}$. Using these values gives $t = 93.8\ \mu\text{S}$.

(c) We want the frequency f'. Using $f' = \dfrac{\omega'}{2\pi} = \dfrac{1}{2\pi}\sqrt{\dfrac{1}{LC}-\dfrac{R^2}{4L^2}}$ gives $f' = 2.67$ kHz.

(d) We want the energy in the capacitor when $t = 0$. $U_0 = \dfrac{Q_0^2}{2C} = 11.3$ J using $Q_0 = 15.0$ mC from (a).

(e) We want the time for the maximum capacitor energy to be 10.0% of its initial energy. First find the charge for which the energy is 10.0% of the initial energy. $\dfrac{U}{U_0} = \dfrac{Q^2/2C}{Q_0^2/2C} = \left(\dfrac{Q}{Q_0}\right)^2 = 0.100$, so $Q = Q_0\sqrt{0.100}$. Now use the equation for $q(t)$. When q is a maximum, $t = 0$ so the cosine factor is equal to one. Using $Q = Q_0\sqrt{0.100}$ gives $Q_0 e^{-(R/2L)t} = Q_0\sqrt{0.100}$. Solve for t giving $t = -\dfrac{2L}{R}\ln\left(\sqrt{0.100}\right)$ $= 1.30$ ms.

EVALUATE: The charge and current continue to oscillate but with decreasing amplitude.

30.54. **IDENTIFY:** The initial energy stored in the capacitor is shared between the inductor and the capacitor.

SET UP: The potential across the capacitor and inductor is always the same, so $\dfrac{q}{C} = L\left|\dfrac{di}{dt}\right|$. The capacitor energy is $U_C = \dfrac{q^2}{2C} = \dfrac{1}{2}CV^2$, and the inductor energy is $U_L = \dfrac{1}{2}Li^2$.

EXECUTE: **(a)** The initial energy in the capacitor is $U_0 = \dfrac{1}{2}Cv_0^2 = \dfrac{1}{2}(6.40\ \text{nF})(24.0\ \text{V})^2 = 1.84\ \mu\text{J}$. This energy is shared between the inductor and the capacitor. The energy in the capacitor at this time is

$$U_C = \frac{q^2}{2C} = \frac{(0.0800\ \mu\text{C})^2}{2(6.40\ \text{nF})} = 0.500\ \mu\text{J}.$$

The energy remaining in the inductor is
$U_L = U_0 - U_C = 1.84\ \mu\text{J} - 0.500\ \mu\text{J} = 1.34\ \mu\text{J}$.

The energy in the inductor is $U_L = \dfrac{1}{2}Li^2$, so

$$i = \sqrt{\frac{2U_L}{L}} = \sqrt{\frac{2(1.34\times10^{-6}\ \text{J})}{0.0660\ \text{H}}} = 6.37\times10^{-3}\ \text{A} = 6.37\ \text{mA}.$$

(b) When the capacitor charge is 0.0800 μC, we found that the energy stored in the capacitor is 0.500 μJ.

$$U_C = \frac{1}{2}Cv_C^2 \;\rightarrow\; v_C = \sqrt{\frac{2U_0}{C}} = \sqrt{\frac{2(0.500\ \mu\text{J})}{6.40\ \text{nF}}} = 12.5\ \text{V}.$$

The potential across the inductor and capacitor is the same, so $v_L = 12.5$ V.

Using $v_L = \mathcal{E}_L = \left|L\dfrac{di}{dt}\right|$, we have $\dfrac{di}{dt} = \dfrac{v_L}{L} = \dfrac{12.5\ \text{V}}{0.0660\ \text{H}} = 189\ \text{A/s}.$

EVALUATE: When the capacitor contains 0.0800 μC of charge, the energy in the inductor is 1.34 μJ. Therefore the current is $U_L = \frac{1}{2}Li^2$, so $i = \sqrt{\frac{2U_L}{L}} = \sqrt{\frac{2(1.34\ \mu\text{J})}{0.0660\ \text{H}}} = 6.4$ mA. The current is only 6.4 mA but is changing at a rate of 189 A/s. However, it only changes at that rate for a tiny fraction of a second.

30.55. **IDENTIFY:** Apply energy conservation to the circuit.

SET UP: For a capacitor $V = q/C$ and $U = q^2/2C$. For an inductor $U = \frac{1}{2}Li^2$.

EXECUTE: **(a)** $V_{\text{max}} = \frac{Q}{C} = \frac{6.00\times10^{-6}\ \text{C}}{2.50\times10^{-4}\ \text{F}} = 0.0240\ \text{V}.$

(b) $\frac{1}{2}Li_{\text{max}}^2 = \frac{Q^2}{2C}$, so $i_{\text{max}} = \frac{Q}{\sqrt{LC}} = \frac{6.00\times10^{-6}\ \text{C}}{\sqrt{(0.0600\ \text{H})(2.50\times10^{-4}\ \text{F})}} = 1.55\times10^{-3}\ \text{A}.$

(c) $U_{\text{max}} = \frac{1}{2}Li_{\text{max}}^2 = \frac{1}{2}(0.0600\ \text{H})(1.55\times10^{-3}\text{A})^2 = 7.21\times10^{-8}\ \text{J}.$

(d) If $i = \frac{1}{2}i_{\text{max}}$ then $U_L = \frac{1}{4}U_{\text{max}} = 1.80\times10^{-8}$ J and $U_C = \frac{3}{4}U_{\text{max}} = \frac{(\sqrt{(3/4)}Q)^2}{2C} = \frac{q^2}{2C}$. This gives $q = \sqrt{\frac{3}{4}}Q = 5.20\times10^{-6}$ C.

EVALUATE: $U_{\text{max}} = \frac{1}{2}Li^2 + \frac{1}{2}\frac{q^2}{C}$ for all times.

30.56. **IDENTIFY:** The total energy is shared between the inductor and the capacitor.

SET UP: The potential across the capacitor and inductor is always the same, so $\frac{q}{C} = L\left|\frac{di}{dt}\right|$. The capacitor energy is $U_C = \frac{q^2}{2C}$ and the inductor energy is $U_L = \frac{1}{2}Li^2$.

EXECUTE: The total energy is $\frac{q^2}{2C} + \frac{1}{2}Li^2 = \frac{Q_{\text{max}}^2}{2C} = \frac{1}{2}CV_{\text{max}}^2$.

$$q = LC\left|\frac{di}{dt}\right| = (0.330\ \text{H})(5.90\times10^{-4}\ \text{F})(73.0\ \text{A/s}) = 1.421\times10^{-2}\ \text{C}.$$

$$\frac{1}{2}CV_{\text{max}}^2 = \frac{q^2}{2C} + \frac{1}{2}Li^2 = \frac{(1.421\times10^{-2}\ \text{C})^2}{2(5.90\times10^{-4}\ \text{F})} + \frac{1}{2}(0.330\ \text{H})(2.50\ \text{A})^2 = 1.202\ \text{J}.$$

$$V_{\text{max}} = \sqrt{\frac{2(1.202\ \text{J})}{5.90\times10^{-4}\ \text{F})}} = 63.8\ \text{V}.$$

EVALUATE: By energy conservation, the maximum energy stored in the inductor will be 1.202 J, and this will occur at the instants when the capacitor is uncharged.

30.57. **IDENTIFY:** The current through an inductor doesn't change abruptly. After a long time the current isn't changing and the voltage across each inductor is zero.

SET UP: For part (c) combine the inductors.

EXECUTE: **(a)** Just after the switch is closed there is no current in the inductors. There is no current in the resistors so there is no voltage drop across either resistor. A reads zero and V reads 20.0 V.

(b) After a long time the currents are no longer changing, there is no voltage across the inductors, and the inductors can be replaced by short-circuits. The circuit becomes equivalent to the circuit shown in Figure 30.57a. $I = (20.0\ \text{V})/(75.0\ \Omega) = 0.267$ A. The voltage between points a and b is zero, so the voltmeter reads zero.

(c) Combine the inductor network into its equivalent, as shown in Figure 30.57b. $R = 75.0\ \Omega$ is the equivalent resistance. The current is $i = (\mathcal{E}/R)(1 - e^{-t/\tau})$ with $\tau = L/R = (10.8\text{ mH})/(75.0\ \Omega) = 0.144\text{ ms}$. $\mathcal{E} = 20.0\text{ V}$, $R = 75.0\ \Omega$, $t = 0.115\text{ ms}$ so $i = 0.147\text{ A}$. $V_R = iR = (0.147\text{ A})(75.0\ \Omega) = 11.0\text{ V}$. $20.0\text{ V} - V_R - V_L = 0$ and $V_L = 20.0\text{ V} - V_R = 9.0\text{ V}$. The ammeter reads 0.147 A and the voltmeter reads 9.0 V.

EVALUATE: The current through the battery increases from zero to a final value of 0.267 A. The voltage across the inductor network drops from 20.0 V to zero.

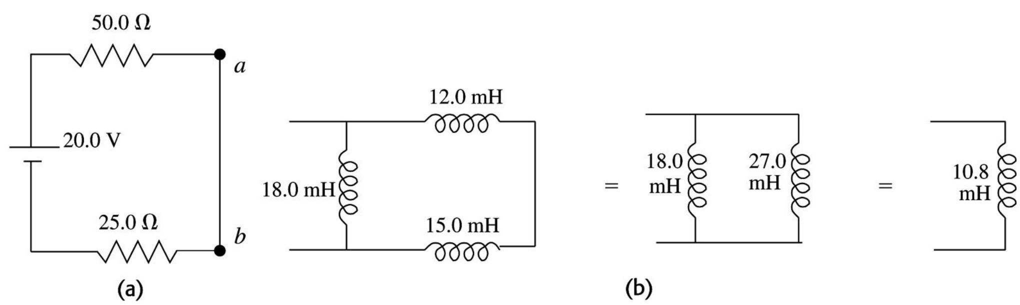


Figure 30.57

30.58. IDENTIFY: At $t = 0$, $i = 0$ through each inductor. At $t \to \infty$, the voltage is zero across each inductor.
SET UP: In each case redraw the circuit. At $t = 0$ replace each inductor by a break in the circuit and at $t \to \infty$ replace each inductor by a wire.
EXECUTE: **(a)** Initially the inductor blocks current through it, so the simplified equivalent circuit is shown in Figure 30.58a. $i = \dfrac{\mathcal{E}}{R} = \dfrac{50\text{ V}}{150\ \Omega} = 0.333\text{ A}$. $V_1 = (100\ \Omega)(0.333\text{ A}) = 33.3\text{ V}$.
$V_4 = (50\ \Omega)(0.333\text{ A}) = 16.7\text{ V}$. $V_3 = 0$ since no current flows through it. $V_2 = V_4 = 16.7\text{ V}$, since the inductor is in parallel with the 50-Ω resistor. $A_1 = A_3 = 0.333\text{ A}$, $A_2 = 0$.
(b) Long after S is closed, steady state is reached, so the inductor has no potential drop across it. The simplified circuit is sketched in Figure 30.58b. $i = \mathcal{E}/R = \dfrac{50\text{ V}}{130\ \Omega} = 0.385\text{ A}$.
$V_1 = (100\ \Omega)(0.385\text{ A}) = 38.5\text{ V}$; $V_2 = 0$; $V_3 = V_4 = 50\text{ V} - 38.5\text{ V} = 11.5\text{ V}$.
$i_1 = 0.385\text{ A}$; $i_2 = \dfrac{11.5\text{ V}}{75\ \Omega} = 0.153\text{ A}$; $i_3 = \dfrac{11.5\text{ V}}{50\ \Omega} = 0.230\text{ A}$.
EVALUATE: Just after the switch is closed the current through the battery is 0.333 A. After a long time the current through the battery is 0.385 A. After a long time there is an additional current path, the equivalent resistance of the circuit is decreased and the current has increased.

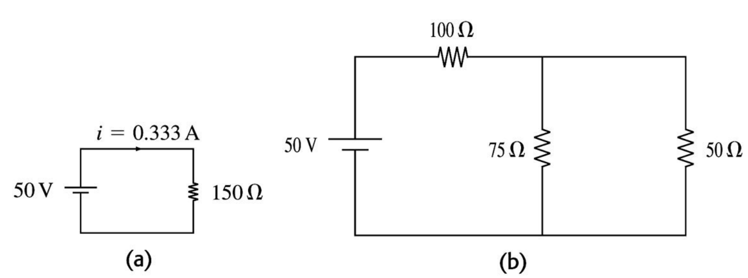

Figure 30.58

30.59. IDENTIFY and SET UP: The current in an *R-L* circuit is given by $i = i_0 e^{-Rt/L}$, where *R* is the total resistance. In our measurements, the current is one-half the initial current, so $i = i_0/2$.

EXECUTE: (a) Taking natural logarithms of the current equation, with $R = R_L + R_{ext}$ and $i = i_0/2$, we get

$\ln(i/i_0) = -Rt/L.$

$\ln(1/2) = -(R_L + R_{ext})t_{half}/L.$

$\ln 2 = t_{half}(R_L + R_{ext})/L.$

where t_{half} is the time for the current to decrease to half its initial value. Solving for $1/t_{half}$ gives $\frac{1}{t_{half}} = \frac{R_{ext}}{L\ln 2} + \frac{R_L}{L\ln 2}$. Therefore a graph of $1/t_{half}$ versus R_{ext} should be a straight line having a slope equal to $1/(L \ln 2)$ and a *y*-intercept equal to $R_L/(L \ln 2)$. Figure 30.59 shows this graph.

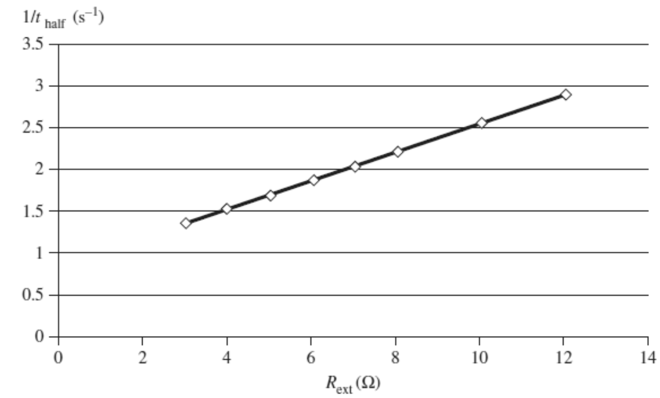

Figure 30.59

(b) The best-fit equation for the line in the graph is $\frac{1}{t_{half}} = 0.1692\ (\Omega\cdot\text{s})^{-1}R_{ext} + 0.8524\ \text{s}^{-1}$. Using the slope and solving for *L* gives $L = \frac{1}{(\text{slope})\ln 2} = \frac{1}{[0.1692\ (\Omega\cdot\text{s})^{-1}]\ln 2} = 8.53\ \text{H}$, which rounds to 8.5 H.

Now use the *y*-intercept and solve for R_L.

$\frac{R_L}{L\ln 2} = y\text{-intercept}$, so $R_L = (y\text{-intercept})(L\ln 2) = (0.8524\ \text{s}^{-1})(8.53\ \text{H})\ln 2 = 5.04\ \Omega$, which rounds to 5.0 Ω.

(c) $U_L = \frac{1}{2}Li^2 = (1/2)(8.53\ \text{H})(20.0\ \text{A})^2 = 1.7\times10^3\ \text{J} = 1.7\ \text{kJ}.$

$P_R = i^2R = (20.0\ \text{A})^2(5.04\ \Omega) = 2.0\times10^3\ \text{W} = 2.0\ \text{kW}.$

EVALUATE: Whether the 5.0-Ω resistance of this inductor would be significant would depend on the external resistance in the circuit. For the data of this problem, the solenoid resistance would definitely be significant for the external resistances used.

30.60. IDENTIFY: Closing S_2 and simultaneously opening S_1 produces an *L-C* circuit with initial current through the inductor of 3.50 A. When the current is a maximum the charge *q* on the capacitor is zero and when the charge *q* is a maximum the current is zero. Conservation of energy says that the maximum energy $\frac{1}{2}Li_{max}^2$ stored in the inductor equals the maximum energy $\frac{1}{2}\frac{q_{max}^2}{C}$ stored in the capacitor.

SET UP: $i_{max} = 3.50$ A, the current in the inductor just after the switch is closed.

EXECUTE: (a) $\frac{1}{2}Li_{max}^2 = \frac{1}{2}\frac{q_{max}^2}{C}.$

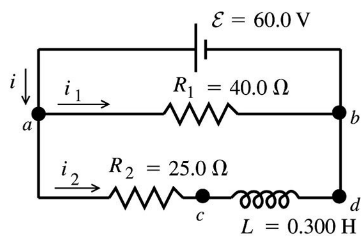
$q_{max} = (\sqrt{LC})i_{max} = \sqrt{(2.0\times10^{-3}\text{ H})(5.0\times10^{-6}\text{ F})}(3.50\text{ A}) = 3.50\times10^{-4}\text{ C} = 0.350\text{ mC}.$

(b) When q is maximum, $i = 0.$

EVALUATE: In the final circuit the current will oscillate.

30.61. **IDENTIFY:** Apply the loop rule to each parallel branch. The voltage across a resistor is given by iR and the voltage across an inductor is given by $L|di/dt|$. The rate of change of current through the inductor is limited.

SET UP: With S closed the circuit is sketched in Figure 30.61a.



The rate of change of the current through the inductor is limited by the induced emf. Just after the switch is closed the current in the inductor has not had time to increase from zero, so $i_2 = 0.$

Figure 30.61a

EXECUTE : **(a)** $\mathcal{E} - v_{ab} = 0$, so $v_{ab} = 60.0$ V.

(b) The voltage drops across R, as we travel through the resistor in the direction of the current, so point a is at higher potential.

(c) $i_2 = 0$ so $v_{R_2} = i_2R_2 = 0.$

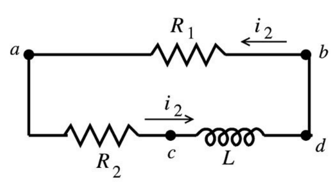
$\mathcal{E} - v_{R_2} - v_L = 0$ so $v_L = \mathcal{E} = 60.0$ V.

(d) The voltage rises when we go from b to a through the emf, so it must drop when we go from a to b through the inductor. Point c must be at higher potential than point d.

(e) After the switch has been closed a long time, $\frac{di_2}{dt} \to 0$ so $v_L = 0.$ Then $\mathcal{E} - v_{R_2} = 0$ and $i_2R_2 = \mathcal{E}$

so $i_2 = \frac{\mathcal{E}}{R_2} = \frac{60.0\text{ V}}{25.0\ \Omega} = 2.40$ A.

SET UP: The rate of change of the current through the inductor is limited by the induced emf. Just after the switch is opened again the current through the inductor hasn't had time to change and is still $i_2 = 2.40$ A. The circuit is sketched in Figure 30.61b.



EXECUTE: The current through R_1 is $i_2 = 2.40$ A in the direction b to a.
Thus $v_{ab} = -i_2R_1 = -(2.40\text{ A})(40.0\ \Omega).$
$v_{ab} = -96.0$ V.

Figure 30.61b

(f) Point where current enters resistor is at higher potential; point b is at higher potential.

(g) $v_L - v_{R_1} - v_{R_2} = 0.$

$v_L = v_{R_1} + v_{R_2}.$

$v_{R_1} = -v_{ab} = 96.0$ V; $v_{R_2} = i_2R_2 = (2.40\text{ A})(25.0\ \Omega) = 60.0$ V.

Then $v_L = v_{R_1} + v_{R_2} = 96.0\text{ V} + 60.0\text{ V} = 156$ V.

As you travel counterclockwise around the circuit in the direction of the current, the voltage drops across each resistor, so it must rise across the inductor and point *d* is at higher potential than point *c*. The current is decreasing, so the induced emf in the inductor is directed in the direction of the current. Thus, $v_{cd} = -156\text{ V}$.

(h) Point *d* is at higher potential.

EVALUATE: The voltage across R_1 is constant once the switch is closed. In the branch containing R_2, just after S is closed the voltage drop is all across *L* and after a long time it is all across R_2. Just after S is opened the same current flows in the single loop as had been flowing through the inductor and the sum of the voltage across the resistors equals the voltage across the inductor. This voltage dies away, as the energy stored in the inductor is dissipated in the resistors.

30.62. IDENTIFY: Apply the loop rule to the two loops. The current through the inductor doesn't change abruptly.

SET UP: For the inductor $|\mathcal{E}| = L\left|\dfrac{di}{dt}\right|$ and $\mathcal{E}$ is directed to oppose the change in current.

EXECUTE: **(a)** Switch is closed, then at some later time

$$\frac{di}{dt} = 50.0\text{ A/s} \Rightarrow v_{cd} = L\frac{di}{dt} = (0.300\text{ H})(50.0\text{ A/s}) = 15.0\text{ V}.$$

<u>The top circuit loop:</u> $60.0\text{ V} = i_1 R_1 \Rightarrow i_1 = \dfrac{60.0\text{ V}}{40.0\ \Omega} = 1.50\text{ A}.$

<u>The bottom loop:</u> $60.0\text{ V} - i_2 R_2 - 15.0\text{ V} = 0 \Rightarrow i_2 = \dfrac{45.0\text{ V}}{25.0\ \Omega} = 1.80\text{ A}.$

(b) After a long time: $i_2 = \dfrac{60.0\text{ V}}{25.0\ \Omega} = 2.40\text{ A},$ and immediately when the switch is opened, the inductor maintains this current, so $i_1 = i_2 = 2.40\text{ A}.$

EVALUATE: The current through R_1 changes abruptly when the switch is closed.

30.63. IDENTIFY and SET UP: The circuit is sketched in Figure 30.63a. Apply the loop rule. Just after S_1 is closed, $i = 0$. After a long time *i* has reached its final value and $di/dt = 0$. The voltage across a resistor depends on *i* and the voltage across an inductor depends on di/dt.

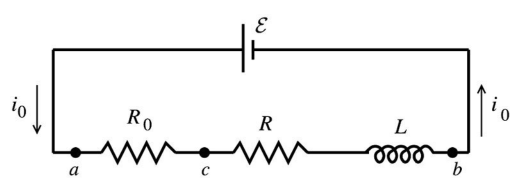


Figure 30.63a

EXECUTE: **(a)** At time $t = 0$, $i_0 = 0$ so $v_{ac} = i_0 R_0 = 0$. By the loop rule $\mathcal{E} - v_{ac} - v_{cb} = 0$ so $v_{cb} = \mathcal{E} - v_{ac} = \mathcal{E} = 36.0\text{ V}$. ($i_0 R = 0$ so this potential difference of 36.0 V is across the inductor and is an induced emf produced by the changing current.)

(b) After a long time $\dfrac{di_0}{dt} \to 0$ so the potential $-L\dfrac{di_0}{dt}$ across the inductor becomes zero. The loop rule gives $\mathcal{E} - i_0(R_0 + R) = 0.$

$$i_0 = \frac{\mathcal{E}}{R_0 + R} = \frac{36.0\text{ V}}{50.0\ \Omega + 150\ \Omega} = 0.180\text{ A}.$$

$v_{ac} = i_0 R_0 = (0.180\text{ A})(50.0\ \Omega) = 9.0\text{ V}.$

Thus $v_{cb} = i_0 R + L\dfrac{di_0}{dt} = (0.180\text{ A})(150\ \Omega) + 0 = 27.0\text{ V}.$ (Note that $v_{ac} + v_{cb} = \mathcal{E}$.)

(c) $\mathcal{E} - v_{ac} - v_{cb} = 0.$

$$\mathcal{E} - iR_0 - iR - L\frac{di}{dt} = 0.$$

$$L\frac{di}{dt} = \mathcal{E} - i(R_0 + R) \text{ and } \left(\frac{L}{R+R_0}\right)\frac{di}{dt} = -i + \frac{\mathcal{E}}{R+R_0}.$$

$$\frac{di}{-i + \mathcal{E}/(R+R_0)} = \left(\frac{R+R_0}{L}\right)dt.$$

Integrate from $t = 0$, when $i = 0$, to t, when $i = i_0$:

$$\int_0^{i_0} \frac{di}{-i + \mathcal{E}/(R+R_0)} = \frac{R+R_0}{L}\int_0^t dt = -\ln\left[-i + \frac{\mathcal{E}}{R+R_0}\right]_0^{i_0} = \left(\frac{R+R_0}{L}\right)t, \text{ so}$$

$$\ln\left(-i_0 + \frac{\mathcal{E}}{R+R_0}\right) - \ln\left(\frac{\mathcal{E}}{R+R_0}\right) = -\left(\frac{R+R_0}{L}\right)t.$$

$$\ln\left(\frac{-i_0 + \mathcal{E}/(R+R_0)}{\mathcal{E}/(R+R_0)}\right) = -\left(\frac{R+R_0}{L}\right)t.$$

Taking exponentials of both sides gives $\dfrac{-i_0 + \mathcal{E}/(R+R_0)}{\mathcal{E}/(R+R_0)} = e^{-(R+R_0)t/L}$ and $i_0 = \dfrac{\mathcal{E}}{R+R_0}(1 - e^{-(R+R_0)t/L}).$

Substituting in the numerical values gives $i_0 = \dfrac{36.0\text{ V}}{50\ \Omega + 150\ \Omega}(1 - e^{-(200\ \Omega/4.00\text{ H})t}) = (0.180\text{ A})(1 - e^{-t/0.020\text{ s}}).$

At $t \to 0, i_0 = (0.180\text{ A})(1-1) = 0$ (agrees with part (a)). At $t \to \infty, i_0 = (0.180\text{ A})(1-0) = 0.180\text{ A}$ (agrees with part (b)).

$$v_{ac} = i_0 R_0 = \frac{\mathcal{E}R_0}{R+R_0}(1 - e^{-(R+R_0)t/L}) = 9.0\text{ V}(1 - e^{-t/0.020\text{ s}}).$$

$$v_{cb} = \mathcal{E} - v_{ac} = 36.0\text{ V} - 9.0\text{ V}(1 - e^{-t/0.020\text{ s}}) = 9.0\text{ V}(3.00 + e^{-t/0.020\text{ s}}).$$

At $t \to 0, v_{ac} = 0, v_{cb} = 36.0\text{ V}$ (agrees with part (a)). At $t \to \infty, v_{ac} = 9.0\text{ V}, v_{cb} = 27.0\text{ V}$ (agrees with part (b)). The graphs are given in Figure 30.63b.

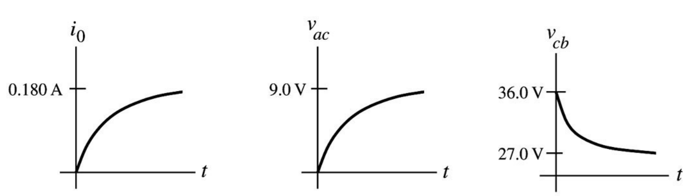

Figure 30.63b

EVALUATE: The expression for $i(t)$ we derived becomes $i = \dfrac{\mathcal{E}}{R}(1 - e^{-(R/L)t})$ if the two resistors R_0 and R in series are replaced by a single equivalent resistance $R_0 + R$.

30.64. **IDENTIFY:** Apply the loop rule. The current through the inductor doesn't change abruptly.

SET UP: With S_2 closed, v_{cb} must be zero.

EXECUTE: **(a)** Immediately after S_2 is closed, the inductor maintains the current $i = 0.180\text{ A}$ through R. The loop rule around the outside of the circuit yields

$\mathcal{E} + \mathcal{E}_L - iR - i_0 R_0 = 36.0\text{ V} + (0.18\text{ A})(150\ \Omega) - (0.18\text{ A})(150\ \Omega) - i_0(50\ \Omega) = 0.$ $i_0 = \dfrac{36\text{ V}}{50\ \Omega} = 0.720\text{ A}.$

$v_{ac} = (0.72\text{ A})(50\ \Omega) = 36.0\text{ V}$ and $v_{cb} = 0.$

(b) After a long time, $v_{ac} = 36.0\text{ V},$ and $v_{cb} = 0.$ Thus $i_0 = \dfrac{\mathcal{E}}{R_0} = \dfrac{36.0\text{ V}}{50\ \Omega} = 0.720\text{ A},$ $i_R = 0$ and

$i_{s2} = 0.720\text{ A}.$

(c) $i_0 = 0.720\text{ A},$ $i_R(t) = \dfrac{\mathcal{E}}{R_{\text{total}}} e^{-(R/L)t}$ and $i_R(t) = (0.180\text{ A})e^{-(37.5\text{ s}^{-1})t}.$

$i_{s2}(t) = (0.720\text{ A}) - (0.180\text{ A})e^{-(37.5\text{ s}^{-1})t} = (0.180\text{ A})(4 - e^{-(37.5\text{ s}^{-1})t}).$ The graphs of the currents are given in Figure 30.64.

EVALUATE: R_0 is in a loop that contains just $\mathcal{E}$ and $R_0,$ so the current through R_0 is constant. After a long time the current through the inductor isn't changing and the voltage across the inductor is zero. Since v_{cb} is zero, the voltage across *R* must be zero and i_R becomes zero.

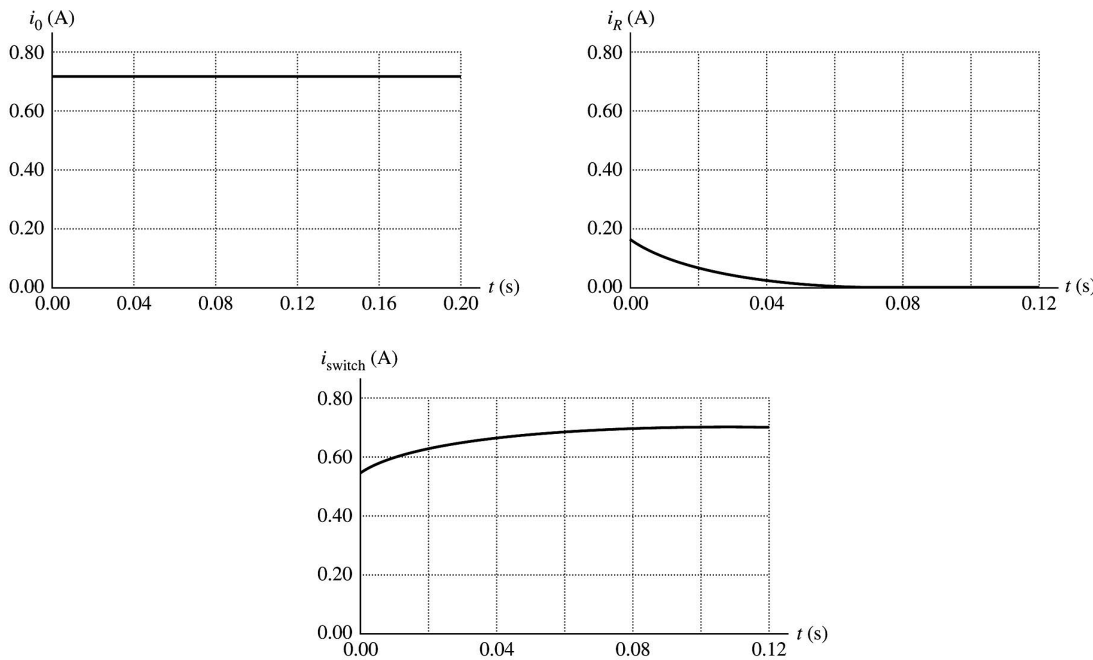

Figure 30.64

30.65. **IDENTIFY:** At $t = 0,$ $i = 0$ through each inductor. At $t \to \infty,$ the voltage is zero across each inductor.

SET UP: In each case redraw the circuit. At $t = 0$ replace each inductor by a break in the circuit and at $t \to \infty$ replace each inductor by a wire.

EXECUTE: **(a)** Just after the switch is closed there is no current through either inductor and they act like breaks in the circuit. The current is the same through the $40.0\text{-}\Omega$ and $15.0\text{-}\Omega$ resistors and is equal to $(25.0\text{ V})/(40.0\ \Omega + 15.0\ \Omega) = 0.455\text{ A}.$ $A_1 = A_4 = 0.455\text{ A};$ $A_2 = A_3 = 0.$

(b) After a long time the currents are constant, there is no voltage across either inductor, and each inductor can be treated as a short-circuit. The circuit is equivalent to the circuit sketched in Figure 30.65. $I = (25.0\text{ V})/(42.73\ \Omega) = 0.585\text{ A}.$ A_1 reads $0.585\text{ A}.$ The voltage across each parallel branch is $25.0\text{ V} - (0.585\text{ A})(40.0\ \Omega) = 1.60\text{ V}.$ A_2 reads $(1.60\text{ V})/(5.0\ \Omega) = 0.320\text{ A}.$ A_3 reads $(1.60\text{ V})/(10.0\ \Omega) = 0.160\text{ A}.$ A_4 reads $(1.60\text{ V})/(15.0\ \Omega) = 0.107\text{ A}.$

EVALUATE: Just after the switch is closed the current through the battery is 0.455 A. After a long time the current through the battery is 0.585 A. After a long time there are additional current paths, the equivalent resistance of the circuit is decreased and the current has increased.

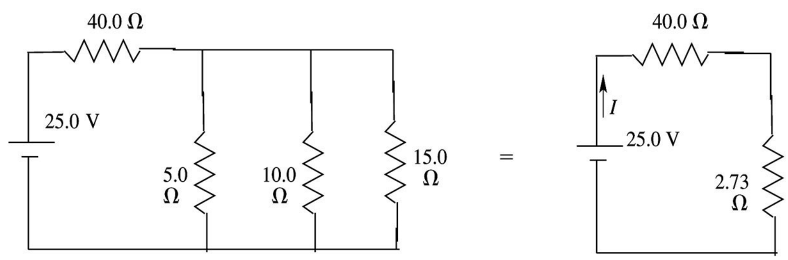

Figure 30.65

30.66. IDENTIFY: At steady state with the switch in position 1, no current flows to the capacitors and the inductors can be replaced by wires. Apply conservation of energy to the circuit with the switch in position 2.

SET UP: Replace the series combinations of inductors and capacitors by their equivalents.

EXECUTE: **(a)** At steady state $i = \dfrac{\mathcal{E}}{R} = \dfrac{75.0\text{ V}}{125\ \Omega} = 0.600\text{ A}.$

(b) The equivalent circuit capacitance of the two capacitors is given by $\dfrac{1}{C_s} = \dfrac{1}{25\ \mu\text{F}} + \dfrac{1}{35\ \mu\text{F}}$ and

$C_s = 14.6\ \mu\text{F}.$ $L_s = 15.0\text{ mH} + 5.0\text{ mH} = 20.0\text{ mH}.$ The equivalent circuit is sketched in Figure 30.66a.

Energy conservation: $\dfrac{q^2}{2C} = \dfrac{1}{2}Li_0^2.$ $q = i_0\sqrt{LC} = (0.600\text{ A})\sqrt{(20\times10^{-3}\text{ H})(14.6\times10^{-6}\text{ F})} = 3.24\times10^{-4}\text{ C}.$

As shown in Figure 30.66b, the capacitors have their maximum charge at $t = T/4$.

$t = \frac{1}{4}T = \frac{1}{4}(2\pi\sqrt{LC}) = \dfrac{\pi}{2}\sqrt{LC} = \dfrac{\pi}{2}\sqrt{(20\times10^{-3}\text{ H})(14.6\times10^{-6}\text{ F})} = 8.49\times10^{-4}\text{ s}.$

EVALUATE: With the switch closed the battery stores energy in the inductors. This then is the energy in the *L*-*C* circuit when the switch is in position 2.

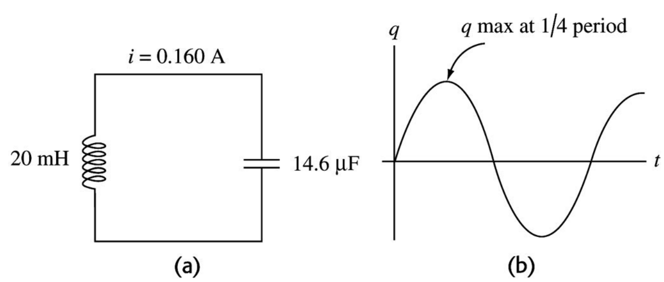

Figure 30.66

30.67. IDENTIFY and **SET UP:** Kirchhoff's loop rule applies, the emf across an inductor is $\mathcal{E}_L = -L\dfrac{di}{dt}$, the potential across a resistor is $V = Ri$, and the time constant for an *L*-*R* circuit is $\tau = L/R$.

EXECUTE: **(a)** First find the current as a function of time. The inductor has a resistance R_L which is in series with the 10.0-Ω resistor *R*. Apply Kirchhoff's loop rule to the circuit: $\mathcal{E} - iR - iR_L - L\dfrac{di}{dt} = 0.$

Now separate variables and integrate.

$$\int_0^t -\frac{R+R_L}{L}dt' = \int_0^i \frac{di'}{i' - \varepsilon/(R+R_L)}.$$

$$-\frac{R+R_L}{L}t = \ln\left(\frac{i-\mathcal{E}/(R+R_L)}{-\mathcal{E}/(R+R_L)}\right).$$

$$i = \frac{\mathcal{E}}{R+R_L}(1-e^{-(R+R_L)t/L}).$$

The potential across the inductor is the sum of the potential due to the resistance and the potential due to the inductance, so $v_L = iR_L + L\,di/dt$. Using the equation we just found for the current i and taking $L\,di/dt$, we get $v_L = iR_L + L\frac{di}{dt} = \left[\frac{\mathcal{E}}{R+R_L}(1-e^{-(R+R_L)t/L})\right]R_L + \mathcal{E}e^{-(R+R_L)t/L}$.

Collecting terms and taking out common factors, the result is $v_L = \frac{\mathcal{E}}{R+R_L}(R_L + Re^{-(R+R_L)t/L})$.

(b) Initially there is no current in the circuit due to the inductor, so the potential across the resistance R is zero. Therefore the potential across the inductor is equal to the emf of the battery.

$v_L(0) = \frac{\mathcal{E}}{R+R_L}(R_L+R) = \mathcal{E} = 50.0$ V.

(c) As $t \to \infty$, we know that $v_L = 20.0$ V. So $v_R = \mathcal{E} - v_L = 50.0\text{ V} - 20.0\text{ V} = 30.0$ V. The current in R is therefore $i = (30.0\text{ V})/(10.0\ \Omega) = 3.00$ A, which is also the current in the circuit.

(d) As $t \to \infty$, the potential across the inductor is due only to its resistance R_L, the potential across it is 20.0 V, and the current through it is 3.00 A. Therefore $R_L = (20.0\text{ V})/(3.00\text{ A}) = 6.67\ \Omega$.

(e) The time constant for this circuit is $\tau = L/(R+R_L)$. Using the equation derived in (a) for v_L, at the end of one time constant v_L is $v_L = \frac{\mathcal{E}}{R+R_L}(R_L + Re^{-1}) = \frac{50.0\text{ V}}{16.67\ \Omega}\left[6.67\,\Omega + (10.0\,\Omega)e^{-1}\right] = 31.0\text{ V}.$

From the graph shown with the problem in the textbook, we read that $t = 2.4$ ms when $v_L = 31.0$ V. So the time constant is 2.4 ms. Solving $\tau = L/(R+R_L)$ for L gives

$L = \tau(R+R_L) = (2.4\text{ ms})(10.0\ \Omega + 6.67\ \Omega) = 40$ mH.

EVALUATE: In this case, the resistance of the inductor is close to the external resistance in the circuit, so it is significant and cannot be ignored.

30.68. **IDENTIFY** and **SET UP:** The current grows in the circuit after the switch is closed. In an R-L circuit the full emf initially is across the inductance and after a long time is totally across the resistance because the inductor opposes changes in the current through it. A solenoid in a circuit is represented as a resistance in series with an inductance. Apply the loop rule to the circuit; the voltage across a resistance is given by Ohm's law, and emf across an inductor is $\mathcal{E}_L = -L\frac{di}{dt}$.

EXECUTE: **(a)** In the R-L circuit the voltage across the resistor starts at zero and increases to the battery voltage. The voltage across the solenoid (inductor) starts at the battery voltage and decreases to zero. As $t \to \infty$ the current in the circuit approaches its final, steady-state value. The final voltage across the solenoid is iR_L, where I is the final current in the circuit. The potential across the external resistor R is 25.0 V after the switch has been closed for a very long time, which is when steady-state has been achieved. Using $V_R = iR$ and $i = \frac{\mathcal{E}}{R+R_L}$ gives $V_R = \frac{\mathcal{E}}{R+R_L}R$. Solving for R_L gives

$R_L = R\left(\frac{\mathcal{E}}{V_R} - 1\right) = (50.0\ \Omega)\left(\frac{25.0\text{ V}}{25.0\text{ V}} - 1\right) = 0.$ The solenoid has no appreciable resistance.

(b) Kirchhoff's loop rule gives $\mathcal{E} - iR - L\frac{di}{dt} = 0.$ Separating variables and integrating gives

$$\int_0^i \frac{di'}{i' - \mathcal{E}/R} = -\int_0^t \frac{R}{L}dt' \qquad \rightarrow \qquad \ln\left(\frac{i - \mathcal{E}/R}{-\mathcal{E}/R}\right) = -\frac{R}{L}t.$$

$$i = \frac{\mathcal{E}}{R}(1 - e^{-Rt/L}) \qquad \rightarrow \qquad v_R = \mathcal{E}(1 - e^{-Rt/L}).$$

(c) At the end of the first time constant, we have $\mathcal{E}(1 - e^{-Rt/L}) = \mathcal{E}(1 - e^{-1})$ = (24.0 V)(1 – 1/*e*) = 15.8 V.

From the graph with the problem in the text, we determine that when v_R = 15.8 V, t = 8.0 ms, so the time constant is τ = 8.0 ms. Using $\tau = L/R$, we have $L = \tau R$ = (8.0 ms)(50.0 Ω) = 0.40 H.

(d) At steady-state the current is (25.0 V)/(50.0 Ω) = 0.500 A. The energy stored in the inductor is $U_L = \frac{1}{2}Li^2$ = (1/2)(0.40 H)(0.500 A)^2 = 0.050 J = 50 mJ.

EVALUATE: We found that the resistance of the inductor is zero. However that really just means that it is much less than the external resistance of 50.0 Ω, so it does not affect the measurements. In reality every inductor has *some* resistance since it is made out of real metal.

30.69. IDENTIFY: This problem deals with a solenoid that is within another solenoid.

SET UP: $B = \mu_0 nI$, $\Phi_B = BA\cos\phi = BA$ since the fields are uniform within an ideal solenoid. Refer to Fig. P30.69 in the textbook for the quantities involved.

EXECUTE: **(a)** We want the flux through the inner coil. The magnetic fields due to both solenoids point in the same direction, so $\Phi_{\text{in}} = B_1A_2 - B_2A_2 = \mu_0 In_1\pi a^2 - \mu_0 In_2\pi a^2$. Using $n = N/\lambda$ this reduces to $\Phi_{\text{in}} = \dfrac{\mu_0 I(N_1 - N_2)\pi a^2}{\lambda}$.

(b) We want the flux through the outer coil. $\Phi_{\text{out}} = B_1A_1 - B_2A_2 = \mu_0 In_1\pi b^2 - \mu_0 In_2\pi a^2$, which reduces to $\Phi_{\text{out}} = \dfrac{\mu_0 I\pi}{\lambda}(N_1b^2 - N_2a^2)$.

(c) We want L. $\Phi_{\text{in}} = B_1A_2 - B_2A_2 = \mu_0 In_1\pi a^2 - \mu_0 In_2\pi a^2$ and $\Phi_{\text{out}} = B_1A_1 - B_2A_2 = \mu_0 In_1\pi b^2 - \mu_0 In_2\pi a^2$, which reduce to $\Phi_{\text{in}} = \dfrac{\mu_0 I(N_1 - N_2)\pi a^2}{\lambda}$ and $\Phi_{\text{out}} = \dfrac{\mu_0 I\pi}{\lambda}(N_1b^2 - N_2a^2)$. The self-inductance is $L = \dfrac{\Phi_B}{I} = \dfrac{N_1\Phi_{\text{out}} + N_2\Phi_{\text{in}}}{I}$. Using the fluxes and simplifying gives $L = \dfrac{\mu_0\pi}{\lambda}(N_1^2b^2 - N_2^2a^2)$.

(d) We want the self-inductance if the inner current is reversed. In this case, B_2 reverses direction. $L = \dfrac{\Phi_B}{I} = \dfrac{N_1\Phi_{\text{out}} + N_2\Phi_{\text{in}}}{I}$. Substituting the fluxes with B_2 reversed and simplifying gives

$$L = \frac{\mu_0\pi}{\lambda}(N_1^2b^2 + 2N_1N_2a^2 + N_2^2a^2).$$

(e) We want L for the original configuration. Using $L = \dfrac{\mu_0\pi}{\lambda}(N_1^2b^2 - N_2^2a^2)$ with the same numbers gives L = 10.3 mH.

(f) We want L for the reversed configuration. Using $L = \dfrac{\mu_0\pi}{\lambda}(N_1^2b^2 + 2N_1N_2a^2 + N_2^2a^2)$ with λ = 20.0 cm, a = 1.00 cm, b = 2.00 cm, N_1 = 1200 turns, and N_2 = 750 turns, we get L = 16.0 mH.

EVALUATE: In case (d) if a = 0 (no inner coil), $L = \dfrac{\mu_0\pi}{\lambda}(N_1^2b^2) = \dfrac{\mu_0\pi b^2N_1^2}{\lambda}$, which is just the formula for the self-inductance of a single solenoid.

30.70. **IDENTIFY:** Apply $L = \dfrac{N\Phi_B}{i}$ to calculate L.

SET UP: In the air the magnetic field is $B_{\text{Air}} = \dfrac{\mu_0 Ni}{W}$. In the liquid, $B_{\text{L}} = \dfrac{\mu Ni}{W}$.

EXECUTE: **(a)** $\Phi_B = BA = B_{\text{L}}A_{\text{L}} + B_{\text{Air}}A_{\text{Air}} = \dfrac{\mu_0 Ni}{W}[(D-d)W] + \dfrac{K\mu_0 Ni}{W}(dW) = \mu_0 Ni[(D-d)+Kd]$.

$$L = \frac{N\Phi_B}{i} = \mu_0 N^2[(D-d)+Kd] = L_0 - L_0\frac{d}{D} + L_{\text{f}}\frac{d}{D} = L_0 + \left(\frac{L_{\text{f}}-L_0}{D}\right)d.$$

$$d = \left(\frac{L-L_0}{L_{\text{f}}-L_0}\right)D, \text{ where } L_0 = \mu_0 N^2 D, \text{ and } L_{\text{f}} = K\mu_0 N^2 D.$$

(b) and **(c)** Using $K = \chi_{\text{m}} + 1$ we can find the inductance for any height $L = L_0\left(1 + \chi_{\text{m}}\dfrac{d}{D}\right)$.

Height of Fluid	Inductance of Liquid Oxygen	Inductance of Mercury
$d = D/4$	0.63024 H	0.63000 H
$d = D/2$	0.63048 H	0.62999 H
$d = 3D/4$	0.63072 H	0.62999 H
$d = D$	0.63096 H	0.62998 H

The values $\chi_{\text{m}}(O_2) = 1.52\times10^{-3}$ and $\chi_{\text{m}}(\text{Hg}) = -2.9\times10^{-5}$ have been used.

EVALUATE: **(d)** The volume gauge is much better for the liquid oxygen than the mercury because there is an easily detectable spread of values for the liquid oxygen, but not for the mercury.

30.71. **IDENTIFY:** Apply Kirchhoff's loop rule to the to and bottom branches of the circuit.

SET UP: Just after the switch is closed the current through the inductor is zero and the charge on the capacitor is zero.

EXECUTE: **(a)** $\mathcal{E} - i_1R_1 - L\dfrac{di_1}{dt} = 0 \Rightarrow i_1 = \dfrac{\mathcal{E}}{R_1}(1 - e^{-(R_1/L)t})$.

$$\mathcal{E} - i_2R_2 - \frac{q_2}{C} = 0 \Rightarrow -\frac{di_2}{dt}R_2 - \frac{i_2}{C} = 0 \Rightarrow i_2 = \frac{\mathcal{E}}{R_2}e^{-(1/R_2C)t}.$$

$$q_2 = \int_0^t i_2 dt' = -\frac{\mathcal{E}}{R_2}R_2Ce^{-(1/R_2C)t'}\Big|_0^t = \mathcal{E}C(1 - e^{-(1/R_2C)t}).$$

(b) $i_1(0)\dfrac{\mathcal{E}}{R_1}(1-e^0) = 0, i_2 = \dfrac{\mathcal{E}}{R_2}e^0 = \dfrac{48.0\text{ V}}{5000\ \Omega} = 9.60\times10^{-3}$ A.

(c) As $t \to \infty$: $i_1(\infty) = \dfrac{\mathcal{E}}{R_1}(1-e^{-\infty}) = \dfrac{\mathcal{E}}{R_1} = \dfrac{48.0\text{ V}}{25.0\ \Omega} = 1.92$ A, $i_2 = \dfrac{\mathcal{E}}{R_2}e^{-\infty} = 0$. A good definition of a "long time" is many time constants later.

(d) $i_1 = i_2 \Rightarrow \dfrac{\mathcal{E}}{R_1}(1-e^{-(R_1/L)t}) = \dfrac{\mathcal{E}}{R_2}e^{-(1/R_2C)t} \Rightarrow (1-e^{-(R_1/L)t}) = \dfrac{R_1}{R_2}e^{-(1/R_2C)t}$. Expanding the exponentials like $e^x = 1 + x + \dfrac{x^2}{2} + \dfrac{x^3}{3!} + \ldots$, we find: $\dfrac{R_1}{L}t - \dfrac{1}{2}\left(\dfrac{R_1}{L}\right)^2 t^2 + \ldots = \dfrac{R_1}{R_2}\left(1 - \dfrac{t}{RC} + \dfrac{t^2}{2R^2C^2} - \ldots\right)$ and

$t\left(\dfrac{R_1}{L} + \dfrac{R_1}{R_2{}^2C}\right) + O(t^2) + \ldots = \dfrac{R_1}{R_2}$, if we have assumed that $t << 1$. Therefore:

$$t \approx \frac{1}{R_2}\left(\frac{1}{(1/L)+(1/R_2^2C)}\right) = \left(\frac{LR_2C}{L+R_2^2C}\right) = \left(\frac{(8.0\text{ H})(5000\ \Omega)(2.0\times10^{-5}\text{ F})}{8.0\text{ H} + (5000\ \Omega)^2(2.0\times10^{-5}\text{ F})}\right) = 1.6\times10^{-3}\text{s}.$$

(e) At $t = 1.57\times10^{-3}$ s: $i_1 = \dfrac{\mathcal{E}}{R_1}(1-e^{-(R_1/L)t}) = \dfrac{48\text{ V}}{25\ \Omega}(1-e^{-(25/8)t}) = 9.4\times10^{-3}$ A.

(f) We want to know when the current is half its final value. We note that the current i_2 is very small to begin with, and just gets smaller, so we ignore it and find:

$$i_{1/2} = 0.960\text{ A} = i_1 = \frac{\mathcal{E}}{R_1}(1-e^{-(R_1/L)t}) = (1.92\text{ A})(1-e^{-(R_1/L)t}).$$

$$e^{-(R_1/L)t} = 0.500 \Rightarrow t = -\frac{L}{R_1}\ln(0.5) = -\frac{8.0\text{ H}}{25\ \Omega}\ln(0.5) = 0.22\text{ s}.$$

EVALUATE: i_1 is initially zero and rises to a final value of 1.92 A. i_2 is initially 9.60 mA and falls to zero, q_2 is initially zero and rises to $q_2 = \mathcal{E}C = 960\ \mu$C.

30.72. **IDENTIFY** and **SET UP:** Apply $L = \dfrac{N\Phi_B}{i}$ to calculate L, then solve for the number of turns N. Treat the solenoid as being ideal.

EXECUTE: $L = \dfrac{N\Phi}{i} = \dfrac{N\mu_0 inA}{i} = \dfrac{\mu_0 N^2 A}{l}$. $N = \sqrt{\dfrac{Ll}{\mu_0 A}} = \sqrt{\dfrac{(4.4\text{ H})(2\text{ m})}{\mu_0\pi(0.5\text{ m})^2}} = 3000$, which is choice (b).

EVALUATE: This solenoid is far from ideal since its diameter is half its length, but we can get a rough estimate of the number of coils.

30.73. **IDENTIFY** and **SET UP:** The current in the circuit is $i = i_0 e^{-Rt/L}$. Solve for the time t_{half} for the current to reach one-half its original value.

EXECUTE: $i_0/2 = i_0 e^{-Rt/L}$, so $t_{\text{half}} = (L/R)\ln 2 = [(4.4\text{ H})/(0.005\ \Omega)]\ln 2 = 610\text{ s} \approx 10$ min, choice (b).

EVALUATE: This result is true if no more of the magnet loses its superconductivity. If more of it does so, the time will be less than this because R will be greater.

30.74. **IDENTIFY** and **SET UP:** In Problem 30.73, we saw that $t_{\text{half}} = (L/R)\ln 2$.

EXECUTE: The resistance is increasing, and t_{half} is inversely proportional to R, so the time will be shorter, which is choice (a).

EVALUATE: How much shorter the time will be will depend on how fast the magnet is losing its superconductivity.

30.75. **IDENTIFY:** The magnetic energy stored in the magnet is converted into thermal energy which evaporates the liquid helium.

SET UP: The magnetic energy is $U_L = \frac{1}{2}Li^2$. The heat Q to evaporate a mass m of liquid is $Q = mL_v$.

EXECUTE: $\frac{1}{2}Li^2 = mL_v$. Solving for m gives

$m = Li^2/2L_v = (4.4\text{ H})(750\text{ A})^2/[2(20900\text{ J/kg})] = 59\text{ kg} \approx 60$ kg, which is choice (c).

EVALUATE: This is a lot of liquid helium! It is important to avoid quenches!

31

ALTERNATING CURRENT

VP31.3.1. **IDENTIFY:** We are investigating an inductor in an ac circuit.

SET UP: $X_L = \omega L.$

EXECUTE: **(a)** We want the inductive reactance. $X_L = \omega L = 2\pi fL$ = 2π(108 Hz)(2.50 mH) = 1.70 MΩ.

(b) We want the current amplitude. $I_L = \dfrac{V_L}{X_L} =$ (4.20 kV)/(1.70 MΩ) = 2.48 mA.

EVALUATE: The answer in (b) is the current amplitude, but the current does not always have this value since it varies sinusoidally.

VP31.3.2. **IDENTIFY:** This is an ac circuit containing a resistor and a capacitor.

SET UP: The current is of the form $i(t) = I\cos\omega t,\ \ X_C = 1/\omega C.$

EXECUTE: **(a)** We want $v_R(t)$. $v_R = Ri = R\,I\cos\omega t$ = (125 V)(2.40 mA) cos(1750 rad/s t) = (0.300 V)cos(1750 rad/s t).

(b) We want X_C. $X_C = 1/\omega C$ = 1/[(1750 rad/s)(7.00 μF)] = 81.6 Ω.

(c) We want $v_C(t)$. v_C lags the current by π/2, so

$v_C = V_C\cos(\omega t - \pi/2) = IX_C\cos(\omega t - \pi/2) = (2.40\text{ mA})(81.6\ \Omega)\cos(1750\text{ rad/s }t - \pi/2)$

$= (0.196\text{ V})\cos[(1750\text{ rad/s})t - \pi/2].$

EVALUATE: There is a π/2 phase different between v_C and i because when i is a maximum the capacitor is uncharged.

VP31.3.3. **IDENTIFY:** We have a resistor and capacitor in an ac circuit.

SET UP: $X_C = 1/\omega C,\ \ \omega = 2\pi f$, and $X_C = R$ in this case.

EXECUTE: **(a)** We want the frequency. $X_C = R$, so $X_C = 1/\omega C = R.$ $\omega = 2\pi f$, so $f = \dfrac{1}{2\pi RC}$. This gives f = 1/[2π(155 Ω)(8.00 μF)] = 128 Hz.

(b) We want the amplitudes. $V_R = RI$ = (155 Ω)(4.00 mA) = 0.620 V. $V_C = IX_C$ = 0.620 V since $X_C = R$

(c) v_C lags v_R by π/2 so when v_R is a maximum, v_C = 0. When v_C is a maximum, v_R = 0 because of the π/2 phase difference.

EVALUATE: Minimum current mean s no potential across R but maximum potential across C.

VP31.3.4. **IDENTIFY:** We have a resistor and capacitor in an ac circuit.

SET UP and **EXECUTE:** **(a)** We want the current amplitude. $I = V/R$ = (2.45 V)/(115 Ω) = 21.3 mA.

(b) What is I at t = 3.50 ms? i is a maximum at t = 0, so $i = I\cos\omega t$. Using I = 21.3 mA and the given quantities gives i = 11.5 mA.

(c) We want V_C. When $i = 0$, $v_R = 0$, so $v_C = V_C$ and is equal to V_R which is 2.45 V.

(d) We want C. $V_C = IX_C = I/C$. $C = \dfrac{I}{\omega V_C}$ = (21.3 mA)/[(5100 rad/s)(2.45 V)] = 1.71 μF.

EVALUATE: When $v_R = 0$, $v_C = V_C$ and when $v_C = 0$, $v_R = V_R$ and $V_R = V_C$ but $v_R \neq v_C$.

VP31.5.1. **IDENTIFY:** We have an *L-R-C* series ac circuit.

SET UP: $X_L = \omega L$, $X_C = 1/\omega C$, $Z = \sqrt{R^2 + (X_L - X_C)^2}$, $\tan\phi = \dfrac{X_L - X_C}{R}$, $\omega = 2\pi f$.

EXECUTE: **(a)** We want f. $X_L = \omega L = 2\pi fL = R$. $f = R/2\pi L$ = (255 Ω)[2π(4.50 mH)] = 9020 Hz.

(b) We want the impedance. Use $Z = \sqrt{R^2 + (X_L - X_C)^2}$ with $X_L = R$, $X_C = 1/\omega C$, and $\omega = 2\pi f$ = 56,670 rad/s. This gives X_C = 6.64 Ω. Put these values into the equation for Z giving Z = 356 Ω.

(c) We want the current amplitude. $I = V/Z$ = (55.0 V)/(356 Ω) = 0.154 A.

(d) We want ϕ. $\tan\phi = \dfrac{X_L - X_C}{R}$ = (255 Ω – 6.64 Ω)/(255 Ω), so ϕ = 44.2°.

(e) Since ϕ is positive, the voltage *leads* the current.

EVALUATE: The resistance never changes but the impedance depends on the frequency.

VP31.5.2. **IDENTIFY:** We have an *L-R-C* series ac circuit.

SET UP: $X_L = \omega L$, $X_C = 1/\omega C$, $Z = \sqrt{R^2 + \left(\omega L - \dfrac{1}{\omega C}\right)^2}$.

EXECUTE: **(a)** We want R. Calculate ωL and $1/\omega C$ from the given quantities, which gives ωL = 35.1 Ω and $1/\omega C$ = 308.6 Ω. Solve $Z = \sqrt{R^2 + \left(\omega L - \dfrac{1}{\omega C}\right)^2}$ for R using the known Z.

The result is R = 387 Ω.

(b) We want the current amplitude. $I = V/Z$ = (20.0 V)/(474 Ω) = 0.0422 A = 42.2 mA.

(c) We want V_R. $V_R = RI$ = (387 Ω)(0.0422 A) = 16.3 V.

(d) We want V_L. $V_L = IX_L$ = (0.0422 A)(35.1 Ω) = 1.48 V.

(e) We want V_C. $V_C = IX_C$ = (0.0422 A)(308.6 Ω) = 13.0 V.

EVALUATE: Note that the amplitudes do *not* add up to the voltage amplitude. This is not a problem because these amplitudes do not all occur at the same time due to phase differences.

VP31.5.3. **IDENTIFY:** We are dealing with an *L-R-C* series ac circuit.

SET UP: $\tan\phi = \dfrac{X_L - X_C}{R}$, $X_L = \omega L$, $X_C = 1/\omega C$.

EXECUTE: **(a)** We want $X_L - X_C$. Solve $\tan\phi = \dfrac{X_L - X_C}{R}$. $X_L - X_C$ = (65.0 Ω)tan 15.0° = 17.4 Ω.

(b) We want L. X_L = 17.4 Ω + X_C. Use $X_L = \omega L$ and $X_C = 1/\omega C$ and solve for L, giving $L = \dfrac{17.4\ \Omega\ + 1/\omega C}{\omega}$. Using the given values gives L = 8.65 mH.

EVALUATE: If we wanted the current to lead the voltage, we would need $X_L - X_C$ to be negative, so we would need $X_C > X_L$.

VP31.5.4. **IDENTIFY:** This problem involves an *L-R-C* series ac circuit.

SET UP and **EXECUTE:** **(a)** We want the voltage amplitudes.

$V_R = IR$ = (0.120 A)(95.0 Ω) = 11.4 V.

$V_L = IX_L = I\omega L$ = (0.120 A)(8000 rad/s)(6.50 mH) = 6.24 V.

$V_C = IX_C = I/\omega C$ = (0.120 A)/[(8000 rad/s)(0.440 μF)] = 34.1 V.

(b) We want the instantaneous voltages at $t = 0.305$ ms. The current is a maximum at $t = 0$, so $i(t) = I\cos\omega t$. Use the voltage amplitudes from part (a).

$v_R = Ri = RI\cos\omega t = (11.4\text{ V})\cos[(8000\text{ rad/s})(0.305\text{ ms})] = -8.71$ V.

v_L leads the current by $\pi/2$ so $v_L = V_L\cos(\omega t + \pi/2)$ = (6.24 V) cos[(8000 rad/s)(0.305 s) + π/2)] = –4.03 V.

v_C lags the current by $\pi/2$ so $v_C = V_C\cos(\omega t - \pi/2)$ = 22.0 V.

EVALUATE: Note that the voltage amplitudes add upto 51.7 V while the instantaneous voltages add up to 9.26 V. The instantaneous voltages all occur at the same time (0.305 s), but the voltage amplitudes do not.

VP31.7.1. **IDENTIFY:** We are dealing with power in an ac circuit.

SET UP and **EXECUTE:** The toaster is a pure resistor. **(a)** We want the average power. $P_{av} = V_{rms}I_{rms}$ = (120 V)(3.95 A) = 474 W.

(b) We want the maximum power. $P_{max} = 2P_{av}$ = 948 W.

(c) We want R. $P_{av} = I_{rms}^2 R$, so $R = P_{av}/I_{rms}^2$ = (474 W)/(3.95 A)^2 = 30.4 Ω.

EVALUATE: Check: $P_{max} = I_{max}V_{max} = \left(I_{rms}\sqrt{2}\right)\left(V_{rms}\sqrt{2}\right) = 2I_{rms}V_{rms} = 2P_{av}$. It's OK.

VP31.7.2. **IDENTIFY:** We have an L-R-C series ac circuit.

SET UP: $X_L = \omega L$, $X_C = 1/\omega C$, $\tan\phi = \dfrac{X_L - X_C}{R}$, power factor = $\cos\phi$.

EXECUTE: **(a)** We want X_L and X_C. $X_L = \omega L$ = (1300 rad/s)(82.3 mH) = 107 Ω.

$X_C = 1/\omega C$ = 1/[(1300 rad/s)(1.10 μF)] = 699 Ω.

(b) We want ϕ. $\phi = \arctan\left(\dfrac{X_L - X_C}{R}\right)$ = (107 Ω – 699 Ω)/(275 Ω) = –65.1°.

(c) We want the power factor. cos ϕ = cos(–65.1°) = 0.421.

EVALUATE: Since ϕ is negative, the voltage lags the current by 65.1°.

VP31.7.3. **IDENTIFY:** We have an L-R-C series ac circuit.

SET UP: $Z = \sqrt{R^2 + (X_L - X_C)^2}$, $X_L = \omega L$, $X_C = 1/\omega C$.

EXECUTE: **(a)** We want the impedance. $X_L = \omega L$ = (1300 rad/s)(1.10 μF) = 107 Ω.

$X_C = 1/\omega C$ = 1/[(1300 rad/s)(1.10 μF)] = 699 Ω. Now use $Z = \sqrt{R^2 + (X_L - X_C)^2}$ with the above values, giving Z = 653 Ω.

(b) We want the current amplitude. $I = V/Z$ = (35.0 V)/(653 Ω) = 53.6 mA.

(c) We want the average power in the resistor. $P_{av} = \dfrac{1}{2}IV_R = \dfrac{1}{2}I^2R$ = (0.0536 A)^2(275 Ω)/2 = 0.395 W.

EVALUATE: The average power is *not* I^2R because the current is not equal to its maximum value I all the time; it is usually less than this value. That's where the factor of ½ comes from in part (c).

VP31.7.4. **IDENTIFY:** This problem involves power in an ac series circuit.

SET UP: $X_L = \omega L$, $X_C = 1/\omega C$, $\tan\phi = \dfrac{X_L - X_C}{R}$, power factor = $\cos\phi$.

EXECUTE: **(a)** We want the reactances. Using the given quantities, the results are $X_C = 1/\omega C$ = 85.5 Ω, $X_L = \omega L$ = 97.5 Ω.

(b) We want ϕ. $\cos\phi$ = power factor = 0.800, so ϕ = 36.9°.

(c) We want R. Solve $\tan\phi = \dfrac{X_L - X_C}{R}$ for R, giving $R = \dfrac{X_L - X_C}{\tan\phi}$ = (97.8 Ω – 85.5 Ω)/tan 36.9° = 16.0 Ω.

EVALUATE: Since $X_L > X_C$, ϕ is positive.

31.1. **IDENTIFY:** The maximum current is the current amplitude, and it must not ever exceed 1.50 A.

SET UP: $I_{\text{rms}} = I/\sqrt{2}$. I is the current amplitude, the maximum value of the current.

EXECUTE: $I = 1.50\text{A}$ gives $I_{\text{rms}} = \dfrac{1.50\text{ A}}{\sqrt{2}} = 1.06\text{ A}.$

EVALUATE: The current amplitude is larger than the root-mean-square current.

31.2. **IDENTIFY** and **SET UP:** Apply $V_{\text{rms}} = \dfrac{V}{\sqrt{2}}.$

EXECUTE: **(a)** $V_{\text{rms}} = \dfrac{V}{\sqrt{2}} = \dfrac{45.0\text{ V}}{\sqrt{2}} = 31.8\text{ V}.$

(b) Since the voltage is sinusoidal, the average is zero.

EVALUATE: The voltage amplitude is larger than V_{rms}.

31.3. **IDENTIFY:** We want the phase angle for the source voltage relative to the current, and we want the inductance if we know the current amplitude.

SET UP: $X_L = \dfrac{V}{I}$ and $X_L = 2\pi fL.$

EXECUTE: **(a)** $\phi = +90°.$ The source voltage leads the current by $90°.$

(b) $X_L = \dfrac{V}{I} = \dfrac{45.0\text{ V}}{3.90\text{ A}} = 11.54\;\Omega.$ Solving $X_L = 2\pi fL$ for f gives

$$f = \frac{X_L}{2\pi L} = \frac{11.54\;\Omega}{2\pi(9.50\times10^{-3}\text{ H})} = 193\text{ Hz}.$$

EVALUATE: The angular frequency is about $1200\text{ rad/s}.$

31.4. **IDENTIFY:** We want the phase angle for the source voltage relative to the current, and we want the capacitance if we know the current amplitude.

SET UP: $X_C = \dfrac{V}{I}$ and $X_C = \dfrac{1}{2\pi fC}.$

EXECUTE: **(a)** $\phi = -90°.$ The source voltage lags the current by $90°.$

(b) $X_C = \dfrac{V}{I} = \dfrac{60.0\text{ V}}{5.30\text{ A}} = 11.3\;\Omega.$ Solving $X_C = \dfrac{1}{2\pi fC}$ for C gives

$$C = \frac{1}{2\pi fX_C} = \frac{1}{2\pi(80.0\text{ Hz})(11.3\;\Omega)} = 1.76\times10^{-4}\text{ F}.$$

EVALUATE: This is a $176\text{-}\mu\text{F}$ capacitor, which is not unreasonable.

31.5. **IDENTIFY** and **SET UP:** Use $X_L = \omega L$ and $X_C = \dfrac{1}{\omega C}.$

EXECUTE: **(a)** $X_L = \omega L = 2\pi fL = 2\pi(80.0\text{ Hz})(3.00\text{ H}) = 1510\;\Omega.$

(b) $X_L = 2\pi fL$ gives $L = \dfrac{X_L}{2\pi f} = \dfrac{120\;\Omega}{2\pi(80.0\text{ Hz})} = 0.239\text{ H}.$

(c) $X_C = \dfrac{1}{\omega C} = \dfrac{1}{2\pi fC} = \dfrac{1}{2\pi(80.0\text{ Hz})(4.00\times10^{-6}\text{ F})} = 497\;\Omega.$

(d) $X_C = \dfrac{1}{2\pi fC}$ gives $C = \dfrac{1}{2\pi fX_C} = \dfrac{1}{2\pi(80.0\text{ Hz})(120\ \Omega)} = 1.66\times10^{-5}$ F.

EVALUATE: X_L increases when L increases; X_C decreases when C increases.

31.6. **IDENTIFY:** The reactance of capacitors and inductors depends on the angular frequency at which they are operated, as well as their capacitance or inductance.

SET UP: The reactances are $X_C = 1/\omega C$ and $X_L = \omega L$.

EXECUTE: **(a)** Equating the reactances gives $\omega L = \dfrac{1}{\omega C} \Rightarrow \omega = \dfrac{1}{\sqrt{LC}}$.

(b) Using the numerical values we get $\omega = \dfrac{1}{\sqrt{LC}} = \dfrac{1}{\sqrt{(5.00\text{ mH})(3.50\ \mu\text{F})}} = 7560$ rad/s.

$$X_C = X_L = \omega L = (7560\text{ rad/s})(5.00\text{ mH}) = 37.8\ \Omega.$$

EVALUATE: At other angular frequencies, the two reactances could be very different.

31.7. **IDENTIFY:** The reactance of an inductor is $X_L = \omega L = 2\pi fL$. The reactance of a capacitor is $X_C = \dfrac{1}{\omega C} = \dfrac{1}{2\pi fC}$.

SET UP: The frequency f is in Hz.

EXECUTE: **(a)** At 60.0 Hz, $X_L = 2\pi(60.0\text{ Hz})(0.450\text{ H}) = 170\ \Omega$. X_L is proportional to f so at 600 Hz, $X_L = 1700\ \Omega$.

(b) At 60.0 Hz, $X_C = \dfrac{1}{2\pi(60.0\text{ Hz})(2.50\times10^{-6}\text{ F})} = 1.06\times10^{3}\ \Omega$. X_C is proportional to $1/f$, so at 600 Hz, $X_C = 106\ \Omega$.

(c) $X_L = X_C$ says $2\pi fL = \dfrac{1}{2\pi fC}$ and $f = \dfrac{1}{2\pi\sqrt{LC}} = \dfrac{1}{2\pi\sqrt{(0.450\text{ H})(2.50\times10^{-6}\text{ F})}} = 150$ Hz.

EVALUATE: X_L increases when f increases. X_C decreases when f increases.

31.8. **IDENTIFY:** $V_L = I\omega L$.

SET UP: ω is the angular frequency, in rad/s. $f = \dfrac{\omega}{2\pi}$ is the frequency in Hz.

EXECUTE: $V_L = I\omega L = 2\pi fIL$, so $f = \dfrac{V_L}{2\pi IL} = \dfrac{(12.0\text{ V})}{2\pi(1.80\times10^{-3}\text{ A})(4.50\times10^{-4}\text{ H})} = 2.36\times10^{6}$ Hz = 2.36 MHz.

EVALUATE: When f is increased, I decreases.

31.9. **IDENTIFY:** In an L-R ac circuit, we want to find out how the voltage across a resistor varies with time if we know how the voltage varies across the inductor.

SET UP: $v_L = -I\omega L\sin\omega t$ and $v_R = V_R\cos(\omega t)$.

EXECUTE: **(a)** $v_L = -I\omega L\sin\omega t$. $\omega = 480$ rad/s. $I\omega L = 12.0$ V.

$I = \dfrac{12.0\text{ V}}{\omega L} = \dfrac{12.0\text{ V}}{(480\text{ rad/s})(0.180\text{ H})} = 0.1389$ A. $V_R = IR = (0.1389\text{ A})(90.0\ \Omega) = 12.5$ V.

$v_R = V_R\cos(\omega t) = (12.5\text{ V})\cos[(480\text{ rad/s})t]$.

(b) $v_R = (12.5\text{ V})\cos[(480\text{ rad/s})(2.00\times10^{-3}\text{ s})] = 7.17$ V.

EVALUATE: The instantaneous voltage (7.17 V) is less than the voltage amplitude (12.5 V).

31.10. IDENTIFY: Compare v_C that is given in the problem to the general form $v_C = \dfrac{I}{\omega C}\sin\omega t$ and determine ω.

SET UP: $X_C = \dfrac{1}{\omega C}$. $v_R = iR$ and $i = I\cos\omega t$.

EXECUTE: **(a)** $X_C = \dfrac{1}{\omega C} = \dfrac{1}{(120\text{ rad/s})(4.80\times10^{-6}\text{ F})} = 1736\ \Omega$.

(b) $I = \dfrac{V_C}{X_C} = \dfrac{7.60\text{ V}}{1736\ \Omega} = 4.378\times10^{-3}\text{ A}$ and $i = I\cos\omega t = (4.378\times10^{-3}\text{ A})\cos[(120\text{ rad/s})t]$. Then

$v_R = iR = (4.38\times10^{-3}\text{ A})(250\ \Omega)\cos[(120\text{ rad/s})t] = (1.10\text{ V})\cos[(120\text{ rad/s})t]$.

EVALUATE: The voltage across the resistor has a different phase than the voltage across the capacitor.

31.11. IDENTIFY and SET UP: The voltage and current for a resistor are related by $v_R = iR$. Deduce the frequency of the voltage and use this in $X_L = \omega L$ to calculate the inductive reactance. The equation $v_L = I\omega L\cos(\omega t + 90°)$ gives the voltage across the inductor.

EXECUTE: **(a)** $v_R = (3.80\text{ V})\cos[(720\text{ rad/s})t]$.

$v_R = iR$, so $i = \dfrac{v_R}{R} = \left(\dfrac{3.80\text{ V}}{150\ \Omega}\right)\cos[(720\text{ rad/s})t] = (0.0253\text{ A})\cos[(720\text{ rad/s})t]$.

(b) $X_L = \omega L$.

$\omega = 720$ rad/s, $L = 0.250$ H, so $X_L = \omega L = (720\text{ rad/s})(0.250\text{ H}) = 180\ \Omega$.

(c) If $i = I\cos\omega t$ then $v_L = V_L\cos(\omega t + 90°)$ (from Eq. 31.10).

$V_L = I\omega L = IX_L = (0.02533\text{ A})(180\ \Omega) = 4.56$ V.

$v_L = (4.56\text{ V})\cos[(720\text{ rad/s})t + 90°]$.

But $\cos(a + 90°) = -\sin a$ (Appendix B), so $v_L = -(4.56\text{ V})\sin[(720\text{ rad/s})t]$.

EVALUATE: The current is the same in the resistor and inductor and the voltages are $90°$ out of phase, with the voltage across the inductor leading.

31.12. IDENTIFY: Calculate the reactance of the inductor and of the capacitor. Calculate the impedance and use that result to calculate the current amplitude.

SET UP: With no capacitor, $Z = \sqrt{R^2 + X_L^2}$ and $\tan\phi = \dfrac{X_L}{R}$. $X_L = \omega L$. $I = \dfrac{V}{Z}$. $V_L = IX_L$ and $V_R = IR$. For an inductor, the voltage leads the current.

EXECUTE: **(a)** $X_L = \omega L = (250\text{ rad/s})(0.400\text{ H}) = 100\ \Omega$. $Z = \sqrt{(200\ \Omega)^2 + (100\ \Omega)^2} = 224\ \Omega$.

(b) $I = \dfrac{V}{Z} = \dfrac{30.0\text{ V}}{224\ \Omega} = 0.134$ A.

(c) $V_R = IR = (0.134\text{ A})(200\ \Omega) = 26.8$ V. $V_L = IX_L = (0.134\text{ A})(100\ \Omega) = 13.4$ V.

(d) $\tan\phi = \dfrac{X_L}{R} = \dfrac{100\ \Omega}{200\ \Omega}$ and $\phi = +26.6°$. Since ϕ is positive, the source voltage leads the current.

(e) The phasor diagram is sketched in Figure 31.12.

EVALUATE: Note that $V_R + V_L$ is greater than V. The loop rule is satisfied at each instance of time but the voltages across R and L reach their maxima at different times.

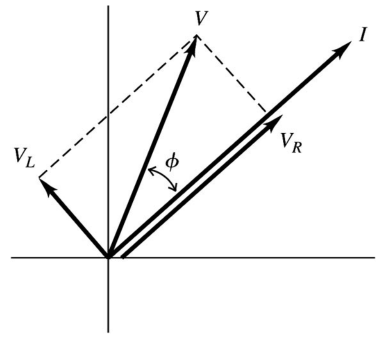

Figure 31.12

31.13. **IDENTIFY:** Apply the equations in Section 31.3.

SET UP: $\omega = 250$ rad/s, $R = 200\ \Omega$, $L = 0.400$ H, $C = 6.00\ \mu$F and $V = 30.0$ V.

EXECUTE: **(a)** $Z = \sqrt{R^2 + (\omega L - 1/\omega C)^2}$.

$Z = \sqrt{(200\ \Omega)^2 + ((250\text{ rad/s})(0.400\text{ H}) - 1/((250\text{ rad/s})(6.00\times 10^{-6}\text{ F})))^2} = 601\ \Omega.$

(b) $I = \dfrac{V}{Z} = \dfrac{30\text{ V}}{601\ \Omega} = 0.0499$ A.

(c) $\phi = \arctan\left(\dfrac{\omega L - 1/\omega C}{R}\right) = \arctan\left(\dfrac{100\ \Omega - 667\ \Omega}{200\ \Omega}\right) = -70.6°$, and the voltage lags the current.

(d) $V_R = IR = (0.0499\text{ A})(200\ \Omega) = 9.98$ V; $V_L = I\omega L = (0.0499\text{ A})(250\text{ rad/s})(0.400\text{ H}) = 4.99$ V;

$V_C = \dfrac{I}{\omega C} = \dfrac{(0.0499\text{ A})}{(250\text{ rad/s})(6.00\times 10^{-6}\text{ F})} = 33.3$ V.

EVALUATE: **(e)** At any instant, $v = v_R + v_C + v_L$. But v_C and v_L are 180° out of phase, so v_C can be larger than v at a value of t, if $v_L + v_R$ is negative at that t.

31.14. **IDENTIFY:** For an *L-R-C* series ac circuit, we want to find the voltages and voltage amplitudes across all the circuit elements.

SET UP: $X_C = \dfrac{1}{\omega C}$, $X_L = \omega L$, $Z = \sqrt{R^2 + (X_L - X_C)^2}$, $I = \dfrac{V}{Z}$ and $\tan\phi = \dfrac{X_L - X_C}{R}$. The instantaneous voltages are $v_R = V_R\cos(\omega t) = IR\cos(\omega t)$, $v_L = -V_L\sin(\omega t) = -IX_L\sin(\omega t)$, $v_C = V_C\sin(\omega t) = IX_C\sin(\omega t)$ and $v = V\cos(\omega t + \phi)$.

EXECUTE: $X_C = \dfrac{1}{\omega C} = \dfrac{1}{(250\text{ rad/s})(6.00\times 10^{-6}\text{ F})} = 666.7\ \Omega.$

$X_L = \omega L = (250\text{ rad/s})(0.900\text{ H}) = 225\ \Omega.$

$Z = \sqrt{R^2 + (X_L - X_C)^2} = \sqrt{(200\ \Omega)^2 + (225\ \Omega - 666.7\ \Omega)^2} = 484.9\ \Omega.$

$I = \dfrac{V}{Z} = \dfrac{30.0\text{ V}}{484.9\ \Omega} = 0.06187\text{ A} = 61.87\text{ mA}.$

$\tan\phi = \dfrac{X_L - X_C}{R} = \dfrac{225\ \Omega - 666.7\ \Omega}{200\ \Omega} = -2.2085$ and $\phi = -1.146$ rad.

(a) $v_R = V_R\cos(\omega t) = IR\cos(\omega t) = (0.06187\text{ A})(200\ \Omega)\cos[(250\text{ rad/s})(20.0\times 10^{-3}\text{ s})] = 3.51$ V.

$v_L = -V_L\sin(\omega t) = -IX_L\sin(\omega t) = -(0.06187\text{ A})(225\ \Omega)\sin[(250\text{ rad/s})(20.0\times 10^{-3}\text{ s})] = 13.35$ V.

$v_C = V_C \sin(\omega t) = IX_C \sin(\omega t) = (0.06187\text{ A})(666.7\ \Omega)\sin[(250\text{ rad/s})(20.0\times10^{-3}\text{ s})] = -39.55\text{ V}.$

$v = V\cos(\omega t + \phi) = (30.0\text{ V})\cos[(250\text{ rad/s})(20.0\times10^{-3}\text{ s}) - 1.146\text{ rad}] = -22.70\text{ V}.$

$v_R + v_L + v_C = 3.51\text{ V} + 13.35\text{ V} + (-39.55\text{ V}) = -22.7\text{ V}.$ $v_R + v_L + v_C$ is equal to v.

(b) $V_R = IR = (0.06187\text{ A})(200\ \Omega) = 12.4\text{ V}$, $V_L = IX_L = (0.06187\text{ A})(225\ \Omega) = 13.9\text{ V}$, and $V_C = IX_C = (0.06187\text{ A})(666.7\ \Omega) = 41.2\text{ V}$.

$V_R + V_C + V_L = 12.4\text{ V} + 41.2\text{ V} + 13.9\text{ V} = 67.5\text{ V}.$ $V_R + V_C + V_L$ is not equal to V.

EVALUATE: The instantaneous voltages do add up to v because they all occur at the same time, so they must add to v by Kirchhoff's loop rule. The amplitudes do not add to V because the maxima do not occur at the same time due to phase differences between the inductor, capacitor and resistor.

31.15. **IDENTIFY** and **SET UP:** Use the equation that preceeds Eq. (31.20): $V^2 = V_R^2 + (V_L - V_C)^2$.

EXECUTE: $V = \sqrt{(30.0\text{ V})^2 + (50.0\text{ V} - 90.0\text{ V})^2} = 50.0\text{ V}.$

EVALUATE: The equation follows directly from the phasor diagrams of Fig. 31.13 (b or c) in the textbook. Note that the voltage amplitudes do not simply add to give 170.0 V for the source voltage.

31.16. **IDENTIFY:** This is an L-R-C series ac circuit.

SET UP: The voltage across the resistor is $v_R(t) = V_R\cos\omega t$, so $v_L(t) = -V_L\sin\omega t$.

EXECUTE: Using $v_L(t) = -V_L\sin\omega t$, we get $\sin\omega t = -\dfrac{v_L}{V_L} = -\dfrac{80.0\text{ mV}}{180\text{ mV}} = -0.4444.$ So $\omega t = -26.39°$.

$v_R(t) = V_R\cos\omega t = (160\text{ V})\cos(-26.39°) = 143\text{ V}.$

$v_C(t) = V_C\sin\omega t = (120\text{ V})\sin(26.39°) = 53.3\text{ V}.$

EVALUATE: The instantaneous voltages add to 80.0 V + 143 V + 53.3 V = 276 V, but the voltage amplitudes add to 180 V + 120 V + 160 V = 440 V. At any time the instantaneous voltages all add to the same value. But the voltage amplitudes do not add to that value because they do not all occur at the same time.

31.17. **IDENTIFY:** We are dealing with an L-R-C series ac circuit.

SET UP: $\tan\phi = \dfrac{V_L - V_C}{V_R}$, $V = \sqrt{V_R^2 + (V_L - V_C)^2}$. The target variable is ϕ. Solve $V = \sqrt{V_R^2 + (V_L - V_C)^2}$ for V_R. Then use $\tan\phi = \dfrac{V_L - V_C}{V_R}$ to find ϕ.

EXECUTE: Solve for V_R: $V_R = \sqrt{V^2 - (V_L - V_C)^2} = \sqrt{(240\text{ V})^2 - (310\text{ V} - 180\text{ V})^2} = 201.7\text{ V}.$ Now find ϕ. $\phi = \arctan\left(\dfrac{V_L - V_C}{V_R}\right) = \arctan\left(\dfrac{310\text{ V} - 180\text{ V}}{201.7\text{ V}}\right) = 32.8°.$

EVALUATE: The angle of the voltage with respect to the current is 32.8°.

31.18. **IDENTIFY:** For an L-R ac circuit, we want to use the resistance, voltage amplitude of the source and power in the resistor to find the impedance, the voltage amplitude across the inductor and the power factor.

SET UP: $P_{\text{av}} = \dfrac{1}{2}I^2R$, $Z = \dfrac{V}{I}$, $V_R = IR$, and $\tan\phi = \dfrac{X_L}{R}$.

EXECUTE: **(a)** $P_{\text{av}} = \dfrac{1}{2}I^2R.$ $I = \sqrt{\dfrac{2P_{\text{av}}}{R}} = \sqrt{\dfrac{2(286\text{ W})}{300\ \Omega}} = 1.381\text{ A}.$ $Z = \dfrac{V}{I} = \dfrac{500\text{ V}}{1.381\text{ A}} = 362\ \Omega.$

(b) $V_R = IR = (1.381\text{ A})(300\ \Omega) = 414\text{ V}.$ $V_L = \sqrt{V^2 - V_R^2} = \sqrt{(500\text{ V})^2 - (414\text{ V})^2} = 280\text{ V}.$

(c) $\tan\phi = \dfrac{X_L}{R} = \dfrac{V_L}{V_R} = \dfrac{280\text{ V}}{414\text{ V}}$ gives $\phi = 34.1°$. The power factor is $\cos\phi = 0.828$.

EVALUATE: The voltage amplitude across the resistor cannot exceed the voltage amplitude (500 V) of the ac source.

31.19. **IDENTIFY:** For a pure resistance, $P_{\text{av}} = V_{\text{rms}}I_{\text{rms}} = I_{\text{rms}}^2 R.$

SET UP: 20.0 W is the average power P_{av}.

EXECUTE: **(a)** The average power is one-half the maximum power, so the maximum instantaneous power is 40.0 W.

(b) $I_{\text{rms}} = \dfrac{P_{\text{av}}}{V_{\text{rms}}} = \dfrac{20.0\text{ W}}{120\text{ V}} = 0.167\text{ A}.$

(c) $R = \dfrac{P_{\text{av}}}{I_{\text{rms}}^2} = \dfrac{20.0\text{ W}}{(0.167\text{ A})^2} = 720\ \Omega.$

EVALUATE: We can also calculate the average power as $P_{\text{av}} = \dfrac{V_{R,\text{rms}}^2}{R} = \dfrac{V_{\text{rms}}^2}{R} = \dfrac{(120\text{ V})^2}{720\ \Omega} = 20.0\text{ W}.$

31.20. **IDENTIFY:** The average power supplied by the source is $P_{\text{av}} = V_{\text{rms}}I_{\text{rms}}\cos\phi.$ The power consumed in the resistance is $P_{\text{av}} = I_{\text{rms}}^2 R.$

SET UP: $\omega = 2\pi f = 2\pi(1.25\times10^3\text{ Hz}) = 7.854\times10^3\text{ rad/s}.$ $X_L = \omega L = 157\ \Omega.$ $X_C = \dfrac{1}{\omega C} = 909\ \Omega.$

EXECUTE: **(a)** First, let us find the phase angle between the voltage and the current:
$\tan\phi = \dfrac{X_L - X_C}{R} = \dfrac{157\ \Omega - 909\ \Omega}{350\ \Omega}$ and $\phi = -65.04°$. The impedance of the circuit is
$Z = \sqrt{R^2 + (X_L - X_C)^2} = \sqrt{(350\ \Omega)^2 + (-752\ \Omega)^2} = 830\ \Omega.$ The average power provided by the generator is then $P_{\text{av}} = V_{\text{rms}}I_{\text{rms}}\cos(\phi) = \dfrac{V_{\text{rms}}^2}{Z}\cos(\phi) = \dfrac{(120\text{ V})^2}{830\ \Omega}\cos(-65.04°) = 7.32\text{ W}.$

(b) The average power dissipated by the resistor is $P_R = I_{\text{rms}}^2 R = \left(\dfrac{120\text{ V}}{830\ \Omega}\right)^2 (350\ \Omega) = 7.32\text{ W}.$

EVALUATE: Conservation of energy requires that the answers to parts (a) and (b) are equal.

31.21. **IDENTIFY:** We are dealing with power in an *L-R-C* series ac circuit.
SET UP and **EXECUTE:** **(a)** From Fig. 31.13(b) in the textbook, $\cos\phi = V_R/V = IR/V$. Thus $V\cos\phi = IR.$ From Eq. (31.31), $P_{\text{av}} = \dfrac{1}{2}IV\cos\phi = \dfrac{1}{2}I(IR) = \dfrac{1}{2}I^2R.$

(b) We want *R*. Use our results from part (a). $P_{\text{av}} = \dfrac{1}{2}I^2R = \dfrac{1}{2}\dfrac{(IR)^2}{R} = \dfrac{1}{2}\dfrac{(V\cos\phi)^2}{R}$. Solve for *R*.

$R = \dfrac{(V\cos\phi)^2}{2P_{\text{av}}} = \dfrac{[(120\text{ V})(\cos 53.1°)]^2}{2(80.0\text{ W})} = 32.4\ \Omega.$

EVALUATE: The current amplitude is $I = \sqrt{2P_{av}/R} = 2.22\ A.$

31.22. **IDENTIFY:** This is an *R-C* ac circuit.

SET UP and **EXECUTE:** **(a)** We want V_R. Solve $V = \sqrt{V_R^2 + V_C^2}$ for V_R.

$V_R = \sqrt{V^2 - V_C^2} = \sqrt{(900\text{ V})^2 - (500\text{ V})^2} = 748\text{ V}.$

(b) We want C. $\dfrac{V_R}{V_C} = \dfrac{IR}{IX_C} = \dfrac{R}{1/\omega C} = R\omega C.C = \dfrac{V_R/V_C}{R\omega}$. Using the numbers gives $C = 249\ \mu$F.

(c) $\tan\phi = \dfrac{-1/\omega C}{R} = -\dfrac{1}{R\omega C}$. Since ϕ is negative, the voltage *lags* the current.

(d) $P_{\text{av}} = \dfrac{1}{2} IV\cos\phi = \dfrac{1}{2} V\left(\dfrac{V_R}{R}\right)\cos\phi = \left(\dfrac{VV_R}{2R}\right)\dfrac{R}{\sqrt{R^2 + (1/\omega C)^2}}$. Using the given numbers, this gives

$P_{\text{av}} = 932$ W.

EVALUATE: The power is all used up in the resistor.

31.23. IDENTIFY and SET UP: Use the equations of Section 31.3 to calculate ϕ, Z, and V_{rms}. The average power delivered by the source is given by $P_{\text{av}} = I_{\text{rms}}V_{\text{rms}}\cos\phi$ and the average power dissipated in the resistor is $I_{\text{rms}}^2 R$.

EXECUTE: (a) $X_L = \omega L = 2\pi fL = 2\pi(400\text{ Hz})(0.120\text{ H}) = 301.6\ \Omega$.

$X_C = \dfrac{1}{\omega C} = \dfrac{1}{2\pi fC} = \dfrac{1}{2\pi(400\text{ Hz})(7.3\times10^{-6}\text{ F})} = 54.51\ \Omega$.

$\tan\phi = \dfrac{X_L - X_C}{R} = \dfrac{301.6\ \Omega - 54.41\ \Omega}{240\ \Omega}$, so $\phi = +45.8°$. The power factor is $\cos\phi = +0.697$.

(b) $Z = \sqrt{R^2 + (X_L - X_C)^2} = \sqrt{(240\ \Omega)^2 + (301.6\ \Omega - 54.51\ \Omega)^2} = 344\ \Omega$.

(c) $V_{\text{rms}} = I_{\text{rms}}Z = (0.450\text{ A})(344\ \Omega) = 155$ V.

(d) $P_{\text{av}} = I_{\text{rms}}V_{\text{rms}}\cos\phi = (0.450\text{ A})(155\text{ V})(0.697) = 48.6$ W.

(e) $P_{\text{av}} = I_{\text{rms}}^2 R = (0.450\text{ A})^2(240\ \Omega) = 48.6$ W.

EVALUATE: The average electrical power delivered by the source equals the average electrical power consumed in the resistor.

(f) All the energy stored in the capacitor during one cycle of the current is released back to the circuit in another part of the cycle. There is no net dissipation of energy in the capacitor.

(g) The answer is the same as for the capacitor. Energy is repeatedly being stored and released in the inductor, but no net energy is dissipated there.

31.24. IDENTIFY and SET UP: $P_{\text{av}} = V_{\text{rms}}I_{\text{rms}}\cos\phi$. $I_{\text{rms}} = \dfrac{V_{\text{rms}}}{Z}$. $\cos\phi = \dfrac{R}{Z}$.

EXECUTE: $I_{\text{rms}} = \dfrac{80.0\text{ V}}{105\ \Omega} = 0.762$ A. $\cos\phi = \dfrac{75.0\ \Omega}{105\ \Omega} = 0.714$.

$P_{\text{av}} = (80.0\text{ V})(0.762\text{ A})(0.714) = 43.5$ W.

EVALUATE: Since the average power consumed by the inductor and by the capacitor is zero, we can also calculate the average power as $P_{\text{av}} = I_{\text{rms}}^2 R = (0.762\text{ A})^2(75.0\ \Omega) = 43.5$ W.

31.25. IDENTIFY: The angular frequency and the capacitance can be used to calculate the reactance X_C of the capacitor. The angular frequency and the inductance can be used to calculate the reactance X_L of the inductor. Calculate the phase angle ϕ and then the power factor is $\cos\phi$. Calculate the impedance of the circuit and then the rms current in the circuit. The average power is $P_{\text{av}} = V_{\text{rms}}I_{\text{rms}}\cos\phi$. On the average no power is consumed in the capacitor or the inductor, it is all consumed in the resistor.

SET UP: The source has rms voltage $V_{\text{rms}} = \dfrac{V}{\sqrt{2}} = \dfrac{45\text{ V}}{\sqrt{2}} = 31.8$ V.

EXECUTE: **(a)** $X_L = \omega L = (360\ \text{rad/s})(15\times10^{-3}\ \text{H}) = 5.4\ \Omega.$

$X_C = \dfrac{1}{\omega C} = \dfrac{1}{(360\ \text{rad/s})(3.5\times10^{-6}\ \text{F})} = 794\ \Omega.$ $\tan\phi = \dfrac{X_L - X_C}{R} = \dfrac{5.4\ \Omega - 794\ \Omega}{250\ \Omega}$ and $\phi = -72.4°.$

The power factor is $\cos\phi = 0.302.$

(b) $Z = \sqrt{R^2 + (X_L - X_C)^2} = \sqrt{(250\ \Omega)^2 + (5.4\ \Omega - 794\ \Omega)^2} = 827\ \Omega.$ $I_{\text{rms}} = \dfrac{V_{\text{rms}}}{Z} = \dfrac{31.8\ \text{V}}{827\ \Omega} = 0.0385\ \text{A}.$

$P_{\text{av}} = V_{\text{rms}} I_{\text{rms}} \cos\phi = (31.8\ \text{V})(0.0385\ \text{A})(0.302) = 0.370\ \text{W}.$

(c) The average power delivered to the resistor is $P_{\text{av}} = I_{\text{rms}}^2 R = (0.0385\ \text{A})^2(250\ \Omega) = 0.370\ \text{W}.$ The average power delivered to the capacitor and to the inductor is zero.

EVALUATE: On average the power delivered to the circuit equals the power consumed in the resistor. The capacitor and inductor store electrical energy during part of the current oscillation but each return the energy to the circuit during another part of the current cycle.

31.26. **IDENTIFY:** At resonance in an *L-R-C* ac circuit, we know the reactance of the capacitor and the voltage amplitude across it. From this information, we want to find the voltage amplitude of the source.

SET UP: At resonance, $Z = R.$ $V_C = IX_C.$

EXECUTE: $I = \dfrac{V}{X_C} = \dfrac{600\ \text{V}}{200\ \Omega} = 3.00\ \text{A}.$ $Z = R = 300\ \Omega.$ $V = IZ = (3.00\ \text{A})(300\ \Omega) = 900\ \text{V}.$

EVALUATE: At resonance, $Z = R,$ but X_C is not zero.

31.27. **IDENTIFY** and **SET UP:** The current is largest at the resonance frequency. At resonance, $X_L = X_C$ and $Z = R.$ For part (b), calculate Z and use $I = V/Z.$

EXECUTE: **(a)** $f_0 = \dfrac{1}{2\pi\sqrt{LC}} = 113\ \text{Hz}.$ $I = V/R = 15.0\ \text{mA}.$

(b) $X_C = 1/\omega C = 500\ \Omega.$ $X_L = \omega L = 160\ \Omega.$

$Z = \sqrt{R^2 + (X_L - X_C)^2} = \sqrt{(200\ \Omega)^2 + (160\ \Omega - 500\ \Omega)^2} = 394.5\ \Omega.$ $I = V/Z = 7.61\ \text{mA}.$ $X_C > X_L$ so the source voltage lags the current.

EVALUATE: $\omega_0 = 2\pi f_0 = 710\ \text{rad/s}.$ $\omega = 400\ \text{rad/s}$ and is less than ω_0. When $\omega < \omega_0,$ $X_C > X_L.$ Note that I in part (b) is less than I in part (a).

31.28. **IDENTIFY:** The impedance and individual reactances depend on the angular frequency at which the circuit is driven.

SET UP: The impedance is $Z = \sqrt{R^2 + \left(\omega L - \dfrac{1}{\omega C}\right)^2},$ the current amplitude is $I = V/Z$ and the instantaneous values of the potential and current are $v = V\cos(\omega t + \phi),$ where $\tan\phi = (X_L - X_C)/R,$ and $i = I\cos\omega t.$

EXECUTE: **(a)** Z is a minimum when $\omega L = \dfrac{1}{\omega C},$ which gives

$\omega = \dfrac{1}{\sqrt{LC}} = \dfrac{1}{\sqrt{(8.00\ \text{mH})(12.5\ \mu\text{F})}} = 3162\ \text{rad/s},$ which rounds to 3160 rad/s. $Z = R = 175\ \Omega.$

(b) $I = V/Z = (25.0\ \text{V})/(175\ \Omega) = 0.143\ \text{A}.$

(c) $i = I\cos\omega t = I/2,$ so $\cos\omega t = \frac{1}{2},$ which gives $\omega t = 60° = \pi/3\ \text{rad}.$ $v = V\cos(\omega t + \phi),$ where $\tan\phi = (X_L - X_C)/R = 0/R = 0.$ So, $v = (25.0\ \text{V})\cos\omega t = (25.0\ \text{V})(1/2) = 12.5\ \text{V}.$

$v_R = Ri = (175\ \Omega)(1/2)(0.143\ \text{A}) = 12.5\ \text{V}.$

$v_C = V_C \cos(\omega t - 90°) = IX_C \cos(\omega t - 90°) = \dfrac{0.143 \text{ A}}{(3162 \text{ rad/s})(12.5\ \mu\text{F})} \cos(60° - 90°) = +3.13 \text{ V}.$

$v_L = V_L \cos(\omega t + 90°) = IX_L \cos(\omega t + 90°) = (0.143 \text{ A})(3162 \text{ rad/s})(8.00 \text{ mH}) \cos(60° + 90°).$

$v_L = -3.13 \text{ V}.$

(d) $v_R + v_L + v_C = 12.5 \text{ V} + (-3.13 \text{ V}) + 3.13 \text{ V} = 12.5 \text{ V} = v_{\text{source}}.$

EVALUATE: The instantaneous potential differences across all the circuit elements always add up to the value of the source voltage at that instant. In this case (resonance), the potentials across the inductor and capacitor have the same magnitude but are $180°$ out of phase, so they add to zero, leaving all the potential difference across the resistor.

31.29. IDENTIFY and SET UP: At the resonance frequency, $Z = R$. Use that $V = IZ$, $V_R = IR$, $V_L = IX_L$, and $V_C = IX_C$. P_{av} is given by $P_{\text{av}} = \frac{1}{2} VI \cos\phi$.

EXECUTE: **(a)** $V = IZ = IR = (0.500 \text{ A})(300\ \Omega) = 150 \text{ V}.$

(b) $V_R = IR = 150 \text{ V}.$

$X_L = \omega L = L(1/\sqrt{LC}) = \sqrt{L/C} = 2582\ \Omega;\ V_L = IX_L = 1290 \text{ V}.$

$X_C = 1/(\omega C) = \sqrt{L/C} = 2582\ \Omega;\ V_C = IX_C = 1290 \text{ V}.$

(c) $P_{\text{av}} = \frac{1}{2} VI \cos\phi = \frac{1}{2} I^2 R$, since $V = IR$ and $\cos\phi = 1$ at resonance.

$P_{\text{av}} = \frac{1}{2}(0.500 \text{ A})^2 (300\ \Omega) = 37.5 \text{ W}.$

EVALUATE: At resonance $V_L = V_C$. Note that $V_L + V_C > V$. However, at any instant $v_L + v_C = 0$.

31.30. IDENTIFY: The current is maximum at the resonance frequency, so choose C such that $\omega = 50.0$ rad/s is the resonance frequency. At the resonance frequency $Z = R$.

SET UP: $V_L = I\omega L.$

EXECUTE: **(a)** The amplitude of the current is given by $I = \dfrac{V}{\sqrt{R^2 + \left(\omega L - \dfrac{1}{\omega C}\right)^2}}$. Thus, the current will have a maximum amplitude when $\omega L = \dfrac{1}{\omega C}$. Therefore,

$$C = \frac{1}{\omega^2 L} = \frac{1}{(50.0 \text{ rad/s})^2 (3.00 \text{ H})} = 1.33 \times 10^{-4} \text{ F} = 133\ \mu\text{F}.$$

(b) With the capacitance calculated above we find that $Z = R$, and the amplitude of the current is $I = \dfrac{V}{R} = \dfrac{120 \text{ V}}{400\ \Omega} = 0.300 \text{ A}$. Thus, the amplitude of the voltage across the inductor is

$V_L = I(\omega L) = (0.300 \text{ A})(50.0 \text{ rad/s})(3.00 \text{ H}) = 45.0 \text{ V}.$

EVALUATE: For the value of C found in part (a), the resonance angular frequency is 50.0 rad/s.

31.31. IDENTIFY and SET UP: At resonance $X_L = X_C$, $\phi = 0$ and $Z = R$. $R = 150\ \Omega$, $L = 0.750$ H, $C = 0.0180\ \mu\text{F}$, $V = 150$ V

EXECUTE: **(a)** At the resonance frequency $X_L = X_C$ and from $\tan\phi = \dfrac{X_L - X_C}{R}$ we have that $\phi = 0°$ and the power factor is $\cos\phi = 1.00$.

(b) $P_{\text{av}} = \frac{1}{2} VI \cos\phi$ (Eq. 31.31).

At the resonance frequency $Z = R$, so $I = \dfrac{V}{Z} = \dfrac{V}{R}$.

$$P_{av} = \frac{1}{2}V\left(\frac{V}{R}\right)\cos\phi = \frac{1}{2}\frac{V^2}{R} = \frac{1}{2}\frac{(150\text{ V})^2}{150\ \Omega} = 75.0\text{ W}.$$

EVALUATE: (c) When *C* and *f* are changed but the circuit is kept on resonance, nothing changes in $P_{av} = V^2/(2R)$, so the average power is unchanged: $P_{av} = 75.0$ W. The resonance frequency changes but since $Z = R$ at resonance the current doesn't change.

31.32. **IDENTIFY:** This problem is about resonance in an *L-R-C* series ac circuit.

SET UP and **EXECUTE:** At resonance, $Z = R$ and $P = V^2/2R = (80.0\text{ V})^2/[2(400\ \Omega)] = 8.00$ W.

EVALUATE: At resonance, $\cos\phi = 1$.

31.33. **IDENTIFY:** At resonance $Z = R$ and $X_L = X_C$.

SET UP: $\omega_0 = \dfrac{1}{\sqrt{LC}}$. $V = IZ$. $V_R = IR$, $V_L = IX_L$ and $V_C = V_L$.

EXECUTE: (a) $\omega_0 = \dfrac{1}{\sqrt{LC}} = \dfrac{1}{\sqrt{(0.280\text{ H})(4.00\times10^{-6}\text{ F})}} = 945$ rad/s.

(b) $I = 1.70$ A at resonance, so $R = Z = \dfrac{V}{I} = \dfrac{120\text{ V}}{1.70\text{ A}} = 70.6\ \Omega$.

(c) At resonance, $V_R = 120$ V, $V_L = V_C = I\omega L = (1.70\text{ A})(945\text{ rad/s})(0.280\text{ H}) = 450$ V.

EVALUATE: At resonance, $V_R = V$ and $V_L - V_C = 0$.

31.34. **IDENTIFY:** Let I_1, V_1 and I_2, V_2 be rms values for the primary and secondary. A transformer transforms voltages according to $\dfrac{V_2}{V_1} = \dfrac{N_2}{N_1}$. The effective resistance of a secondary circuit of resistance *R* is $R_{eff} = \dfrac{R}{(N_2/N_1)^2}$. Resistance *R* is related to P_{av} and V_{rms} by $P_{av} = \dfrac{V_{rms}^2}{R}$. Conservation of energy requires $P_{av,1} = P_{av,2}$ so $V_1I_1 = V_2I_2$.

SET UP: Let $V_1 = 240$ V and $V_2 = 120$ V, so $P_{2,av} = 1600$ W. These voltages are rms.

EXECUTE: (a) $V_1 = 240$ V and we want $V_2 = 120$ V, so use a step-down transformer with $N_2/N_1 = \frac{1}{2}$.

(b) $P_{av} = V_1I_1$, so $I_1 = \dfrac{P_{av}}{V_1} = \dfrac{1600\text{ W}}{240\text{ V}} = 6.67$ A.

(c) The resistance *R* of the blower is $R = \dfrac{V_2^2}{P_{av}} = \dfrac{(120\text{ V})^2}{1600\text{ W}} = 9.00\ \Omega$. The effective resistance of the blower is $R_{eff} = \dfrac{9.00\ \Omega}{(1/2)^2} = 36.0\ \Omega$.

EVALUATE: $I_2 = V_2/R_2 = (120\text{ V})/(9.00\ \Omega) = 13.3$ A, so $I_2V_2 = (13.3\text{ A})(120\text{ V}) = 1600$ W. Energy is provided to the primary at the same rate that it is consumed in the secondary. Step-down transformers step up resistance and the current in the primary is less than the current in the secondary.

31.35. **IDENTIFY** and **SET UP:** The equation $\dfrac{V_2}{V_1} = \dfrac{N_2}{N_1}$ relates the primary and secondary voltages to the number of turns in each. $I = V/R$ and the power consumed in the resistive load is $I_{rms}^2 = V_{rms}^2/R$. Let I_1, V_1 and I_2, V_2 be rms values for the primary and secondary.

EXECUTE: (a) $\dfrac{V_2}{V_1} = \dfrac{N_2}{N_1}$ so $\dfrac{N_1}{N_2} = \dfrac{V_1}{V_2} = \dfrac{120\text{ V}}{12.0\text{ V}} = 10$.

(b) $I_2 = \dfrac{V_2}{R} = \dfrac{12.0\text{ V}}{5.00\ \Omega} = 2.40\text{ A}.$

(c) $P_{\text{av}} = I_2^2 R = (2.40\text{ A})^2(5.00\ \Omega) = 28.8\text{ W}.$

(d) The power drawn from the line by the transformer is the 28.8 W that is delivered by the load.

$P_{\text{av}} = \dfrac{V_1^2}{R}$ so $R = \dfrac{V_1^2}{P_{\text{av}}} = \dfrac{(120\text{ V})^2}{28.8\text{ W}} = 500\ \Omega.$

And $\left(\dfrac{N_1}{N_2}\right)^2 (5.00\ \Omega) = (10)^2(5.00\ \Omega) = 500\ \Omega,$ as was to be shown.

EVALUATE: The resistance is "transformed." A load of resistance R connected to the secondary draws the same power as a resistance $(N_1/N_2)^2 R$ connected directly to the supply line, without using the transformer.

31.36. IDENTIFY: $P_{\text{av}} = V_{\text{rms}} I_{\text{rms}}$ and $P_{\text{av},1} = P_{\text{av},2}$. $\dfrac{N_1}{N_2} = \dfrac{V_1}{V_2}$. Let I_1, V_1 and I_2, V_2 be rms values for the primary and secondary.

SET UP: $V_1 = 120\text{ V}$. $V_2 = 13{,}000\text{ V}$.

EXECUTE: **(a)** $\dfrac{N_2}{N_1} = \dfrac{V_2}{V_1} = \dfrac{13{,}000\text{ V}}{120\text{ V}} = 108.$

(b) $P_{\text{av}} = V_2 I_2 = (13{,}000\text{ V})(8.50\times 10^{-3}\text{ A}) = 110\text{ W}.$

(c) $I_1 = \dfrac{P_{\text{av}}}{V_1} = \dfrac{110\text{ W}}{120\text{ V}} = 0.917\text{ A}.$

EVALUATE: Since the power supplied to the primary must equal the power delivered by the secondary, in a step-up transformer the current in the primary is greater than the current in the secondary.

31.37. IDENTIFY and **SET UP:** Use $\tan\phi = \dfrac{\omega L - \dfrac{1}{\omega C}}{R}$ to relate L and R to ϕ. The voltage across the coil leads the current in it by $52.3°$, so $\phi = +52.3°$.

EXECUTE: $\tan\phi = \dfrac{X_L - X_C}{R}$. But there is no capacitance in the circuit so $X_C = 0$. Thus

$\tan\phi = \dfrac{X_L}{R}$ and $X_L = R\tan\phi = (48.0\ \Omega)\tan 52.3° = 62.1\ \Omega.$

$X_L = \omega L = 2\pi f L$ so $L = \dfrac{X_L}{2\pi f} = \dfrac{62.1\ \Omega}{2\pi(80.0\text{ Hz})} = 0.124\text{ H}.$

EVALUATE: $\phi > 45°$ when $(X_L - X_C) > R$, which is the case here.

31.38. IDENTIFY: We have an *L-R-C* series ac circuit.

SET UP: $\tan\phi = \dfrac{X_L - X_C}{R}$, $P_{\text{av}} = \dfrac{1}{2} I^2 R$, $P_{\text{av}} = \dfrac{1}{2} IV\cos\phi.$

EXECUTE: **(a)** We want X_L. Use $\tan\phi = \dfrac{X_L - X_C}{R}$. $X_L = R\tan\phi + X_C$. Using the numbers gives

$X_L = (300\ \Omega)\tan(-53.0°) + 500\ \Omega = 102\ \Omega.$

(b) We want I. Use $P_{\text{av}} = \dfrac{1}{2} I^2 R$ and solve for I. $I = \sqrt{2P_{\text{av}}/R}$ gives $I = 0.730$ A.

(c) We want V. Use $P_{\text{av}} = \frac{1}{2}IV\cos\phi$ and solve for V. $V = \frac{2P_{\text{av}}}{I\cos\phi} = 364\text{ V}$.

EVALUATE: The circuit is not close to resonance because X_L is very different from X_C (102 Ω compared to 500 Ω).

31.39. **IDENTIFY:** An L-R-C ac circuit operates at resonance. We know L, C, and V and want to find R.

SET UP: At resonance, $Z = R$ and $\omega = \omega_0 = \frac{1}{\sqrt{LC}}$. $X_C = \frac{1}{\omega C}$, $I = V/Z$.

EXECUTE: $\omega = \frac{1}{\sqrt{LC}} = 633.0\text{ rad/s}$ $X_C = \frac{1}{\omega C} = \frac{1}{(633\text{ rad/s})(4.80\times10^{-6}\text{ F})} = 329.1\,\Omega.$

$I = \frac{V_C}{X_C} = \frac{80.0\text{ V}}{329.1\,\Omega} = 0.2431\text{ A}$. At resonance $Z = R$, so $I = \frac{V}{R}$. $R = \frac{V}{I} = \frac{56.0\text{ V}}{0.2431\text{ A}} = 230\,\Omega.$

EVALUATE: At resonance, the impedance is a minimum.

31.40. **IDENTIFY:** $Z = \sqrt{R^2 + (X_L - X_C)^2}$. $I_{\text{rms}} = \frac{V_{\text{rms}}}{Z}$. $V_{\text{rms}} = I_{\text{rms}}R$. $V_{C,\text{rms}} = I_{\text{rms}}X_C$. $V_{L,\text{rms}} = I_{\text{rms}}X_L$.

SET UP: $V_{\text{rms}} = \frac{V}{\sqrt{2}} = \frac{30.0\text{ V}}{\sqrt{2}} = 21.2\text{ V}.$

EXECUTE: **(a)** $\omega = 200\text{ rad/s}$, so $X_L = \omega L = (200\text{ rad/s})(0.400\text{ H}) = 80.0\,\Omega$ and

$X_C = \frac{1}{\omega C} = \frac{1}{(200\text{ rad/s})(6.00\times10^{-6}\text{ F})} = 833\,\Omega$. $Z = \sqrt{(200\,\Omega)^2 + (80.0\,\Omega - 833\,\Omega)^2} = 779\,\Omega.$

$I_{\text{rms}} = \frac{V_{\text{rms}}}{Z} = \frac{21.2\text{ V}}{779\,\Omega} = 0.0272\text{ A}$. V_1 reads $V_{R,\text{rms}} = I_{\text{rms}}R = (0.0272\text{ A})(200\,\Omega) = 5.44\text{ V}.$

V_2 reads $V_{L,\text{rms}} = I_{\text{rms}}X_L = (0.0272\text{ A})(80.0\,\Omega) = 2.18\text{ V}.$

V_3 reads $V_{C,\text{rms}} = I_{\text{rms}}X_C = (0.0272\text{ A})(833\,\Omega) = 22.7\text{ V}.$

V_4 reads $\left|\frac{V_L - V_C}{\sqrt{2}}\right| = |V_{L,\text{rms}} - V_{C,\text{rms}}| = |2.18\text{ V} - 22.7\text{ V}| = 20.5\text{ V}.$

V_5 reads $V_{\text{rms}} = 21.2\text{ V}.$

(b) $\omega = 1000\text{ rad/s}$ so $X_L = \omega L = (5)(80.0\,\Omega) = 400\,\Omega$ and $X_C = \frac{1}{\omega C} = \frac{833\,\Omega}{5} = 167\,\Omega.$

$Z = \sqrt{(200\,\Omega)^2 + (400\,\Omega - 167\,\Omega)^2} = 307\,\Omega$. $I_{\text{rms}} = \frac{V_{\text{rms}}}{Z} = \frac{21.2\text{ V}}{307\,\Omega} = 0.0691\text{ A}.$

V_1 reads $V_{R,\text{rms}} = 13.8\text{ V}$. V_2 reads $V_{L,\text{rms}} = 27.6\text{ V}$. V_3 reads $V_{C,\text{rms}} = 11.5\text{ V}.$

V_4 reads $|V_{L,\text{rms}} - V_{C,\text{rms}}| = |27.6\text{ V} - 11.5\text{ V}| = 16.1\text{ V}$. V_5 reads $V_{\text{rms}} = 21.2\text{ V}.$

EVALUATE: The resonance frequency for this circuit is $\omega_0 = \frac{1}{\sqrt{LC}} = 645\text{ rad/s}$. 200 rad/s is less than the resonance frequency and $X_C > X_L$. 1000 rad/s is greater than the resonance frequency and $X_L > X_C$.

31.41. **IDENTIFY:** We can use geometry to calculate the capacitance and inductance, and then use these results to calculate the resonance angular frequency.

SET UP: The capacitance of an air-filled parallel plate capacitor is $C = \frac{\epsilon_0 A}{d}$. The inductance of a long solenoid is $L = \frac{\mu_0 A N^2}{l}$. The inductor has $N = (125\text{ coils/cm})(9.00\text{ cm}) = 1125$ coils. The resonance frequency is $f_0 = \frac{1}{2\pi\sqrt{LC}}$. $\epsilon_0 = 8.85\times10^{-12}\text{ C}^2/\text{N}\cdot\text{m}^2$. $\mu_0 = 4\pi\times10^{-7}\text{ T}\cdot\text{m/A}$.

EXECUTE: $C = \dfrac{\epsilon_0 A}{d} = \dfrac{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(4.50\times10^{-2}\ \text{m})^2}{8.00\times10^{-3}\ \text{m}} = 2.24\times10^{-12}\ \text{F}.$

$$L = \frac{\mu_0 AN^2}{l} = \frac{(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})\pi(0.250\times10^{-2}\ \text{m})^2(1125)^2}{9.00\times10^{-2}\ \text{m}} = 3.47\times10^{-4}\ \text{H}.$$

$$\omega_0 = \frac{1}{\sqrt{(3.47\times10^{-4}\ \text{H})(2.24\times10^{-12}\ \text{F})}} = 3.59\times10^7\ \text{rad/s}.$$

EVALUATE: The result is a rather high angular frequency.

31.42. **IDENTIFY:** Use geometry to calculate the self-inductance of the toroidal solenoid. Then find its reactance and use this to find the impedance, and finally the current amplitude, of the circuit.

SET UP: $L = \dfrac{\mu_0 N^2 A}{2\pi r}$, $X_L = 2\pi f L$, $Z = \sqrt{R^2 + X_L^2}$, and $I = V/Z$.

EXECUTE: $L = \dfrac{\mu_0 N^2 A}{2\pi r} = (2\times10^{-7}\ \text{T}\cdot\text{m/A})\dfrac{(2900)^2(0.450\times10^{-4}\ \text{m}^2)}{9.00\times10^{-2}\ \text{m}} = 8.41\times10^{-4}\ \text{H}.$

$X_L = 2\pi f L = (2\pi)(495\ \text{Hz})(8.41\times10^{-4}\ \text{H}) = 2.616\ \Omega.$ $Z = \sqrt{R^2 + X_L^2} = 3.832\ \Omega.$

$$I = \frac{V}{Z} = \frac{24.0\ \text{V}}{3.832\ \Omega} = 6.26\ \text{A}.$$

EVALUATE: The inductance is physically reasonable.

31.43. **IDENTIFY** and **SET UP:** Source voltage lags current so it must be that $X_C > X_L$.

EXECUTE: **(a)** We must add an inductor in series with the circuit. When $X_C = X_L$ the power factor has its maximum value of unity, so calculate the additional L needed to raise X_L to equal X_C.

(b) Power factor $\cos\phi$ equals 1 so $\phi = 0$ and $X_C = X_L$. Calculate the present value of $X_C - X_L$ to see how much more X_L is needed: $R = Z\cos\phi = (60.0\ \Omega)(0.720) = 43.2\ \Omega$

$\tan\phi = \dfrac{X_L - X_C}{R}$ so $X_L - X_C = R\tan\phi$.

$\cos\phi = 0.720$ gives $\phi = -43.95°$ (ϕ is negative since the voltage lags the current).

Then $X_L - X_C = R\tan\phi = (43.2\ \Omega)\tan(-43.95°) = -41.64\ \Omega$.

Therefore need to add $41.64\ \Omega$ of X_L.

$X_L = \omega L = 2\pi f L$ and $L = \dfrac{X_L}{2\pi f} = \dfrac{41.64\ \Omega}{2\pi(50.0\ \text{Hz})} = 0.133\ \text{H}$, amount of inductance to add.

EVALUATE: From the information given we can't calculate the original value of L in the circuit, just how much to add. When this L is added the current in the circuit will increase.

31.44. **IDENTIFY:** We are dealing with a transformer as an ac adapter.

SET UP and **EXECUTE:** **(a)** Voltage = 19.5 V, current = 6.7 A.

(b) Power = 130 W. IV = (19.5 V)(6.7 A) = 131 W, so $P = IV$.

(c) Primary: 120 V rms, 200 turns. The full-wave rectifier following the secondary coil maintains a voltage amplitude V = 19.5 V. We want the number of turns in the secondary. $V_1 = V_{\text{rms}}\sqrt{2}$. The secondary output should be V_2 = 19.5 V. $N_2 = \dfrac{V_2}{V_1}N_1 = \dfrac{19.5\ \text{V}}{120\sqrt{2}\ \text{V}}(200) = 23$ turns.

(d) We want I_1. $P = IV$ gives 130 W = I_1(120 V), so I_1 = 1.1 A.

(e) Estimate the size: Outside: 5 cm by 5 cm by 1.5 cm. Inside: 3 cm by 3 cm by 1 cm. One coil: 4 cm. 200 coils: 800 cm = 8.0 m.

(f) We want B inside the core. Apply Ampere's law. Use permeability μ instead of μ_0, where $\mu = K_m\mu_0$, with K_m– being the relative permeability. $\oint \vec{B} \cdot d\hat{l} = K_m\mu_0 I_{\text{encl}}$. Use a rectangular path with one side of length l = 3 cm inside the core enclosing all the loops. $Bl = K\mu_0 N_1 I_{\text{encl}}$.

$B = K\mu_0 N_1 I_{\text{encl}}/l$ = (5000) μ_0 (200)(1.1 A)/(0.030 m) = 46 T.

EVALUATE: The very large field in the core is due to the large permeability of the metal. If it were air-filled, B would be only about 9 mT.

31.45. **IDENTIFY:** We know the impedances and the average power consumed. From these we want to find the power factor and the rms voltage of the source.

SET UP: $P = I_{\text{rms}}^2 R$. $\cos\phi = \dfrac{R}{Z}$. $Z = \sqrt{R^2 + (X_L - X_C)^2}$. $V_{\text{rms}} = I_{\text{rms}} Z$.

EXECUTE: **(a)** $I_{\text{rms}} = \sqrt{\dfrac{P}{R}} = \sqrt{\dfrac{60.0\ \text{W}}{300\ \Omega}} = 0.447\ \text{A}$. $Z = \sqrt{(300\ \Omega)^2 + (500\ \Omega - 300\ \Omega)^2} = 361\ \Omega$.

$\cos\phi = \dfrac{R}{Z} = \dfrac{300\ \Omega}{361\ \Omega} = 0.831$.

(b) $V_{\text{rms}} = I_{\text{rms}} Z = (0.447\ \text{A})(361\ \Omega) = 161\ \text{V}$.

EVALUATE: The voltage amplitude of the source is $V_{\text{rms}}\sqrt{2} = 228\ \text{V}$.

31.46. **IDENTIFY** and **SET UP:** $X_C = \dfrac{1}{\omega C}$. $X_L = \omega L$.

EXECUTE: **(a)** $\dfrac{1}{\omega_1 C} = \omega_1 L$ and $LC = \dfrac{1}{\omega_1^2}$. At angular frequency ω_2,

$\dfrac{X_L}{X_C} = \dfrac{\omega_2 L}{1/\omega_2 C} = \omega_2^2 LC = (2\omega_1)^2 \dfrac{1}{\omega_1^2} = 4$. $X_L > X_C$.

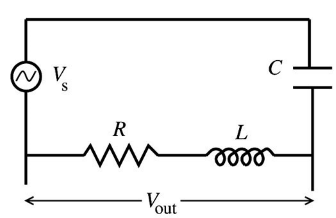
(b) At angular frequency ω_3, $\dfrac{X_L}{X_C} = \omega_3^2 LC = \left(\dfrac{\omega_1}{3}\right)^2 \left(\dfrac{1}{\omega_1^2}\right) = \dfrac{1}{9}$. $X_C > X_L$.

(c) The resonance angular frequency ω_0 is the value of ω for which $X_C = X_L$, so $\omega_0 = \omega_1$.

EVALUATE: When ω increases, X_L increases and X_C decreases. When ω decreases, X_L decreases and X_C increases.

31.47. **IDENTIFY** and **SET UP:** Express Z and I in terms of ω, L, C, and R. The voltages across the resistor and the inductor are 90° out of phase, so $V_{\text{out}} = \sqrt{V_R^2 + V_L^2}$.

EXECUTE: The circuit is sketched in Figure 31.47.



$$X_L = \omega L,\ X_C = \frac{1}{\omega C}$$

$$Z = \sqrt{R^2 + \left(\omega L - \frac{1}{\omega C}\right)^2}$$

$$I = \frac{V_s}{Z} = \frac{V_s}{\sqrt{R^2 + \left(\omega L - \frac{1}{\omega C}\right)^2}}$$

Figure 31.47

$$V_{\text{out}} = I\sqrt{R^2 + X_L^2} = I\sqrt{R^2 + \omega^2 L^2} = V_{\text{s}}\sqrt{\frac{R^2 + \omega^2 L^2}{R^2 + \left(\omega L - \dfrac{1}{\omega C}\right)^2}}$$

$$\frac{V_{\text{out}}}{V_{\text{s}}} = \sqrt{\frac{R^2 + \omega^2 L^2}{R^2 + \left(\omega L - \dfrac{1}{\omega C}\right)^2}}$$

$\underline{\omega \text{ small}}$:

As ω gets small, $R^2 + \left(\omega L - \dfrac{1}{\omega C}\right)^2 \to \dfrac{1}{\omega^2 C^2}$, $R^2 + \omega^2 L^2 \to R^2$.

Therefore, $\dfrac{V_{\text{out}}}{V_{\text{s}}} \to \sqrt{\dfrac{R^2}{(1/\omega^2 C^2)}} = \omega RC$ as ω becomes small.

$\underline{\omega \text{ large}}$:

As ω gets large, $R^2 + \left(\omega L - \dfrac{1}{\omega C}\right)^2 \to R^2 + \omega^2 L^2 \to \omega^2 L^2$, $R^2 + \omega^2 L^2 \to \omega^2 L^2$.

Therefore, $\dfrac{V_{\text{out}}}{V_{\text{s}}} \to \sqrt{\dfrac{\omega^2 L^2}{\omega^2 L^2}} = 1$ as ω becomes large.

EVALUATE: $V_{\text{out}}/V_{\text{s}} \to 0$ as ω becomes small, so there is V_{out} only when the frequency ω of V_{s} is large. If the source voltage contains a number of frequency components, only the high frequency ones are passed by this filter.

31.48. IDENTIFY: $V = V_C = IX_C$. $I = V/Z$.

SET UP: $X_L = \omega L$, $X_C = \dfrac{1}{\omega C}$.

EXECUTE: $V_{\text{out}} = V_C = \dfrac{I}{\omega C} \Rightarrow \dfrac{V_{\text{out}}}{V_{\text{s}}} = \dfrac{1}{\omega C\sqrt{R^2 + (\omega L - 1/\omega C)^2}}$.

If ω is large: $\dfrac{V_{\text{out}}}{V_{\text{s}}} = \dfrac{1}{\omega C\sqrt{R^2 + (\omega L - 1/\omega C)^2}} \approx \dfrac{1}{\omega C\sqrt{(\omega L)^2}} = \dfrac{1}{(LC)\omega^2}$.

If ω is small: $\dfrac{V_{\text{out}}}{V_{\text{s}}} \approx \dfrac{1}{\omega C\sqrt{(1/\omega C)^2}} = \dfrac{\omega C}{\omega C} = 1$.

EVALUATE: When ω is large, X_C is small and X_L is large so Z is large and the current is small. Both factors in $V_C = IX_C$ are small. When ω is small, X_C is large and the voltage amplitude across the capacitor is much larger than the voltage amplitudes across the resistor and the inductor.

31.49. IDENTIFY: $I = V/Z$ and $P_{\text{av}} = \frac{1}{2}I^2 R$.

SET UP: $Z = \sqrt{R^2 + (\omega L - 1/\omega C)^2}$.

EXECUTE: **(a)** $I = \dfrac{V}{Z} = \dfrac{V}{\sqrt{R^2 + (\omega L - 1/\omega C)^2}}$.

(b) $P_{av} = \frac{1}{2}I^2R = \frac{1}{2}\left(\frac{V}{Z}\right)^2 R = \frac{V^2R/2}{R^2 + (\omega L - 1/\omega C)^2}$.

(c) The average power and the current amplitude are both greatest when the denominator is smallest, which occurs for $\omega_0 L = \frac{1}{\omega_0 C}$, so $\omega_0 = \frac{1}{\sqrt{LC}}$.

(d) The average power is

$$P_{av} = \frac{(100\text{ V})^2(200\ \Omega)/2}{(200\ \Omega)^2 + \left[\omega(2.00\text{ H}) - 1/[\omega(0.500\times 10^{-6}\text{ F})]\right]^2} = \frac{1{,}000{,}000\,\omega^2}{40{,}000\omega^2 + (2\omega^2 - 2{,}000{,}000\text{ s}^{-2})^2}\text{ W}.$$

The graph of P_{av} versus ω is sketched in Figure 31.49.

EVALUATE: Note that as the angular frequency goes to zero, the power and current are zero, just as they are when the angular frequency goes to infinity. This graph exhibits the same strongly peaked nature as the light purple curve in Figure 31.19 in the textbook.

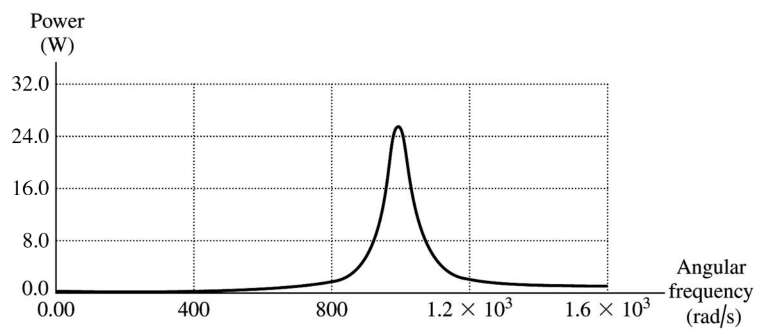


Figure 31.49

31.50. IDENTIFY: $V_L = I\omega L$ and $V_C = \frac{I}{\omega C}$.

SET UP: Problem 31.49 shows that $I = \frac{V}{\sqrt{R^2 + [\omega L - 1/(\omega C)]^2}}$.

EXECUTE: **(a)** $V_L = I\omega L = \frac{V\omega L}{\sqrt{R^2 + [\omega L - 1/(\omega C)]^2}}$.

(b) $V_C = \frac{I}{\omega C} = \frac{V}{\omega C\sqrt{R^2 + [\omega L - 1/(\omega C)]^2}}$.

(c) The graphs are given in Figure 31.50.

EVALUATE: **(d)** When the angular frequency is zero, the inductor has zero voltage while the capacitor has voltage of 100 V (equal to the total source voltage). At very high frequencies, the capacitor voltage goes to zero, while the inductor's voltage goes to 100 V. At resonance, $\omega_0 = \frac{1}{\sqrt{LC}} = 1000$ rad/s, the two voltages are equal, and are a maximum, 1000 V.

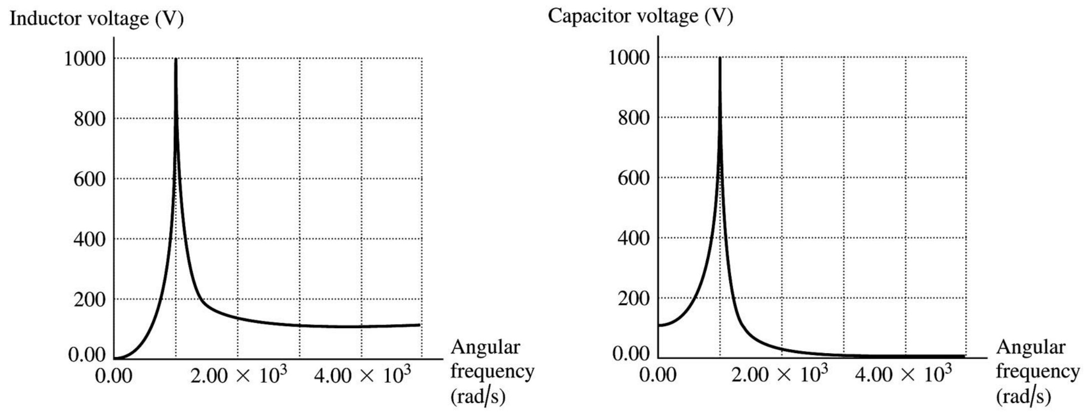

Figure 31.50

31.51. IDENTIFY: We know R, X_C, and ϕ so $\tan\phi = \dfrac{X_L - X_C}{R}$ tells us X_L. Use $P_{av} = I_{rms}^2 R$ to calculate I_{rms}. Then calculate Z and use $V_{rms} = I_{rms}Z$ to calculate V_{rms} for the source.

SET UP: Source voltage lags current so $\phi = -54.0°$. $X_C = 350\ \Omega$, $R = 180\ \Omega$, $P_{av} = 140$ W.

EXECUTE: (a) $\tan\phi = \dfrac{X_L - X_C}{R}$.

$X_L = R\tan\phi + X_C = (180\ \Omega)\tan(-54.0°) + 350\ \Omega = -248\ \Omega + 350\ \Omega = 102\ \Omega$.

(b) $P_{av} = V_{rms}I_{rms}\cos\phi = I_{rms}^2 R$ (Exercise 31.22). $I_{rms} = \sqrt{\dfrac{P_{av}}{R}} = \sqrt{\dfrac{140\text{ W}}{180\ \Omega}} = 0.882$ A.

(c) $Z = \sqrt{R^2 + (X_L - X_C)^2} = \sqrt{(180\ \Omega)^2 + (102\ \Omega - 350\ \Omega)^2} = 306\ \Omega$.

$V_{rms} = I_{rms}Z = (0.882\text{ A})(306\ \Omega) = 270$ V.

EVALUATE: We could also use $P_{av} = V_{rms}I_{rms}\cos\phi$.

$V_{rms} = \dfrac{P_{av}}{I_{rms}\cos\phi} = \dfrac{140\text{ W}}{(0.882\text{ A})\cos(-54.0°)} = 270$ V, which agrees. The source voltage lags the current when $X_C > X_L$, and this agrees with what we found.

31.52. IDENTIFY: We have an *L-R-C* series ac circuit.

SET UP and EXECUTE: (a) To detect a 4.0n GHz signal, a relevant characteristic is the resonance angular frequency. $\omega_0 = 1/\sqrt{LC}$. Solve for LC. $LC = 1/\omega_0^2 = 1/(2\pi f_0)^2 = 1/[2\pi(4\text{ GHz})]^2$ $= 1.6\times10^{-21}\text{ s}^2$.

(b) Use the result from (a). $L(1.0\times10^{-15}\text{ F}) = 1.6\times10^{-21}\text{ s}^2$. $L = 1.6\ \mu$H.

(c) Estimate: Thickness of phone = 2 mm; area = 4 mm^2.

(d) Use $L = \dfrac{\mu_0 N^2 A}{2\pi r}$, solve for N, and use the given numbers. $N = \sqrt{\dfrac{2\pi rL}{\mu_0 A}}$ = 160 turns.

EVALUATE: I would be difficult for a do-it-yourselfer to actually make such a small inductor.

31.53. IDENTIFY: We have a variable capacitor in an *L-R-C* series ac circuit.

SET UP and EXECUTE: (a) We want C. Use $C = \dfrac{\epsilon_0 A}{d}$. $d = g/2$ and A is the area in common. The maximum area in common is $A_{max} = \pi a^2/2$ when $\theta = \pi$. So $A = A_{max}(\theta/\pi) = (\pi a^2/2)(\theta/\pi) = a^2\theta/2$. The capacitance at any θ is $C = \dfrac{\epsilon_0 \left(a^2\theta/2\right)}{g/2} = \epsilon_0 a^2\theta/g$. There are 5 sets of capacitors, all in parallel, so the total capacitance is $C = 5\epsilon_0 a^2\theta/g$.

(b) We want θ to receive a 1180 kHz signal. This frequency should be the resonance frequency f_0 of the circuit. Solve $1/\sqrt{LC} = 2\pi f_0$ for C and use f_0 = 1180 kHz and L = 100 μH. This gives $C = 1/L(2\pi f_0)^2 =$ 182 pF. Now find the angle θ to get that capacitance. Solve $C = 5\epsilon_0 a^2\theta/g$ for θ, giving $\theta = \dfrac{gC}{5\epsilon_0 a^2}$ = 2.29 rad = 131°.

(c) We want the amplitude of the output voltage. The output voltage is the amplitude V_C, so $V_{\text{out}} = V_C = IX_C$. At resonance $I = V/R$, so $V_{\text{out}} = IX_C = \left(\dfrac{V}{R}\right)X_C = \left(\dfrac{V}{R}\right)\left(\dfrac{1}{\omega C}\right) = \dfrac{V}{R\omega C} = 7.41$ V.

(d) We want f when θ = 120°. $\omega_0 = 1/\sqrt{LC}$ where $C = 5\epsilon_0 a^2\theta/g$ and θ = 120° = $2\pi/3$ rad. First find C with these quantities, which gives $C = 1.668\times10^{-10}$ F. Now use $1/\sqrt{LC} = 2\pi f_0$ to find f_0. With the numbers this gives $f_0 = \dfrac{1}{2\pi\sqrt{LC}} =$ 1230 kHz.

(e) We want the amplitude of the output voltage at this frequency. $V_{\text{out}} = \dfrac{V}{R\omega C} = 7.74$ V.

Evaluate: A device like this allows continuous tuning to signals within its range. Simply turn a dial to rotate the capacitor plates. This design was actually used for tuning equipment.

31.54. Identify: At any instant of time the same rules apply to the parallel ac circuit as to the parallel dc circuit: the voltages are the same and the currents add.

Set Up: For a resistor the current and voltage in phase. For an inductor the voltage leads the current by 90° and for a capacitor the voltage lags the current by 90°.

Execute: **(a)** The parallel L-R-C circuit must have equal potential drops over the capacitor, inductor and resistor, so $v_R = v_L = v_C = v$. Also, the sum of currents entering any junction must equal the current leaving the junction. Therefore, the sum of the currents in the branches must equal the current through the source: $i = i_R + i_L + i_C$.

(b) $i_R = \dfrac{v}{R}$ is always in phase with the voltage. $i_L = \dfrac{v}{\omega L}$ lags the voltage by 90°, and $i_C = v\omega C$ leads the voltage by 90°. The phasor diagram is sketched in Figure 31.54.

(c) From the diagram, $I^2 = I_R^2 + (I_C - I_L)^2 = \left(\dfrac{V}{R}\right)^2 + \left(V\omega C - \dfrac{V}{\omega L}\right)^2$.

(d) From part (c): $I = V\sqrt{\dfrac{1}{R^2} + \left(\omega C - \dfrac{1}{\omega L}\right)^2}$. But $I = \dfrac{V}{Z}$, so $\dfrac{1}{Z} = \sqrt{\dfrac{1}{R^2} + \left(\omega C - \dfrac{1}{\omega L}\right)^2}$.

Evaluate: For large ω, $Z \to \dfrac{1}{\omega C}$. The current in the capacitor branch is much larger than the current in the other branches. For small ω, $Z \to \omega L$. The current in the inductive branch is much larger than the current in the other branches.

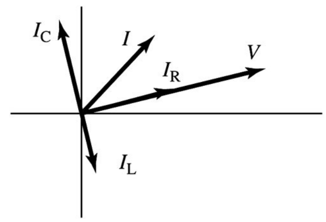

Figure 31.54

31.55. **IDENTIFY:** Apply the expression for $1/Z$ from Problem 31.54.

SET UP: From Problem 31.54, $\frac{1}{Z}=\sqrt{\frac{1}{R^2}+\left(\omega C-\frac{1}{\omega L}\right)^2}$.

EXECUTE: **(a)** Using $\frac{1}{Z}=\sqrt{\frac{1}{R^2}+\left(\omega C-\frac{1}{\omega L}\right)^2}$, we see that the impedance Z is a maximum when the square root is a minimum, and that occurs when $\omega C-\frac{1}{\omega L}=0$. But that occurs when $\omega=\frac{1}{\sqrt{LC}}$, which is the resonance angular frequency $\omega_0=\frac{1}{\sqrt{LC}}$. Since $I = V/Z$, the current is then a minimum when Z is a maximum.

(b) Using the result from part (a) gives $\omega=\frac{1}{\sqrt{LC}}=\frac{1}{\sqrt{(0.300\text{ H})(0.100\times10^{-6}\text{ F})}}=5770\text{ rad/s}$.

(c) At resonance, $Z = R = 100\ \Omega$, so $I = V/R = (240\text{ V})/(100\ \Omega) = 2.40\text{ A}$.

(d) At resonance, the amplitude of the current in the resistor is $I = V/R = (240\text{ V})/(100\ \Omega) = 2.40\text{ A}$.

(e) At resonance, $X_L = \omega L = (5770\text{ rad/s})(0.300\text{ H}) = 1730\ \Omega$, which is also X_C. The amplitude of the maximum current through the inductor is $I = V/X_L = (240\text{ V})/(1730\ \Omega) = 0.139\text{ A}$.

(f) Since we are at resonance, $X_L = X_C = 1730$ A. Therefore $I = V/X_C = (240\text{ V})/(1730\ \Omega) = 0.139\text{ A}$.

EVALUATE: The parallel circuit is sketched in Figure 31.55. At resonance, $|i_C|=|i_L|$ and at any instant of time these two currents are in opposite directions. Therefore, the net current between a and b is always zero. If the inductor and capacitor each have some resistance, and these resistances aren't the same, then it is no longer true that $i_C+i_L=0$. The result in part (a) for a parallel L-R-C circuit at resonance that the impedance is a maximum and the current is a minimum is the opposite of the behavior of a series L-R-C circuit at resonance.

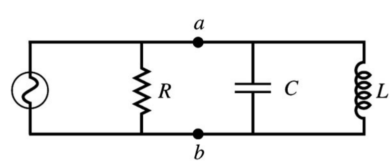

Figure 31.55

31.56. **IDENTIFY:** Refer to the results and the phasor diagram in Problem 31.54. The source voltage is applied across each parallel branch.

SET UP: $V=\sqrt{2}V_{\text{rms}}=254.6\text{ V}$.

EXECUTE: **(a)** $I_R=\frac{V}{R}=\frac{254.6\text{ V}}{400\ \Omega}=0.636\text{ A}$.

(b) $I_C = V\omega C = (254.6\ \text{V})(360\ \text{rad/s})(6.00\times10^{-6}\ \text{F}) = 0.550\ \text{A}.$

(c) $\phi = \arctan\left(\dfrac{I_C}{I_R}\right) = \arctan\left(\dfrac{0.550\ \text{A}}{0.636\ \text{A}}\right) = 40.8°.$

(d) $I = \sqrt{I_R^2 + I_C^2} = \sqrt{(0.636\ \text{A})^2 + (0.550\ \text{A})^2} = 0.841\ \text{A}.$

(e) Leads since $\phi > 0$.

EVALUATE: The phasor diagram shows that the current in the capacitor always leads the source voltage.

31.57. IDENTIFY: The average power depends on the phase angle ϕ.

SET UP: The average power is $P_{\text{av}} = V_{\text{rms}} I_{\text{rms}} \cos\phi$, and the impedance is $Z = \sqrt{R^2 + \left(\omega L - \dfrac{1}{\omega C}\right)^2}$.

EXECUTE: **(a)** $P_{\text{av}} = V_{\text{rms}} I_{\text{rms}} \cos\phi = \frac{1}{2}(V_{\text{rms}} I_{\text{rms}})$, which gives $\cos\phi = \frac{1}{2}$, so $\phi = \pi/3 = 60°$. $\tan\phi = (X_L - X_C)/R$, which gives $\tan 60° = (\omega L - 1/\omega C)/R$. Using $R = 75.0\ \Omega$, $L = 5.00$ mH and $C = 2.50\ \mu\text{F}$ and solving for ω we get $\omega = 28760$ rad/s $= 28{,}800$ rad/s.

(b) $Z = \sqrt{R^2 + (X_L - X_C)^2}$, where $X_L = \omega L = (28{,}760\ \text{rad/s})(5.00\ \text{mH}) = 144\ \Omega$ and $X_C = 1/\omega C = 1/[(28{,}760\ \text{rad/s})(2.50\ \mu\text{F})] = 13.9\ \Omega$, giving $Z = \sqrt{(75\ \Omega)^2 + (144\ \Omega - 13.9\ \Omega)^2} = 150\ \Omega$; $I = V/Z = (15.0\ \text{V})/(150\ \Omega) = 0.100\ \text{A}$ and $P_{\text{av}} = \frac{1}{2} VI\cos\phi = \frac{1}{2}(15.0\ \text{V})(0.100\ \text{A})(1/2) = 0.375\ \text{W}.$

EVALUATE: All this power is dissipated in the resistor because the average power delivered to the inductor and capacitor is zero.

31.58. IDENTIFY and **SET UP:** The maximum energy in the inductor depends on the current amplitude in the inductor. $U_L = \frac{1}{2}LI^2$ and $U_C = \frac{1}{2}CV^2$. The impedance of a series *L-R-C* circuit is

$$Z = \sqrt{R^2 + \left(\omega L - \frac{1}{\omega C}\right)^2},\quad X_C = \frac{1}{\omega C}.$$

EXECUTE: **(a)** Use $Z = \sqrt{R^2 + \left(\omega L - \dfrac{1}{\omega C}\right)^2}$ to find the impedance of the circuit.

$$Z = \sqrt{(60.0\ \Omega)^2 + \left[(120\ \text{rad/s})(0.800\ \text{H}) - \frac{1}{(120\ \text{rad/s})(3.00\times10^{-4}\ \text{F})}\right]^2} = 90.85\,\Omega.$$

The amplitude of the current is therefore $I = V/Z = (90.0\ \text{V})/(90.85\ \Omega) = 0.9906$ A, so the maximum energy stored in the inductor is $U_L = \frac{1}{2}LI^2 = (1/2)(0.800\ \text{H})(0.9906\ \text{A})^2 = 0.393$ J.

(b) The energy stored in the capacitor is $U_C = \frac{1}{2}CV^2$, but the capacitor voltage is 90° out of phase with the current. Thus when the current is a maximum, the voltage across the capacitor is zero, so the energy stored in the capacitor is also zero.

(c) The capacitor stores its maximum energy when it is at maximum voltage, which is

$V_C = IX_C = I\dfrac{1}{\omega C} = (0.9906\ \text{A})\left[\dfrac{1}{(120\ \text{rad/s})(3.00\times10^{-4}\ \text{F})}\right] = 27.52$ V. The maximum energy in the capacitor at this time is $U_C = \frac{1}{2}CV^2 = (1/2)(3.00\times10^{-4}\ \text{F})(27.52\ \text{V})^2 = 0.114$ J.

EVALUATE: The maximum energy stored in the inductor is not the same as in the capacitor due to the presence of resistance.

31.59. IDENTIFY and SET UP: The equation $V_C = IX_C$ allows us to calculate I and then $V = IZ$ gives Z. Solve $Z=\sqrt{R^2+(X_L-X_C)^2}$ for X_L.

EXECUTE: (a) $V_C = IX_C$ so $I=\dfrac{V_C}{X_C}=\dfrac{360\text{ V}}{480\ \Omega}=0.750\text{ A}.$

(b) $V = IZ$ so $Z=\dfrac{V}{I}=\dfrac{120\text{ V}}{0.750\text{ A}}=160\ \Omega.$

(c) $Z^2=R^2+(X_L-X_C)^2.$

$X_L-X_C=\pm\sqrt{Z^2-R^2}$, so

$X_L=X_C\pm\sqrt{Z^2-R^2}=480\ \Omega\pm\sqrt{(160\ \Omega)^2-(80.0\ \Omega)^2}=480\ \Omega\pm139\ \Omega.$

$X_L=619\ \Omega$ or $341\ \Omega.$

EVALUATE: (d) $X_C=\dfrac{1}{\omega C}$ and $X_L=\omega L.$ At resonance, $X_C=X_L.$ As the frequency is lowered below the resonance frequency X_C increases and X_L decreases. Therefore, for $\omega<\omega_0,\ X_L<X_C.$ So for $X_L=341\ \Omega$ the angular frequency is less than the resonance angular frequency. ω is greater than ω_0 when $X_L=619\ \Omega.$ But at these two values of $X_L,$ the magnitude of X_L-X_C is the same so Z and I are the same. In one case $(X_L=691\ \Omega)$ the source voltage leads the current and in the other $(X_L=341\ \Omega)$ the source voltage lags the current.

31.60. IDENTIFY and SET UP: The capacitive reactance is $X_C=\dfrac{1}{\omega C},$ the inductive reactance is $X_L=\omega L,$ and the impedance of an L-R-C series circuit is $Z=\sqrt{R^2+(X_L-X_C)^2}.$

EXECUTE: (a) The current amplitude is $I = V/R = (135\text{ V})/(90.0\ \Omega) = 1.50\text{ A}$.
(b) The voltage amplitude across the inductor is $V_L = IX_L = (1.50\ \Omega)(320\ \Omega) = 480\text{ V}$.
(c) The impedance is $Z = V/I = (240\text{ V})/(1.50\text{ A}) = 160\ \Omega$. We also know that the impedance is $Z=\sqrt{R^2+(X_L-X_C)^2}.$ We know that $X_{-L} = 320\ \Omega$, so we can find X_C.

$160\ \Omega=\sqrt{(90.0\ \Omega)^2+(320\ \Omega-X_C)^2}.$ Squaring and solving for X_C gives two values, $X_C = 188\ \Omega$ and $X_C = 452\ \Omega$.

(d) At resonance, $\omega L=\dfrac{1}{\omega C}.$ $X_C < X_L$ for $\omega>\omega_{\text{res}}$ and $X_C > X_L$ for $\omega<\omega_{\text{res}}$. In this circuit, $X_L = 320\ \Omega$, so $\omega<\omega_{\text{res}}$ for $X_C = 452\ \Omega$.

EVALUATE: Due to the square of $(X_L - X_C)$ in the impedance, we get two possibilities in (c).

31.61. IDENTIFY: At resonance, $Z=R.$ $I=V/R.$ $V_R=IR,$ $V_C=IX_C$ and $V_L=IX_L.$ $U_C=\tfrac{1}{2}CV_C^2$ and $U_L=\tfrac{1}{2}LI^2.$

SET UP: The amplitudes of each time-dependent quantity correspond to the maximum values of those quantities.

EXECUTE: (a) $I=\dfrac{V}{Z}=\dfrac{V}{\sqrt{R^2+(\omega L-1/\omega C)^2}}.$ At resonance $\omega L=\dfrac{1}{\omega C}$ and $I_{\max}=\dfrac{V}{R}.$

(b) $V_C=IX_C=\dfrac{V}{R\omega_0 C}=\dfrac{V}{R}\sqrt{\dfrac{L}{C}}.$

(c) $V_L = IX_L = \dfrac{V}{R}\omega_0 L = \dfrac{V}{R}\sqrt{\dfrac{L}{C}}.$

(d) $U_C = \dfrac{1}{2}CV_C^2 = \dfrac{1}{2}C\dfrac{V^2}{R^2}\dfrac{L}{C} = \dfrac{1}{2}L\dfrac{V^2}{R^2}.$

(e) $U_L = \dfrac{1}{2}LI^2 = \dfrac{1}{2}L\dfrac{V^2}{R^2}.$

EVALUATE: At resonance $V_C = V_L$ and the maximum energy stored in the inductor equals the maximum energy stored in the capacitor.

31.62. **IDENTIFY** and **SET UP:** We use $I = V/Z$, $X_L = \omega L$, and $Z = \sqrt{R^2 + X_L^2}$.

EXECUTE: $I = \dfrac{V}{Z} = \dfrac{V}{\sqrt{R^2 + X_L^2}}$. Squaring and rearranging gives $\dfrac{1}{I^2} = \left(\dfrac{L}{V}\right)^2 \omega^2 + \left(\dfrac{R}{V}\right)^2$. Therefore a graph of $1/I^2$ versus ω^2 should be a straight line having slope equal to $(L/V)^2$ and y-intercept equal to $(R/V)^2$. We can find the slope using two convenient points on the graph, giving

slope = $\dfrac{(21.0 - 9.0)\ \text{A}^{-2}}{(3500 - 500)\ \text{rad}^2/\text{s}^2} = 4.00\times 10^{-3}\ \text{s}^2/\text{rad}^2 \cdot \text{A}^2.$

Solving for L gives $L = V\sqrt{\text{slope}} = (12.0\ \text{V})\sqrt{4.00\times 10^{-3}\ \text{s}^2/\text{rad}^2 \cdot \text{A}^2} = 0.759\ \text{H}.$

Extending the line, we find the y-intercept is 7.0 A^{-2}. Using this value to solve for R gives

$R = V\sqrt{y\text{-intercept}} = (12.0\ \text{V})\sqrt{7.00\,\text{A}^{-2}} = 32\ \Omega.$

EVALUATE: These are reasonable values for L and R for a large solenoid, so we're confident in the results.

31.63. **IDENTIFY** and **SET UP:** For an L-R-C series circuit, the maximum current occurs at resonance, and the resonance angular frequency is $\omega_{\text{res}} = \dfrac{1}{\sqrt{LC}}.$

EXECUTE: At resonance, the angular frequency is $\omega_{\text{res}} = \dfrac{1}{\sqrt{LC}}$. Squaring gives $\omega_{\text{res}}^2 = \dfrac{1}{L}\cdot\dfrac{1}{C}$, so a graph of ω_{res}^2 versus $1/C$ should be a straight line with a slope equal to $1/L$. Using two convenient points on the graph, we find the slope to be $\dfrac{(25.0 - 1.00)\times 10^4\ \text{rad}^2/\text{s}^2}{(4.50 - 1.75)\ \times 10^3\ \text{F}^{-1}} = 5.455\ \text{F/s}^2$. Solving for L gives $L = (\text{slope})^{-1} = (5.455\ \text{F/s}^2)^{-1} = 0.183$ H, which rounds to 0.18 H, since we cannot determine the slope of the graph in the text with anything better than 2 significant figures. To find R, we realize that at resonance $Z = R$, so $R = V/I = (90.0\ \text{V})/(4.50\ \text{A}) = 20.0\ \Omega$.

EVALUATE: These are reasonable values for L and R for a laboratory solenoid.

31.64. **IDENTIFY** and **SET UP:** For an L-R-C series circuit, $\tan\phi = \dfrac{\omega L - \dfrac{1}{\omega C}}{R}$ and the power factor is $\cos\phi = R/Z$.

EXECUTE: **(a)** $\cos\phi = R/Z$, so $R = Z\cos\phi$.

At 80 Hz: $R = (15\ \Omega)\cos(-71°) = 4.88\ \Omega$.

At 160 Hz: $R = (13\ \Omega)\cos(67°) = 5.08\ \Omega$.

The average resistance is $(4.88\ \Omega + 5.08\ \Omega)/2 = 5.0\ \Omega$.

(b) We use $\tan\phi = \dfrac{\omega L - \dfrac{1}{\omega C}}{R}$ with $R = 5.0\ \Omega$ from part (a).

At 80 Hz: $\tan(-71°) = \dfrac{2\pi(80\text{ Hz})L - \dfrac{1}{2\pi(80\text{ Hz})C}}{5.0\ \Omega}$.

$-14.52 = 160\pi$ Hz $L - 1/[(160\pi\text{ Hz})C]$. Eq. (1)

At 160 Hz: $\tan(67°) = \dfrac{2\pi(160\text{ Hz})L - \dfrac{1}{2\pi(160\text{ Hz})C}}{5.0\ \Omega}$.

$11.78 = 320\pi$ Hz $L - 1/[(320\pi\text{ Hz})C]$. Eq. (2)

Multiply Eq. (1) by –2 and add it to Eq. (2), giving

$2(14.52) + 11.78 = (1/C)(1/80\pi - 1/320\pi)$.

$C = 7.31\times10^{-5}$ F, which rounds to $C = 73\ \mu$F.

Substituting this result into either Eq. (1) or Eq. (2) gives $L = 25.3$ mH, which rounds to $L = 25$ mH.

(c) The resonance angular frequency is $\omega_0 = \dfrac{1}{\sqrt{LC}}$, so the resonance frequency is

$$f_0 = \frac{\omega_0}{2\pi} = \frac{1}{2\pi\sqrt{LC}} = \frac{1}{2\pi\sqrt{(2.53\times10^{-2}\text{ H})(73.1\times10^{-6}\text{ F})}} = 117\text{ Hz}.$$

At resonance, $Z = R = 5.0\ \Omega$ and $\phi = 0$.

EVALUATE: It is only at resonance that $Z = R$, not at the other frequencies.

31.65. IDENTIFY: We have an *L-R* ac circuit.

SET UP: $v_{in} = V_{in}\cos\omega t$, $G = (20\text{ dB})\ln(V_{out}/V_{in})$, $I = V_{in}/Z$, $Z = \sqrt{R^2 + (\omega L)^2}$, $\phi = \arctan\left(\dfrac{\omega L}{R}\right)$.

EXECUTE: **(a)** We want the current. $I = \dfrac{V_{in}}{Z} = \dfrac{V_{in}}{\sqrt{R^2 + (\omega L)^2}}$.

(b) We want ϕ. $\phi = \arctan\left(\dfrac{\omega L}{R}\right)$.

(c) We want V_{out}/V_{in}. $\dfrac{V_{out}}{V_{in}} = \dfrac{V_L}{V_{in}} = \dfrac{IX_L}{V_{in}} = \dfrac{\dfrac{V_{in}}{\sqrt{R^2+(\omega L)^2}}\cdot \omega L}{V_{in}} = \dfrac{\omega L}{\sqrt{R^2 + (\omega L)^2}} = \dfrac{1}{\sqrt{1 + (R/\omega L)^2}}$.

(d) We want *f* so $G = -3.0$ dB. Use $G = (20\text{ dB})\ln(V_{out}/V_{in})$. $-3.0\text{ dB} = (20\text{ dB})\ln(V_{out}/V_{in})$.

$-3.0/20 = \ln(V_{out}/V_{in})$. Write this result in terms of exponents and use the result from (c).

$10^{-3.0/20} = 0.708 = \dfrac{V_{out}}{V_{in}} = \dfrac{1}{\sqrt{1+(R/\omega L)^2}}$. Use $\omega = 2\pi f$ and solve for *f*, giving $f = \dfrac{R}{2.00\pi L}$.

(e) We want *L*. Solve the result in (d) when $f = 10.0$ kHz and $R = 100\ \Omega$, giving $L = 1.6$ mH.

EVALUATE: By varying the ration *R/L* we can tune to any desired frequency.

31.66. IDENTIFY: We have an *L-R-C* series ac circuit.

SET UP: The output is across the capacitor. $v_{in} = V_{in}\cos\omega t$, $v_{out} = V_{out}\cos(\omega t + \theta)$,

$$Z = \sqrt{R^2 + \left(\omega L - \frac{1}{\omega C}\right)^2},\quad \phi = \arctan\left(\frac{\omega L - 1/\omega C}{R}\right),\quad \omega_0 = 1/\sqrt{LC}.$$

EXECUTE: **(a)** We want V_{out}. $V_{\text{out}} = V_C = IX_C = \dfrac{V_{\text{in}}}{Z} X_C = \dfrac{V_{\text{in}}}{\omega C\sqrt{R^2 + \left(\omega L - \dfrac{1}{\omega C}\right)^2}}$, which we can express as $V_{\text{out}} = \dfrac{V_{\text{in}}}{\sqrt{(R\omega C)^2 + \left(\omega^2 LC - 1\right)^2}}$.

(b) We want the phase angle for v_{out}. The output voltage is across the capacitor, so the phase angle θ is the same as for the capacitor. The capacitor voltage lags the current by $\pi/2$, so the phase angle is $\theta = \phi - \pi/2$. $\phi = \arctan\left(\dfrac{\omega L - 1/\omega C}{R}\right) = \arctan\left(\dfrac{\omega^2 LC - 1}{\omega RC}\right)$. So $\theta = \arctan\left(\dfrac{\omega^2 LC - 1}{\omega RC}\right) - \dfrac{\pi}{2}$.

(c) We want θ at resonance. At resonance $\omega_0 = 1/\sqrt{LC}$, so $\phi = 0$. Thus $\theta = -\pi/2$.

(d) We want C. Solving $\omega_0 = 1/\sqrt{LC}$ for C and using the given values, we get

$C = \dfrac{1}{\omega_0^2 L} = \dfrac{1}{(2\pi f_0)^2 L} = 2.53\ \mu\text{F}$.

(e) We want V_{out}. $V_{\text{out}} = V_C$. Use the result from part (a) at resonance. $V_{\text{out}} = \dfrac{V_{\text{in}}}{R\omega C} = \dfrac{V_{\text{in}}}{2\pi fRC}$. Using the numbers gives $V_{\text{out}} = 62.9$ mV.

EVALUATE: Simply by varying the frequency the output voltage amplitude changes.

31.67. **IDENTIFY:** $p_R = i^2 R$. $p_L = iL\dfrac{di}{dt}$. $p_C = \dfrac{q}{C}i$.

SET UP: $i = I\cos\omega t$.

EXECUTE: **(a)** $p_R = i^2 R = I^2\cos^2(\omega t)R = V_R I\cos^2(\omega t) = \dfrac{1}{2}V_R I(1+\cos(2\omega t))$.

$P_{\text{av}}(R) = \dfrac{1}{T}\int_0^T p_R dt = \dfrac{V_R I}{2T}\int_0^T [1+\cos(2\omega t)]dt = \dfrac{V_R I}{2T}[t]_0^T = \tfrac{1}{2}V_R I$.

(b) $p_L = Li\dfrac{di}{dt} = -\omega L I^2\cos(\omega t)\sin(\omega t) = -\tfrac{1}{2}V_L I\sin(2\omega t)$. But $\int_0^T \sin(2\omega t)dt = 0 \Rightarrow P_{\text{av}}(L) = 0$.

(c) $p_C = \dfrac{q}{C}i = v_C i = V_C I\sin(\omega t)\cos(\omega t) = \tfrac{1}{2}V_C I\sin(2\omega t)$. But $\int_0^T \sin(2\omega t)dt = 0 \Rightarrow P_{\text{av}}(C) = 0$.

(d) $p = p_R + p_L + p_c = V_R I\cos^2(\omega t) - \tfrac{1}{2}V_L I\sin(2\omega t) + \tfrac{1}{2}V_C I\sin(2\omega t)$ and

$p = I\cos\omega t(V_R\cos\omega t - V_L\sin\omega t + V_C\sin\omega t)$. But $\cos\phi = \dfrac{V_R}{V}$ and $\sin\phi = \dfrac{V_L - V_C}{V}$, so

$p = VI\cos\omega t(\cos\phi\cos\omega t - \sin\phi\sin\omega t)$, at any instant of time.

EVALUATE: At an instant of time the energy stored in the capacitor and inductor can be changing, but there is no net consumption of electrical energy in these components.

31.68. **IDENTIFY:** $V_L = IX_L$. $\dfrac{dV_L}{d\omega} = 0$ at the ω where V_L is a maximum. $V_C = IX_C$. $\dfrac{dV_C}{d\omega} = 0$ at the ω where V_C is a maximum.

SET UP: Problem 31.49 shows that $I = \dfrac{V}{\sqrt{R^2 + (\omega L - 1/\omega C)^2}}$.

EXECUTE: **(a)** $V_R = \text{maximum}$ when $V_C = V_L \Rightarrow \omega = \omega_0 = \dfrac{1}{\sqrt{LC}}$.

(b) $V_L = \text{maximum}$ when $\dfrac{dV_L}{d\omega} = 0.$ Therefore: $\dfrac{dV_L}{d\omega} = 0 = \dfrac{d}{d\omega}\left(\dfrac{V\omega L}{\sqrt{R^2 + (\omega L - 1/\omega C)^2}}\right).$

$$0 = \frac{VL}{\sqrt{R^2 + (\omega L - 1/\omega C)^2}} - \frac{V\omega^2 L(L - 1/\omega^2 C)(L + 1/\omega^2 C)}{\left[R^2 + (\omega L - 1/\omega C)^2\right]^{3/2}}.\quad R^2 + (\omega L - 1/\omega C)^2 = \omega^2(L^2 - 1/\omega^4 C^2).$$

$$R^2 + \frac{1}{\omega^2 C^2} - \frac{2L}{C} = -\frac{1}{\omega^2 C^2}.\quad \frac{1}{\omega^2} = LC - \frac{R^2 C^2}{2} \text{ and } \omega = \frac{1}{\sqrt{LC - R^2 C^2/2}}.$$

(c) $V_C = \text{maximum}$ when $\dfrac{dV_C}{d\omega} = 0.$ Therefore: $\dfrac{dV_C}{d\omega} = 0 = \dfrac{d}{d\omega}\left(\dfrac{V}{\omega C\sqrt{R^2 + (\omega L - 1/\omega C)^2}}\right).$

$$0 = -\frac{V}{\omega^2 C\sqrt{R^2 + (\omega L - 1/\omega C)^2}} - \frac{V(L - 1/\omega^2 C)(L + 1/\omega^2 C)}{C(R^2 + (\omega L - 1/\omega C)^2)^{3/2}}.\quad R^2 + (\omega L - 1/\omega C)^2 = -\omega^2(L^2 - 1/\omega^4 C^2).$$

$$R^2 + \omega^2 L^2 - \frac{2L}{C} = -\omega^2 L^2 \text{ and } \omega = \sqrt{\frac{1}{LC} - \frac{R^2}{2L^2}}.$$

EVALUATE: V_L is maximum at a frequency greater than the resonance frequency and V_C is a maximum at a frequency less than the resonance frequency. These frequencies depend on R, as well as on L and on C.

31.69. **IDENTIFY** and **SET UP:** We are told that the platinum electrode behaves like an ideal capacitor in series with the resistance of the fluid. The impedance of an *R*-*C* circuit is $Z = \sqrt{R^2 + X_C^2}$, where $X_C = \dfrac{1}{\omega C}.$

EXECUTE: For a dc signal we have $\omega = 2\pi f = 0.$ Using $X_C = \dfrac{1}{\omega C}$ we see that as $\omega \to 0$ we have $X_C \to \infty$, and so $Z \to \infty$. The correct choice is (b).

EVALUATE: The oscillation period of such a circuit is $T = 1/f$, so $T \to \infty$ as $\omega \to 0.$

31.70. **IDENTIFY** and **SET UP:** We are told that the platinum electrode behaves like an ideal capacitor in series with the resistance of the fluid, which is given by $R_A = \rho/(10a)$, where $\rho = 100\ \Omega\cdot\text{cm} = 1\ \Omega\cdot\text{m}$ and $d = 2a = 20\ \mu\text{m}$. We know that $X_C = \dfrac{1}{\omega C}$, where we are given $C = 10\ \text{nF} = 10^{-8}\ \text{F}$ and $\omega = 2\pi f = 2\pi[(5000/\pi)\text{Hz}] = 10^4\ \text{rad/s}.$ For an *R*-*C* circuit we know that the impedance is given by s

EXECUTE: $R_A = \rho/(10a) = (1\ \Omega\cdot\text{m})/[10(10^{-5}\ \text{m})] = 10^4\ \Omega.$ The capacitive reactance is $X_C = \dfrac{1}{\omega C} = \dfrac{1}{(10^4\ \text{rad/s})(10^{-8}\ \text{F})} = 10^4\ \Omega.$ Thus the impedance is

$Z = \sqrt{R^2 + X_C^2} = \sqrt{(10^4\ \Omega)^2 + (10^4\ \Omega)^2} = \sqrt{2}\times(10^4\ \Omega)$, so the correct choice is (c).

EVALUATE: In this case, the capacitance contributes as much to the impedance as the resistance does.

31.71. **IDENTIFY** and **SET UP:** We know that $V_{\text{rms}} = \dfrac{V}{\sqrt{2}}$, where V is the amplitude (peak value) of the voltage. According to the problem, the peak-to-peak voltage V_{pp} is the difference between the two extreme values of voltage.

EXECUTE: Since the voltage oscillates between $+V$ and $-V$ the peak-to-peak voltage is $V_{\text{pp}} = V - (-V) = 2V = 2\sqrt{2}V_{\text{rms}}.$ Thus, the correct answer is (d).

EVALUATE: The voltage amplitude is half the peak-to-peak voltage.

31.72. **IDENTIFY** and **SET UP:** The impedance of an *R*-*C* circuit is $Z = \sqrt{R^2 + X_C^2}$, where $X_C = \dfrac{1}{\omega C}$.

EXECUTE: As the frequency of oscillation gets very large, X_C gets very small, so the impedance approaches the access resistance *R*. So the impedance approaches a constant but nonzero value, which is choice (c).

EVALUATE: For high oscillation frequency, the access resistance has more effect on the circuit than the capacitance does.

32

ELECTROMAGNETIC WAVES

VP32.2.1. **IDENTIFY:** This problem is about the properties of an electromagnetic wave.

SET UP: $E = cB$, the wave propagates in the direction of $\vec{E}\times\vec{B}$.

EXECUTE: **(a)** We want E_{max}. $E_{max} = cB_{max} = c(4.30 \text{ mT}) = 1.29$ MV/m.

(b) We want the wavelength. $\lambda = 2\pi/k = 2\pi/(2.50 \text{ Mrad/m}) = 2.51\ \mu\text{m}$.

(c) We want the frequency. $f = c/\lambda = c/(2.51\ \mu\text{m}) = 1.19\times10^{14}$ Hz.

(d) We want the direction. The direction is the same as $\vec{E}\times\vec{B}$, which is $+z$.

EVALUATE: This wave is not in the visible part of the spectrum.

VP32.2.2. **IDENTIFY:** This problem is about the properties of an electromagnetic wave.

SET UP: $E = cB$, the wave propagates in the direction of $\vec{E}\times\vec{B}$, $\omega/k = c$.

EXECUTE: **(a)** We want λ. $\lambda = 2\pi/k = 2\pi/(6.50 \text{ Mrad/m}) = 967$ nm.

(b) We want ω. $\omega/k = c$, so $\omega = ck = c(6.50 \text{ Mrad/m}) = 1.95\times10^{14}$ rad/s.

(c) Direction of travel? E is of the form $E = E_{max}\cos(kx - \omega t)$, so the wave is traveling in the $+y$-direction.

(d) We want B. $B = E/c = (2.46 \text{ MV/m})/c = 8.20$ mT. The wave travels in the direction of $\vec{E}\times\vec{B}$. We know that $\vec{E}$ is in the $+x$-direction and $\vec{E}\times\vec{B}$ is in the $+y$-direction. So by the right-hand rule for the cross product, $\vec{B}$ must be in the –z-direction. The full equation for $\vec{B}$ is therefore

$\vec{B} = -\hat{k}(8.20\times10^{-3}\text{ T})\cos[(6.50\times10^{6}\text{ rad/m})y - (1.95\times10^{15}\text{ rad/s})t]$.

EVALUATE: With a wavelength of 967 nm, this is not visible light.

VP32.2.3. **IDENTIFY:** This is an electromagnetic wave.

SET UP: $E = cB$, the wave propagates in the direction of $\vec{E}\times\vec{B}$.

EXECUTE: **(a)** We want $\vec{B}$. $B = E/c = (4.20 \text{ MV/m})/c = 14.0$ mT. The direction of $\vec{E}$ is $+y$ and $\vec{E}\times\vec{B}$ is $+x$, so by the right-hand rule for the cross product, $\vec{B}$ must point in the $+z$-direction.

(b) We want $\vec{E}$ at $x = 1.85\ \mu$m. $E_y = E_{max}\cos kx$. $k = 2\pi/\lambda = 2\pi/(2.94\ \mu\text{m}) = 2.14$ Mrad/m. So $E_y = (4.20 \text{ MV/m})\cos[(2.137 \text{ Mrad/m})(1.85\ \mu\text{m})] = -2.89$ MV/m. The magnitude is 2.89 MV/m and the direction is in the $-y$-direction.

(c) We want $\vec{B}$ at $x = 1.85\ \mu$m. $B = E/c = (2.89 \text{ MV/m})/c = 9.63$ mT. The wave travels in the $+x$-direction and $\vec{E}$ is in the $-y$-direction, so $\vec{B}$ must be in the $-z$-direction by the right-hand rule for $\vec{E}\times\vec{B}$.

EVALUATE: Note that the wave has a large-amplitude electric field but a small-amplitude magnetic field. This is typical.

VP32.2.4. **IDENTIFY:** This problem deals with an electromagnetic wave in matter.

SET UP and **EXECUTE:** **(a)** We want *f* in vacuum. $f = c/\lambda = c/(1.16\ \mu\text{m}) = 2.59\times10^{14}$ Hz.

(b) We want *f* in the material. The frequency does not change, only the wavelength and speed change, so $f = 2.59\times10^{14}$ Hz.

(c) We want the speed in the material. Let *v* indicate vacuum. $\dfrac{v}{c} = \dfrac{f\lambda}{f\lambda_v} = \dfrac{\lambda}{\lambda_v}$.

$v = c\dfrac{\lambda}{\lambda_v} = c\dfrac{0.635\ \mu\text{m}}{1.16\ \mu\text{m}} = 1.64\times10^8$ m/s.

(d) We want *K*. $c/v = \sqrt{K} \rightarrow K = (c/v)^2$. Using *v* from (c) gives $K = 3.34$.

EVALUATE: The light slows down and the wavelength decreases as the light enters matter.

VP32.4.1. **IDENTIFY:** We are dealing with the energy in an electromagnetic wave.

SET UP: $E = cB$, $S = \dfrac{1}{\mu_0}EB$, $u = \epsilon_0 E^2$, $S = 11.0\ \text{W/m}^2$.

EXECUTE: **(a)** We want the magnitudes of the fields. Combine $S = \dfrac{1}{\mu_0}EB$ and $E = cB$ to obtain $S = \dfrac{c}{\mu_0}B^2$. Solve for *B* and using the given numbers. $B = \sqrt{\mu_0 S/c} = 0.215\ \mu\text{T}$. $E = cB = 64.4$ V/m using the *B* we just found.

(b) We want the energy density. $u = \epsilon_0 E^2 = 36.7\ \text{nJ/m}^3$ using the value of *E* that we just found.

EVALUATE: This energy density is typical of many electromagnetic waves.

VP32.4.2. **IDENTIFY:** This problem deals with the Poynting vector $\vec{S}$.

SET UP: $\vec{S} = \dfrac{1}{\mu_0}\vec{E}\times\vec{B}$, $S = \dfrac{1}{\mu_0}EB$, $k = 2\pi/\lambda$. We want $\vec{S}$ at the following times.

EXECUTE: **(a)** At $x = 0$ and $t = 0$: $\vec{S} = \dfrac{E_{\max}B_{\max}}{\mu_0}\hat{i}$.

(b) At $x = \lambda/4$, $t = 0$: $E = E_{\max}\cos(kx - 0) = E_{\max}\cos\left[\left(\dfrac{2\pi}{\lambda}\right)\left(\dfrac{\lambda}{4}\right)\right] = E_{\max}\cos(\pi/2) = 0$. So it follows that $S = 0$.

(c) At $x = \lambda/4$, $t = \pi/4\omega$:

$E = E_{\max}\cos(kx - \omega t) = E_{\max}\cos\left[\left(\dfrac{2\pi}{\lambda}\right)\left(\dfrac{\lambda}{4}\right) - \omega\left(\dfrac{\pi}{4\omega}\right)\right] = E_{\max}\cos\left(\dfrac{\pi}{2} - \dfrac{\pi}{4}\right) = E_{\max}\dfrac{1}{\sqrt{2}}$. And likewise $B = B_{\max}\dfrac{1}{\sqrt{2}}$. Multiplying these two magnitudes together gives $\vec{S} = \dfrac{E_{\max}B_{\max}}{2\mu_0}\hat{i}$.

EVALUATE: It is clear that *S* also varies as the fields vary.

VP32.4.3. **IDENTIFY:** We are dealing with the power in electromagnetic waves.

SET UP: $E = cB$, $I = \dfrac{1}{2}\epsilon_0 cE_{\max}^2$

EXECUTE: **(a)** We want *B* and *I*. Magnetic field: $B = E/c = (0.360\ \text{V/m})/c = 1.20$ nT.

Intensity: Use $I = \dfrac{1}{2}\epsilon_0 cE_{\max}^2$ with $E_{\max} = 0.360$ V/m, giving $I = 172\ \mu\text{W/m}^2$.

(b) We want the power radiated. $P = IA = I[(4\pi r^2)/2] = 156$ kW.

EVALUATE: The answer in (b) assumes that none of the energy is transformed into other types of energy (such as kinetic energy of air molecules) as the waves travel through the air.

VP32.4.4. **IDENTIFY:** This problem is about the energy in electromagnetic waves.

SET UP: $I = \dfrac{E_{\max}^2}{2\mu_0 c}$, $E = cB$.

EXECUTE: **(a)** We want the amplitudes of the fields. Solve $I = \dfrac{E_{\max}^2}{2\mu_0 c}$ for $E_{\max}$ and use $I = 1.36\text{ kW/m}^2$. $E_{\max} = \sqrt{2\mu_0 cI} = 1.01\text{ kV/m}$. $B_{\max} = (1.01\text{ kV/m})/c = 3.38\ \mu\text{T}$.

(b) We want the total power radiated by the sun. Use I from (a) and $r = 1.50\times 10^{11}$ m. $P = IA = I(4\pi r^2) = 3.85\times 10^{26}$ W.

EVALUATE: At half the earth-sun distance the intensity would be 4 times as great, so a planet there would be much hotter than the earth.

VP32.7.1. **IDENTIFY:** We are dealing with standing electromagnetic waves.

SET UP: $S = \dfrac{1}{\mu_0}EB$. We want the Poynting vector in the standing wave at the following times.

EXECUTE: **(a)** We want the maximum the Poynting vector can be. Using Eq. (32.34) and (32.35), we have $S = \dfrac{(2E_{\max}\sin kx\cos\omega t)(2B_{\max}\cos kx\sin\omega t)}{\mu_0}$. The largest that sin kx can be is 1, but then cos kx = 0, and likewise with $\sin\omega t$. The largest product is when sin kx = cos kx, which is when kx = π/4, and likewise for the $\sin\omega t$ factors. In this case, each factor is equal to $1/\sqrt{2}$. Since we have 4 such factors, the final result is $S_{\max} = \dfrac{1}{\mu_0}E_{\max}B_{\max}$. Using the given amplitudes gives $S_{\max} = 0.215\text{ W/m}^2$.

(b) At $t = 0$: $\sin\omega t = 0$, so $S = 0$.

(c) At $x = 0.125$ mm, $t = 3.15\times 10^{-13}$ s: As in Example 32.6, $S = \dfrac{E_{\max}B_{\max}\sin 2kx\sin 2\omega t)}{\mu_0}$. Using the given values for x, t, k, etc., we get $\vec{S} = 0.0907\text{ W/m}^2\,\hat{\boldsymbol{i}}$.

(d) Same approach except $t = 9.45\times 10^{-13}$ s. $\vec{S} = -0.207\text{ W/m}^2\,\hat{\boldsymbol{i}}$.

EVALUATE: Note that $\vec{S}$ can have negative components.

VP32.7.2. **IDENTIFY:** This problem is about a standing electromagnetic wave.
SET UP: $E = cB$, $f\lambda = c$.

EXECUTE: **(a)** We want the wavelength. The nearest nodal plane is $\lambda/4$ from the conductor, so $\lambda/4$ = 3.60 mm. λ = 14.4 mm.
(b) We want the frequency. $f = c/\lambda = c/(14.4\text{ mm}) = 2.08\times 10^{10}$ Hz.

(c) We want the amplitude of E in the first nodal plane of B. The nodal planes of B are antinodal planes of E, so at this point $E = E_{\max} = cB_{\max} = c(0.120\ \mu\text{T}) = 36.0$ V/m.
EVALUATE: The electric and magnetic fields are out of phase by π/2 in this polarized light.

VP32.7.3. **IDENTIFY:** We are looking at standing electromagnetic waves in a cavity.
SET UP: The walls are at $x = 0$ and $x = 4.50$ cm, $\lambda_n = 2L/n$, $f\lambda = c$.

EXECUTE: **(a)** We want the frequencies and wavelengths. Use $\lambda_n = 2L/n$.

$\lambda_1 = 2L/1 = 2L = 9.00$ cm. $f_1 = c/(9.00\text{ cm}) = 3.33$ GHz.

$\lambda_2 = L = 4.50$ cm. $f_2 = c/(4.50\text{ cm}) = 6.67$ GHz.

$\lambda_3 = 2L/3 = 3.00$ cm. $f_3 = c/(3.00\text{ cm}) = 10.0$ GHz.

(b) We want the nodal planes for E. The nodal planes are $\lambda/2$ apart.

For λ_1 : 0, 4.50 cm.

For λ_2 : 0, 2.25 cm, 4.50 cm.

For λ_3 : 0, 1.50 cm, 3.00 cm, 4.50 cm.

EVALUATE: The antinodal planes for E are midway between the nodal planes.

VP32.7.4. **IDENTIFY:** We are looking at standing electromagnetic waves in a cavity.

SET UP: The walls are 48.8 cm apart, λ = 12.2 cm. $\lambda_n = 2L/n$, $f\lambda = c$

EXECUTE: **(a)** What is the frequency? $f = c/\lambda$ = c/(12.2 cm) = 2.46 GHz.

(b) How many antinodal planes between the walls? Nodes occur when $\lambda_n = 2L/n$. $n_{\max} = 2L/\lambda$ = 2(48.8 cm)/(12.2 cm) = 8. The antinodal planes are between the nodal planes. There are 9 nodes including the node at x = 0, so there are 8 antinodal planes.

EVALUATE: If nodal (and antinodal) planes are too far apart, there could be cold (and hot) spots in the oven.

32.1. **IDENTIFY:** Since the speed is constant, distance $x = ct$.

SET UP: The speed of light is $c = 3.00\times10^8$ m/s. $1\text{ y} = 3.156\times10^7$ s.

EXECUTE: **(a)** $t = \dfrac{x}{c} = \dfrac{3.84\times10^8\text{ m}}{3.00\times10^8\text{ m/s}} = 1.28\text{ s}.$

(b) $x = ct = (3.00\times10^8\text{ m/s})(8.61\text{ y})(3.156\times10^7\text{ s/y}) = 8.15\times10^{16}\text{ m} = 8.15\times10^{13}\text{ km}.$

EVALUATE: The speed of light is very great. The distance between stars is very large compared to terrestrial distances.

32.2. **IDENTIFY:** Find the direction of propagation of an electromagnetic wave if we know the directions of the electric and magnetic fields.

SET UP: The direction of propagation of an electromagnetic wave is in the direction of $\vec{E}\times\vec{B}$, which is related to the directions of $\vec{E}$ and $\vec{B}$ according to the right-hand rule for the cross product. The directions of $\vec{E}$ and $\vec{B}$ in each case are shown in Figure 32.2.

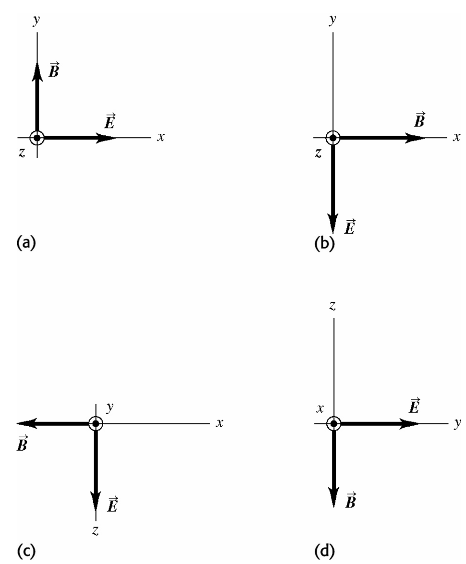

Figure 32.2

EXECUTE: **(a)** The wave is propagating in the $+z$-direction.

(b) $+z$-direction.

(c) $-y$-direction.

(d) $-x$-direction.

EVALUATE: In each case, the direction of propagation is perpendicular to the plane of $\vec{E}$ and $\vec{B}$.

32.3. IDENTIFY: $E_{max} = cB_{max}$. $\vec{E}\times\vec{B}$ is in the direction of propagation.

SET UP: $c = 3.00\times10^8$ m/s. $E_{max} = 4.00$ V/m.

EXECUTE: $B_{max} = E_{max}/c = 1.33\times10^{-8}$ T. For $\vec{E}$ in the $+x$-direction, $\vec{E}\times\vec{B}$ is in the $+z$-direction when $\vec{B}$ is in the $+y$-direction.

EVALUATE: $\vec{E}$, $\vec{B}$, and the direction of propagation are all mutually perpendicular.

32.4. IDENTIFY and **SET UP:** The direction of propagation is given by $\vec{E}\times\vec{B}$.

EXECUTE: **(a)** $\hat{S} = \hat{i}\times(-\hat{j}) = -\hat{k}$.

(b) $\hat{S} = \hat{j}\times\hat{i} = -\hat{k}$.

(c) $\hat{S} = (-\hat{k})\times(-\hat{i}) = \hat{j}$.

(d) $\hat{S} = \hat{i}\times(-\hat{k}) = \hat{j}$.

EVALUATE: In each case the directions of $\vec{E}$, $\vec{B}$, and the direction of propagation are all mutually perpendicular.

32.5. IDENTIFY: Knowing the wavelength and speed of x rays, find their frequency, period, and wave number. All electromagnetic waves travel through vacuum at the speed of light.

SET UP: $c = 3.00\times10^8$ m/s. $c = f\lambda$. $T = \dfrac{1}{f}$. $k = \dfrac{2\pi}{\lambda}$.

EXECUTE: $f = \dfrac{c}{\lambda} = \dfrac{3.0\times10^8 \text{ m/s}}{0.10\times10^{-9} \text{ m}} = 3.0\times10^{18}$ Hz,

$$T = \frac{1}{f} = \frac{1}{3.0\times10^{18} \text{ Hz}} = 3.3\times10^{-19} \text{ s}, \quad k = \frac{2\pi}{\lambda} = \frac{2\pi}{0.10\times10^{-9} \text{ m}} = 6.3\times10^{10} \text{ m}^{-1}.$$

EVALUATE: The frequency of the x rays is much higher than the frequency of visible light, so their period is much shorter.

32.6. IDENTIFY: $c = f\lambda$ and $k = \dfrac{2\pi}{\lambda}$.

SET UP: $c = 3.00\times10^8$ m/s.

EXECUTE: **(a)** $f = \dfrac{c}{\lambda}$. UVA: 7.50×10^{14} Hz to 9.38×10^{14} Hz. UVB: 9.38×10^{14} Hz to 1.07×10^{15} Hz.

(b) $k = \dfrac{2\pi}{\lambda}$. UVA: 1.57×10^7 rad/m to 1.96×10^7 rad/m. UVB: 1.96×10^7 rad/m to 2.24×10^7 rad/m.

EVALUATE: Larger λ corresponds to smaller f and k.

32.7. IDENTIFY: Electromagnetic waves propagate through air at essentially the speed of light. Therefore, if we know their wavelength, we can calculate their frequency or vice versa.

SET UP: The wave speed is $c = 3.00\times10^8$ m/s. $c = f\lambda$.

EXECUTE: **(a)** (i) $f = \dfrac{c}{\lambda} = \dfrac{3.00\times10^8 \text{ m/s}}{5.0\times10^3 \text{ m}} = 6.0\times10^4$ Hz.

(ii) $f = \dfrac{3.00\times10^8 \text{ m/s}}{5.0\times10^{-6} \text{ m}} = 6.0\times10^{13}$ Hz.

(iii) $f = \dfrac{3.00\times10^8 \text{ m/s}}{5.0\times10^{-9} \text{ m}} = 6.0\times10^{16}$ Hz.

(b) (i) $\lambda = \dfrac{c}{f} = \dfrac{3.00\times10^8 \text{ m/s}}{6.50\times10^{21} \text{ Hz}} = 4.62\times10^{-14} \text{ m} = 4.62\times10^{-5}$ nm.

(ii) $\lambda = \dfrac{3.00\times10^8 \text{ m/s}}{590\times10^3 \text{ Hz}} = 508 \text{ m} = 5.08\times10^{11} \text{ nm}.$

EVALUATE: Electromagnetic waves cover a huge range in frequency and wavelength.

32.8. IDENTIFY: $c = f\lambda$. $E_{\text{max}} = cB_{\text{max}}$. Apply Eqs. (32.17) and (32.19).

SET UP: The speed of the wave is $c = 3.00\times10^8$ m/s.

EXECUTE: (a) $f = \dfrac{c}{\lambda} = \dfrac{3.00\times10^8 \text{ m/s}}{435\times10^{-9} \text{ m}} = 6.90\times10^{14} \text{ Hz}.$

(b) $B_{\text{max}} = \dfrac{E_{\text{max}}}{c} = \dfrac{2.70\times10^{-3} \text{ V/m}}{3.00\times10^8 \text{ m/s}} = 9.00\times10^{-12} \text{ T}.$

(c) $k = \dfrac{2\pi}{\lambda} = 1.44\times10^7$ rad/m. $\omega = 2\pi f = 4.34\times10^{15}$ rad/s. If $\vec{E}(z,t) = \hat{i}E_{\text{max}}\cos(kz+\omega t)$, then $\vec{B}(z,t) = -\hat{j}B_{\text{max}}\cos(kz+\omega t)$, so that $\vec{E}\times\vec{B}$ will be in the $-\hat{k}$-direction.

$\vec{E}(z,t) = \hat{i}(2.70\times10^{-3} \text{ V/m})\cos[(1.44\times10^7 \text{ rad/m})z + (4.34\times10^{15} \text{ rad/s})t]$ and

$\vec{B}(z,t) = -\hat{j}(9.00\times10^{-12} \text{ T})\cos[(1.44\times10^7 \text{ rad/m})z + (4.34\times10^{15} \text{ rad/s})t].$

EVALUATE: The directions of $\vec{E}$ and $\vec{B}$ and of the propagation of the wave are all mutually perpendicular. The argument of the cosine is $kz+\omega t$ since the wave is traveling in the $-z$-direction. Waves for visible light have very high frequencies.

32.9. IDENTIFY and SET UP: Compare the $\vec{E}(y,t)$ given in the problem to the general form given by Eq. (32.17). Use the direction of propagation and of $\vec{E}$ to find the direction of $\vec{B}$.

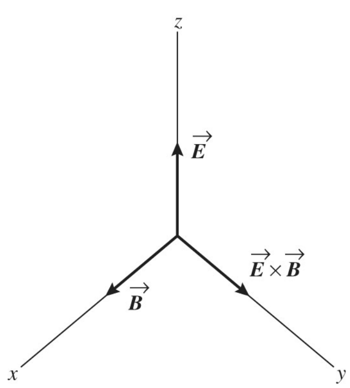
EXECUTE: (a) The equation for the electric field contains the factor $\cos(ky-\omega t)$ so the wave is traveling in the $+y$-direction.

(b) $\vec{E}(y,t) = (3.10\times10^5 \text{ V/m})\hat{k}\cos[ky - (12.65\times10^{12} \text{ rad/s})t].$

Comparing to Eq. (32.17) gives $\omega = 12.65\times10^{12}$ rad/s

$\omega = 2\pi f = \dfrac{2\pi c}{\lambda}$ so $\lambda = \dfrac{2\pi c}{\omega} = \dfrac{2\pi(2.998\times10^8 \text{ m/s})}{(12.65\times10^{12} \text{ rad/s})} = 1.49\times10^{-4} \text{ m}.$

(c)



$\vec{E}\times\vec{B}$ must be in the $+y$-direction (the direction in which the wave is traveling). When $\vec{E}$ is in the $+z$-direction then $\vec{B}$ must be in the $+x$-direction, as shown in Figure 32.9.

Figure 32.9

$k = \dfrac{2\pi}{\lambda} = \dfrac{\omega}{c} = \dfrac{12.65\times10^{12} \text{ rad/s}}{2.998\times10^8 \text{ m/s}} = 4.22\times10^4 \text{ rad/m}.$

$E_{\text{max}} = 3.10\times10^5$ V/m.

Then $B_{\max} = \dfrac{E_{\max}}{c} = \dfrac{3.10\times10^5 \text{ V/m}}{2.998\times10^8 \text{ m/s}} = 1.03\times10^{-3} \text{ T}.$

Using Eq. (32.17) and the fact that $\vec{B}$ is in the $+\hat{\imath}$-direction when $\vec{E}$ is in the $+\hat{k}$-direction,

$\vec{B} = +(1.03\times10^{-3} \text{ T})\hat{\imath}\cos[(4.22\times10^4 \text{ rad/m})y - (12.65\times10^{12} \text{ rad/s})t].$

EVALUATE: $\vec{E}$ and $\vec{B}$ are perpendicular and oscillate in phase.

32.10. **IDENTIFY:** For an electromagnetic wave propagating in the negative x-direction, $E = E_{\max}\cos(kx+\omega t)$. $\omega = 2\pi f$ and $k = \dfrac{2\pi}{\lambda}$. $T = \dfrac{1}{f}$. $E_{\max} = cB_{\max}$.

SET UP: $E_{\max} = 375 \text{ V/m}$, $k = 1.99\times10^7 \text{ rad/m}$, and $\omega = 5.97\times10^{15} \text{ rad/s}$.

EXECUTE: **(a)** $c = \omega/k = (5.97\times10^{15} \text{ rad/s})/(1.99\times10^7 \text{ rad/m}) = 3.00\times10^8 \text{ m/s}$. This is what the wave speed should be for an electromagnetic wave propagating in vacuum.

(b) $E_{\max} = 375$ V/m, the amplitude of the given cosine function for E. $B_{\max} = \dfrac{E_{\max}}{c} = 1.25\ \mu\text{T}$.

(c) $f = \dfrac{\omega}{2\pi} = 9.50\times10^{14} \text{ Hz}$. $\lambda = \dfrac{2\pi}{k} = 3.16\times10^{-7} \text{ m} = 316 \text{ nm}$. $T = \dfrac{1}{f} = 1.05\times10^{-15} \text{ s}$. This wavelength is too short to be visible.

EVALUATE: $c = f\lambda = \left(\dfrac{\omega}{2\pi}\right)\left(\dfrac{2\pi}{k}\right) = \dfrac{\omega}{k}$ is an alternative expression for the wave speed.

32.11. **IDENTIFY** and **SET UP:** $c = f\lambda$ allows calculation of λ. $k = 2\pi/\lambda$ and $\omega = 2\pi f$. $E_{\max} = cB_{\max}$ relates the electric and magnetic field amplitudes.

EXECUTE: **(a)** $c = f\lambda$ so $\lambda = \dfrac{c}{f} = \dfrac{2.998\times10^8 \text{ m/s}}{830\times10^3 \text{ Hz}} = 361 \text{ m}.$

(b) $k = \dfrac{2\pi}{\lambda} = \dfrac{2\pi \text{ rad}}{361 \text{ m}} = 0.0174 \text{ rad/m}.$

(c) $\omega = 2\pi f = (2\pi)(830\times10^3 \text{ Hz}) = 5.22\times10^6 \text{ rad/s}.$

(d) Eq. (32.18): $E_{\max} = cB_{\max} = (2.998\times10^8 \text{ m/s})(4.82\times10^{-11} \text{ T}) = 0.0144 \text{ V/m}.$

EVALUATE: This wave has a very long wavelength; its frequency is in the AM radio broadcast band. The electric and magnetic fields in the wave are very weak.

32.12. **IDENTIFY:** Apply $v = \dfrac{c}{\sqrt{KK_{\text{m}}}}$. $E_{\max} = cB_{\max}$. $v = f\lambda$.

SET UP: $K = 3.64$. $K_{\text{m}} = 5.18$.

EXECUTE: **(a)** $v = \dfrac{c}{\sqrt{KK_{\text{m}}}} = \dfrac{(3.00\times10^8 \text{ m/s})}{\sqrt{(3.64)(5.18)}} = 6.91\times10^7 \text{ m/s}.$

(b) $\lambda = \dfrac{v}{f} = \dfrac{6.91\times10^7 \text{ m/s}}{65.0 \text{ Hz}} = 1.06\times10^6 \text{ m}.$

(c) $B_{\max} = \dfrac{E_{\max}}{v} = \dfrac{7.20\times10^{-3} \text{ V/m}}{6.91\times10^7 \text{ m/s}} = 1.04\times10^{-10} \text{ T}.$

EVALUATE: The wave travels slower in this material than in air.

32.13. **IDENTIFY** and **SET UP:** $v = f\lambda$ relates frequency and wavelength to the speed of the wave. Use $n = \sqrt{KK_{\text{m}}} \approx \sqrt{K}$ to calculate n and K.

EXECUTE: **(a)** $\lambda = \dfrac{v}{f} = \dfrac{2.17\times10^8 \text{ m/s}}{5.70\times10^{14} \text{ Hz}} = 3.81\times10^{-7} \text{ m}.$

(b) $\lambda = \dfrac{c}{f} = \dfrac{2.998\times10^{8}\text{ m/s}}{5.70\times10^{14}\text{ Hz}} = 5.26\times10^{-7}\text{ m}.$

(c) $n = \dfrac{c}{v} = \dfrac{2.998\times10^{8}\text{ m/s}}{2.17\times10^{8}\text{ m/s}} = 1.38.$

(d) $n = \sqrt{KK_{\text{m}}} \approx \sqrt{K}$ so $K = n^2 = (1.38)^2 = 1.90.$

EVALUATE: In the material $v < c$ and f is the same, so λ is less in the material than in air. $v < c$ always, so n is always greater than unity.

32.14. IDENTIFY: We want to find the amount of energy given to each receptor cell and the amplitude of the magnetic field at the cell.

SET UP: Intensity is average power per unit area and power is energy per unit time. $I = \frac{1}{2}\epsilon_0 cE_{\text{max}}^2$, $I = P/A$, and $E_{\text{max}} = cB_{\text{max}}$.

EXECUTE: **(a)** For the beam, the energy is $U = Pt = (2.0\times10^{12}\text{ W})(4.0\times10^{-9}\text{ s}) = 8.0\times10^{3}\text{ J} = 8.0\text{ kJ}.$ This energy is spread uniformly over 100 cells, so the energy given to each cell is 80 J.

(b) The cross-sectional area of each cell is $A = \pi r^2$, with $r = 2.5\times10^{-6}$ m.

$I = \dfrac{P}{A} = \dfrac{2.0\times10^{12}\text{ W}}{(100)\pi(2.5\times10^{-6}\text{ m})^2} = 1.0\times10^{21}\text{ W/m}^2.$

(c) $E_{\text{max}} = \sqrt{\dfrac{2I}{\epsilon_0 c}} = \sqrt{\dfrac{2(1.0\times10^{21}\text{ W/m}^2)}{(8.85\times10^{-12}\text{ C}^2/\text{N}\cdot\text{m}^2)(3.00\times10^{8}\text{ m/s})}} = 8.7\times10^{11}\text{ V/m}.$

$B_{\text{max}} = \dfrac{E_{\text{max}}}{c} = 2.9\times10^{3}\text{ T}.$

EVALUATE: Both the electric field and magnetic field are very strong compared to ordinary fields.

32.15. IDENTIFY: $I = P/A$. $I = \frac{1}{2}\epsilon_0 cE_{\text{max}}^2$. $E_{\text{max}} = cB_{\text{max}}$.

SET UP: The surface area of a sphere of radius r is $A = 4\pi r^2$. $\epsilon_0 = 8.85\times10^{-12}\text{ C}^2/\text{N}\cdot\text{m}^2$.

EXECUTE: **(a)** $I = \dfrac{P}{A} = \dfrac{(0.05)(75\text{ W})}{4\pi(3.0\times10^{-2}\text{ m})^2} = 330\text{ W/m}^2.$

(b) $E_{\text{max}} = \sqrt{\dfrac{2I}{\epsilon_0 c}} = \sqrt{\dfrac{2(330\text{ W/m}^2)}{(8.85\times10^{-12}\text{ C}^2/\text{N}\cdot\text{m}^2)(3.00\times10^{8}\text{ m/s})}} = 500\text{ V/m}.$

$B_{\text{max}} = \dfrac{E_{\text{max}}}{c} = 1.7\times10^{-6}\text{ T} = 1.7\ \mu\text{T}.$

EVALUATE: At the surface of the bulb the power radiated by the filament is spread over the surface of the bulb. Our calculation approximates the filament as a point source that radiates uniformly in all directions.

32.16. IDENTIFY: The intensity of the electromagnetic wave is given by $I = \frac{1}{2}\epsilon_0 cE_{\text{max}}^2 = \epsilon_0 cE_{\text{rms}}^2$. The total energy passing through a window of area A during a time t is IAt.

SET UP: $\epsilon_0 = 8.85\times10^{-12}$ F/m.

EXECUTE: Use the fact that energy $= \epsilon_0 cE_{\text{rms}}^2 At$.

$\text{Energy} = (8.85\times10^{-12}\text{ F/m})(3.00\times10^{8}\text{ m/s})(0.0400\text{ V/m})^2(0.500\text{ m}^2)(30.0\text{ s}) = 6.37\times10^{-5}\text{ J} = 63.7\ \mu\text{J}.$

EVALUATE: The intensity is proportional to the square of the electric field amplitude.

32.17. IDENTIFY: $I = P_{\text{av}}/A$.

SET UP: At a distance r from the star, the radiation from the star is spread over a spherical surface of area $A = 4\pi r^2$.

EXECUTE: $P_{av} = I(4\pi r^2) = (5.0\times10^3\ \text{W/m}^2)(4\pi)(2.0\times10^{10}\ \text{m})^2 = 2.5\times10^{25}\ \text{W}.$

EVALUATE: The intensity decreases with distance from the star as $1/r^2$.

32.18. **IDENTIFY** and **SET UP:** $I = \frac{1}{2}\epsilon_0 c E_{max}{}^2$. $E_{max} = cB_{max}$. At the earth the power radiated by the sun is spread over an area of $4\pi r^2$, where $r = 1.50\times10^{11}$ m is the distance from the earth to the sun. $P = IA$.

EXECUTE: **(a)** $E_{max} = \sqrt{\dfrac{2I}{\epsilon_0 c}} = \sqrt{\dfrac{2(1.4\times10^3\ \text{W/m}^2)}{(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(3.00\times10^8\ \text{m/s})}} = 1.03\times10^3\ \text{N/C}.$

$B_{max} = \dfrac{E_{max}}{c} = \dfrac{1.03\times10^3\ \text{N/C}}{3.00\times10^8\ \text{m/s}} = 3.43\times10^{-6}\ \text{T}.$

(b) $P = I(4\pi r^2) = (1.4\times10^3\ \text{W/m}^2)(4\pi)(1.50\times10^{11}\ \text{m})^2 = 4.0\times10^{26}\ \text{W}.$

EVALUATE: The intensity of the magnetic field of the light waves from the sun is about 1/10 the earth's magnetic field.

32.19. **IDENTIFY:** This problem is about the power carried by an electromagnetic wave.

SET UP: $I = \dfrac{1}{2}\epsilon_0 c E_{max}^2$, $I = P_{av}/A$. We want the average power output of the source.

EXECUTE: The data is plotted as E_{max} versus $1/r$, so we need to relate those quantities to interpret the graph. We know that $I = P_{av}/A$ and $I = \dfrac{1}{2}\epsilon_0 c E_{max}^2$. Equate the intensities and solve for E_{max}.

$\dfrac{1}{2}\epsilon_0 c E_{max}^2 = \dfrac{P_{av}}{A} = \dfrac{P_{av}}{4\pi r^2}$. $E_{max} = \sqrt{\dfrac{2P_{av}}{4\pi\epsilon_0 c}}\dfrac{1}{r}$. A graph of E_{max} versus $1/r$ should be a straight line having slope equal to $\sqrt{\dfrac{2P_{av}}{4\pi\epsilon_0 c}}\dfrac{1}{r}$. Solve for P_{av}. $P_{av} = \dfrac{4\pi\epsilon_0 c}{2}(\text{slope})^2$. Using the given slope, we get $P_{av} = 93.8$ W.

EVALUATE: This power is similar to an ordinary 100-W light bulb.

32.20. **IDENTIFY** and **SET UP:** $c = f\lambda$, $E_{max} = cB_{max}$ and $I = E_{max}B_{max}/2\mu_0$.

EXECUTE: **(a)** $f = \dfrac{c}{\lambda} = \dfrac{3.00\times10^8\ \text{m/s}}{0.354\ \text{m}} = 8.47\times10^8\ \text{Hz}.$

(b) $B_{max} = \dfrac{E_{max}}{c} = \dfrac{0.0540\ \text{V/m}}{3.00\times10^8\ \text{m/s}} = 1.80\times10^{-10}\ \text{T}.$

(c) $I = S_{av} = \dfrac{E_{max}B_{max}}{2\mu_0} = \dfrac{(0.0540\ \text{V/m})(1.80\times10^{-10}\ \text{T})}{2\mu_0} = 3.87\times10^{-6}\ \text{W/m}^2.$

EVALUATE: Alternatively, $I = \frac{1}{2}\epsilon_0 c E_{max}^2$.

32.21. **IDENTIFY:** $P_{av} = IA$ and $I = E_{max}^2/2\mu_0 c$

SET UP: The surface area of a sphere is $A = 4\pi r^2$.

EXECUTE: $P_{av} = S_{av}A = \left(\dfrac{E_{max}^2}{2c\mu_0}\right)(4\pi r^2)$. $E_{max} = \sqrt{\dfrac{P_{av}c\mu_0}{2\pi r^2}} = \sqrt{\dfrac{(60.0\ \text{W})(3.00\times10^8\ \text{m/s})\mu_0}{2\pi(5.00\ \text{m})^2}} = 12.0\ \text{V/m}.$

$B_{max} = \dfrac{E_{max}}{c} = \dfrac{12.0\ \text{V/m}}{3.00\times10^8\ \text{m/s}} = 4.00\times10^{-8}\ \text{T}.$

EVALUATE: E_{max} and B_{max} are both inversely proportional to the distance from the source.

32.22. **IDENTIFY:** The intensity and the energy density of an electromagnetic wave depend on the amplitudes of the electric and magnetic fields.

SET UP: Intensity is $I = P_{av}/A$, and the average radiation pressure is $P_{av} = 2I/c$, where $I = \frac{1}{2}\epsilon_0 cE_{max}^2$. The energy density is $u = \epsilon_0 E^2$.

EXECUTE: **(a)** $I = P_{av}/A = \dfrac{777{,}000\ \text{W}}{2\pi(5000\ \text{m})^2} = 0.004947\ \text{W/m}^2$.

$$p_{rad} = 2I/c = \frac{2(0.004947\ \text{W/m}^2)}{3.00\times10^8\ \text{m/s}} = 3.30\times10^{-11}\ \text{Pa}.$$

(b) $I = \frac{1}{2}\epsilon_0 cE_{max}^2$ gives

$$E_{max} = \sqrt{\frac{2I}{\epsilon_0 c}} = \sqrt{\frac{2(0.004947\ \text{W/m}^2)}{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(3.00\times10^8\ \text{m/s})}} = 1.93\ \text{N/C}.$$

$$B_{max} = E_{max}/c = (1.93\ \text{N/C})/(3.00\times10^8\ \text{m/s}) = 6.43\times10^{-9}\ \text{T}.$$

(c) $u = \epsilon_0 E^2$, so $u_{av} = \epsilon_0 (E_{rms})^2$ and $E_{rms} = \dfrac{E_{max}}{\sqrt{2}}$, so

$$u_{av} = \frac{\epsilon_0 E_{max}^2}{2} = \frac{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(1.93\ \text{N/C})^2}{2} = 1.65\times10^{-11}\ \text{J/m}^3.$$

(d) As was shown in Section 32.4, the energy density is the same for the electric and magnetic fields, so each one has 50% of the energy density.

EVALUATE: Compared to most laboratory fields, the electric and magnetic fields in ordinary radiowaves are extremely weak and carry very little energy.

32.23. **IDENTIFY:** We know the greatest intensity that the eye can safely receive.

SET UP: $I = \dfrac{P}{A}$. $I = \frac{1}{2}\epsilon_0 cE_{max}^2$. $E_{max} = cB_{max}$.

EXECUTE: **(a)** $P = IA = (1.0\times10^2\ \text{W/m}^2)\pi(0.75\times10^{-3}\ \text{m})^2 = 1.8\times10^{-4}\ \text{W} = 0.18\ \text{mW}$.

(b) $E = \sqrt{\dfrac{2I}{\epsilon_0 c}} = \sqrt{\dfrac{2(1.0\times10^2\ \text{W/m}^2)}{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(3.00\times10^8\ \text{m/s})}} = 274\ \text{V/m}$. $B_{max} = \dfrac{E_{max}}{c} = 9.13\times10^{-7}\ \text{T}$.

(c) $P = 0.18\ \text{mW} = 0.18\ \text{mJ/s}$.

(d) $I = (1.0\times10^2\ \text{W/m}^2)\left(\dfrac{1\ \text{m}}{10^2\ \text{cm}}\right)^2 = 0.010\ \text{W/cm}^2$.

EVALUATE: Both the electric and magnetic fields are quite weak compared to normal laboratory fields.

32.24. **IDENTIFY:** Apply $p_{rad} = \dfrac{I}{c}$ and $p_{rad} = \dfrac{2I}{c}$. The average momentum density is given by $\dfrac{dp}{dV} = \dfrac{S_{av}}{c^2}$ with S replaced by $S_{av} = I$.

SET UP: $1\ \text{atm} = 1.013\times10^5\ \text{Pa}$.

EXECUTE: **(a)** Absorbed light: $p_{rad} = \dfrac{I}{c} = \dfrac{2500\ \text{W/m}^2}{3.0\times10^8\ \text{m/s}} = 8.33\times10^{-6}\ \text{Pa}$. Then

$$p_{rad} = \frac{8.33\times10^{-6}\ \text{Pa}}{1.013\times10^5\ \text{Pa/atm}} = 8.23\times10^{-11}\ \text{atm}.$$

(b) Reflecting light: $p_{rad} = \dfrac{2I}{c} = \dfrac{2(2500\ \text{W/m}^2)}{3.0\times10^8\ \text{m/s}} = 1.67\times10^{-5}\ \text{Pa}$. Then

$$p_{rad} = \frac{1.67\times10^{-5}\ \text{Pa}}{1.013\times10^5\ \text{Pa/atm}} = 1.65\times10^{-10}\ \text{atm}.$$

(c) The momentum density is $\dfrac{dp}{dV}=\dfrac{S_{\text{av}}}{c^2}=\dfrac{2500\ \text{W/m}^2}{(3.0\times10^8\ \text{m/s})^2}=2.78\times10^{-14}\ \text{kg/m}^2\cdot\text{s}.$

EVALUATE: The factor of 2 in p_{rad} for the reflecting surface arises because the momentum vector totally reverses direction upon reflection. Thus the *change* in momentum is twice the original momentum.

32.25. IDENTIFY: We know the wavelength and power of the laser beam, as well as the area over which it acts.

SET UP: $P = IA$. $A=\pi r^2$. $E_{\text{max}}=cB_{\text{max}}$. The intensity $I=S_{\text{av}}$ is related to the maximum electric field by $I=\frac{1}{2}\epsilon_0 cE_{\text{max}}^2$. The average energy density u_{av} is related to the intensity I by $I=u_{\text{av}}c$.

EXECUTE: **(a)** $I=\dfrac{P}{A}=\dfrac{0.500\times10^{-3}\ \text{W}}{\pi(0.500\times10^{-3}\ \text{m})^2}=637\ \text{W/m}^2.$

(b) $E_{\text{max}}=\sqrt{\dfrac{2I}{\epsilon_0 c}}=\sqrt{\dfrac{2(637\ \text{W/m}^2)}{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(3.00\times10^8\ \text{m/s})}}=693\ \text{V/m}.$ $B_{\text{max}}=\dfrac{E_{\text{max}}}{c}=2.31\ \mu\text{T}.$

(c) $u_{\text{av}}=\dfrac{I}{c}=\dfrac{637\ \text{W/m}^2}{3.00\times10^8\ \text{m/s}}=2.12\times10^{-6}\ \text{J/m}^3.$

EVALUATE: The fields are very weak, so a cubic meter of space contains only about $2\ \mu\text{J}$ of energy.

32.26. IDENTIFY: This problem deals with radiation pressure.

SET UP: $p_{\text{rad}}=\dfrac{2I}{c}$, $I = P_{\text{av}}/A$. We want the average laser output power. Let subscripts L refer to the laser and D refer to the disk. Also let d be the thickness of the disk, r be the radius of the disk and R the radius of the laser beam. Fig. 32.26 illustrates the arrangement.

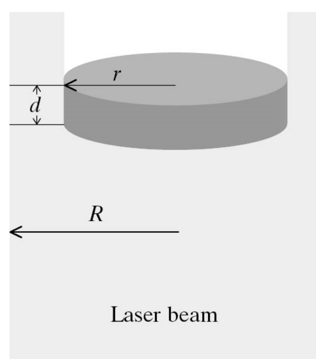


Figure 32.26

EXECUTE: **(a)** The force that the laser exerts on the disk must equal the weight of the disk. The laser force is due to radiation pressure p_{rad}, so $p_{\text{rad}}A_D = p_{\text{rad}}(\pi r^2) = mg = \rho V_D g=\rho(\pi r^2 d)g$. $p_{\text{rad}}=\rho g d$. Using $p_{\text{rad}}=\dfrac{2I}{c}$ gives $\dfrac{2I}{c}=\rho g d$. Using $I = P_{\text{av}}/A_L$ with $A_L = \pi R^2$, we get $\dfrac{2}{c}\left(\dfrac{P_{\text{av}}}{\pi R^2}\right)=\rho g d$. Solving for P_{av} and using the given values, we get $P_{\text{av}}=\dfrac{\pi R^2\rho g c d}{2}=33.3\ \text{W}.$

(b) The power does not depend on the radius of the disk, so the answer is the same as in part (a).

EVALUATE: The result in (b) may be surprising. But doubling r increases the laser force on the disk by a factor of $2^2 = 4$ and it also increase the weight of the disk by the same factor. This result would *not* be true if $r \geq 1.00$ mm, however, because the disk radius would be greater than the laser beam radius. In that case, doubling r would increase the weight of the disk but would not increase the laser force.

32.27. **IDENTIFY:** The nodal and antinodal planes are each spaced one-half wavelength apart.

SET UP: $2\frac{1}{2}$ wavelengths fit in the oven, so $(2\frac{1}{2})\lambda = L$, and the frequency of these waves obeys the equation $f\lambda = c$.

EXECUTE: **(a)** Since $(2\frac{1}{2})\lambda = L$, we have $L = (5/2)(12.2 \text{ cm}) = 30.5$ cm.

(b) Solving for the frequency gives $f = c/\lambda = (3.00\times10^8 \text{ m/s})/(0.122 \text{ m}) = 2.46\times10^9$ Hz.

(c) $L = 35.5$ cm in this case. $(2\frac{1}{2})\lambda = L$, so $\lambda = 2L/5 = 2(35.5 \text{ cm})/5 = 14.2$ cm.

$f = c/\lambda = (3.00\times10^8 \text{ m/s})/(0.142 \text{ m}) = 2.11\times10^9$ Hz.

EVALUATE: Since microwaves have a reasonably large wavelength, microwave ovens can have a convenient size for household kitchens. Ovens using radiowaves would need to be far too large, while ovens using visible light would have to be microscopic.

32.28. **IDENTIFY:** The nodal planes of $\vec{E}$ and $\vec{B}$ are located by Eqs. (32.26) and (32.27).

SET UP: $\lambda = \dfrac{c}{f} = \dfrac{3.00\times10^8 \text{ m/s}}{75.0\times10^6 \text{ Hz}} = 4.00$ m.

EXECUTE: **(a)** $\Delta x = \dfrac{\lambda}{2} = 2.00$ m.

(b) The distance between the electric and magnetic nodal planes is one-quarter of a wavelength, so is $\dfrac{\lambda}{4} = \dfrac{\Delta x}{2} = \dfrac{2.00 \text{ m}}{2} = 1.00$ m.

EVALUATE: The nodal planes of $\vec{B}$ are separated by a distance $\lambda/2$ and are midway between the nodal planes of $\vec{E}$.

32.29. **IDENTIFY:** We are looking at standing electromagnetic waves in a cavity.

SET UP: Nodal planes are a half wavelength apart. $\lambda_n = 2L/n$. We want the distance L between the walls.

EXECUTE: Use $\lambda_n = 2L/n$. For the two frequencies, the values of n differ by 1. $\dfrac{1}{2}\lambda_n = \dfrac{1}{2}\left(\dfrac{2L}{n}\right) =$ 1.50 cm. $\dfrac{1}{2}\lambda_{n+1} = \dfrac{1}{2}\left(\dfrac{2L}{n+1}\right)$ = 1.25 cm. Solving for L gives L = 7.50 cm.

EVALUATE: The antinodal planes have the same spacing as the nodal planes.

32.30. **IDENTIFY:** Evaluate the partial derivatives of the expressions for $E_y(x,t)$ and $B_z(x,t)$.

SET UP: $\dfrac{\partial}{\partial x}\cos(kx-\omega t) = -k\sin(kx-\omega t)$, $\dfrac{\partial}{\partial t}\cos(kx-\omega t) = \omega\sin(kx-\omega t)\cdot$

$\dfrac{\partial}{\partial x}\sin(kx-\omega t) = k\cos(kx-\omega t)$, $\dfrac{\partial}{\partial t}\sin(kx-\omega t) = -\omega\cos(kx-\omega t)$.

EXECUTE: Assume $\vec{E} = E_{\max}\hat{j}\cos(kx-\omega t)$ and $\vec{B} = B_{\max}\hat{k}\cos(kx-\omega t+\phi)$, with $-\pi < \phi < \pi$. Eq. (32.12) is $\dfrac{\partial E_y}{\partial x} = -\dfrac{\partial B_z}{\partial t}$. This gives $kE_{\max}\sin(kx-\omega t) = +\omega B_{\max}\sin(kx-\omega t+\phi)$, so $\phi = 0$, and $kE_{\max} = \omega B_{\max}$, so $E_{\max} = \dfrac{\omega}{k}B_{\max} = \dfrac{2\pi f}{2\pi/\lambda}B_{\max} = f\lambda B_{\max} = cB_{\max}$. Similarly for Eq. (32.14), $-\dfrac{\partial B_z}{\partial x} = \epsilon_0\mu_0\dfrac{\partial E_y}{\partial t}$ gives $kB_{\max}\sin(kx-\omega t+\phi) = \epsilon_0\mu_0\omega E_{\max}\sin(kx-\omega t)$, so $\phi = 0$ and $kB_{\max} = \epsilon_0\mu_0\omega E_{\max}$, so $B_{\max} = \dfrac{\epsilon_0\mu_0\omega}{k}E_{\max} = \dfrac{2\pi f}{c^2 2\pi/\lambda}E_{\max} = \dfrac{f\lambda}{c^2}E_{\max} = \dfrac{1}{c}E_{\max}$.

EVALUATE: The $\vec{E}$ and $\vec{B}$ fields must oscillate in phase.

32.31. **IDENTIFY:** We know the wavelength and power of a laser beam as well as the area over which it acts and the duration of a pulse.

SET UP: The energy is $U = Pt$. For absorption the radiation pressure is $\frac{I}{c}$, where $I = \frac{P}{A}$. The wavelength in the eye is $\lambda = \frac{\lambda_0}{n}$. $I = \frac{1}{2}\epsilon_0 cE_{\max}^2$ and $E_{\max} = cB_{\max}$.

EXECUTE: **(a)** $U = Pt = (250\times10^{-3}\ \text{W})(1.50\times10^{-3}\ \text{s}) = 3.75\times10^{-4}\ \text{J} = 0.375\ \text{mJ}$.

(b) $I = \frac{P}{A} = \frac{250\times10^{-3}\ \text{W}}{\pi(255\times10^{-6}\ \text{m})^2} = 1.22\times10^6\ \text{W/m}^2$. The average pressure is

$\frac{I}{c} = \frac{1.22\times10^6\ \text{W/m}^2}{3.00\times10^8\ \text{m/s}} = 4.08\times10^{-3}\ \text{Pa}$.

(c) $\lambda = \frac{\lambda_0}{n} = \frac{810\ \text{nm}}{1.34} = 604\ \text{nm}$. $f = \frac{v}{\lambda} = \frac{c}{\lambda_0} = \frac{3.00\times10^8\ \text{m/s}}{810\times10^{-9}\ \text{m}} = 3.70\times10^{14}\ \text{Hz}$; f is the same in the air and in the vitreous humor.

(d) $E_{\max} = \sqrt{\frac{2I}{\epsilon_0 c}} = \sqrt{\frac{2(1.22\times10^6\ \text{W/m}^2)}{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(3.00\times10^8\ \text{m/s})}} = 3.03\times10^4\ \text{V/m}$.

$B_{\max} = \frac{E_{\max}}{c} = 1.01\times10^{-4}\ \text{T}$.

EVALUATE: The intensity of the beam is high, as it must be to weld tissue, but the pressure it exerts on the retina is only around 10^{-8} that of atmospheric pressure. The magnetic field in the beam is about twice that of the earth's magnetic field.

32.32. **IDENTIFY:** This problem involves the energy of the waves in a microwave oven.

SET UP and **EXECUTE:** **(a)** Estimate: 1 minute.

(b) We want the heat. Use $Q = mc\Delta T$. T_1 (room temperature) = 20°C, T_2 = 100°C, m = mass of 237 mL of water = 237 g = 0.237 kg, c = 4190 J/kg·K. Q = 79 kJ.

(c) We want the power. $P = Q/t$ = (79 kJ)/(60 s) = 1.3 kW.

(d) We want the average intensity. P = 2.6 kW. $I_{av} = P_{av}/A$. Estimate: Cup diameter = 7.5 cm, so r = 3.75 cm. I_{av} = (2.6 kW)/[π(0.0375 m)^2] = 600 kW/m^2.

(e) We want $E_{\max}$. Use $I = \frac{1}{2}\epsilon_0 cE_{\max}^2$, solve for $E_{\max}$, and use I = 600 kW/m^2. This gives $E_{\max} = \sqrt{\frac{2I}{\epsilon_0 c}}$ = 21 kV/m.

EVALUATE: Since all the estimates are reasonable values, our result for $E_{\max}$ should be fairly reasonable.

32.33. **IDENTIFY:** The intensity of an electromagnetic wave depends on the amplitude of the electric and magnetic fields. Such a wave exerts a force because it carries energy.

SET UP: The intensity of the wave is $I = P_{av}/A = \frac{1}{2}\epsilon_0 cE_{\max}^2$, and the force is $F = p_{rad}A$ where $p_{rad} = I/c$.

EXECUTE: **(a)** $I = P_{av}/A = (25{,}000\ \text{W})/[4\pi(5.75\times10^5\ \text{m})^2] = 6.02\times10^{-9}\ \text{W/m}^2$.

(b) $I = \frac{1}{2}\epsilon_0 cE_{\max}^2$, so $E_{\max} = \sqrt{\frac{2I}{\epsilon_0 c}} = \sqrt{\frac{2(6.02\times10^{-9}\ \text{W/m}^2)}{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(3.00\times10^8\ \text{m/s})}} = 2.13\times10^{-3}\ \text{N/C}$.

$B_{\max} = E_{\max}/c = (2.13\times10^{-3}\ \text{N/C})/(3.00\times10^8\ \text{m/s}) = 7.10\times10^{-12}\ \text{T}$.

(c) $F = p_{rad}A = (I/c)A = (6.02\times10^{-9}\ \text{W/m}^2)(0.150\ \text{m})(0.400\ \text{m})/(3.00\times10^8\ \text{m/s}) = 1.20\times10^{-18}\ \text{N}$.

EVALUATE: The fields are very weak compared to ordinary laboratory fields, and the force is hardly worth worrying about!

32.34. **IDENTIFY:** We are dealing with electromagnetic waves from a moving magnet. In one cycle, the magnet starts right at the coil, then moves 10 cm away, and then moves back to where it started.

SET UP and **EXECUTE:** **(a)** One cycle lasts ½ second. In ½ cycle, $\Delta B = B$ and $\Delta T = \frac{1}{2}\left(\frac{1}{2}\text{ s}\right) = \frac{1}{4}$ s.
Using these results and the given numbers gives $\frac{|\Delta\Phi_B|}{\Delta t} = \frac{A\Delta B}{\Delta t} = \frac{AB}{\Delta t} = \frac{\pi r^2 B}{\Delta t}$ = 50 μWb/s.

(b) We want the average magnitude of E within the loop. Using $\oint E dl = \frac{d\Phi_B}{dt}$ gives $E 2\pi r = \frac{|\Delta\Phi_B|}{\Delta t}$.

Solving for E and using the result from part (a) with r = 2.0 cm gives $E = \frac{1}{2\pi r}\frac{|\Delta\Phi_B|}{\Delta t}$ = 400 μV/m.

(c) We want the intensity. Eq. (32.28): $\vec{S} = \frac{1}{\mu_0}\vec{E}\times\vec{B}$. Using $B = E/c$ this becomes $S = \frac{E^2}{\mu_0 c}$. Using E = 400 μV/m, this gives S = 0.42 nW/m^2.

(d) We want the total power. $P = SA = S(2\pi rl)$ = (0.42 nW/m^2)(2π)(0.0200 m)(0.10 m) = 5.3 pW.

EVALUATE: The radiated energy is extremely small because the fields are weak and the back-and-forth motion is very slow.

32.35. **IDENTIFY:** $I = P_{av}/A$. For an absorbing surface, the radiation pressure is $p_{rad} = \frac{I}{c}$.

SET UP: Assume the electromagnetic waves are formed at the center of the sun, so at a distance r from the center of the sun $I = P_{av}/(4\pi r^2)$.

EXECUTE: **(a)** At the sun's surface: $I = \frac{P_{av}}{4\pi R^2} = \frac{3.9\times10^{26}\text{ W}}{4\pi(6.96\times10^8\text{ m})^2} = 6.4\times10^7\text{ W/m}^2$ and
$p_{rad} = \frac{I}{c} = \frac{6.4\times10^7\text{ W/m}^2}{3.00\times10^8\text{ m/s}} = 0.21\text{ Pa}.$
Halfway out from the sun's center, the intensity is 4 times more intense, and so is the radiation pressure: $I = 2.6\times10^8\text{ W/m}^2$ and $p_{rad} = 0.85$ Pa. At the top of the earth's atmosphere, the measured sunlight intensity is 1400 W/m^2 and $p_{rad} = 5\times10^{-6}$ Pa, which is about 100,000 times less than the values above.

EVALUATE: **(b)** The gas pressure at the sun's surface is 50,000 times greater than the radiation pressure, and halfway out of the sun the gas pressure is believed to be about 6×10^{13} times greater than the radiation pressure. Therefore it is reasonable to ignore radiation pressure when modeling the sun's interior structure.

32.36. **(a) IDENTIFY** and **SET UP:** Calculate I and then use $I = \frac{E_{max}^2}{2\mu_0 c}$ to calculate E_{max} and $E_{max} = cB_{max}$ to calculate B_{max}.

EXECUTE: The intensity is power per unit area: $I = \frac{P}{A} = \frac{5.80\times10^{-3}\text{ W}}{\pi(1.25\times10^{-3}\text{ m})^2} = 1182\text{ W/m}^2.$

$I = \frac{E_{max}^2}{2\mu_0 c}$, so $E_{max} = \sqrt{2\mu_0 cI}$. $E_{max} = \sqrt{2(4\pi\times10^{-7}\text{ T}\cdot\text{m/A})(2.998\times10^8\text{ m/s})(1182\text{ W/m}^2)} = 943.5\text{ V/m},$

which rounds to 943 V/m.

$B_{max} = \frac{E_{max}}{c} = \frac{943.5\text{ V/m}}{2.998\times10^8\text{ m/s}} = 3.148\times10^{-6}\text{ T},$ which rounds to 3.15 μT.

EVALUATE: The magnetic field amplitude is quite small compared to laboratory fields.

(b) IDENTIFY and **SET UP:** $u_E = \frac{1}{2}\epsilon_0 E^2$ and $u_B = \frac{B^2}{2\mu_0}$ give the energy density in terms of the electric and magnetic field values at any time. For sinusoidal fields average over E^2 and B^2 to get the average energy densities.

EXECUTE: The energy density in the electric field is $u_E = \frac{1}{2}\epsilon_0 E^2$. $E = E_{\max}\cos(kx - \omega t)$ and the average value of $\cos^2(kx - \omega t)$ is $\frac{1}{2}$. The average energy density in the electric field then is $u_{E,\text{av}} = \frac{1}{4}\epsilon_0 E_{\max}^2 = \frac{1}{4}(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(943.5\ \text{V/m})^2 = 1.97\times10^{-6}\ \text{J/m}^3 = 1.97\ \mu\text{J/m}^3$. The energy density in the magnetic field is $u_B = \dfrac{B^2}{2\mu_0}$. The average value is

$$u_{B,\text{av}} = \frac{B_{\max}^2}{4\mu_0} = \frac{(3.148\times10^{-6}\ \text{T})^2}{4(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})} = 1.97\times10^{-6}\ \text{J/m}^3 = 1.97\ \mu\text{J/m}^3.$$

EVALUATE: Our result agrees with the statement in Section 32.4 that the average energy density for the electric field is the same as the average energy density for the magnetic field.

(c) IDENTIFY and **SET UP:** The total energy in this length of beam is the average energy density $(u_{\text{av}} = u_{E,\text{av}} + u_{B,\text{av}} = 3.94\times10^{-6}\ \text{J/m}^3)$ times the volume of this part of the beam.

EXECUTE: $U = u_{\text{av}}LA = (3.94\times10^{-6}\ \text{J/m}^3)(1.00\ \text{m})\pi(1.25\times10^{-3}\ \text{m})^2 = 1.93\times10^{-11}\ \text{J}.$

EVALUATE: This quantity can also be calculated as the power output times the time it takes the light to travel $L = 1.00$ m: $U = P\left(\dfrac{L}{c}\right) = (5.80\times10^{-3}\ \text{W})\left(\dfrac{1.00\ \text{m}}{2.998\times10^8\ \text{m/s}}\right) = 1.93\times10^{-11}\ \text{J}$, which checks.

32.37. **IDENTIFY:** The same intensity light falls on both reflectors, but the force on the reflecting surface will be twice as great as the force on the absorbing surface. Therefore there will be a net torque about the rotation axis.

SET UP: For a totally absorbing surface, $F = p_{\text{rad}}A = (I/c)A$, while for a totally reflecting surface the force will be twice as great. The intensity of the wave is $I = \frac{1}{2}\epsilon_0 cE_{\max}^2$. Once we have the torque, we can use the rotational form of Newton's second law, $\tau_{\text{net}} = I\alpha$, to find the angular acceleration.

EXECUTE: The force on the absorbing reflector is $F_{\text{abs}} = p_{\text{rad}}A = (I/c)A = \dfrac{\frac{1}{2}\epsilon_0 cE_{\max}^2 A}{c} = \frac{1}{2}\epsilon_0 AE_{\max}^2$.

For a totally reflecting surface, the force will be twice as great, which is $\epsilon_0 cE_{\max}^2$. The net torque is therefore $\tau_{\text{net}} = F_{\text{refl}}(L/2) - F_{\text{abs}}(L/2) = \epsilon_0 AE_{\max}^2 L/4$.

Newton's second law for rotation gives $\tau_{\text{net}} = I\alpha$. $\epsilon_0 AE_{\max}^2 L/4 = 2m(L/2)^2\alpha$.

Solving for α gives

$$\alpha = \epsilon_0 AE_{\max}^2/(2mL) = \frac{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(0.0150\ \text{m})^2(1.25\ \text{N/C})^2}{(2)(0.00400\ \text{kg})(1.00\ \text{m})} = 3.89\times10^{-13}\ \text{rad/s}^2.$$

EVALUATE: This is an extremely small angular acceleration. To achieve a larger value, we would have to greatly increase the intensity of the light wave or decrease the mass of the reflectors.

32.38. **IDENTIFY:** The intensity of the wave, not the electric field strength, obeys an inverse-square distance law.

SET UP: The intensity is inversely proportional to the distance from the source, and it depends on the amplitude of the electric field by $I = \text{S}_{\text{av}} = \frac{1}{2}\epsilon_0 cE_{\max}^2$.

EXECUTE: Since $I = \frac{1}{2}\epsilon_0 cE_{\max}^2$, $E_{\max} \propto \sqrt{I}$. A point at 20.0 cm (0.200 m) from the source is 50 times closer to the source than a point that is 10.0 m from it. Since $I \propto 1/r^2$ and $(0.200\ \text{m})/(10.0\ \text{m}) = 1/50$, we have $I_{0.20} = 50^2 I_{10}$. Since $E_{\max} \propto \sqrt{I}$, we have $E_{0.20} = 50E_{10} = (50)(3.50\ \text{N/C}) = 175\ \text{N/C}$.

EVALUATE: While the intensity increases by a factor of $50^2 = 2500$, the amplitude of the wave only increases by a factor of 50. Recall that the intensity of *any* wave is proportional to the *square* of its amplitude.

32.39. **IDENTIFY** and **SET UP:** In the wire the electric field is related to the current density by $\vec{E} = \rho\vec{J}$. Use Ampere's law to calculate $\vec{B}$. The Poynting vector is given by $\vec{S} = \dfrac{1}{\mu_0}\vec{E}\times\vec{B}$ and $\vec{P} = \oint\vec{S}\cdot d\vec{A}$ relates the energy flow through a surface to $\vec{S}$.

EXECUTE: **(a)** The direction of $\vec{E}$ is parallel to the axis of the cylinder, in the direction of the current. $E = \rho J = \rho I/\pi a^2$. ($E$ is uniform across the cross section of the conductor.)

(b) A cross-sectional view of the conductor is given in Figure 32.39a; take the current to be coming out of the page.

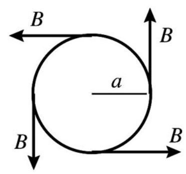

Figure 32.39a

Apply Ampere's law to a circle of radius a.

$\oint\vec{B}\cdot d\vec{l} = B(2\pi ra)$

$I_{\text{encl}} = I$.

$\oint\vec{B}\cdot d\vec{l} = \mu_0 I_{\text{encl}}$ gives $B(2\pi a) = \mu_0 I$ and $B = \dfrac{\mu_0 I}{2\pi a}$.

The direction of $\vec{B}$ is counterclockwise around the circle.

(c) The directions of $\vec{E}$ and $\vec{B}$ are shown in Figure 32.39b.

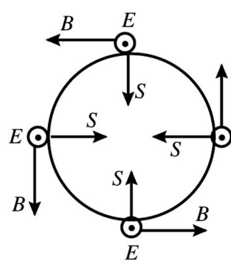

Figure 32.39b

The direction of $\vec{S} = \dfrac{1}{\mu_0}\vec{E}\times\vec{B}$.

is radially inward.

$$S = \frac{1}{\mu_0}EB = \frac{1}{\mu_0}\left(\frac{\rho I}{\pi a^2}\right)\left(\frac{\mu_0 I}{2\pi a}\right).$$

$$S = \frac{\rho I^2}{2\pi^2 a^3}.$$

EVALUATE: **(d)** Since S is constant over the surface of the conductor, the rate of energy flow P is given by S times the surface of a length l of the conductor: $P = SA = S(2\pi al) = \dfrac{\rho I^2}{2\pi^2 a^3}(2\pi al) = \dfrac{\rho l I^2}{\pi a^2}$. But $R = \dfrac{\rho l}{\pi a^2}$, so the result from the Poynting vector is $P = RI^2$. This agrees with $P_R = I^2 R$, the rate at which electrical energy is being dissipated by the resistance of the wire. Since $\vec{S}$ is radially inward at the surface of the wire and has magnitude equal to the rate at which electrical energy is being dissipated in the wire, this energy can be thought of as entering through the cylindrical sides of the conductor.

32.40. **IDENTIFY:** The changing magnetic field of the electromagnetic wave produces a changing flux through the wire loop, which induces an emf in the loop. The wavelength of the wave is much greater than the diameter of the loop, so we can treat the magnetic field as being uniform over the area of the loop.

SET UP: $\Phi_B = B\pi r^2 = \pi r^2 B_{\text{max}}\cos(kx - \omega t)$, taking x for the direction of propagation of the wave. Faraday's law says $|\mathcal{E}| = \left|\dfrac{d\Phi_B}{dt}\right|$. The intensity of the wave is $I = \dfrac{E_{\text{max}}B_{\text{max}}}{2\mu_0} = \dfrac{c}{2\mu_0}B_{\text{max}}^2$, and $f = \dfrac{c}{\lambda}$.

EXECUTE: $|\mathcal{E}| = \left|\dfrac{d\Phi_B}{dt}\right| = \omega B_{\max}\sin(kx-\omega t)\pi r^2$. $|\mathcal{E}|_{\max} = 2\pi f B_{\max}\pi r^2$.

$f = \dfrac{c}{\lambda} = \dfrac{3.00\times10^8\ \text{m/s}}{6.90\ \text{m}} = 4.348\times10^7\ \text{Hz}$. Solving $I = \dfrac{E_{\max}B_{\max}}{2\mu_0} = \dfrac{c}{2\mu_0}B_{\max}^2$ for $B_{\max}$ gives

$B_{\max} = \sqrt{\dfrac{2\mu_0 I}{c}} = \sqrt{\dfrac{2(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A})(0.0275\ \text{W/m}^2)}{3.00\times10^8\ \text{m/s}}} = 1.518\times10^{-8}\ \text{T}$.

$|\mathcal{E}|_{\max} = 2\pi(4.348\times10^7\ \text{Hz})(1.518\times10^{-8}\ \text{T})\pi(0.075\ \text{m})^2 = 7.33\times10^{-2}\ \text{V} = 73.3\ \text{mV}$.

EVALUATE: This voltage is quite small compared to everyday voltages, so it normally would not be noticed. But in very delicate laboratory work, it could be large enough to take into consideration.

32.41. **IDENTIFY:** The nodal planes are one-half wavelength apart.
SET UP: The nodal planes of B are at $x = \lambda/4, 3\lambda/4, 5\lambda/4, \ldots,$ which are $\lambda/2$ apart.

EXECUTE: **(a)** The wavelength is $\lambda = c/f = (2.998\times10^8\ \text{m/s})/(110.0\times10^6\ \text{Hz}) = 2.725\ \text{m}$. So the nodal planes are at $(2.725\ \text{m})/2 = 1.363\ \text{m}$ apart.

(b) For the nodal planes of E, we have $\lambda_n = 2L/n$, so $L = n\lambda/2 = (8)(2.725\ \text{m})/2 = 10.90\ \text{m}$.

EVALUATE: Because radiowaves have long wavelengths, the distances involved are easily measurable using ordinary metersticks.

32.42. **IDENTIFY:** This problem involves an L-R-C ac circuit, electromagnetic waves, and Faraday's law.

SET UP: $\mathcal{E} = -N\dfrac{d\Phi_B}{dt}$, $B = E/c$, $k = \omega/c$. B_x must have the same mathematical form as E_y.

EXECUTE: **(a)** We want the flux. $dA = adz$. $\Phi_B = \int_{-a/2}^{a/2} B_x a dz = aB_{\max}\int_{-a/2}^{a/2}\cos(kx-\omega t)dz$. This gives

$\Phi_B = \dfrac{aB_{\max}}{k}\left[\sin(ka/2-\omega t)+\sin(ka/2+\omega t)\right] = \dfrac{aE_{\max}}{\omega}\left[2\sin(ka/2)\cos\omega t\right]$.

(b) We want the magnitude of the emf. Using the result from part (a) we get $\mathcal{E} = N\dfrac{d\Phi_B}{dt} = \dfrac{d}{dt}\left(\dfrac{aE_{\max}}{\omega}\left[2\sin(ka/2)\cos\omega t\right]\right) = 2NaE_{\max}\sin(ka/2)\sin\omega t$.

(c) We want C. At resonance, $2\pi f_0 = \omega_0 = 1/\sqrt{LC}$. Solve for C and put in the given numbers using f_0 = 4.00 MHz and L = 78.0 μH. The result is $C = \dfrac{1}{L(2\pi f_0)^2}$ = 20.3 pF.

(d) We want the rms current. The circuit is at resonance, so $i = V/Z = V/R$. (Note that we are using i instead of I for the current amplitude so as not to confuse it with the intensity I.) Using the result from part (b) gives $V = \mathcal{E}_{\max} = 2NaE_{\max}$. Now find $E_{\max}$ using the intensity $I = \dfrac{1}{2}\epsilon_0 cE_{\max}^2$. This gives

$E_{\max} = \sqrt{\dfrac{2I}{\epsilon_0 c}}$, so $V = 2NaE_{\max} = 2Na\sqrt{\dfrac{2I}{\epsilon_0 c}}$. Thus $i = \dfrac{V}{R} = \dfrac{2Na}{R}\sqrt{\dfrac{2I}{\epsilon_0 c}}$. Finally $i_{\text{rms}} = i/\sqrt{2}$, so we get

$i_{\text{rms}} = \dfrac{2Na}{R\sqrt{2}}\sqrt{\dfrac{2I}{\epsilon_0 c}} = \dfrac{2Na}{R}\sqrt{\dfrac{I}{\epsilon_0 c}}$. Using the numbers in the problem gives i_{rms} = 19.4 A.

EVALUATE: At resonance, Z is a minimum so the current amplitude is a maximum.

32.43. **IDENTIFY:** The orbiting satellite obeys Newton's second law of motion. The intensity of the electromagnetic waves it transmits obeys the inverse-square distance law, and the intensity of the waves depends on the amplitude of the electric and magnetic fields.

SET UP: Newton's second law applied to the satellite gives $mv^2/r = GmM/r^2$, where M is the mass of the earth and m is the mass of the satellite. The intensity I of the wave is $I = S_{\text{av}} = \frac{1}{2}\epsilon_0 c{E_{\max}}^2$, and by definition, $I = P_{\text{av}}/A$.

EXECUTE: **(a)** The period of the orbit is 12 hr. Applying Newton's second law to the satellite gives $mv^2/r = GmM/r^2$, which gives $\dfrac{m(2\pi r/T)^2}{r} = \dfrac{GmM}{r^2}$. Solving for r, we get

$$r = \left(\frac{GMT^2}{4\pi^2}\right)^{1/3} = \left[\frac{(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(5.97\times10^{24}\ \text{kg})(12\times3600\ \text{s})^2}{4\pi^2}\right]^{1/3} = 2.66\times10^7\ \text{m}.$$

The height above the surface is $h = 2.66\times10^7\ \text{m} - 6.37\times10^6\ \text{m} = 2.02\times10^7\ \text{m}$. The satellite only radiates its energy to the lower hemisphere, so the area is 1/2 that of a sphere. Thus, from the definition of intensity, the intensity at the ground is

$$I = P_{\text{av}}/A = P_{\text{av}}/(2\pi h^2) = (25.0\ \text{W})/[2\pi(2.02\times10^7\ \text{m})^2] = 9.75\times10^{-15}\ \text{W/m}^2$$

(b) $I = S_{\text{av}} = \frac{1}{2}\epsilon_0 cE_{\text{max}}^2$, so

$$E_{\text{max}} = \sqrt{\frac{2I}{\epsilon_0 c}} = \sqrt{\frac{2(9.75\times10^{-15}\ \text{W/m}^2)}{(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(3.00\times10^8\ \text{m/s})}} = 2.71\times10^{-6}\ \text{N/C}.$$

$$B_{\text{max}} = E_{\text{max}}/c = (2.71\times10^{-6}\ \text{N/C})/(3.00\times10^8\ \text{m/s}) = 9.03\times10^{-15}\ \text{T}.$$

$$t = d/c = (2.02\times10^7\ \text{m})/(3.00\times10^8\ \text{m/s}) = 0.0673\ \text{s}.$$

(c) $p_{\text{rad}} = I/c = (9.75\times10^{-15}\ \text{W/m}^2)/(3.00\times10^8\ \text{m/s}) = 3.25\times10^{-23}\ \text{Pa}.$

(d) $\lambda = c/f = (3.00\times10^8\ \text{m/s})/(1575.42\times10^6\ \text{Hz}) = 0.190\ \text{m}.$

EVALUATE: The fields and pressures due to these waves are very small compared to typical laboratory quantities.

32.44. IDENTIFY: For a totally reflective surface the radiation pressure is $\dfrac{2I}{c}$. Find the force due to this pressure and express the force in terms of the power output P of the sun. The gravitational force of the sun is $F_{\text{g}} = G\dfrac{mM_{\text{sun}}}{r^2}$.

SET UP: The mass of the sun is $M_{\text{sun}} = 1.99\times10^{30}\ \text{kg}$. $G = 6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2$.

EXECUTE: **(a)** The sail should be reflective, to produce the maximum radiation pressure.

(b) $F_{\text{rad}} = \left(\dfrac{2I}{c}\right)A$, where A is the area of the sail. $I = \dfrac{P}{4\pi r^2}$, where r is the distance of the sail from the sun. $F_{\text{rad}} = \left(\dfrac{2A}{c}\right)\left(\dfrac{P}{4\pi r^2}\right) = \dfrac{PA}{2\pi r^2 c}\cdot F_{\text{rad}} = F_{\text{g}}$ so $\dfrac{PA}{2\pi r^2 c} = G\dfrac{mM_{\text{sun}}}{r^2}$.

$$A = \frac{2\pi cGmM_{\text{sun}}}{P} = \frac{2\pi(3.00\times10^8\ \text{m/s})(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(10{,}000\ \text{kg})(1.99\times10^{30}\ \text{kg})}{3.9\times10^{26}\ \text{W}}.$$

$A = 6.42\times10^6\ \text{m}^2 = 6.42\ \text{km}^2.$

(c) Both the gravitational force and the radiation pressure are inversely proportional to the square of the distance from the sun, so this distance divides out when we set $F_{\text{rad}} = F_{\text{g}}$.

EVALUATE: A very large sail is needed, just to overcome the gravitational pull of the sun.

32.45. **IDENTIFY and SET UP:** The gravitational force is given by $F_g = G\dfrac{mM}{r^2}$. Express the mass of the particle in terms of its density and volume. The radiation pressure is given by $p_{rad} = \dfrac{I}{c}$; relate the power output L of the sun to the intensity at a distance r. The radiation force is the pressure times the cross-sectional area of the particle.

EXECUTE: **(a)** The gravitational force is $F_g = G\dfrac{mM}{r^2}$. The mass of the dust particle is $m = \rho V = \rho \frac{4}{3}\pi R^3$. Thus $F_g = \dfrac{4\rho G\pi M R^3}{3r^2}$.

(b) For a totally absorbing surface $p_{rad} = \dfrac{I}{c}$. If L is the power output of the sun, the intensity of the solar radiation a distance r from the sun is $I = \dfrac{L}{4\pi r^2}$. Thus $p_{rad} = \dfrac{L}{4\pi c r^2}$. The force F_{rad} that corresponds to p_{rad} is in the direction of propagation of the radiation, so $F_{rad} = p_{rad}A_\perp$, where $A_\perp = \pi R^2$ is the component of area of the particle perpendicular to the radiation direction. Thus

$$F_{rad} = \left(\frac{L}{4\pi c r^2}\right)(\pi R^2) = \frac{LR^2}{4cr^2}.$$

(c) $F_g = F_{rad}$.

$$\frac{4\rho G\pi M R^3}{3r^2} = \frac{LR^2}{4cr^2}.$$

$$\left(\frac{4\rho G\pi M}{3}\right)R = \frac{L}{4c} \text{ and } R = \frac{3L}{16c\rho G\pi M}.$$

$$R = \frac{3(3.9\times10^{26}\text{ W})}{16(2.998\times10^{8}\text{ m/s})(3000\text{ kg/m}^3)(6.673\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)\pi(1.99\times10^{30}\text{ kg})}.$$

$R = 1.9\times10^{-7}\text{ m} = 0.19\ \mu\text{m}$.

EVALUATE: The gravitational force and the radiation force both have a r^{-2} dependence on the distance from the sun, so this distance divides out in the calculation of R.

(d) $\dfrac{F_{rad}}{F_g} = \left(\dfrac{LR^2}{4cr^2}\right)\left(\dfrac{3r^2}{4\rho G\pi M R^3}\right) = \dfrac{3L}{16c\rho G\pi MR}$. F_{rad} is proportional to R^2 and F_g is proportional to R^3, so this ratio is proportional to $1/R$. If $R < 0.20\ \mu\text{m}$ then $F_{rad} > F_g$ and the radiation force will drive the particles out of the solar system.

32.46. **IDENTIFY and SET UP:** The intensity of an electromagnetic wave can be expressed in many ways, including $I = \dfrac{P}{A} = \frac{1}{2}\epsilon_0 c E_{max}^2 = \dfrac{cp_{rad}}{2}$, with the last way valid at a totally reflecting surface. In addition, the average energy density u in a wave is $u = \frac{1}{2}\epsilon_0 E_{max}^2$. Also, $B = E/c$ and $p = \dfrac{F_\perp}{A}$.

EXECUTE: For each laser, we calculate the beam intensity using formula that is appropriate for the information we know about the beam.

Laser A: $I = P/A = (2.6\text{ W})/[\pi(1.3\times10^{-3}\text{ m})^2] = 4.9\times10^5\text{ W/m}^2$.

Laser B: $I = \frac{1}{2}\epsilon_0 c E_{max}^2 = (1/2)(8.854\times10^{-12}\text{ C}^2/\text{N}\cdot\text{m}^2)(3.0\times10^8\text{ m/s})(480\text{ V/m})^2 = 310\text{ W/m}^2$.

Laser C: Combining $I = \frac{1}{2}\epsilon_0 c E_{max}^2$ and $B_{max} = E_{max}/c$, we get

$I = \frac{1}{2}\epsilon_0 c^3 B_{max}^2 = (1/2)(8.854\times10^{-12}\text{ C}^2/\text{N}\cdot\text{m}^2)(3.0\times10^8\text{ m/s})^3(8.7\times10^{-6}\text{ T})^2 = 9000\text{ W/m}^2$.

Laser D: The surface is totally reflecting, so

$I = \dfrac{cp_{rad}}{2} = \dfrac{cF_\perp}{2A} = (3.00\times10^8\text{ m/s})(6.0\times10^{-8}\text{ N})/[2\pi(0.90\times10^{-3}\text{ m})^2] = 3.5\times10^7\text{ W/m}^2$.

Laser E: Combining $I = \frac{1}{2}\epsilon_0 cE_{\max}^2$ and $u = \frac{1}{2}\epsilon_0 E_{\max}^2$ gives $I = \frac{1}{2}\epsilon_0 c\left(\frac{2u}{\epsilon_0}\right) = cu,$ so

$I = (3.0\times10^8 \text{ m/s})(3.0\times10^{-7} \text{ J/m}^3) = 90 \text{ W/m}^2$.

In order of increasing intensity, we have E, B, C, A, D.

EVALUATE: The laser intensities vary a great deal. But even the least intense one is around 10 times as intense as a 100-W lightbulb viewed at 1 m, if the 100 W all went into light (which it certainly does *not*).

32.47. IDENTIFY and SET UP: The intensity of the light beam is $I = \frac{1}{2}\epsilon_0 cE_{\max}^2$.

EXECUTE: **(a)** A graph of I versus $E_{\max}^2$ should be a straight line having slope equal to $\frac{1}{2}\epsilon_0 c$.

(b) Using the slope of the graph given with the problem, we have $\frac{1}{2}\epsilon_0 c = 1.33\times10^{-3} \text{ J/(V}^2\cdot\text{s)}$.

Solving for c gives $c = 2[1.33\times10^{-3} \text{ J/(V}^2\cdot\text{s)}]/(8.854\times10^{-12} \text{ C}^2/\text{N}\cdot\text{m}^2) = 3.00\times10^8$ m/s.

EVALUATE: This result is nearly identical to the speed of light in vacuum.

32.48. IDENTIFY and SET UP: The spacing between antinodes is $\lambda/2$, and $f\lambda = c$.

EXECUTE: The antinode spacing is $d = \lambda/2 = \frac{c}{2}\cdot\frac{1}{f}$. Therefore a graph of d versus $1/f$ should be a straight line having a slope equal to $c/2$. Figure 32.48 shows the graph of d versus $1/f$.

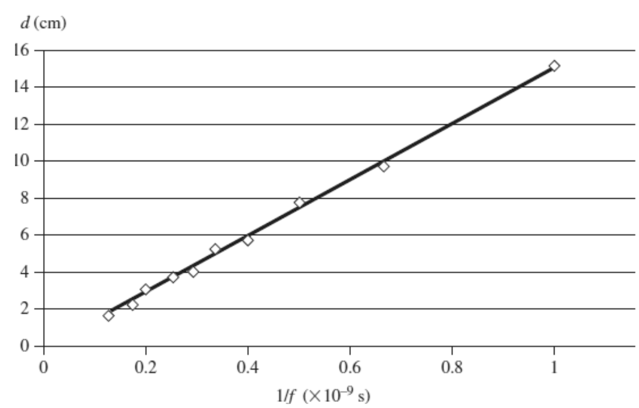

Figure 32.48

The slope of the best-fit line is 15.204×10^9 cm/s = 15.204×10^7 m/s, so $c/2 = 15.204\times10^7$ m/s, which gives $c = 3.0\times10^8$ m/s.

EVALUATE: This result is *very* close to the well-established value for the speed of light in vacuum.

32.49. IDENTIFY: This problem involves radiation pressure.

SET UP: Part of the incident beam is absorbed and part is reflected. The intensity of the incident beam is I_0, that of the transmitted beam is $eI\!-_0$, the that of the reflected beam is $(1 - e)I_0$ as shown in Fig. 32.49.

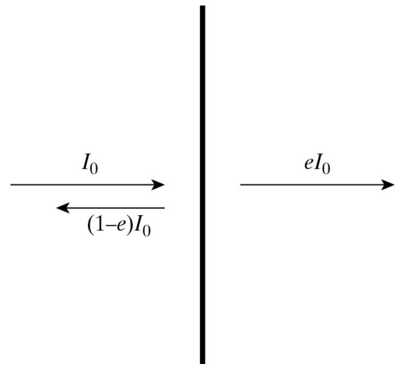

Figure 32.49

EXECUTE: (a) The radiation pressure due to the transmitted part of the beam is $p_{\text{tr}} = I/c$ and the pressure due to the reflected part is $p_{\text{ab}} = 2I/c$. In terms of the incident intensity, these pressures are $p_{\text{tr}} = 2eI_0/c$ and $p_{\text{ab}} = 2(1-e)I_0/c$. The total radiation pressure is the sum of these, which is

$$p_{\text{rad}} = \frac{I_0}{c}(2-e)$$

EVALUATE: Check: For a perfect absorber all the radiation is absorbed, so $e = 1$. In this case, $p_{\text{rad}} = \frac{I_0}{c}(2-e) = = \frac{I_0}{c}(2-1) = \frac{I_0}{c}$, as we have seen in the textbook. For a perfect reflector none of the incident beam is absorbed, so $e = 0$ and $p_{\text{rad}} = \frac{I_0}{c}(2-0) = \frac{2I_0}{c}$, as we have seen. Both extremes agree with the results in the textbook.

EXECUTE: (b) We want the force due to radiation. $F_{\text{rad}} = p_{\text{rad}}A$ and $p_{\text{rad}} = \frac{I_0}{c}(2-e)$.
$F_{\text{rad}} = \frac{I_0}{c}(2-e)\pi r^2$. Using $I_0 = 1.4\ \text{kW/m}^2$ and $r = 4.0\ \mu\text{m}$, we get $F_{\text{rad}} = 3.3\times 10^{-16}$ N.
(c) We want $F_{\text{rad}}/F_{\text{grav}}$. $\frac{F_{\text{rad}}}{F_{\text{grav}}} = \frac{F_{\text{rad}}}{GmM_{\text{sun}}/r^2}$. Using $m = 1.0\times 10^{-13}$ kg, $M_{\text{sun}} = 1.99\times 10^{30}$ kg,

$r = 1.5\times 10^{11}$ m, and the result from part (b), we get $F_{\text{rad}}/F_{\text{grav}} = 0.55$.

EVALUATE: The force of the sun's radiation is about half as great as its gravitational force. Light particles of the same size would feel the same pressure but less gravity, so they could be blown away by the sun. Also closer to the sun the radiation is more intense, so the radiation pressure could blow more particles away from the sun.

32.50. IDENTIFY: This problem is about electromagnetic waves.
SET UP and **EXECUTE: (a)** Evaluate $\oint \vec{E}\cdot d\hat{l}$. $E_z = 0$ and the path is in the xz-plane, so only E_x contributes to the integral. Therefore $\oint \vec{E}\cdot d\hat{l} = \int_{-h/2}^{h/2} E_x(z=0)dx + \int_{h/2}^{-h/2} E_x(z=\lambda/2)dx$. Using the given waves gives $\oint \vec{E}\cdot d\hat{l} = \int_{-h/2}^{h/2} E\cos(0-\omega t)dx + \int_{h/2}^{-h/2} E\cos(k\lambda/2-\omega t)dx$. Integrating gives $\oint \vec{E}\cdot d\hat{l}$ $= hE\left[\cos\omega t - \left(\cos(k\lambda/2)\cos\omega t\right) + \sin(k\lambda/2)\sin\omega t\right]$. $\frac{k\lambda}{2} = \left(\frac{2\pi}{\lambda}\right)\left(\frac{\lambda}{2}\right) = \pi$. $\sin\pi = 0$ and $\cos\pi = -1$, so our result reduces to $\oint \vec{E}\cdot d\hat{l} = 2hE\cos\omega t$.

(b) We want the flux. $dA = h\,dz$. $BdA = h\,dz$. B_y is positive and A_y is negative, so the flux is negative. As in (a), we make use of $k\lambda/2 = \pi$.

$$\Phi_B = -\int B_y dA = -\int_0^{\lambda/2} B\cos(kz-\omega t)h dz = -\frac{Bh}{k}\left[\sin\left(k\lambda/2-\omega t\right) - \sin(-\omega t)\right] = -\frac{2Bh}{k}\sin\omega t.$$

(c) We want to find dB in terms of E and c. Using the result of (b), $\mathcal{E} = -\dfrac{d\Phi_B}{dt} = \dfrac{2Bh}{k}\cos\omega t$. In part (a) we found that $\mathcal{E} = \oint \vec{E}\cdot d\hat{l} = 2hE\cos\omega t$. Equating these two expressions gives $E = cB$.

(d) Follow the directions in the problem: reverse the sign of the sine function and add the two terms. For $\vec{E}$ this gives

$\vec{E} = \vec{E}_R + \vec{E}_L = E\left[\cos(kz-\omega t)\hat{\boldsymbol{i}} + \sin(kz-\omega t)\hat{\boldsymbol{j}}\right] + E\left[\cos(kz-\omega t)\hat{\boldsymbol{i}} - \sin(kz-\omega t)\hat{\boldsymbol{j}}\right]$, which reduces to $\vec{E} = 2E\cos(kz-\omega t)\hat{\boldsymbol{i}}$. The same procedure for $\vec{B}$ leads to $\vec{B} = 2B\cos(kz-\omega t)\hat{\boldsymbol{j}}$.

(e) We want the E and B. $S = \dfrac{E_{\max}^2}{\mu_0 c} = I$. Solve for $E_{\max}$ and use the given intensity.

$E_{\max} = \sqrt{\mu_0 cI} = \sqrt{\mu_0 c(100\ \text{W/m}^2)} = 194\ \text{V/m}$. $B_{\max} = E_{\max}/c = (194\ \text{V/m})/c = 0.647\ \mu\text{T}$.

EVALUATE: Note that B is a weak magnetic field but E is a considerably stronger electric field.

32.51. IDENTIFY: The orbiting particle has acceleration $a = \dfrac{v^2}{R}$.

SET UP: $K = \frac{1}{2}mv^2$. An electron has mass $m_e = 9.11\times10^{-31}$ kg and a proton has mass $m_p = 1.67\times10^{-27}$ kg.

EXECUTE: **(a)** $\left[\dfrac{q^2a^2}{6\pi\epsilon_0 c^3}\right] = \dfrac{\text{C}^2(\text{m/s}^2)^2}{(\text{C}^2/\text{N}\cdot\text{m}^2)(\text{m/s})^3} = \dfrac{\text{N}\cdot\text{m}}{\text{s}} = \dfrac{\text{J}}{\text{s}} = \text{W} = \left[\dfrac{dE}{dt}\right]$.

(b) For a proton moving in a circle, the acceleration is

$a = \dfrac{v^2}{R} = \dfrac{\frac{1}{2}mv^2}{\frac{1}{2}mR} = \dfrac{2(6.00\times10^6\ \text{eV})(1.6\times10^{-19}\ \text{J/eV})}{(1.67\times10^{-27}\ \text{kg})(0.75\ \text{m})} = 1.53\times10^{15}\ \text{m/s}^2$. The rate at which it emits energy because of its acceleration is

$\dfrac{dE}{dt} = \dfrac{q^2a^2}{6\pi\epsilon_0 c^3} = \dfrac{(1.6\times10^{-19}\ \text{C})^2(1.53\times10^{15}\ \text{m/s}^2)^2}{6\pi\epsilon_0(3.0\times10^8\ \text{m/s})^3} = 1.33\times10^{-23}\ \text{J/s} = 8.32\times10^{-5}\ \text{eV/s}$.

Therefore, the fraction of its energy that it radiates every second is

$\dfrac{(dE/dt)(1\ \text{s})}{E} = \dfrac{8.32\times10^{-5}\ \text{eV}}{6.00\times10^6\ \text{eV}} = 1.39\times10^{-11}$.

(c) Carry out the same calculations as in part (b), but now for an electron at the same speed and radius. That means the electron's acceleration is the same as the proton, and thus so is the rate at which it emits energy, since they also have the same charge. However, the electron's initial energy differs from the proton's by the ratio of their masses: $E_e = E_p\dfrac{m_e}{m_p} = (6.00\times10^6\ \text{eV})\dfrac{(9.11\times10^{-31}\ \text{kg})}{(1.67\times10^{-27}\ \text{kg})} = 3273\ \text{eV}$.

Therefore, the fraction of its energy that it radiates every second is

$\dfrac{(dE/dt)(1\ \text{s})}{E} = \dfrac{8.32\times10^{-5}\ \text{eV}}{3273\ \text{eV}} = 2.54\times10^{-8}$.

EVALUATE: The proton has speed $v = \sqrt{\dfrac{2E}{m_p}} = \sqrt{\dfrac{2(6.0\times10^6\ \text{eV})(1.60\times10^{-19}\ \text{J/eV})}{1.67\times10^{-27}\ \text{kg}}} = 3.39\times10^7\ \text{m/s}$.

The electron has the same speed and kinetic energy 3.27 keV. The particles in the accelerator radiate at a much smaller rate than the electron in Problem 32.52 does, because in the accelerator the orbit radius is very much larger than in the atom, so the acceleration is much less.

32.52. **IDENTIFY:** The electron has acceleration $a = \dfrac{v^2}{R}$.

SET UP: $1\ \text{eV} = 1.60\times10^{-19}$ C. An electron has $|q| = e = 1.60\times10^{-19}$ C.

EXECUTE: For the electron in the classical hydrogen atom, its acceleration is

$a = \dfrac{v^2}{R} = \dfrac{\frac{1}{2}mv^2}{\frac{1}{2}mR} = \dfrac{2(13.6\ \text{eV})(1.60\times10^{-19}\ \text{J/eV})}{(9.11\times10^{-31}\ \text{kg})(5.29\times10^{-11}\ \text{m})} = 9.03\times10^{22}\ \text{m/s}^2$. Then using the formula for the rate of energy emission given in Problem 32.51:

$\dfrac{dE}{dt} = \dfrac{q^2a^2}{6\pi\epsilon_0 c^3} = \dfrac{(1.60\times10^{-19}\ \text{C})^2(9.03\times10^{22}\ \text{m/s}^2)^2}{6\pi\epsilon_0(3.00\times10^8\ \text{m/s})^3} = 4.64\times10^{-8}\ \text{J/s} = 2.89\times10^{11}\ \text{eV/s}$. This large value of $\dfrac{dE}{dt}$ would mean that the electron would almost immediately lose all its energy!

EVALUATE: The classical physics result in Problem 32.51 must not apply to electrons in atoms.

32.53. **IDENTIFY** and **SET UP:** Follow the steps specified in the problem.

EXECUTE: **(a)** $E_y(x,t) = E_{\max}e^{-k_C x}\cos(k_C x - \omega t)$.

$$\frac{\partial E_y}{\partial x} = E_{\max}(-k_C)e^{-k_C x}\cos(k_C x - \omega t) + E_{\max}(-k_C)e^{-k_C x}\sin(k_C x - \omega t).$$

$$\frac{\partial^2 E_y}{\partial x^2} = E_{\max}(+k_C^2)e^{-k_C x}\cos(k_C x - \omega t) + E_{\max}(+k_C^2)e^{-k_C x}\sin(k_C x - \omega t).$$

$$+E_{\max}(+k_C^2)e^{-k_C x}\sin(k_C x - \omega t) + E_{\max}(-k_C^2)e^{-k_C x}\cos(k_C x - \omega t).$$

$\dfrac{\partial^2 E_y}{\partial x^2} = +2E_{\max}k_C^2 e^{-k_C x}\sin(k_C x - \omega t)$. $\dfrac{\partial E_y}{\partial t} = +E_{\max}e^{-k_C x}\,\omega\sin(k_C x - \omega t)$.

Setting $\dfrac{\partial^2 E_y}{\partial x^2} = \dfrac{\mu \partial E_y}{\rho \partial t}$ gives $2E_{\max}k_C^2 e^{-k_C x}\sin(k_C x - \omega t) = \mu/\rho E_{\max}e^{-k_C x}\,\omega\sin(k_C x - \omega t)$. This will only be true if $\dfrac{2k_C^2}{\omega} = \dfrac{\mu}{\rho}$, or $k_C = \sqrt{\dfrac{\omega\mu}{2\rho}}$.

(b) The energy in the wave is dissipated by the i^2R heating of the conductor.

(c) $E_y = \dfrac{E_{y0}}{e} \Rightarrow k_C x = 1$, $x = \dfrac{1}{k_C} = \sqrt{\dfrac{2\rho}{\omega\mu}} = \sqrt{\dfrac{2(1.72\times10^{-8}\ \Omega\cdot\text{m})}{2\pi(1.0\times10^6\ \text{Hz})\mu_0}} = 6.60\times10^{-5}\,\text{m}$.

EVALUATE: The lower the frequency of the waves, the greater is the distance they can penetrate into a conductor. A dielectric (insulator) has a much larger resistivity and these waves can penetrate a greater distance in these materials.

32.54. **IDENTIFY** and **SET UP:** Since 60 Hz is in the range 25 Hz to 3 kHz, we use the formula $E_{\max} = \dfrac{350}{f}$ V/m, where f is in kHz. The intensity is $I = \frac{1}{2}\epsilon_0 cE_{\max}^2$.

EXECUTE: The maximum electric field is $E_{\max} = \dfrac{350}{f}$ V/m $= \dfrac{350}{0.060}$ V/m = 5800 V/m. Now find the intensity for the maximum field.

$I = \frac{1}{2}\epsilon_0 cE_{\max}^2 = (1/2)(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)(3.0\times10^8\ \text{m/s})(5800\ \text{V/m})^2 = 4.5\times10^4\ \text{W/m}^2$

$= 45\ \text{kW/m}^2$, which is choice (c).

EVALUATE: At higher frequencies the intensity would be less because the maximum electric field, which is inversely proportional to the frequency, would be smaller.

32.55. **IDENTIFY and SET UP:** The maximum electric field is proportional to $1/f$, and the intensity is proportional to E_{max}^2.

EXECUTE: Since E_{max} is proportional to $1/f$, doubling f decreases the maximum field by $\frac{1}{2}$. Because the intensity is proportional to E_{max}^2, decreasing E_{max} by a factor of $\frac{1}{2}$ will decrease the intensity by a factor of $(\frac{1}{2})^2 = \frac{1}{4}$, which is choice (d).

EVALUATE: Higher frequencies could be more harmful, so we tolerate lower fields at higher frequency.

32.56. **IDENTIFY and SET UP:** In the frequency range 25 Hz to 3 kHz, for a given frequency the maximum electric field is $E_{\text{max}} = 350/f$ and the maximum electric field is $B_{\text{max}} = 5/f$. $B = cE$.

EXECUTE: For the electric field, the maximum intensity at a frequency f is $I_{\text{max}} = \frac{1}{2}\epsilon_0 cE_{\text{max}}^2$. Since $E_{\text{max}} = 350/f$, the intensity is $I_{\text{max}}^E = \frac{1}{2}\epsilon_0 c\left(\frac{350}{f}\right)^2$.

The intensity in terms of the magnetic field is $I = \frac{1}{2}\epsilon_0 cE_{\text{max}}^2 = \frac{1}{2}\epsilon_0 c(B_{\text{max}}c)^2 = \frac{1}{2}\epsilon_0 c^3 B_{\text{max}}^2$, where we have used $E_{\text{max}} = cB_{\text{max}}$. The maximum magnetic field is $B_{\text{max}} = 5/f$, so the maximum intensity for this magnetic field is $I_{\text{max}}^B = \frac{1}{2}\epsilon_0 c^3\left(\frac{5}{f}\right)^2$. Taking the ratio of the two intensities gives

$$\frac{I_{\text{max}}^E}{I_{\text{max}}^B} = \frac{\frac{1}{2}\epsilon_0 c\left(\frac{350}{f}\right)^2}{\frac{1}{2}\epsilon_0 c^3\left(\frac{5}{f}\right)^2} = \frac{1}{c^2}\left(\frac{350}{5}\right)^2 = 5.4\times10^{-14}.$$ The allowed intensity using the electric field limitation is *much* less than the allowed intensity using the magnetic field limitation, which is choice (b).

EVALUATE: The magnetic force on a charge due to an electromagnetic wave is normally much less than the electric force, so the intensity allowed for the electric field is much less than for the magnetic field.

33

THE NATURE AND PROPAGATION OF LIGHT

VP33.2.1. **IDENTIFY:** We have reflection and refraction. Snell's law applies.

SET UP: $n_a \sin\theta_a = n_b \sin\theta_b$.

EXECUTE: **(a)** For reflected rays, the angle of reflection is equal to the angle of incidence. So the angle of reflection is 70.0°.

(b) Apply Snell's law. $n_a \sin\theta_a = n_b \sin\theta_b$. $(1.00)\sin 70.0° = (1.80)\sin\theta_b$. $\theta_b = 31.5°$.

EVALUATE: The light is bent toward the normal in the glass.

VP33.2.2. **IDENTIFY:** We have refraction at a flat surface, so Snell's law applies.

SET UP: $n_a \sin\theta_a = n_b \sin\theta_b$, $n = c/v$.

EXECUTE: **(a)** We want n. (1.33) sin 55.0° = $n$sin37.0°. n = 1.81.

(b) We want speed of light in the glass. $v = c/n = c/1.81 = 1.66\times10^8$ m/s.

EVALUATE: The light is bent toward the normal in the glass because $n_{glass} > n_{water}$.

VP33.2.3. **IDENTIFY:** We have refraction at a flat surface, so Snell's law applies.

SET UP: $n_a \sin\theta_a = n_b \sin\theta_b$, $\lambda_n = \dfrac{\lambda_0}{n}$, λ_{air} is almost the same as λ_{vacuum} .

EXECUTE: **(a)** We want n. $\lambda_n = \dfrac{\lambda_0}{n}$. $n = \lambda_0/\lambda_n$ = (635 nm)/(508 nm) = 1.25.

(b) We want θ_b (in the liquid). Apply $n_a \sin\theta_a = n_b \sin\theta_b$. $(1.00)\sin 35.0° = (1.25)\sin\theta_b$. $\theta_b = 27.3°$.

(c) We want the frequency in air. $f_a = c/\lambda_a$ = c/(635 nm) = 4.72×10^{14} Hz.

(d) We want the frequency in the liquid. The frequency does not change, so it is the same as in part (c): $f_a = 4.72\times10^{14}$ Hz.

EVALUATE: Our answer to (a) gives n = 1.25, which is reasonable because n is always greater than one.

VP33.2.4. **IDENTIFY:** We have refraction at a flat surface, so Snell's law applies.

SET UP: $n_a \sin\theta_a = n_b \sin\theta_b$, $\lambda_n = \dfrac{\lambda_0}{n}$, λ_{air} is almost the same as λ_{vacuum} .

EXECUTE: **(a)** We want θ_a (in ethanol). Apply $n_a \sin\theta_a = n_b \sin\theta_b$. $(1.36)\sin\theta_a = (1.309)\sin 85.0°$. $\theta_a = 73.5°$.

(b) We want $\lambda_{ice}/\lambda_{ethanol}$. Use $\lambda_n = \dfrac{\lambda_0}{n}$. $\lambda_{ice}/\lambda_{ethanol} = \dfrac{\dfrac{\lambda_0}{n_i}}{\dfrac{\lambda_0}{n_e}} = \dfrac{n_e}{n_i} = \dfrac{1.36}{1.309} = 1.04.$

EVALUATE: Since $n_i < n_e$, we expect that $\theta_i > \theta_e$, which is what we have found.

VP33.5.1. **IDENTIFY:** This problem deals with polarized light, so Malus's law applies.

SET UP: $I = I_0 \cos^2 \phi$.

EXECUTE: We want the intensity. $I = I_0 \cos^2 \phi$ = (255 W/m^2) $\cos^2$ 15.0° = 238 W/m^2.

EVALUATE: The filter axis and the polarization direction of the beam are closely aligned, so most of the light should get through, which our result shows.

VP33.5.2. **IDENTIFY:** This problem involves a polarizing filter, so Malus's law applies.

SET UP: Fig. VP33.5.2 illustrates the situation. $I = I_0 \cos^2 \phi$.

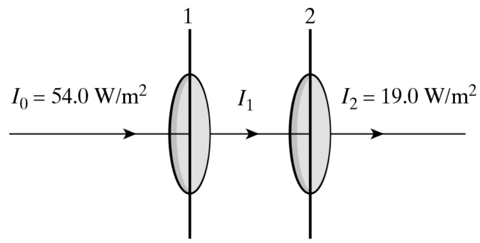

Figure VP33.5.2

EXECUTE: **(a)** We want the intensity after the first polarizer. A polarizer absorbs half the unpolarized light, so I_1 = (52.0 W/m^2)/2 = 27.0 W/m^2.

(b) We want ϕ . $I_2 = I_1 \cos^2 \phi$. 19.0 W/m^2 = (27.0 W/m^2) $\cos^2 \phi$. ϕ = 33.0°.

EVALUATE: The first polarizer reduced the intensity of the incident light by a greater percent than the second filter did.

VP33.5.3. **IDENTIFY:** This problem involves a polarizing filter, so Malus's law applies.

SET UP: Fig. VP33.5.3 illustrates the arrangement. $I = I_0 \cos^2 \phi$.

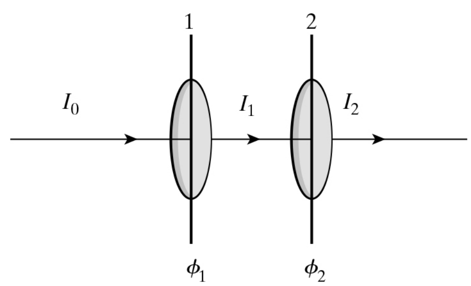

Figure VP33.5.3

EXECUTE: **(a)** We want I_1. $I_1 = I_0 \cos^2 \phi_1$ = (60.0 W/m^2) $\cos^2$ 25.0° = 49.3 W/m^2.

(b) We want I_2. I_1 is polarized at 25.0° from the *y* direction, so ϕ_2 = 50.0° – 25.0° = 25.0°.

$I_2 = I_1 \cos^2 \phi_2$ = (49.3 W/m^2) $\cos^2$ 25.0° = 40.5 W/m^2.

(c) We want I_2. ϕ = 50.0°. I_2 = (60.0 W/m^2) $\cos^2$ 50.0° = 25.8 W/m^2.

EVALUATE: Surprisingly we remove more of the light with just one filter, even though it is at the same angle as it was in the first case.

VP33.5.4. **IDENTIFY:** We are dealing with polarized light, so Malus's law applies.

SET UP: $I = I_0 \cos^2 \phi$. Two beams, one polarized and the other unpolarized, pass through the same filter simultaneously. We want the intensity of the emerging light.

EXECUTE: The emerging light has intensity $I = I_p + I_u$. $I_p = I_0 \cos^2\phi = I_0 \cos^2 30° = 0.750 I_0$.

$I_u = 0.500 I_0$. $I = 0.750I_0 + 0.500I_0 = 1.25I_0 = \dfrac{5}{4}I_0$.

EVALUATE: If there were no filter, the emerging intensity would be $2I_0$. With the filter, it is $1.25I_0$. So the final intensity is $1.25I_0/2.00I_0 = 0.625 = 62.5\%$ of the initial intensity. Therefore the filter has removed 37.5% of the light.

VP33.6.1. **IDENTIFY:** We are looking at polarization by reflection, so Brewster's law applies.
SET UP: $\tan\theta_p = n_b/n_a$.

EXECUTE: **(a)** We want the angle of incidence so the reflected light will be totally polarized. This is true at Brewster's angle $\tan\theta_p = n_b/n_a$, where $n_a = 1.00$ (air) and $n_b = 1.73$ (solid). This gives

$\tan\theta_p = 1.73/1.00$, so $\theta_p = 60.0°$.

(b) The reflected light is 100% polarized, but not all the light with that angle of polarization is reflected – some goes into the solid. So the transmitted light is only *partially* polarized.
EVALUATE: If water ($n = 1.33$) were on the solid, the polarizing angle would be arctan(1.73/1.33) = 52.4°.

VP33.6.2. **IDENTIFY:** This problem involves polarization by reflection, so Brewster's law applies as well as Snell's law.
SET UP: $\tan\theta_p = n_b/n_a$, $n_a \sin\theta_a = n_b \sin\theta_b$.

EXECUTE: **(a)** We want n for the glass. Since the reflected light is completely polarized, the angle of incidence must have Brewster's angle. Use $\tan\theta_p = n_b/n_a$ and solve for n.

$n = n_a \tan\theta_p = (1.00)\tan 57.0° = 1.54$.

(b) We want the angle of refraction. Use $n_a \sin\theta_a = n_b \sin\theta_b$. $(1.00)\sin 57.0° = (1.54)\sin\theta_b$. $\theta_b = 33.0°$.

EVALUATE: Since $n_{glass} > n_{air}$, the light should have been bent toward the normal in the glass, which in fact it was, so our results are reasonable.

VP33.6.3. **IDENTIFY:** This problem involves polarization by reflection, so Brewster's law applies.
SET UP: $\tan\theta_p = n_b/n_a$. We want the angle of incidence so no light reflects from the glass.

EXECUTE: **(a)** The incident light is already polarized perpendicular to the plane of incidence, so there is *no angle* at which no light reflects.
(b) At Brewster's angle, all the reflected light is polarized perpendicular to the plane of incidence. But for this light, none of it is polarized that way. So at Brewster's angle, none of it reflects. $\tan\theta_p = n_b/n_a$ = 1.66/1.00 = 1.66, so $\theta_p = 58.9°$.

EVALUATE: In part (b) all the light enters the glass.

VP33.6.4. **IDENTIFY:** This problem involves polarization by reflection, so Brewster's law applies.
SET UP: $\tan\theta_p = n_b/n_a$. At Brewster's angle, the refracted light is perpendicular to the reflected light.

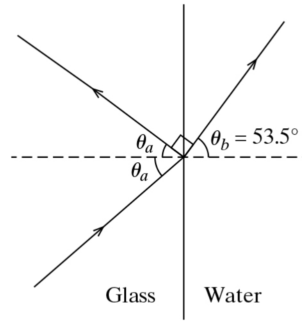

Figure VP33.6.4

EXECUTE: (a) We want θ_p. For 100% of the reflected light to be polarized, the angle of incidence must be Brewster's angle. The reflected and refracted rays are perpendicular, so $\theta_b + 90° + \theta_a = 180°$, which gives $\theta_a = 180° - 90° - \theta_b = 90° - 53.5° = 36.5°$.

EVALUATE: $n_{\text{glass}} > n_{\text{water}}$ so the light should be bent away from the normal in the water, which agrees with our result since θ_b (53.5°) > θ_a (36.5°).

33.1. IDENTIFY: For reflection, $\theta_r = \theta_a$.

SET UP: The desired path of the ray is sketched in Figure 33.1.

EXECUTE: $\tan\phi = \dfrac{14.0 \text{ cm}}{11.5 \text{ cm}}$, so $\phi = 50.6°$. $\theta_r = 90° - \phi = 39.4°$ and $\theta_r = \theta_a = 39.4°$.

EVALUATE: The angle of incidence is measured from the normal to the surface.

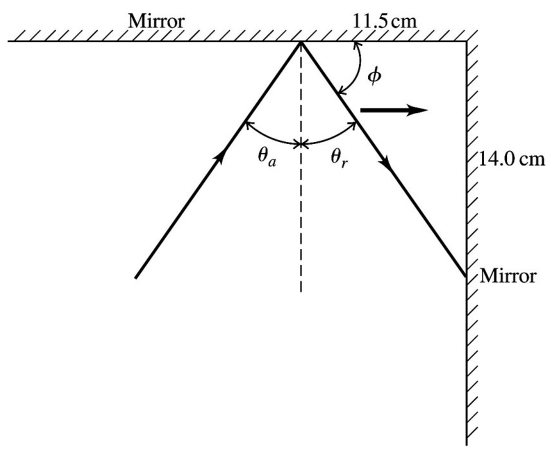

Figure 33.1

33.2. IDENTIFY: The speed and the wavelength of the light will be affected by the vitreous humor, but not the frequency.

SET UP: $n = \dfrac{c}{v}$. $v = f\lambda$. $\lambda = \dfrac{\lambda_0}{n}$.

EXECUTE: (a) $\lambda_v = \dfrac{\lambda_{0,v}}{n} = \dfrac{380 \text{ nm}}{1.34} = 284 \text{ nm}$. $\lambda_r = \dfrac{\lambda_{0,r}}{n} = \dfrac{750 \text{ nm}}{1.34} = 560 \text{ nm}$. The range is 284 nm to 560 nm.

(b) Calculate the frequency in air, where $v = c = 3.00\times10^8$ m/s.

$f_r = \dfrac{c}{\lambda_r} = \dfrac{3.00\times10^8 \text{ m/s}}{750\times10^{-9} \text{ m}} = 4.00\times10^{14}$ Hz. $f_v = \dfrac{c}{\lambda_v} = \dfrac{3.00\times10^8 \text{ m/s}}{380\times10^{-9} \text{ m}} = 7.89\times10^{14}$ Hz. The range is 4.00×10^{14} Hz to 7.89×10^{14} Hz.

(c) $v = \dfrac{c}{n} = \dfrac{3.00\times10^8 \text{ m/s}}{1.34} = 2.24\times10^8$ m/s.

EVALUATE: The frequency range in air is the same as in the vitreous humor.

33.3. **IDENTIFY** and **SET UP:** Use $n = \dfrac{c}{v}$ and $\lambda = \dfrac{\lambda_0}{n}$ to calculate v and λ in the liquid.

EXECUTE: **(a)** $n = \dfrac{c}{v}$ so $v = \dfrac{c}{n} = \dfrac{2.998\times10^8 \text{ m/s}}{1.47} = 2.04\times10^8$ m/s.

(b) $\lambda = \dfrac{\lambda_0}{n} = \dfrac{650 \text{ nm}}{1.47} = 442$ nm.

EVALUATE: Light is slower in the liquid than in vacuum. By $v = f\lambda$, when v is smaller, λ is smaller.

33.4. **IDENTIFY:** In air, $c = f\lambda_0$. In glass, $\lambda = \dfrac{\lambda_0}{n}$.

SET UP: $c = 3.00\times10^8$ m/s.

EXECUTE: **(a)** $\lambda_0 = \dfrac{c}{f} = \dfrac{3.00\times10^8 \text{ m/s}}{5.80\times10^{14} \text{ Hz}} = 517$ nm.

(b) $\lambda = \dfrac{\lambda_0}{n} = \dfrac{517 \text{ nm}}{1.52} = 340$ nm.

EVALUATE: In glass the light travels slower than in vacuum and the wavelength is smaller.

33.5. **IDENTIFY:** This problem involves refraction at a glass-liquid boundary. Snell's law applies.

SET UP: $n_a \sin\theta_a = n_b \sin\theta_b$, $n = c/v$, $\lambda_n = \dfrac{\lambda_0}{n}$. In the liquid we want the speed, wavelength, and frequency of the light. Let subscript g denote glass and L denote the liquid.

EXECUTE: Find n_g: $n_g = c/v = c/(1.85\times10^8 \text{ m/s}) = 1.622$.

Find n_L: Use $n_a \sin\theta_a = n_b \sin\theta_b$. $(1.622)\sin 38.0° = n_L \sin 44.7°$. $n_L = 1.419$.

$v_L = c/n_L = c/(1.419) = 2.11\times10^8$ m/s. $\lambda_L = \dfrac{\lambda_0}{n_L}$. $\lambda_g = \dfrac{\lambda_0}{n_g}$, so $\lambda_0 = n_g\lambda_g$. Combining gives

$$\lambda_L = \frac{\lambda_g n_g}{n_L} = \frac{(365 \text{ nm})(1.622)}{1.419} = 417 \text{ nm}.$$

The frequency does not change, so $f_L = f_g = 5.07\times10^{14}$ Hz.

EVALUATE: The light was bent away from the normal in the liquid, so it should be true that $n_L < n_g$. We found that $n_g = 1.622$ and $n_L = 1.419$, so our result is reasonable.

33.6. **IDENTIFY:** $\lambda = \dfrac{\lambda_0}{n}$.

SET UP: From Table 33.1, $n_{\text{water}} = 1.333$ and $n_{\text{benzene}} = 1.501$.

EXECUTE: $\lambda_{\text{water}} n_{\text{water}} = \lambda_{\text{benzene}} n_{\text{benzene}} = \lambda_0$. $\lambda_{\text{benzene}} = \lambda_{\text{water}}\left(\dfrac{n_{\text{water}}}{n_{\text{benzene}}}\right) = (526 \text{ nm})\left(\dfrac{1.333}{1.501}\right) = 467$ nm.

EVALUATE: λ is smallest in benzene, since n is largest for benzene.

33.7. **IDENTIFY:** Apply the law of reflection and Snell's law to calculate θ_r and θ_b. The angles in these equations are measured with respect to the normal, not the surface.

SET UP: The incident, reflected and refracted rays are shown in Figure 33.7. The law of reflection is $\theta_r = \theta_a$, and Snell's law is $n_a \sin\theta_a = n_b \sin\theta_b$.

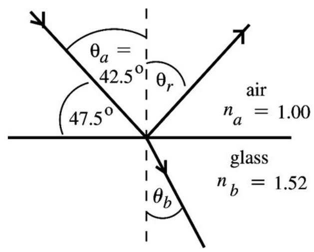

Figure 33.7

EXECUTE: **(a)** $\theta_r = \theta_a = 42.5°$ The reflected ray makes an angle of $90.0° - \theta_r = 47.5°$ with the surface of the glass.

(b) $n_a \sin\theta_a = n_b \sin\theta_b$, where the angles are measured from the normal to the interface.

$$\sin\theta_b = \frac{n_a \sin\theta_a}{n_b} = \frac{(1.00)(\sin 42.5°)}{1.66} = 0.4070.$$

$\theta_b = 24.0°$.

The refracted ray makes an angle of $90.0° - \theta_b = 66.0°$ with the surface of the glass.

EVALUATE: The light is bent toward the normal when the light enters the material of larger refractive index.

33.8. **IDENTIFY:** The time delay occurs because the beam going through the transparent material travels slower than the beam in air.

SET UP: $v = \dfrac{c}{n}$ in the material, but $v = c$ in air.

EXECUTE: The time for the beam traveling in air to reach the detector is

$t = \dfrac{d}{c} = \dfrac{2.50 \text{ m}}{3.00\times10^8 \text{ m/s}} = 8.33\times10^{-9}$ s. The light traveling in the block takes time

$t = 8.33\times10^{-9} \text{ s} + 6.25\times10^{-9} \text{ s} = 1.46\times10^{-8}$ s. The speed of light in the block is

$v = \dfrac{d}{t} = \dfrac{2.50 \text{ m}}{1.46\times10^{-8} \text{ s}} = 1.71\times10^8$ m/s. The refractive index of the block is $n = \dfrac{c}{v} = \dfrac{3.00\times10^8 \text{ m/s}}{1.71\times10^8 \text{ m/s}} = 1.75.$

EVALUATE: $n > 1$, as it must be, and 1.75 is a reasonable index of refraction for a transparent material such as plastic.

33.9. **IDENTIFY** and **SET UP:** Use Snell's law to find the index of refraction of the plastic and then use $n = \dfrac{c}{v}$ to calculate the speed v of light in the plastic.

EXECUTE: $n_a \sin\theta_a = n_b \sin\theta_b$.

$$n_b = n_a\left(\frac{\sin\theta_a}{\sin\theta_b}\right) = 1.00\left(\frac{\sin 62.7°}{\sin 48.1°}\right) = 1.194.$$

$n = \dfrac{c}{v}$ so $v = \dfrac{c}{n} = (3.00\times10^8 \text{ m/s})/1.194 = 2.51\times10^8$ m/s.

EVALUATE: Light is slower in plastic than in air. When the light goes from air into the plastic it is bent toward the normal.

33.10. IDENTIFY: Apply Snell's law at both interfaces.

SET UP: The path of the ray is sketched in Figure 33.10. Table 33.1 gives $n = 1.329$ for the methanol.

EXECUTE: **(a)** At the air-glass interface $(1.00)\sin 41.3° = n_{\text{glass}} \sin\alpha$. At the glass-methanol interface $n_{\text{glass}} \sin\alpha = (1.329)\sin\theta$. Combining these two equations gives $\sin 41.3° = 1.329 \sin\theta$ and $\theta = 29.8°$.

(b) The same figure applies apply as for part (a), except $\theta = 20.2°$. $(1.00)\sin 41.3° = n\sin 20.2°$ and $n = 1.91$.

EVALUATE: The angle α is 25.2°. The index of refraction of methanol is less than that of the glass and the ray is bent away from the normal at the glass $\rightarrow$ methanol interface. The unknown liquid has an index of refraction greater than that of the glass, so the ray is bent toward the normal at the glass $\rightarrow$ liquid interface.

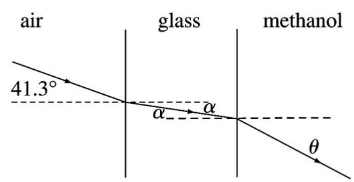

Figure 33.10

33.11. IDENTIFY: The figure shows the angle of incidence and angle of refraction for light going from the water into material *X*. Snell's law applies at the air-water and water-*X* boundaries.

SET UP: Snell's law says $n_a \sin\theta_a = n_b \sin\theta_b$. Apply Snell's law to the refraction from material *X* into the water and then from the water into the air.

EXECUTE: **(a)** Material *X* to water: $n_a = n_X$, $n_b = n_{\text{w}} = 1.333$. $\theta_a = 25°$ and $\theta_b = 48°$.

$$n_a = n_b\left(\frac{\sin\theta_b}{\sin\theta_a}\right) = (1.333)\left(\frac{\sin 48°}{\sin 25°}\right) = 2.34.$$

(b) Water to air: As Figure 33.11 shows, $\theta_a = 48°$. $n_a = 1.333$ and $n_b = 1.00$.

$$\sin\theta_b = \left(\frac{n_a}{n_b}\right)\sin\theta_a = (1.333)\sin 48° = 82°.$$

EVALUATE: $n > 1$ for material *X*, as it must be.

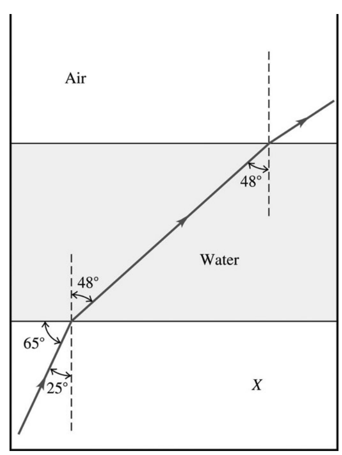

Figure 33.11

33.12. **IDENTIFY:** Apply Snell's law to the refraction at each interface.

SET UP: $n_{\text{air}} = 1.00$. $n_{\text{water}} = 1.333$.

EXECUTE: **(a)** $\theta_{\text{water}} = \arcsin\left(\dfrac{n_{\text{air}}}{n_{\text{water}}}\sin\theta_{\text{air}}\right) = \arcsin\left(\dfrac{1.00}{1.333}\sin 35.0^\circ\right) = 25.5^\circ$.

EVALUATE: **(b)** This calculation has no dependence on the glass because we can omit that step in the chain: $n_{\text{air}}\sin\theta_{\text{air}} = n_{\text{glass}}\sin\theta_{\text{glass}} = n_{\text{water}}\sin\theta_{\text{water}}$.

33.13. **IDENTIFY:** This problem involves refraction at a boundary, so Snell's law applies.

SET UP: $n_a \sin\theta_a = n_b \sin\theta_b$, $\lambda_n = \dfrac{\lambda_0}{n}$. Let the subscript s denote the solid and g denote the glass. We want θ_s.

EXECUTE: Snell's law gives $n_g \sin\theta_g = n_s \sin\theta_s$, so see that we need n_g and n_s. $\lambda_g = \dfrac{\lambda_0}{n_g}$ and $\lambda_s = \dfrac{\lambda_0}{n_s}$.

$\dfrac{\lambda_g}{\lambda_s} = \dfrac{447\text{ nm}}{315\text{ nm}} = 1.419 = \dfrac{\lambda_0/n_g}{\lambda_0/n_s} = \dfrac{n_s}{n_g}$, so $n_g = 1.419n_g$. Thus $n_g \sin 62.0^\circ = 1.419 n_g \sin\theta_s$, so $\theta_s = 38.5^\circ$.

EVALUATE: $n_s > n_g$, so the light should be bent toward the normal, which agrees with our result.

33.14. **IDENTIFY:** The wavelength of the light depends on the index of refraction of the material through which it is traveling, and Snell's law applies at the water-glass interface.

SET UP: $\lambda_0 = \lambda n$ so $\lambda_{\text{w}} n_{\text{w}} = \lambda_{\text{gl}} n_{\text{gl}}$. Snell's law gives $n_{\text{gl}}\sin\theta_{\text{gl}} = n_{\text{w}}\sin\theta_{\text{w}}$.

EXECUTE: $n_{\text{gl}} = n_{\text{w}}\left(\dfrac{\lambda_{\text{w}}}{\lambda_{\text{gl}}}\right) = (1.333)\left(\dfrac{726\text{ nm}}{544\text{ nm}}\right) = 1.779$. Now apply $n_{\text{gl}}\sin\theta_{\text{gl}} = n_{\text{w}}\sin\theta_{\text{w}}$.

$\sin\theta_{\text{gl}} = \left(\dfrac{n_{\text{w}}}{n_{\text{gl}}}\right)\sin\theta_{\text{w}} = \left(\dfrac{1.333}{1.779}\right)\sin 56.0^\circ = 0.6212$. $\theta_{\text{gl}} = 38.4^\circ$.

EVALUATE: $\theta_{\text{gl}} < \theta_{\text{w}}$ because $n_{\text{gl}} > n_{\text{w}}$.

33.15. **IDENTIFY:** The critical angle for total internal reflection is θ_a that gives $\theta_b = 90^\circ$ in Snell's law.

SET UP: In Figure 33.15 the angle of incidence θ_a is related to angle β by $\theta_a + \beta = 90^\circ$.

EXECUTE: **(a)** Calculate θ_a that gives $\theta_b = 90^\circ$. $n_a = 1.60$, $n_b = 1.00$ so $n_a \sin\theta_a = n_b \sin\theta_b$ gives $(1.60)\sin\theta_a = (1.00)\sin 90^\circ$. $\sin\theta_a = \dfrac{1.00}{1.60}$ and $\theta_a = 38.7^\circ$. $\beta = 90^\circ - \theta_a = 51.3^\circ$.

(b) $n_a = 1.60$, $n_b = 1.333$. $(1.60)\sin\theta_a = (1.333)\sin 90^\circ$. $\sin\theta_a = \dfrac{1.333}{1.60}$ and $\theta_a = 56.4^\circ$. $\beta = 90^\circ - \theta_a = 33.6^\circ$.

EVALUATE: The critical angle increases when the ratio $\dfrac{n_a}{n_b}$ decreases.

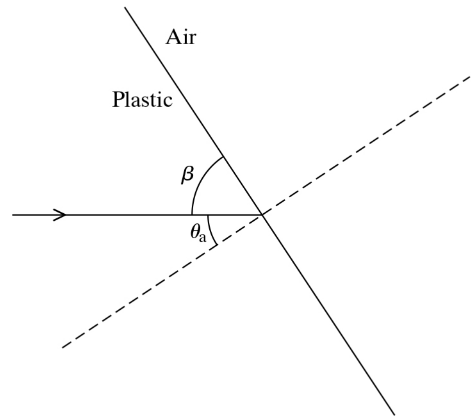

Figure 33.15

33.16. **IDENTIFY:** No light will enter the water if total internal reflection occurs at the glass-water boundary. Snell's law applies at the boundary.

SET UP: Find n_g, the refractive index of the glass. Then apply Snell's law at the boundary.

$n_a \sin\theta_a = n_b \sin\theta_b$.

EXECUTE: $n_g \sin 36.2° = n_w \sin 49.8°$. $n_g = (1.333)\left(\dfrac{\sin 49.8°}{\sin 36.2°}\right) = 1.724$. Now find θ_{crit} for the glass to water refraction. $n_g \sin\theta_{crit} = n_w \sin 90.0°$. $\sin\theta_{crit} = \dfrac{1.333}{1.724}$ and $\theta_{crit} = 50.6°$.

EVALUATE: For $\theta > 50.6°$ at the glass-water boundary, no light is refracted into the water.

33.17. **IDENTIFY:** Use the critical angle to find the index of refraction of the liquid.

SET UP: Total internal reflection requires that the light be incident on the material with the larger n, in this case the liquid. Apply $n_a \sin\theta_a = n_b \sin\theta_b$ with a = liquid and b = air, so $n_a = n_{liq}$ and $n_b = 1.0$.

EXECUTE: $\theta_a = \theta_{crit}$ when $\theta_b = 90°$, so $n_{liq} \sin\theta_{crit} = (1.0)\sin 90°$.

$$n_{liq} = \frac{1}{\sin\theta_{crit}} = \frac{1}{\sin 42.5°} = 1.48.$$

(a) $n_a \sin\theta_a = n_b \sin\theta_b$ (a = liquid, b = air).

$$\sin\theta_b = \frac{n_a \sin\theta_a}{n_b} = \frac{(1.48)\sin 35.0°}{1.0} = 0.8489 \text{ and } \theta_b = 58.1°.$$

(b) Now $n_a \sin\theta_a = n_b \sin\theta_b$ with a = air, b = liquid.

$$\sin\theta_b = \frac{n_a \sin\theta_a}{n_b} = \frac{(1.0)\sin 35.0°}{1.48} = 0.3876 \text{ and } \theta_b = 22.8°.$$

EVALUATE: Light traveling from liquid to air is bent away from the normal. Light traveling from air to liquid is bent toward the normal.

33.18. **IDENTIFY:** Since the refractive index of the glass is greater than that of air or water, total internal reflection will occur at the cube surface if the angle of incidence is greater than or equal to the critical angle.

SET UP: At the critical angle θ_{crit}, Snell's law gives $n_{glass} \sin\theta_{crit} = n_{air} \sin 90°$ and likewise for water.

EXECUTE: **(a)** At the critical angle θ_{crit}, $n_{glass} \sin\theta_{crit} = n_{air} \sin 90°$.

$1.62 \sin\theta_{crit} = (1.00)(1)$ and $\theta_{crit} = 38.1°$.

(b) Using the same procedure as in part (a), we have $1.62 \sin\theta_{crit} = 1.333 \sin 90°$ and $\theta_{crit} = 55.4°$.

EVALUATE: Since the refractive index of water is closer to the refractive index of glass than the refractive index of air is, the critical angle for glass-to-water is greater than for glass-to-air.

33.19. IDENTIFY and **SET UP:** For glass $\rightarrow$ water, $\theta_{\text{crit}} = 48.7°$. Apply Snell's law with $\theta_a = \theta_{\text{crit}}$ to calculate the index of refraction n_a of the glass.

EXECUTE: $n_a \sin\theta_{\text{crit}} = n_b \sin 90°$, so $n_a = \dfrac{n_b}{\sin\theta_{\text{crit}}} = \dfrac{1.333}{\sin 48.7°} = 1.77$

EVALUATE: For total internal reflection to occur the light must be incident in the material of larger refractive index. Our results give $n_{\text{glass}} > n_{\text{water}}$, in agreement with this.

33.20. IDENTIFY: The largest angle of incidence for which any light refracts into the air is the critical angle for water $\rightarrow$ air.

SET UP: Figure 33.20 shows a ray incident at the critical angle and therefore at the edge of the circle of light. The radius of this circle is r and $d = 10.0$ m is the distance from the ring to the surface of the water.

EXECUTE: From the figure, $r = d\tan\theta_{\text{crit}}$. θ_{crit} is calculated from $n_a \sin\theta_a = n_b \sin\theta_b$ with $n_a = 1.333$, $\theta_a = \theta_{\text{crit}}$, $n_b = 1.00$, and $\theta_b = 90°$. $\sin\theta_{\text{crit}} = \dfrac{(1.00)\sin 90°}{1.333}$ and $\theta_{\text{crit}} = 48.6°$.

$r = (10.0\text{ m})\tan 48.6° = 11.3\text{ m}.$

$A = \pi r^2 = \pi(11.3\text{ m})^2 = 401\text{ m}^2.$

EVALUATE: When the incident angle in the water is larger than the critical angle, no light refracts into the air.

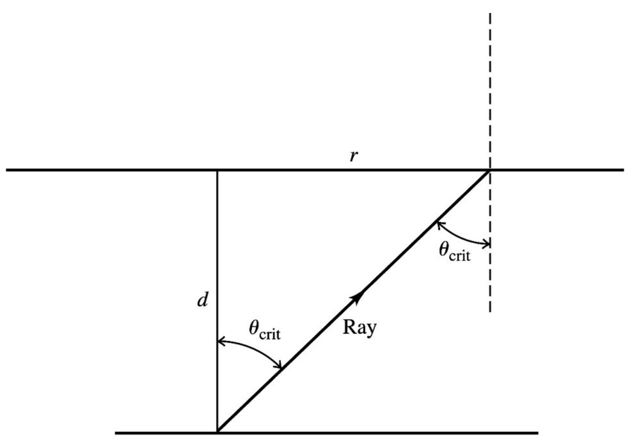

Figure 33.20

33.21. IDENTIFY: If no light refracts out of the glass at the glass to air interface, then the incident angle at that interface is θ_{crit}.

SET UP: The ray has an angle of incidence of $0°$ at the first surface of the glass, so enters the glass without being bent, as shown in Figure 33.21. The figure shows that $\alpha + \theta_{\text{crit}} = 90°$.

EXECUTE: **(a)** For the glass-air interface $\theta_a = \theta_{\text{crit}}$, $n_a = 1.52$, $n_b = 1.00$, and $\theta_b = 90°$.

$n_a \sin\theta_a = n_b \sin\theta_b$ gives $\sin\theta_{\text{crit}} = \dfrac{(1.00)(\sin 90°)}{1.52}$ and $\theta_{\text{crit}} = 41.1°$. $\alpha = 90° - \theta_{\text{crit}} = 48.9°$.

(b) Now the second interface is glass $\rightarrow$ water and $n_b = 1.333$. $n_a \sin\theta_a = n_b \sin\theta_b$ gives

$\sin\theta_{\text{crit}} = \dfrac{(1.333)(\sin 90°)}{1.52}$ and $\theta_{\text{crit}} = 61.3°$. $\alpha = 90° - \theta_{\text{crit}} = 28.7°$.

EVALUATE: The critical angle increases when the air is replaced by water.

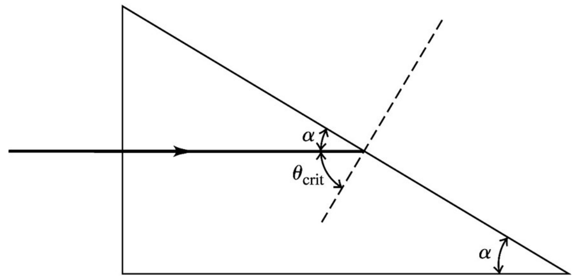

Figure 33.21

33.22. **IDENTIFY:** This problem involves Snell's law and total internal reflection.
SET UP: We want the wavelength in the plastic. Let subscript p denote the plastic and g denote the glass. $n_a \sin\theta_a = n_b \sin\theta_b$, $\lambda_n = \dfrac{\lambda_0}{n}$.

EXECUTE: At the critical angle $n_g \sin 48.6° = n_p \sin 90° = n_p$. $\lambda_p = \dfrac{\lambda_0}{n_p} = \dfrac{\lambda_0}{\lambda_g \sin 48.6°}$. $\lambda_g = \dfrac{\lambda_0}{n_g}$, so $\lambda_0 = n_g \lambda_g$. Combining gives $\lambda_p = \dfrac{n_g \lambda_g}{n_g \sin 48.6°} = \dfrac{\lambda_g}{\sin 48.6°} = \dfrac{350 \text{ nm}}{\sin 48.6°} = 467$ nm.

EVALUATE: Total internal reflection occurs only for light going from a high-n material to a low-n material, such as glass to water or water to air.

33.23. **IDENTIFY:** The index of refraction depends on the wavelength of light, so the light from the red and violet ends of the spectrum will be bent through different angles as it passes into the glass. Snell's law applies at the surface.
SET UP: $n_a \sin\theta_a = n_b \sin\theta_b$. From the graph in Figure 33.17 in the textbook, for $\lambda = 400$ nm (the violet end of the visible spectrum), $n = 1.67$ and for $\lambda = 700$ nm (the red end of the visible spectrum), $n = 1.62$. The path of a ray with a single wavelength is sketched in Figure 33.23.

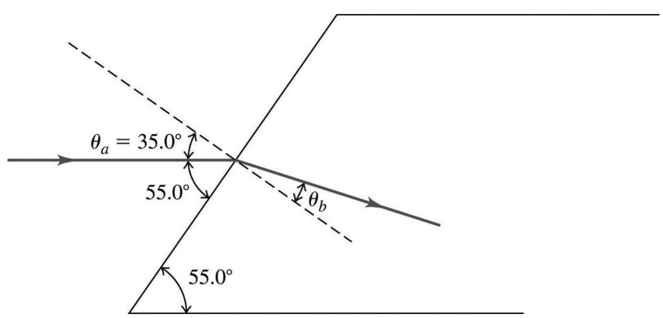

Figure 33.23

EXECUTE: For $\lambda = 400$ nm, $\sin\theta_b = \dfrac{n_a}{n_b}\sin\theta_a = \dfrac{1.00}{1.67}\sin 35.0°$, so $\theta_b = 20.1°$. For $\lambda = 700$ nm, $\sin\theta_b = \dfrac{1.00}{1.62}\sin 35.0°$, so $\theta_b = 20.7°$. $\Delta\theta$ is about $0.6°$.

EVALUATE: This angle is small, but the separation of the beams could be fairly large if the light travels through a fairly large slab.

33.24. **IDENTIFY:** The red and violet light will be bent through different angles in the glass because they have slightly different indexes of refraction. Use Snell's law, $n_a \sin\theta_a = n_b \sin\theta_b$.

SET UP: Apply Snell's law twice: the first time use the index of refraction for red light $(n = 2.41)$ and the second time use the index of refraction for violet light $(n = 2.46)$. Assume that the index of refraction for air is $n = 1.00$.

EXECUTE: For red light Snell's law gives $(1.00)\sin 53.5^\circ = (2.41)\sin\theta_{\text{red}}$. Solving this equation we find $\theta_{\text{red}} = 19.48^\circ$. For violet light Snell's law gives $(1.00)\sin 53.5^\circ = (2.46)\sin\theta_{\text{violet}}$. Solving this equation we find $\theta_{\text{violet}} = 19.07^\circ$. From these two values we can calculate the angle between the two initially coincident rays: $\Delta\theta = \theta_{\text{red}} - \theta_{\text{violet}} = 19.48° - 19.07° = 0.41^\circ$.

EVALUATE: Violet light is refracted more than red light since it has the larger index of refraction. Although the angular separation between the red and the blue rays is small, it is easily noticeable under the right circumstances.

33.25. **IDENTIFY:** Snell's law is $n_a \sin\theta_a = n_b \sin\theta_b$. $v = \dfrac{c}{n}$.

SET UP: $a = \text{air}$, $b = \text{glass}$.

EXECUTE: **(a)** red: $n_b = \dfrac{n_a \sin\theta_a}{\sin\theta_b} = \dfrac{(1.00)\sin 57.0°}{\sin 38.1°} = 1.36$. violet: $n_b = \dfrac{(1.00)\sin 57.0°}{\sin 36.7°} = 1.40$.

(b) red: $v = \dfrac{c}{n} = \dfrac{3.00\times10^8 \text{ m/s}}{1.36} = 2.21\times10^8 \text{ m/s}$; violet: $v = \dfrac{c}{n} = \dfrac{3.00\times10^8 \text{ m/s}}{1.40} = 2.14\times10^8 \text{ m/s}$.

EVALUATE: n is larger for the violet light and therefore this light is bent more toward the normal, and the violet light has a smaller speed in the glass than the red light.

33.26. **IDENTIFY:** This problem involves birefringence and a quarter-wave plate.

SET UP: For calcite, n = 1.658 and 1.486 for λ = 589 nm in vacuum, $v = c/n$, and $\lambda = cT$. For this light, what should be the minimum thickness of the quarter-wave plate?

EXECUTE: To cancel, the difference in time between the two waves must be ¼ of the period T. The two waves differ because there are two indices of refraction. $t_1 = d/v_1$ and $t_2 = d/v_2$.

$\Delta t = t_2 - t_1 = \dfrac{d}{v_2} - \dfrac{d}{v_1} = \dfrac{1}{4}T$. Using $v = c/n$ and $\lambda = cT$ gives $\dfrac{d}{c/n_2} - \dfrac{d}{c/n_1} = \dfrac{1}{4}T = \dfrac{1}{4}\left(\dfrac{\lambda}{c}\right)$. Simplifying and solving for d gives $d = \dfrac{\lambda}{4(n_2 - n_2)} = \dfrac{589 \text{ nm}}{4(1.658 - 1.486)} = 856 \text{ nm}$.

EVALUATE: This is the minimum thickness. If the time difference is $T + T/4$, $2T + T/4$, … , cancellation will also occur.

33.27. **IDENTIFY:** The first polarizer filters out half the incident light. The fraction filtered out by the second polarizer depends on the angle between the axes of the two filters.

SET UP: Use Malus's law: $I = I_0 \cos^2\phi$.

EXECUTE: After the first filter, $I = \frac{1}{2}I_0$. After the second filter, $I = (\frac{1}{2}I_0)\cos^2\phi$, which gives $I = \left(\frac{1}{2}I_0\right)\cos^2 30.0° = 0.375I_0$.

EVALUATE: The only variable that affects the answer is the angle between the axes of the two polarizers.

33.28. IDENTIFY: This problem involves polarization by reflection and Snell's law.

SET UP: $\tan\theta_p = n_b/n_a$, $n_a \sin\theta_a = n_b \sin\theta_b$. We want to find polarizing angles. For light traveling from *a* to *b*, the polarizing angle is given by $\tan\theta_p = n_b/n_a$. At this angle, 100% of the reflected light is polarized. Use the critical angle to relate the indices of refraction. Let subscript *L* denote the liquid and *s* the solid.

EXECUTE: **(a)** $n_s \sin 38.7° = 0.6252 n_s = n_L \sin 90° = n_L$. Now use Brewster's law. $\tan\theta_p = n_L/n_s = 0.6252 n_s/n_s = 0.6252$. $\theta_p = 32.0°$.

(b) If we reverse the rays, we get $\tan\theta_p = n_s/n_L = n_s/(0.6252 n_s) = 1.599$. $\theta_p = 58.0°$.

EVALUATE: Of course we would not have total internal reflection for the rays in part (b) since that only occurs for light going from high-*n* to low-*n* materials. However polarization would still occur in the reflected beam.

33.29. IDENTIFY: When unpolarized light passes through a polarizer the intensity is reduced by a factor of $\frac{1}{2}$ and the transmitted light is polarized along the axis of the polarizer. When polarized light of intensity I_{max} is incident on a polarizer, the transmitted intensity is $I = I_{max}\cos^2\phi$, where ϕ is the angle between the polarization direction of the incident light and the axis of the filter.

SET UP: For the second polarizer $\phi = 60°$. For the third polarizer, $\phi = 90° - 60° = 30°$.

EXECUTE: **(a)** At point *A* the intensity is $I_0/2$ and the light is polarized along the vertical direction. At point *B* the intensity is $(I_0/2)(\cos 60°)^2 = 0.125 I_0$, and the light is polarized along the axis of the second polarizer. At point *C* the intensity is $(0.125 I_0)(\cos 30°)^2 = 0.0938 I_0$.

(b) Now for the last filter $\phi = 90°$ and $I = 0$.

EVALUATE: Adding the middle filter increases the transmitted intensity.

33.30. IDENTIFY: Set $I = I_0/10$, where *I* is the intensity of light passed by the second polarizer.

SET UP: When unpolarized light passes through a polarizer the intensity is reduced by a factor of $\frac{1}{2}$ and the transmitted light is polarized along the axis of the polarizer. When polarized light of intensity I_{max} is incident on a polarizer, the transmitted intensity is $I = I_{max}\cos^2\phi$, where ϕ is the angle between the polarization direction of the incident light and the axis of the filter.

EXECUTE: **(a)** After the first filter $I = \dfrac{I_0}{2}$ and the light is polarized along the vertical direction. After the second filter we want $I = \dfrac{I_0}{10}$, so $\dfrac{I_0}{10} = \left(\dfrac{I_0}{2}\right)(\cos\phi)^2$. $\cos\phi = \sqrt{2/10}$ and $\phi = 63.4°$.

(b) Now the first filter passes the full intensity I_0 of the incident light. For the second filter $\dfrac{I_0}{10} = I_0(\cos\phi)^2$. $\cos\phi = \sqrt{1/10}$ and $\phi = 71.6°$.

EVALUATE: When the incident light is polarized along the axis of the first filter, ϕ must be larger to achieve the same overall reduction in intensity than when the incident light is unpolarized.

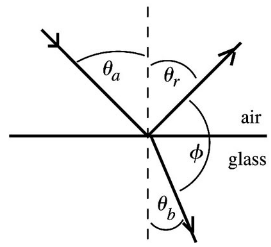
33.31. IDENTIFY and SET UP: Reflected beam completely linearly polarized implies that the angle of incidence equals the polarizing angle, so $\theta_p = 54.5°$. Use Brewster's law, $\tan\theta_p = \dfrac{n_b}{n_a}$, to calculate the refractive index of the glass. Then use Snell's law to calculate the angle of refraction. See Figure 33.29.

EXECUTE: **(a)** $\tan\theta_p = \dfrac{n_b}{n_a}$ gives $n_{glass} = n_{air}\tan\theta_p = (1.00)\tan 54.5° = 1.40$.

(b) $n_a \sin\theta_a = n_b \sin\theta_b$.

$\sin\theta_b = \dfrac{n_a \sin\theta_a}{n_b} = \dfrac{(1.00)\sin 54.5°}{1.40} = 0.5815$ and $\theta_b = 35.5°$.

EVALUATE:



Note: $\phi = 180.0° - \theta_r - \theta_b$ and $\theta_r = \theta_a$. Thus $\phi = 180.0° - 54.5° - 35.5° = 90.0°$; the reflected ray and the refracted ray are perpendicular to each other. This agrees with Figure 33.28 in the textbook.

Figure 33.29

33.32. **IDENTIFY:** The reflected light is completely polarized when the angle of incidence equals the polarizing angle θ_p, where $\tan\theta_\text{p} = \dfrac{n_b}{n_a}$.

SET UP: $n_b = 1.66$.

EXECUTE: **(a)** $n_a = 1.00$. $\tan\theta_\text{p} = \dfrac{1.66}{1.00}$ and $\theta_\text{p} = 58.9°$.

(b) $n_a = 1.333$. $\tan\theta_\text{p} = \dfrac{1.66}{1.333}$ and $\theta_\text{p} = 51.2°$.

EVALUATE: The polarizing angle depends on the refractive indicies of both materials at the interface.

33.33. **IDENTIFY:** When unpolarized light of intensity I_0 is incident on a polarizing filter, the transmitted light has intensity $\frac{1}{2}I_0$ and is polarized along the filter axis. When polarized light of intensity I_0 is incident on a polarizing filter the transmitted light has intensity $I_0 \cos^2\phi$.

SET UP: For the second filter, $\phi = 62.0° - 25.0° = 37.0°$.

EXECUTE: After the first filter the intensity is $\frac{1}{2}I_0 = 10.0\ \text{W/cm}^2$ and the light is polarized along the axis of the first filter. The intensity after the second filter is $I = I_0\cos^2\phi$, where $I_0 = 10.0\ \text{W/cm}^2$ and $\phi = 37.0°$. This gives $I = 6.38\ \text{W/cm}^2$.

EVALUATE: The transmitted intensity depends on the angle between the axes of the two filters.

33.34. **IDENTIFY:** Use the transmitted intensity when all three polarizers are present to solve for the incident intensity I_0. Then repeat the calculation with only the first and third polarizers.

SET UP: For unpolarized light incident on a filter, $I = \frac{1}{2}I_0$ and the light is linearly polarized along the filter axis. For polarized light incident on a filter, $I = I_\text{max}(\cos\phi)^2$, where I_max is the intensity of the incident light, and the emerging light is linearly polarized along the filter axis.

EXECUTE: With all three polarizers, if the incident intensity is I_0 the transmitted intensity is

$I = \frac{1}{2}I_0 \cos^2 23.0° \cos^2(62.0° - 23.0°) = 0.2559 I_0$. $I_0 = \dfrac{I}{0.2559} = \dfrac{55.0\ \text{W/cm}^2}{0.2559} = 215\ \text{W/cm}^2$. With only the first and third polarizers, $I = \frac{1}{2}I_0 \cos^2 62.0° = 0.110 I_0 = (0.110)(215\ \text{W/cm}^2) = 23.7\ \text{W/cm}^2$.

EVALUATE: The transmitted intensity is greater when all three filters are present.

33.35. IDENTIFY: The shorter the wavelength of light, the more it is scattered. The intensity is inversely proportional to the fourth power of the wavelength.

SET UP: The intensity of the scattered light is proportional to $1/\lambda^4$; we can write it as $I = (\text{constant})/\lambda^4$.

EXECUTE: **(a)** Since I is proportional to $1/\lambda^4$, we have $I = (\text{constant})/\lambda^4$. Taking the ratio of the intensity of the red light to that of the green light gives

$$\frac{I_\text{R}}{I} = \frac{(\text{constant})/\lambda_\text{R}^4}{(\text{constant})/\lambda_\text{G}^4} = \left(\frac{\lambda_\text{G}}{\lambda_\text{R}}\right)^4 = \left(\frac{532\text{ nm}}{685\text{ nm}}\right)^4 = 0.364, \text{ so } I_\text{R} = 0.364I.$$

(b) Following the same procedure as in part (a) gives $\dfrac{I_\text{V}}{I} = \left(\dfrac{\lambda_\text{G}}{\lambda_\text{V}}\right)^4 = \left(\dfrac{532\text{ nm}}{415\text{ nm}}\right)^4 = 2.70$, so $I_\text{V} = 2.70I$.

EVALUATE: In the scattered light, the intensity of the short-wavelength violet light is about 7 times as great as that of the red light, so this scattered light will have a blue-violet color.

33.36. IDENTIFY: We use measurements to determine the index of refraction for water. Snell's law applies. $n_a \sin\theta_a = n_b \sin\theta_b$

SET UP and EXECUTE: **(a)** Estimate: s = 8.0 mm.

(b) Estimate: d = 25 mm.

(c) Using Fig. P33.36 in the textbook, we have $\tan\theta_a = \dfrac{d}{H}$, $\tan\theta_b = \dfrac{s+d}{H}$.

(d) Apply Snell's law. $n_a \sin\theta_a = (1.00)\sin\theta_b$. $\sin\theta_a \approx \tan\theta_a$. $n\dfrac{d}{H} = \dfrac{s+d}{H}$. $n = \dfrac{s+d}{d} = 1 + \dfrac{s}{d}$.

(e) $n = 1 + \dfrac{8.0\text{ mm}}{25\text{ mm}} = 1.3$.

EVALUATE: This result is very close to the accepted value of 1.33, which is surprising given the rather crude estimates involved.

33.37. IDENTIFY: Snell's law applies to the sound waves in the heart.

SET UP: $n_a \sin\theta_a = n_b \sin\theta_b$. If θ_a is the critical angle then $\theta_b = 90°$. For air, $n_\text{air} = 1.00$. For heart muscle, $n_\text{mus} = \dfrac{344\text{ m/s}}{1480\text{ m/s}} = 0.2324$.

EXECUTE: **(a)** $n_a \sin\theta_a = n_b \sin\theta_b$ gives $(1.00)\sin(9.73°) = (0.2324)\sin\theta_b$. $\sin\theta_b = \dfrac{\sin(9.73°)}{0.2324}$ so $\theta_b = 46.7°$.

(b) $(1.00)\sin\theta_\text{crit} = (0.2324)\sin 90°$ gives $\theta_\text{crit} = 13.4°$.

EVALUATE: To interpret a sonogram, it should be important to know the true direction of travel of the sound waves within muscle. This would require knowledge of the refractive index of the muscle.

33.38. IDENTIFY: Use the change in transit time to find the speed v of light in the slab, and then apply $n = \dfrac{c}{v}$ and $\lambda = \dfrac{\lambda_0}{n}$.

SET UP: It takes the light an additional 4.2 ns to travel 0.840 m after the glass slab is inserted into the beam.

EXECUTE: $\dfrac{0.840\text{ m}}{c/n} - \dfrac{0.840\text{ m}}{c} = (n-1)\dfrac{0.840\text{ m}}{c} = 4.2\text{ ns}$. We can now solve for the index of refraction: $n = \dfrac{(4.2\times10^{-9}\text{ s})(3.00\times10^{8}\text{ m/s})}{0.840\text{ m}} + 1 = 2.50$. The wavelength inside of the glass is $\lambda = \dfrac{490\text{ nm}}{2.50} = 196\text{ nm}$.

EVALUATE: Light travels slower in the slab than in air and the wavelength is shorter.

33.39. IDENTIFY: The angle of incidence at *A* is to be the critical angle. Apply Snell's law at the air to glass refraction at the top of the block.

SET UP: The ray is sketched in Figure 33.39.

EXECUTE: For glass $\rightarrow$ air at point *A*, Snell's law gives $(1.38)\sin\theta_{\text{crit}} = (1.00)\sin 90°$ and $\theta_{\text{crit}} = 46.4°$. $\theta_b = 90° - \theta_{\text{crit}} = 43.6°$. Snell's law applied to the refraction from air to glass at the top of the block gives $(1.00)\sin\theta_a = (1.38)\sin(43.6°)$ and $\theta_a = 72.1°$.

EVALUATE: If θ_a is larger than $72.1°$ then the angle of incidence at point *A* is less than the initial critical angle and total internal reflection doesn't occur.

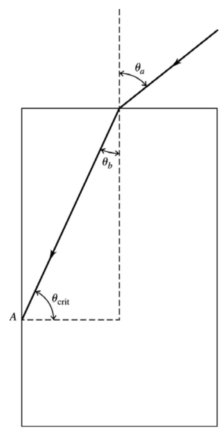


Figure 33.39

33.40. IDENTIFY: As the light crosses the glass-air interface along *AB*, it is refracted and obeys Snell's law.

SET UP: Snell's law is $n_a \sin\theta_\text{a} = n_b \sin\theta_\text{b}$ and $n = 1.000$ for air. At point *B* the angle of the prism is $30.0°$.

EXECUTE: Apply Snell's law at *AB*. The prism angle at *A* is 60.0°, so for the upper ray, the angle of refraction at *AB* is $60.0° + 12.0° = 72.0°$. Using this value gives $n_1 \sin 60.0° = \sin 72.0°$ and $n_1 = 1.10$. For the lower ray, the angle of refraction at *AB* is $60.0° + 12.0° + 8.50° = 80.5°$, giving $n_2 \sin 60.0° = \sin 80.5°$ and $n_2 = 1.14$.

EVALUATE: The lower ray is deflected more than the upper ray because that wavelength has a slightly greater index of refraction than the upper ray.

33.41. IDENTIFY: For total internal reflection, the angle of incidence must be at least as large as the critical angle.

SET UP: The angle of incidence for the glass-oil interface must be the critical angle, so $\theta_b = 90°$. $n_a \sin\theta_a = n_b \sin\theta_b$.

EXECUTE: $n_a \sin\theta_a = n_b \sin\theta_b$ gives $(1.52)\sin 57.2° = n_{\text{oil}} \sin 90°$. $n_{\text{oil}} = (1.52)\sin 57.2° = 1.28$.

EVALUATE: $n_{\text{oil}} > 1$, which it must be, and 1.28 is a reasonable value for an oil.

33.42. **IDENTIFY:** Because the prism is a right-angle prism, the normals at point A and at surface BC are perpendicular to each other (see Figure 33.42). Therefore the angle of incidence at A is 50.0°, and this is the critical angle at that surface. Apply Snell's law at A and at surface BC. For light incident at the critical angle, the angle of refraction is 90°.

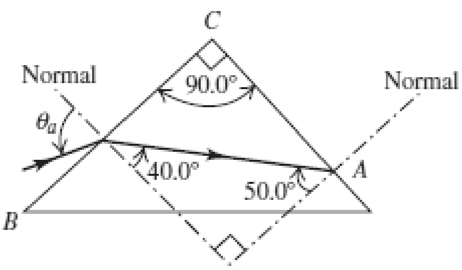

Figure 33.42

SET UP: Apply Snell's law: $n_a \sin\theta_a = n_b \sin\theta_b$. Use n = 1.00 for air, and let n be the index of refraction of the glass.

EXECUTE: Apply Snell's law at point A.

n sin(50.0°) = (1.00) sin(90°) = 1.00.

n = 1.305.

Now apply Snell's law at surface BC.

(1.00) $\sin\theta$ = (1.305) sin(40.0°).

θ = 57.0°.

EVALUATE: The critical angle at A would not be 50.0° if the prism were not a right-angle prism.

33.43. **IDENTIFY:** Apply $\lambda = \frac{\lambda_0}{n}$. The number of wavelengths in a distance d of a material is $\frac{d}{\lambda}$ where λ is the wavelength in the material.

SET UP: The distance in glass is $d_{\text{glass}} = 0.00250\text{ m}$. The distance in air is $d_{\text{air}} = 0.0180\text{ m} - 0.00250\text{ m} = 0.0155\text{ m}$.

EXECUTE: number of wavelengths = number in air + number in glass.

$$\text{number of wavelengths} = \frac{d_{\text{air}}}{\lambda} + \frac{d_{\text{glass}}}{\lambda}n = \frac{0.0155\text{ m}}{5.40\times 10^{-7}\text{ m}} + \frac{0.00250\text{ m}}{5.40\times 10^{-7}\text{ m}}(1.40) = 3.52\times 10^4.$$

EVALUATE: Without the glass plate the number of wavelengths between the source and screen is $\frac{0.0180\text{ m}}{5.40\times 10^{-3}\text{ m}} = 3.33\times 10^4$. The wavelength is shorter in the glass so there are more wavelengths in a distance in glass than there are in the same distance in air.

33.44. **IDENTIFY:** Apply Snell's law to the refraction of the light as it passes from water into air.

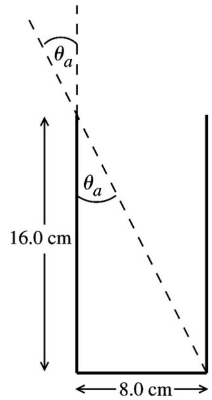
SET UP: $\theta_a = \arctan\left(\frac{1.5\text{ m}}{1.2\text{ m}}\right) = 51°$. $n_a = 1.00$. $n_b = 1.333$.

EXECUTE: $\theta_b = \arcsin\left(\frac{n_a}{n_b}\sin\theta_a\right) = \arcsin\left(\frac{1.00}{1.333}\sin 51°\right) = 36°$. Therefore, the distance along the bottom of the pool from directly below where the light enters to where it hits the bottom is $x = (4.0\text{ m})\tan\theta_b = (4.0\text{ m})\tan 36° = 2.9\text{ m}$. $x_{\text{total}} = 1.5\text{ m} + x = 1.5\text{ m} + 2.9\text{ m} = 4.4\text{ m}$.

EVALUATE: The light ray from the flashlight is bent toward the normal when it refracts into the water.

33.45. **IDENTIFY:** Use Snell's law to determine the effect of the liquid on the direction of travel of the light as it enters the liquid.

SET UP: Use geometry to find the angles of incidence and refraction. Before the liquid is poured in, the ray along your line of sight has the path shown in Figure 33.45a.

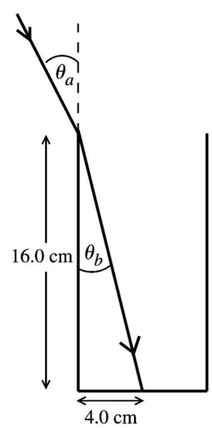


$$\tan\theta_a = \frac{8.0\text{ cm}}{16.0\text{ cm}} = 0.500.$$

$$\theta_a = 26.57°.$$

Figure 33.45a

After the liquid is poured in, θ_a is the same and the refracted ray passes through the center of the bottom of the glass, as shown in Figure 33.45b.



$$\tan\theta_b = \frac{4.0\text{ cm}}{16.0\text{ cm}} = 0.250.$$

$$\theta_b = 14.04°.$$

Figure 33.45b

EXECUTE: Use Snell's law to find n_b, the refractive index of the liquid:

$$n_a \sin\theta_a = n_b \sin\theta_b.$$

$$n_b = \frac{n_a \sin\theta_a}{\sin\theta_b} = \frac{(1.00)(\sin 26.57°)}{\sin 14.04°} = 1.84.$$

EVALUATE: When the light goes from air to liquid (larger refractive index) it is bent toward the normal.

33.46. **IDENTIFY:** Apply Snell's law. For light incident at the critical angle, the angle of refraction is 90°.

SET UP: Apply $n_a \sin\theta_a = n_b \sin\theta_b$ and use n = 1.00 for air.

EXECUTE: **(a)** Apply Snell's law at the interface between the cladding and the core. At that surface, the angle of incidence is the critical angle.

$n_1 \sin\theta_{\text{crit}} = n_2 \sin(90°) = n_2$.

$1.465 \sin\theta_{\text{crit}} = 1.450.$

$\theta_{\text{crit}} = 81.8°.$

(b) Apply Snell's law at the flat end of the cable and then at the core-cladding interface. Call θ the angle of refraction at the flat end, and α the angle of incidence at the core-cladding interface. Because the flat end is perpendicular to the surface at the core-cladding interface, $\sin\alpha = \cos\theta$. (See Figure 33.46.)

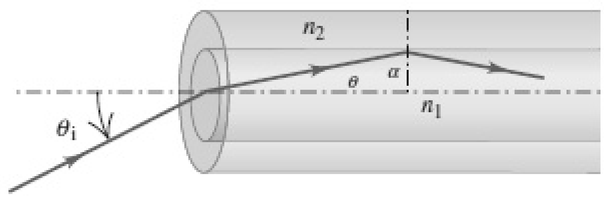


Figure 33.46

At the flat end of the cable: $(1.00)\sin\theta_i = n_1 \sin\theta \quad \rightarrow \quad \sin\theta = \dfrac{\sin\theta_i}{n_1}.$

At the core-cladding interface: $n_1 \sin\alpha = n_2 \sin(90°) = n_2 \quad \rightarrow \quad n_1 \cos\theta = n_2 \rightarrow \cos\theta = n_2/n_1.$

Using the fact that $\sin^2\theta + \cos^2\theta = 1$, we get $\left(\dfrac{\sin\theta_i}{n_1}\right)^2 + \left(\dfrac{n_2}{n_1}\right)^2 = 1.$ Solving for $\sin\theta_i$ gives

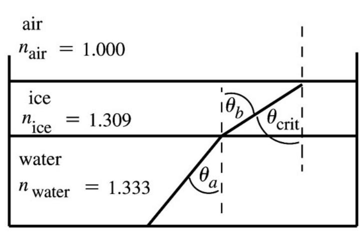
$\sin\theta_i = \sqrt{n_1^2 - n_2^2}.$

(c) Using the formula we just derived gives $\sin\theta_i = \sqrt{1.465^2 - 1.450^2} = 0.20911$, so $\theta_i = 12.1°$.

EVALUATE: If $n_2 > n_1$, the square root in (b) is not a real number, so there is no solution for θ_i. This is reasonable since total internal reflection will not occur unless $n_2 < n_1$.

33.47. **IDENTIFY:** Apply Snell's law to the water $\rightarrow$ ice and ice $\rightarrow$ air interfaces.

(a) SET UP: Consider the ray shown in Figure 33.47.



We want to find the incident angle θ_a at the water-ice interface that causes the incident angle at the ice-air interface to be the critical angle.

Figure 33.47

EXECUTE: ice-air interface: $n_{\text{ice}} \sin\theta_{\text{crit}} = 1.0 \sin 90°.$

$n_{\text{ice}} \sin\theta_{\text{crit}} = 1.0$ so $\sin\theta_{\text{crit}} = \dfrac{1}{n_{\text{ice}}}.$

But from the diagram we see that $\theta_b = \theta_{\text{crit}}$, so $\sin\theta_b = \dfrac{1}{n_{\text{ice}}}.$

water-ice interface: $n_{\text{w}} \sin\theta_a = n_{\text{ice}} \sin\theta_b.$

But $\sin\theta_b = \dfrac{1}{n_{\text{ice}}}$ so $n_w \sin\theta_a = 1.0$. $\sin\theta_a = \dfrac{1}{n_{\text{w}}} = \dfrac{1}{1.333} = 0.7502$ and $\theta_a = 48.6°.$

EVALUATE: **(b)** The angle calculated in part (a) is the critical angle for a water-air interface; the answer would be the same if the ice layer wasn't there!

33.48. **IDENTIFY:** This problem is about polarizing filters, so Malus's law applies.

SET UP: $I = I_0 \cos^2 \phi$. We are looking for the intensity after light has pass through *N* polarizers, each with its polarizing axis turned slightly from the one before it.

EXECUTE: **(a)** Each time turn the polarizers are turned through an angle ϕ = 90°/*N* from each other.

After the first polarizer: $I = I_0 \cos^2 (90° / N)$.

After the second polarizer: $I = \left[I_0 \cos^2 (90°/N)\right] \cos^2 (90°/N) = I_0 \cos^4 (90°/N)$.

After the third polarizer: $I = \left[I_0 \cos^4 (90°/N)\right] \cos^2 (90°/N) = I_0 \cos^6 (90°/N)$.

As we can see, the emerging pattern is $I = I_0 \cos^{2N} (90°/N)$.

(b) We want the minimum *N* so that the light is rotated by 90° yet retains more than 90° of its intensity. Use $I = I_0 \cos^{2N} (90°/N) = 0.90 I_0$. We want I/I_0 to be 0.90 or greater. Using a calculator, try several values to zero in on the appropriate value of *N*. For example:

$2N = 10$: $I/I_0 = \cos^{10}(90°/5) = 0.605$.

$2N = 30$: $I/I_0 = \cos^{30}(90°/15) = 0.85$.

$2N = 50$: $I/I_0 = \cos^{50}(90°/25) = 0.91$.

We want the minimum intensity ratio to be 0.90, so try $2N = 48$:

$2N = 48$: $I/I_0 = \cos^{48}(90°/24) = 0.90$.

$2N = 48$ gives the required intensity, so $N = 24$ polarizers.

(c) Use the same procedure as in (b). In both cases we want the *minimum N*. For $I/I_0 = 0.95$, $2N = 98$, so $N = 49$ polarizers. For $I/I_0 = 0.99$, $2N = 492$, so $N = 246$ polarizers.

EVALUATE: It takes a great number of polarizers to retain a high intensity. If the material of which the polarizers are made absorbs light due to impurities, it could be self-defeating to use so many of them unless they are extremely pure.

33.49. **IDENTIFY:** Apply Snell's law to the refraction of each ray as it emerges from the glass. The angle of incidence equals the angle $A = 25.0°$.

SET UP: The paths of the two rays are sketched in Figure 33.49.

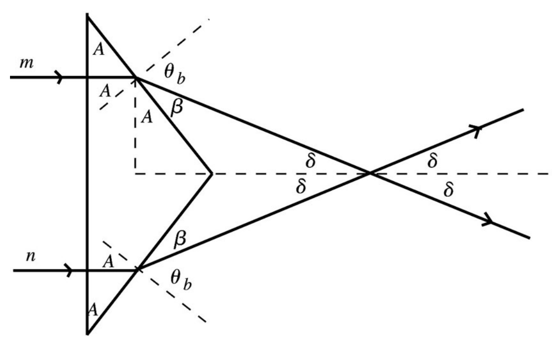


Figure 33.49

EXECUTE: $n_a \sin\theta_a = n_b \sin\theta_b$.

$n_{\text{glass}} \sin 25.0° = 1.00 \sin\theta_b$.

$\sin\theta_b = n_{\text{glass}} \sin 25.0°$.

$\sin\theta_b = 1.66 \sin 25.0° = 0.7015$.

$\theta_b = 44.55°$.

$\beta = 90.0° - \theta_b = 45.45°.$

Then $\delta = 90.0° - A - \beta = 90.0° - 25.0° - 45.45° = 19.55°.$ The angle between the two rays is $2\delta = 39.1°.$

EVALUATE: The light is incident normally on the front face of the prism so the light is not bent as it enters the prism.

33.50. IDENTIFY: The ray shown in the figure that accompanies the problem is to be incident at the critical angle.

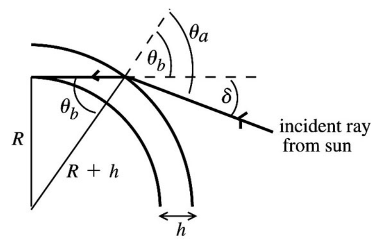
SET UP: $\theta_b = 90°.$ The incident angle for the ray in the figure is $60°.$

EXECUTE: $n_a \sin\theta_a = n_b \sin\theta_b$ gives $n_b = \left(\dfrac{n_a \sin\theta_a}{\sin\theta_b}\right) = \left(\dfrac{1.56 \sin 60°}{\sin 90°}\right) = 1.35.$

EVALUATE: Total internal reflection occurs only when the light is incident in the material of the greater refractive index.

33.51. IDENTIFY: Apply Snell's law to the refraction of the light as it enters the atmosphere.

SET UP: The path of a ray from the sun is sketched in Figure 33.51.



$\delta = \theta_a - \theta_b.$

From the diagram $\sin\theta_b = \dfrac{R}{R+h}.$

$\theta_b = \arcsin\left(\dfrac{R}{R+h}\right).$

Figure 33.51

EXECUTE: **(a)** Apply Snell's law to the refraction that occurs at the top of the atmosphere: $n_a \sin\theta_a = n_b \sin\theta_b$ (a = vacuum of space, refractive index 1.0; b = atmosphere, refractive index n).

$\sin\theta_a = n\sin\theta_b = n\left(\dfrac{R}{R+h}\right)$ so $\theta_a = \arcsin\left(\dfrac{nR}{R+h}\right).$

$\delta = \theta_a - \theta_b = \arcsin\left(\dfrac{nR}{R+h}\right) - \arcsin\left(\dfrac{R}{R+h}\right).$

(b) $\dfrac{R}{R+h} = \dfrac{6.38\times10^6 \text{ m}}{6.38\times10^6 \text{ m} + 20\times10^3 \text{ m}} = 0.99688.$

$\dfrac{nR}{R+h} = 1.0003(0.99688) = 0.99718.$

$\theta_b = \arcsin\left(\dfrac{R}{R+h}\right) = 85.47°.$

$\theta_a = \arcsin\left(\dfrac{nR}{R+h}\right) = 85.70°.$

$\delta = \theta_a - \theta_b = 85.70° - 85.47° = 0.23°.$

EVALUATE: The calculated δ is about the same as the angular radius of the sun.

33.52. IDENTIFY: Apply Snell's law to each refraction.

SET UP: Refer to the angles and distances defined in the figure that accompanies the problem.

EXECUTE: **(a)** For light in air incident on a parallel-faced plate, Snell's Law yields:
$n\sin\theta_a = n'\sin\theta_b' = n'\sin\theta_b = n\sin\theta_a' \Rightarrow \sin\theta_a = \sin\theta_a' \Rightarrow \theta_a = \theta_a'.$

(b) Adding more plates just adds extra steps in the middle of the above equation that always cancel out. The requirement of parallel faces ensures that the angle $\theta'_n = \theta_n$ and the chain of equations can continue.

(c) The lateral displacement of the beam can be calculated using geometry:

$d = L\sin(\theta_a - \theta'_b)$ and $L = \dfrac{t}{\cos\theta'_b} \Rightarrow d = \dfrac{t\sin(\theta_a - \theta'_b)}{\cos\theta'_b}$.

(d) $\theta'_b = \arcsin\left(\dfrac{n\sin\theta_a}{n'}\right) = \arcsin\left(\dfrac{\sin 66.0°}{1.80}\right) = 30.5°$ and $d = \dfrac{(2.40\text{ cm})\sin(66.0° - 30.5°)}{\cos 30.5°} = 1.62\text{ cm}.$

EVALUATE: The lateral displacement in part (d) is large, of the same order as the thickness of the plate.

33.53. IDENTIFY: The reflected light is totally polarized when light strikes a surface at Brewster's angle.

SET UP: At the plastic wall, Brewster's angle obeys the equation $\tan\theta_\text{p} = n_b/n_a$, and Snell's law, $n_a \sin\theta_a = n_b \sin\theta_b$, applies at the air-water surface.

EXECUTE: To be totally polarized, the reflected sunlight must have struck the wall at Brewster's angle. $\tan\theta_\text{p} = n_b/n_a = (1.61)/(1.00)$ and $\theta_\text{p} = 58.15°$.

This is the angle of incidence at the wall. A little geometry tells us that the angle of incidence at the water surface is $90.00° - 58.15° = 31.85°$. Applying Snell's law at the water surface gives $(1.00)\sin 31.85° = 1.333\sin\theta$ and $\theta = 23.3°$.

EVALUATE: We have two different principles involved here: Reflection at Brewster's angle at the wall and Snell's law at the water surface.

33.54. IDENTIFY: We are dealing with circularly polarized electromagnetic waves.

SET UP: $\tan\theta_\text{p} = n_b/n_a$, $n_a\sin\theta_a = n_b\sin\theta_b$

EXECUTE: **(a)** We want the angle of refraction. First find θ_p. $\tan\theta_\text{p} = n_b/n_a$ = (1.62)/(1.00) = 1.62, so θ_p = 58.31°. Now use Snell's law. $(1.00)\sin 58.31° = (1.62)\sin\theta_b$. θ_b = 31.7°.

(b) We want the reflected intensity. The reflecting surface is perpendicular to the xz-plane, so the component of the incident electric field parallel to that is E_y. Using Fresnel's equation gives

$\dfrac{E_\text{refl}}{E_{\text{inc},y}} = \dfrac{\sin(\theta_\text{p} - \theta_b)}{\sin(\theta_\text{p} + \theta_b)} = \dfrac{\sin(58.32° - 31.7°)}{\sin(58.32° + 31.7°)} = 0.448.$ $E_{\text{inc},y} = \dfrac{E_\text{inc}}{\sqrt{2}}$, so $E_\text{refl} = (0.448)\dfrac{E_\text{inc}}{\sqrt{2}} = 0.3168E_\text{inc}.$

The intensity is proportional to E^2, so $\dfrac{I_\text{refl}}{I_\text{inc}} = \dfrac{E^2_\text{refl}}{E^2_\text{inc}} = \dfrac{(0.3168E_\text{inc})^2}{E^2_\text{inc}} = 0.1004.$ Therefore we have

$I_\text{refl} = 0.1004I_\text{inc} =$ (0.1004)(150 W/m^2) = 15.1 W/m^2.

(c) and **(d)** We want $I_\parallel$. $I_\text{refr} = I_\text{inc} - I_\text{refl}$ = 150 W/m^2 – 15.1 W/m^2 = 134.9 W/m^2. In the incident light, $E_x = E_y$, so the intensity is the same for both of them, which is (150 W/m^2)/2 = 75.0 W/m^2. After reflection, none of the E_x light is reflected since the reflected light is 100% polarized in the y direction. Therefore E_x is the same in the transmitted (refracted) light, so that intensity is 75.0 W/m^2. The remainder of the light in the refracted beam is 134.9 W/m^2 – 75.0 W/m^2 = 59.9 W/m^2. Therefore the final answers are: (c) 59.9 W/m^2 and (d) 75.0 W/m^2.

(e) We want e. $e = \sqrt{1 - (E_1/E_2)^2}$. I is proportional to E^2, so $e = \sqrt{1 - I_1/I_2} = \sqrt{1 - \dfrac{59.9\text{ W/m}^2}{75.0\text{ W/m}^2}} = 0.449.$

EVALUATE: In the transmitted light E_x and E_y have different amplitudes so the light is elliptically polarized.

33.55. IDENTIFY: Apply Snell's law in part (a). In part (b), we know from Chapter 32 that in a dielectric, $n^2 = KK_\text{m}$. In this case, we are told that K_m is very close to 1, so $n^2 \approx K$, where K is the dielectric constant of the material.

SET UP: Use $n_a\sin\theta_a = n_b\sin\theta_b$ (Snell's law) in (a) and $n^2 \approx K$ in (b). Use n = 1.00 for air. $f\lambda = c$.

EXECUTE: **(a)** For each liquid, apply $n_a \sin\theta_a = n_b \sin\theta_b$ using the data in the table with the problem. The angle of incidence is 60.0° in each case.

$\sin(60.0°) = n \sin\theta_b$, which gives $n = \dfrac{\sin(60.0°)}{\sin\theta_b}$. Apply this formula for each liquid and then use the information in Table 33.1 to identify the liquids.

Liquid A: $n_\text{A} = \dfrac{\sin(60.0°)}{\sin(36.4°)} = 1.46$ (carbon tetrachloride).

Liquid B: $n_\text{B} = \dfrac{\sin(60.0°)}{\sin(40.5°)} = 1.33$ (water).

Liquid C: $n_\text{C} = \dfrac{\sin(60.0°)}{\sin(32.1°)} = 1.63$ (carbon disulfide).

Liquid D: $n_\text{D} = \dfrac{\sin(60.0°)}{\sin(35.2°)} = 1.50$ (benzene).

(b) Use $K = n^2$ for each liquid.

$K_\text{A} = (1.46)^2 = 2.13$.

$K_\text{B} = (1.33)^2 = 1.77$.

$K_\text{C} = (1.63)^2 = 2.66$.

$K_\text{D} = (1.50)^2 = 2.25$.

(c) Use $f\lambda = c$: $f = c/\lambda = (3.00\times10^8\ \text{m/s})/(589\times10^{-9}\ \text{m}) = 5.09\times10^{14}$ Hz. This is the frequency in air and also in each liquid.

EVALUATE: The indexes of refraction are accurate, but the dielectric constants are less so because $n^2 \approx K$ is an approximation.

33.56. **IDENTIFY:** Apply Snell's law at the air-glass interface and also at the glass-liquid interface. For light incident at the critical angle, the angle of refraction is 90°.

SET UP: Use Snell's law: $n_a \sin\theta_a = n_b \sin\theta_b$. If θ_b is the angle of refraction at the air-glass interface and θ_c is the angle of incidence at the glass-liquid interface, then $\sin\theta_c = \cos\theta_b$. This is true because the normal at the air-glass interface and the glass-liquid interface are perpendicular to each other. We also know that θ_c is the critical angle for the glass-liquid boundary. Use 1.00 for the index of refraction of air, and call n the index of refraction for the liquid.

EXECUTE: First apply Snell's law at the air-glass boundary to find θ_b, and then use that result to find $\sin\theta_c$. Finally use Snell's law at the glass-liquid boundary to find n for the liquid.

Liquid A: At the air-glass boundary we have

$(1.00)\sin(52.0°) = (1.52)\sin\theta_b$, which gives $\theta_b = 31.226°$ and $\cos\theta_b = 0.85512 = \sin\theta_c$.

At the glass-liquid boundary we have

$(1.52)\sin\theta_c = n\sin(90°) = n$.

$n_\text{A} = (1.52)(0.85512) = 1.30$.

Liquid B: At the air-glass boundary we have

$(1.00)\sin(44.3°) = (1.52)\sin\theta_b$, so $\theta_b = 27.3538°$, so $\cos\theta_b = 0.8882 = \sin\theta_c$.

At the glass-liquid boundary we have

$n_\text{B} = (1.52)(0.8882) = 1.35$.

Liquid C: Air-glass boundary: $(1.00)\sin(36.3°) = (1.52)\sin\theta_b$, $\theta_b = 22.922°$, $\cos\theta_b = 0.9210 = \sin\theta_c$.

Glass-liquid boundary: $n_\text{C} = (1.52)(0.9210) = 1.40$.

EVALUATE: The indexes of refraction would be slightly different at wavelengths other than 638 nm since n depends on the wavelength of the light. All the values for n are greater than 1, which they must be.

33.57. **IDENTIFY** and **SET UP**: The polarizer passes $\frac{1}{2}$ of the intensity of the unpolarized component, independent of α. Malus's law tells us that out of the intensity I_p of the polarized component, the polarizer passes intensity $I_p \cos^2(\alpha - \theta)$, where $\alpha - \theta$ is the angle between the plane of polarization and the axis of the polarizer.

EXECUTE: **(a)** Use the angle where the transmitted intensity is maximum or minimum to find θ. See Figure 33.57.

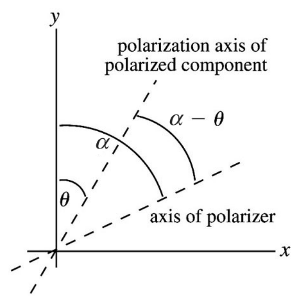


Figure 33.57

The total transmitted intensity is $I = \frac{1}{2} I_0 + I_p \cos^2(\alpha - \theta)$. This is maximum when $\theta = \alpha$, and from the graph in the problem this occurs when α is approximately 35°, so $\theta = 35°$. Alternatively, the total transmitted intensity is minimum when $\alpha - \theta = 90°$ and from the graph this occurs for $\alpha = 125°$. Thus, $\theta = \alpha - 90° = 125° - 90° = 35°$, which is in agreement with what we just found.

(b) For the equation, $I = \frac{1}{2} I_0 + I_p \cos^2(\alpha - \theta)$, we use data at two values of α to determine I_0 and I_p. It is easiest to use data where *I* is a maximum and a minimum. From the graph, we see that these extremes are 25 W/m^2 at α = 35° and 5.0 W/m^2 at $\alpha = 125°$.

At $\alpha = 125°$ the net intensity is 5.0 W/m^2, so we have

$5.0 \text{ W/m}^2 = \frac{1}{2} I_0 + I_p \cos^2(125° - 35°) = \frac{1}{2} I_0 + I_p \cos^2(90°) = \frac{1}{2} I_0 \;\rightarrow\; I_0 = 10 \text{ W/m}^2.$

At $\alpha = 35°$ the net intensity is 25 W/m^2, so we have

$25 \text{ W/m}^2 = \frac{1}{2} I_0 + I_p \cos^2 0° = \frac{1}{2} I_0 + I_p = 5 \text{ W/m}^2 + I_p \;\rightarrow\; I_p = 20 \text{ W/m}^2.$

EVALUATE: Now that we have I_0, I_p, and θ we can verify that $I = \frac{1}{2} I_0 + I_p \cos^2(\phi - \theta)$ describes the data in the graph.

33.58. **IDENTIFY:** This problem involves refraction at a spherical surface.

SET UP: Refer to Fig. P33.58 in the textbook and follow the items requested. Snell's law applies: $n_a \sin\theta_a = n_b \sin\theta_b$.

EXECUTE: **(a)** We want $\sin\theta_a$. The hypotenuse is *R*, so $\sin\theta_a = r/R$.

(b) We want $\sin\theta_b$. From the figure we see that $\sin\theta_b = r'/R$.

(c) Apply Snell's law at the surface of the sphere, giving $n \sin\theta_a = (1.00)\sin\theta_b$. Use the results from parts (a) and (b). $n\left(\frac{r}{R}\right) = \frac{r'}{R}$, which gives $r' = nr$.

(d) The diameter is $D = 2r' = 2nr$ = (1.53)(45.0 mm) = 68.9 mm.

EVALUATE: The seed head will be magnified by a factor of 68.9/45.0 = 1.53 times.

33.59. **IDENTIFY:** This problem deals with total internal reflection and Snell's law.

SET UP: $n_a \sin\theta_a = n_b \sin\theta_b$. Follow the items requested in the parts of the problem.

EXECUTE: **(a)** We want θ. Follow the suggestion in the problem and refer to Fig. P33.59 in the textbook. $\sin\theta = \frac{bc}{ac} = \frac{R-d/2}{R+d/2} = \frac{2R-d}{2R+d}.$

(b) We want *R*. θ should be the critical angle, so $n_1 \sin\theta = n_2 \sin 90° = n_2$. Now use the result from part (a). $n_1\left(\frac{2R-d}{2R+d}\right) = n_2$. Solve for *R*, giving $R = \frac{d(n_1+n_2)}{2(n_1-n_2)}$.

(c) Using the given values, we get *R* = 2.07 cm.

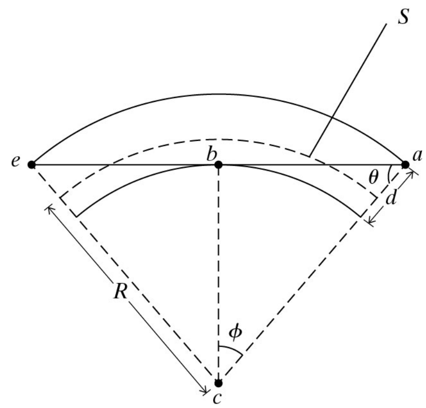

Figure 33.59

(d) The pattern shown in Fig. 33.59 keeps repeating as light goes down the cable. The dashed curve represents the path without reflections, which is a total of 1.00 km. In Fig. 33.59, the light follows the path *ae*, but without reflections it would follow the dashed curve. The angle θ is the critical angle. First find the distance *ae*. Referring to Fig. 33.59, we can see the following. *ae* = 2*ab*. $(ab)^2 + (R-d/2)^2 = (R+d/2)^2$. Solving for *ab* gives $(ab)^2 = 2Rd$, so $ab = \sqrt{2Rd}$. *ae* = 2*ab*, so $ae = 2\sqrt{2Rd} = 2\sqrt{2(0.02065 \text{ m})(50.0\ \mu\text{m})}$ = 2.8740 mm. Now get the length *S* of the dashed curved path. Since θ is the critical angle, $\sin\theta = n_2/n_1$ = 1.4440/1.4475, which gives θ = 86.015°. The length of *S* is the length of the curved path of radius *R* that subtends an angle 2ϕ. With ϕ in radians, we get $S = R(2\phi) = 2R\phi$. $\phi = 90° - \theta = 90° - 86.015° = 3.985° = 0.06955$ rad. Therefore $S = 2R\phi =$ 2(0.02065 m)(0.06955 rad) = 2.8726 mm. So while the unreflected ray has traveled 2.8726 mm, the reflected ray has traveled 2.8740 mm. Now find the distance the reflected ray travels (call it *L*) while the unreflected ray has traveled 1.00 km. Using proportionality, we have $\frac{L}{1.00 \text{ km}} = \frac{ae}{S}$, so $L = (1.00 \text{ km})\frac{ae}{S}$. We want the *difference* in distance between these two rays, which is *L* – 1.00 km. This is $L - 1.00 \text{ km} = (1.00 \text{ km})\frac{ae}{S} - 1.00 \text{ km} = (1.00 \text{ km})\left(\frac{ae}{S} - 1\right)$. Using the results we just found for *ae* and *S* gives $L - 1.00 \text{ km} = (1.00 \text{ km})\left(\frac{2.8740 \text{ mm}}{2.8726 \text{ mm}} - 1\right) = 48.7 \text{ cm},$ which is about 50 cm. (Note that this part involves the subtraction of two numbers that are nearly equal. Therefore the answer is heavily dependent on the amount of rounding in the intermediate numerical calculations.)

(e) From part (d), we saw that the extra distance is only around 50 cm, so that makes a negligible time difference for the two rays. However there is a time difference because the ray in an air-filled cable travels at the speed of light c while one in the filled cable travels at speed c/n. Calling x the length of the cable, we have $\Delta t = t_{\text{cable}} - t_{\text{air}} = \dfrac{x}{c/n} - \dfrac{x}{c} = \dfrac{x}{c}(n-1) = \dfrac{1.00\text{ km}}{c}(1.4475-1) = 1.49\,\mu\text{s}$.

EVALUATE: Compare the times: $t_{\text{cable}}/t_{\text{air}} = (nx/c)/(x/c) = n = 1.744$. So the time through the cable is over 1.7 times as long as through the air. The difference is small but the *fractional* difference is large.

33.60. **IDENTIFY:** Apply Snell's law to each refraction.

SET UP: Refer to the figure that accompanies the problem.

EXECUTE: **(a)** By the symmetry of the triangles, $\theta_b^A = \theta_a^B$, and $\theta_a^C = \theta_r^B = \theta_a^B = \theta_b^A$. Therefore,

$\sin\theta_b^C = n\sin\theta_a^C = n\sin\theta_b^A = \sin\theta_a^A = \theta_b^C = \theta_a^A$.

(b) The total angular deflection of the ray is $\Delta = \theta_a^A - \theta_b^A + \pi - 2\theta_a^B + \theta_b^C - \theta_a^C = 2\theta_a^A - 4\theta_b^A + \pi$.

(c) From Snell's law, $\sin\theta_a^A = n\sin\theta_b^A \Rightarrow \theta_b^A = \arcsin\left(\dfrac{1}{n}\sin\theta_a^A\right)$.

$$\Delta = 2\theta_a^A - 4\theta_b^A + \pi = 2\theta_a^A - 4\arcsin\left(\frac{1}{n}\sin\theta_a^A\right) + \pi.$$

(d) $$\frac{d\Delta}{d\theta_a^A} = 0 = 2 - 4\frac{d}{d\theta_a^A}\left(\arcsin\left(\frac{1}{n}\sin\theta_a^A\right)\right) \Rightarrow 0 = 2 - \frac{4}{\sqrt{1-\dfrac{\sin^2\theta_1}{n^2}}}\cdot\left(\frac{\cos\theta_1}{n}\right)\cdot 4\left(1-\frac{\sin^2\theta_1}{n^2}\right) = \left(\frac{16\cos^2\theta_1}{n^2}\right).$$

$$4\cos^2\theta_1 = n^2 - 1 + \cos^2\theta_1.\ 3\cos^2\theta_1 = n^2 - 1.\ \cos^2\theta_1 = \frac{1}{3}(n^2-1).$$

(e) For violet: $\theta_1 = \arccos\left(\sqrt{\tfrac{1}{3}(n^2-1)}\right) = \arccos\left(\sqrt{\tfrac{1}{3}(1.342^2-1)}\right) = 58.89°$.

$\Delta_{\text{violet}} = 139.2° \Rightarrow \theta_{\text{violet}} = 40.8°$.

For red: $\theta_1 = \arccos\left(\sqrt{\tfrac{1}{3}(n^2-1)}\right) = \arccos\left(\sqrt{\tfrac{1}{3}(1.330^2-1)}\right) = 59.58°$.

$\Delta_{\text{red}} = 137.5° \Rightarrow \theta_{\text{red}} = 42.5°$.

EVALUATE: The angles we have calculated agree with the values given in Figure 33.19d in the textbook. θ_1 is larger for red than for violet, so red in the rainbow is higher above the horizon.

33.61. **IDENTIFY:** Follow similar steps to Challenge Problem 33.60.

SET UP: Refer to Figure 33.19e in the textbook.

EXECUTE: **(a)** The total angular deflection of the ray is

$\Delta = \theta_a^A - \theta_b^A + \pi - 2\theta_b^A + \pi - 2\theta_b^A + \theta_a^A - \theta_b^A = 2\theta_a^A - 6\theta_b^A + 2\pi$, where we have used the fact from the previous problem that all the internal angles are equal and the two external equals are equal. Also using the Snell's law relationship,

we have: $\theta_b^A = \arcsin\left(\dfrac{1}{n}\sin\theta_a^A\right)$. $\Delta = 2\theta_a^A - 6\theta_b^A + 2\pi = 2\theta_a^A - 6\arcsin\left(\dfrac{1}{n}\sin\theta_a^A\right) + 2\pi$.

(b) $$\frac{d\Delta}{d\theta_a^A} = 0 = 2 - 6\frac{d}{d\theta_a^A}\left(\arcsin\left(\frac{1}{n}\sin\theta_a^A\right)\right) \Rightarrow 0 = 2 - \frac{6}{\sqrt{1-\dfrac{\sin\theta_2}{n^2}}}\cdot\left(\frac{\cos\theta_2}{n}\right).$$

$$n^2\left(1-\frac{\sin^2\theta_2}{n^2}\right) = (n^2 - 1 + \cos^2\theta_2) = 9\cos^2\theta_2.\ \cos^2\theta_2 = \frac{1}{8}(n^2-1).$$

(c) For violet, $\theta_2 = \arccos\left(\sqrt{\frac{1}{8}(n^2-1)}\right) = \arccos\left(\sqrt{\frac{1}{8}(1.342^2-1)}\right) = 71.55°$. $\Delta_{\text{violet}} = 233.2°$ and $\theta_{\text{violet}} = 53.2°$.

For red, $\theta_2 = \arccos\left(\sqrt{\frac{1}{8}(n^2-1)}\right) = \arccos\left(\sqrt{\frac{1}{8}(1.330^2-1)}\right) = 71.94°$. $\Delta_{\text{red}} = 230.1°$ and $\theta_{\text{red}} = 50.1°$.

EVALUATE: The angles we calculated agree with those given in Figure 33.19e in the textbook. The color that appears higher above the horizon is violet. The colors appear in reverse order in a secondary rainbow compared to a primary rainbow.

33.62. **IDENTIFY** and **SET UP:** Light polarized at 45° with the horizontal has both a horizontal component and a vertical component to its electric field.
EXECUTE: Since the light has both horizontal and vertical components, both H-type and V-type cells will be able to detect it, which makes choice (a) correct.
EVALUATE: Since the light is polarized at 45° with the horizontal, its horizontal and vertical components will be equal. So both types of cells should respond to it equally.

33.63. **IDENTIFY:** Light reflected from a glass surface is polarized to varying degrees, depending on the angle of incidence. At Brewster's angle the reflected light is 100% polarized parallel to the surface.
SET UP: Brewster's angle is given by $\tan\theta_p = n_b/n_a$. $n = 1.5$ for glass and $n = 1.0$ for air.
EXECUTE: For reflection from glass, $\tan\theta_p = n_b/n_a = (1.5)/(1.0) = 1.5$, so $\theta_p = 56°$. This is the angle with the normal to the glass. The light in this case makes an angle of 35° with the plane of the glass, so its angle of incidence is 55°, which is very close to Brewster's angle. Therefore the reflected light is almost totally polarized horizontally (since the glass is horizontal). Thus H cells will respond much more strongly to this light than will V cells, which is choice (d).
EVALUATE: The incident light is not *exactly* at Brewster's angle, so the reflected light will not be 100% horizontally polarized. Therefore the V cells will respond slightly to the reflect light.

33.64. **IDENTIFY** and **SET UP:** A polarizer reduces the intensity of unpolarized light by 50%.
EXECUTE: The first polarizer, with a vertical transmission axis, decreases the light intensity by half and leaves the transmitted light vertically polarized, so the intensity I after the first polarizer is $I = I_0/2$. The second polarizer removed none of the light, so it must have had a vertical transmission axis. Therefore the light emerging from both polarizers is vertically polarized. Thus only the V cells of the insect will detect this light, which is choice (b).
EVALUATE: If the second polarizer were rotated by 90°, no light would have emerged from the system.

34

GEOMETRIC OPTICS

VP34.4.1. **IDENTIFY:** We have a concave mirror.

SET UP: $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}$, $m=-s'/s$.

EXECUTE: **(a)** We want f. $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}$ = 1/(15.0 cm) + 1/(450 cm). f = 14.5 cm.

(b) We want m. $m=-s'/s$ = –(450 cm)/(15.0 cm) = –30.0.

EVALUATE: The image is real and inverted.

VP34.4.2. **IDENTIFY:** We have a concave mirror.

SET UP: $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}$, $m=-s'/s$, $f = R/2$. We want the location and characteristics of the image.

EXECUTE: **(a)** s = 11.0 cm. $\frac{1}{s'}=\frac{1}{f}-\frac{1}{s}$ = 1/(18.5 cm) – 1/(1/11.0 cm). s' = –27.1 cm. $m=-s'/s$ = –(–27.1 cm)/(11.0 cm) = +2.47. Since m is positive and greater than 1, the image is erect and larger than the object. s' is negative, so the image is virtual.

(b) s = 31.0 cm. $\frac{1}{s'}=\frac{1}{f}-\frac{1}{s}$ = 1/(18.5 cm) – 1/(31.0 cm). s' = +45.9 cm. $m=-s'/s$ = –(45.9 cm)/(31.0 cm) = –1.48. s' is positive, so the image is real. m is negative, so the image is inverted, and it is larger than the object since $|m| > 1$.

(c) s = 55.0 cm. $\frac{1}{s'}=\frac{1}{f}-\frac{1}{s}$ = 1/(18.5 cm) – 1/(55.0 cm). s' = +27.9 cm. $m=-s'/s$ = –(27.9 cm)/(55.0 cm) = –0.507. s' is positive so the image is real. m is negative so the image is inverted, and $|m| < 1$ so the image is smaller than the object.

EVALUATE: Notice the variation in the type of image a lens can produce, depending on where the object is placed.

VP34.4.3. **IDENTIFY:** We have a curved mirror.

SET UP: $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}$, $m=-s'/s$.

EXECUTE: **(a)** $f = R/2$ = (–44.0 cm)/2 = –22.0 cm. Since f is negative, this is a *convex* mirror.

(b) We want s. $\frac{1}{s}=\frac{1}{f}-\frac{1}{s'}$ = 1/(–22.0 cm) – 1/(–18.0 cm). s = 99.0 cm.

(c) We want m. $m=-s'/s$ = –(–18.0 cm)/(99.0 cm) = +0.182. The image is virtual (s' is negative), smaller than the eye ($|m| < 1$), and erect (m is positive).

EVALUATE: For a single convex mirror, $\frac{1}{s'}=\frac{1}{f}-\frac{1}{s}$ tells us that s' is always negative because f is negative and s is positive.

VP34.4.4. **IDENTIFY:** We have a convex mirror.

SET UP: $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}$, $m=-s'/s$, $f = R/2 = -18.5$ cm. We want s' and the characteristics of the image.

EXECUTE: **(a)** $s = 11.0$ cm. $\frac{1}{s'}=\frac{1}{f}-\frac{1}{s}$ = 1/(–18.5 cm) – 1/(11.0 cm). s' = –6.90 cm. $m=-s'/s$ = –(–6.90 cm)/(11.0 cm) = +0.627. The image is virtual, erect, and smaller than the object.

(b) $s = 31.0$ cm. $\frac{1}{s'}=\frac{1}{f}-\frac{1}{s}$ = 1/(–18.5 cm) – 1/(31.0 cm). s' = –11.6 cm. $m=-s'/s$ = $-(-11.6$ cm) / (31.0 cm) = +0.374. The image is virtual, erect, and smaller than the object.

(c) $s = 55.0$ cm. $\frac{1}{s'}=\frac{1}{f}-\frac{1}{s}$ = 1/(–18.5 cm) – 1/(55.0 cm). s' = –13.8 cm. $m=-s'/s$ = $-(-13.8$ cm) / (55.0 cm) = +0.252. The image is virtual, erect, and smaller than the object.

EVALUATE: Compare these results with those of problem VP34.4.2 to see the big differences when a mirror is changed from concave to convex.

VP34.8.1. **IDENTIFY:** This problem involves a comvex lens and the lensmaker's equation.

SET UP: $\frac{1}{f}=(n-1)\left(\frac{1}{R_1}-\frac{1}{R_2}\right)$, $|R_1| = |R_2|$, $f = +30.0$ cm, $n = 1.65$. We want R_1 and R_2.

EXECUTE: **(a)** R_1 is positive and R_2 is negative, so $R_1 = R$ and $R_2 = -R$. $\frac{1}{f}=(n-1)\left(\frac{1}{R_1}-\frac{1}{R_2}\right)$ becomes $\frac{1}{f}=(n-1)\left(\frac{1}{R}-\frac{1}{-R}\right)=(n-1)\frac{2}{R}$. $R_1 = R = 2(n-1)f = 2(0.65)(30.0 \text{ cm}) = 39$ cm.

(b) $R_2 = -R = -39$ cm.

EVALUATE: Careful! The radii of curvature have signs and can be negative.

VP34.8.2. **IDENTIFY:** We are dealing with a thin lens and the lensmaker's equation.

SET UP: $\frac{1}{f}=(n-1)\left(\frac{1}{R_1}-\frac{1}{R_2}\right)$. Carefully sketch the lens showing the radii of curvature and C_1 and C_2. Fig. VP34.8.2 shows the lens.

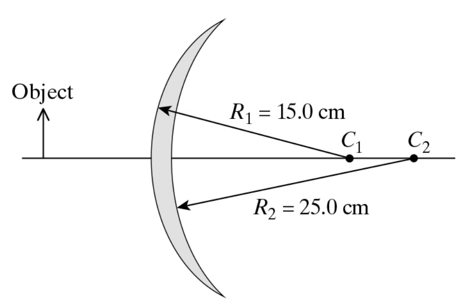

Figure VP34.8.2

EXECUTE: **(a)** As Fig. VP34.8.2 shows, this lens is thicker at its center than at the edges.

(b) We want *f*. $\frac{1}{f}=(n-1)\left(\frac{1}{R_1}-\frac{1}{R_2}\right)=(1.55-1)\left(\frac{1}{15.0\text{ cm}}-\frac{1}{25.0\text{ cm}}\right)$. $f = +68$ cm.

(c) f is positive, so this is a *converging* lens.

EVALUATE: The fact that the lens is thicker in the middle than at the ends is consistent with its being a converging lens with a positive focal length.

VP34.8.3. **IDENTIFY:** We are dealing with a thin lens and the lensmaker's equation.

SET UP: $\frac{1}{f}=(n-1)\left(\frac{1}{R_1}-\frac{1}{R_2}\right)$, both radii of curvature are positive since C_1 and C_2 are on the outgoing side of the lens. Carefully sketch the lens showing the radii of curvature and C_1 and C_2. Fig. VP34.8.3 shows the lens.

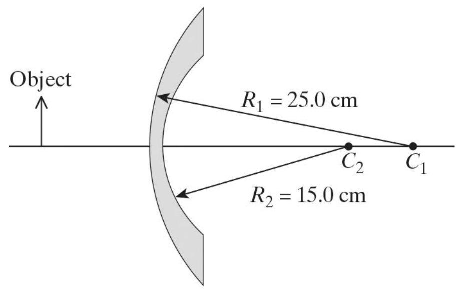

Figure VP34.8.3

EXECUTE: **(a)** As Fig. VP34.8.3 shows, this lens is thicker at its edges than at the center.

(b) We want *f*. $\frac{1}{f}=(n-1)\left(\frac{1}{R_1}-\frac{1}{R_2}\right)=(1.55-1)\left(\frac{1}{25.0\text{ cm}}-\frac{1}{15.0\text{ cm}}\right)$. $f = -68$ cm.

EVALUATE: Compare this result with that of VP34.8.2 to see the difference when the radii of curvature are reversed.

VP34.8.4. **IDENTIFY:** We are dealing the lensmaker's equation.

SET UP: $\frac{1}{f}=(n-1)\left(\frac{1}{R_1}-\frac{1}{R_2}\right)$, $R_1 = +28.0$ cm, $f = 14.0$ cm. We want R_2.

EXECUTE: **(a)** $\frac{1}{f}=(n-1)\left(\frac{1}{R_1}-\frac{1}{R_2}\right)$ gives $\frac{1}{14.0\text{ cm}}=(1.70-1)\left(\frac{1}{28.0\text{ cm}}-\frac{1}{R_2}\right)$. $R_2=-15$ cm.

(b) Since f is positive, the lens is *convex*.

EVALUATE: Since R_2 is negative, the lens will be thicker in the middle than at its edges, which is consistent with a converging (convex) lens.

VP34.10.1. **IDENTIFY:** This problem is about image formation by a converging lens.

SET UP: $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}$, $m=-s'/s$.

EXECUTE: **(a)** We want s'. $\frac{1}{s'}=\frac{1}{f}-\frac{1}{s}$ = 1/(25.0 cm) – 1/(15.0 cm). s' = –37.5 cm. The image is on the same side as the strawberry.

(b) We want m. $m=-s'/s$ = –(–37.5 cm)/(15.0 cm) = +2.50.

(c) s' is negative, so the image is virtual. m is positive so the image is erect, and $|m| > 1$, so it is larger than the strawberry.

EVALUATE: An object within the focal point of a converging lens always forms a virtual erect image on the same side of the les as the object, as we have seen here.

VP34.10.2. **IDENTIFY:** This problem is about image formation by a thin lens.

SET UP: $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}$, $m=-s'/s$.

EXECUTE: **(a)** We want *f*. $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}$ = 1/(28.0 cm) + 1/(42.0 cm). f = +16.8 cm. Since f is positive, this is a *converging* lens.

(b) We want *m*. $m=-s'/s$ = –(42.0 cm)/(28.0 cm) = –1.50.

(c) Since s' is positive, the image is real. *m* is negative, so the image is inverted, and $|m| > 1$ so it is larger than the eraser.

EVALUATE: $s > f$, so the object is *outside* the focal point of the lens. Therefore the image should be real and inverted, as we have found.

VP34.10.3. **IDENTIFY:** This problem is about image formation by a thin lens.

SET UP: $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}$, $m=-s'/s$, $h_{\text{image}} = h_{\text{object}}$.

EXECUTE: **(a)** This lens forms an image on the opposite side from the object, so it is a *converging* lens.

(b) We want s'. $m=-s'/s$ = –1, so s' = s = +48.0 cm.

(c) $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}$ = 1/(48.0 cm) 1/(48.0 cm), so f = 24.0 cm.

EVALUATE: In general for a converging lens, if $s = 2f$, then s' = s = $2f$ and m = +1.

VP34.10.4. **IDENTIFY:** This problem is about image formation by a thin lens.

SET UP: $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}$, $m=-s'/s$.

EXECUTE: **(a)** We want *m*. $m = h_{\text{image}}/h_{\text{object}}$ = (4.00 cm)/(20.00 cm) = +0.200.

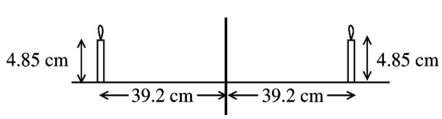
(b) We want s'. Use the result from part (a). $m=-s'/s$ = – s'/(250 cm) = +0.200. This gives s' = –50.0 cm.

(c) We want *f*. $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}$ = 1/(250 cm) 1/(–50.0 cm), so f = –62.5 cm.

EVALUATE: For such a device to be of any use, it must *always* produce an erect image on the same side as the object. A diverging lens always gives this result. A converging lens would do it only if the object is within the focal point of the lens, which would not always be the case if someone outside were standing back from the door.

34.1. **IDENTIFY** and **SET UP:** Plane mirror: $s=-s'$ and $m=y'/y=-s'/s=+1$. We are given s and y and are asked to find s' and y'.

EXECUTE: The object and image are shown in Figure 34.1.



$s'=-s=-39.2$ cm.

$|y'|=|m||y|=(+1)(4.85\text{ cm})$.

$|y'|=4.85$ cm.

Figure 34.1

The image is 39.2 cm to the right of the mirror and is 4.85 cm tall.

EVALUATE: For a plane mirror the image is always the same distance behind the mirror as the object is in front of the mirror. The image always has the same height as the object.

34.2. **IDENTIFY:** Similar triangles say $\dfrac{h_{\text{tree}}}{h_{\text{mirror}}} = \dfrac{d_{\text{tree}}}{d_{\text{mirror}}}$.

SET UP: $d_{\text{mirror}} = 0.350$ m, $h_{\text{mirror}} = 0.0400$ m, and $d_{\text{tree}} = 28.0 \text{ m} + 0.350 \text{ m}$.

EXECUTE: $h_{\text{tree}} = h_{\text{mirror}} \dfrac{d_{\text{tree}}}{d_{\text{mirror}}} = 0.040 \text{ m} \dfrac{28.0 \text{ m} + 0.350 \text{ m}}{0.350 \text{ m}} = 3.24 \text{ m}.$

EVALUATE: The image of the tree formed by the mirror is 28.0 m behind the mirror and is 3.24 m tall.

34.3. **IDENTIFY** and **SET UP:** The virtual image formed by a plane mirror is the same size as the object and the same distance from the mirror as the object.

EXECUTE: $s' = -s$. The image of the tip is 12.0 cm behind the mirror surface and the image of the end of the eraser is 21.0 cm behind the mirror surface. The length of the image is 9.0 cm, the same as the length of the object. The image of the tip of the lead is the closest to the mirror surface.

EVALUATE: The same result would hold no matter how far the pencil was from the mirror.

34.4. **IDENTIFY:** $f = R/2$.

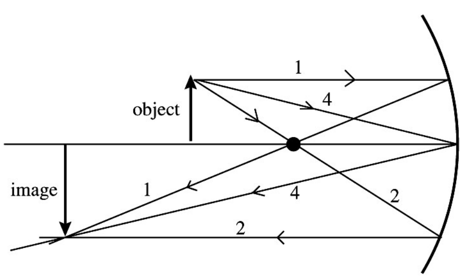
SET UP: For a concave mirror $R > 0$.

EXECUTE: **(a)** $f = \dfrac{R}{2} = \dfrac{34.0 \text{ cm}}{2} = 17.0 \text{ cm}.$

EVALUATE: **(b)** The image formation by the mirror is determined by the law of reflection and that is unaffected by the medium in which the light is traveling. The focal length remains 17.0 cm.

34.5. **IDENTIFY** and **SET UP:** Use $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$ to calculate s' and use $m = \dfrac{y'}{y} = -\dfrac{s'}{s}$ to calculate y'. The image is real if s' is positive and is erect if $m > 0$. Concave means R and f are positive, $R = +22.0$ cm; $f = R/2 = +11.0$ cm.

EXECUTE: **(a)**



Three principal rays, numbered as in Section 34.2, are shown in Figure 34.5. The principal-ray diagram shows that the image is real, inverted, and enlarged.

Figure 34.5

(b) $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}.$

$\dfrac{1}{s'} = \dfrac{1}{f} - \dfrac{1}{s} = \dfrac{s-f}{sf}$ so $s' = \dfrac{sf}{s-f} = \dfrac{(16.5 \text{ cm})(11.0 \text{ cm})}{16.5 \text{ cm} - 11.0 \text{ cm}} = +33.0 \text{ cm}.$

$s' > 0$ so real image, 33.0 cm to left of mirror vertex.

$m = -\dfrac{s'}{s} = -\dfrac{33.0 \text{ cm}}{16.5 \text{ cm}} = -2.00$ ($m < 0$ means inverted image) $|y'| = |m||y| = 2.00(0.600 \text{ cm}) = 1.20 \text{ cm}.$

EVALUATE: The image is 33.0 cm to the left of the mirror vertex. It is real, inverted, and is 1.20 cm tall (enlarged). The calculation agrees with the image characterization from the principal-ray diagram. A concave mirror used alone always forms a real, inverted image if $s > f$ and the image is enlarged if $f < s < 2f$.

34.6. IDENTIFY: Apply $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ and $m=-\frac{s'}{s}$.

SET UP: For a convex mirror, $R<0$. $R=-22.0\text{ cm}$ and $f=\frac{R}{2}=-11.0\text{ cm}$.

EXECUTE: **(a)** The principal-ray diagram is sketched in Figure 34.6.

(b) $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$. $s'=\frac{sf}{s-f}=\frac{(16.5\text{ cm})(-11.0\text{ cm})}{16.5\text{ cm}-(-11.0\text{ cm})}=-6.6\text{ cm}$. $m=-\frac{s'}{s}=-\frac{-6.6\text{ cm}}{16.5\text{ cm}}=+0.400$.

$|y'|=|m||y|=(0.400)(0.600\text{ cm})=0.240\text{ cm}$. The image is 6.6 cm to the right of the mirror. It is 0.240 cm tall. $s'<0$, so the image is virtual. $m>0$, so the image is erect.

EVALUATE: The calculated image properties agree with the image characterization from the principal-ray diagram.

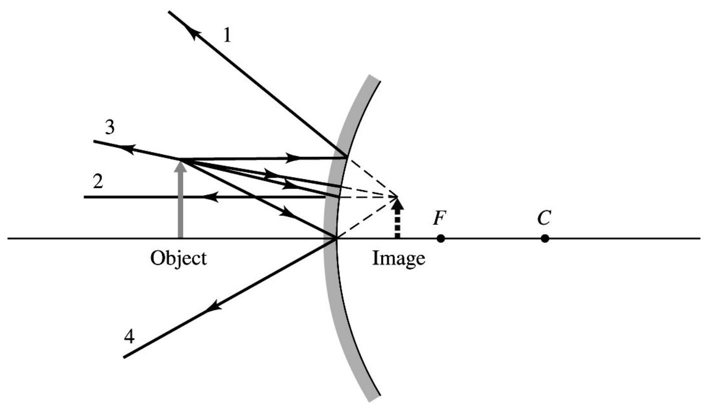


Figure 34.6

34.7. IDENTIFY: $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$. $m=-\frac{s'}{s}$. $|m|=\frac{|y'|}{y}$. Find m and calculate y'.

SET UP: $f=+1.75\text{ m}$.

EXECUTE: $s \gg f$ so $s'=f=1.75\text{ m}$.

$$m=-\frac{s'}{s}=-\frac{1.75\text{ m}}{5.58\times10^{10}\text{ m}}=-3.14\times10^{-11}.$$

$|y'|=|m||y|=(3.14\times10^{-11})(6.794\times10^{6}\text{ m})=2.13\times10^{-4}\text{ m}=0.213\text{ mm}$.

EVALUATE: The image is real and is 1.75 m in front of the mirror.

34.8. IDENTIFY: Apply $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ and $m=-\frac{s'}{s}$.

SET UP: The mirror surface is convex so $R=-3.00\text{ cm}$. $s=18.0\text{ cm}-3.00\text{ cm}=15.0\text{ cm}$.

EXECUTE: $f = \frac{R}{2} = -1.50 \text{ cm}.$ $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}.$ $s' = \frac{sf}{s - f} = \frac{(15.0 \text{ cm})(-1.50 \text{ cm})}{15.0 \text{ cm} - (-1.50 \text{ cm})} = -1.3636 \text{ cm},$ which rounds to –1.36 cm. The image is 1.36 cm behind the surface so it is $3.00 \text{ cm} - 1.36 \text{ cm} = 1.64 \text{ cm}$ from the center of the ornament, on the same side of the center as the object.

$m = -\frac{s'}{s} = -\frac{-1.3636 \text{ cm}}{15.0 \text{ cm}} = +0.0909.$

EVALUATE: The image is virtual, upright and much smaller than the object.

34.9. IDENTIFY: The shell behaves as a spherical mirror.

SET UP: The equation relating the object and image distances to the focal length of a spherical mirror is $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f},$ and its magnification is given by $m = -\frac{s'}{s}.$

EXECUTE: $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f} \Rightarrow \frac{1}{s} = \frac{2}{-18.0 \text{ cm}} - \frac{1}{-6.00 \text{ cm}} \Rightarrow s = 18.0 \text{ cm}$ from the vertex.

$m = -\frac{s'}{s} = -\frac{-6.00 \text{ cm}}{18.0 \text{ cm}} = \frac{1}{3} \Rightarrow y' = \frac{1}{3}(1.5 \text{ cm}) = 0.50 \text{ cm}.$ The image is 0.50 cm tall, erect and virtual.

EVALUATE: Since the magnification is less than one, the image is smaller than the object.

34.10. IDENTIFY: The bottom surface of the bowl behaves as a spherical convex mirror.

SET UP: The equation relating the object and image distances to the focal length of a spherical mirror is $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f},$ and its magnification is given by $m = -\frac{s'}{s}.$

EXECUTE: $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f} \Rightarrow \frac{1}{s'} = \frac{-2}{35 \text{ cm}} - \frac{1}{60 \text{ cm}} \Rightarrow s' = -13.5 \text{ cm},$ which rounds to 14 cm behind the bowl.

$m = -\frac{s'}{s} = \frac{13.5 \text{ cm}}{60 \text{ cm}} = 0.225 \Rightarrow y' = (0.225)(5.0 \text{ cm}) = 1.1 \text{ cm}.$ The image is 1.1 cm tall, erect and virtual.

EVALUATE: Since the magnification is less than one, the image is smaller than the object.

34.11. IDENTIFY: Apply $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$ and $m = -\frac{s'}{s}.$

SET UP: For a concave mirror, $R > 0.$ $R = 32.0 \text{ cm}$ and $f = \frac{R}{2} = 16.0 \text{ cm}.$

EXECUTE: (a) $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}.$ $s' = \frac{sf}{s - f} = \frac{(12.0 \text{ cm})(16.0 \text{ cm})}{12.0 \text{ cm} - 16.0 \text{ cm}} = -48.0 \text{ cm}.$

$m = -\frac{s'}{s} = -\frac{-48.0 \text{ cm}}{12.0 \text{ cm}} = +4.00.$

(b) $s' = -48.0 \text{ cm},$ so the image is 48.0 cm to the right of the mirror. $s' < 0$ so the image is virtual.

(c) The principal-ray diagram is sketched in Figure 34.11. The rules for principal rays apply only to paraxial rays. Principal ray 2, which travels to the mirror along a line that passes through the focus, makes a large angle with the optic axis and is not described well by the paraxial approximation. Therefore, principal ray 2 is not included in the sketch.

EVALUATE: A concave mirror forms a virtual image whenever $s < f.$

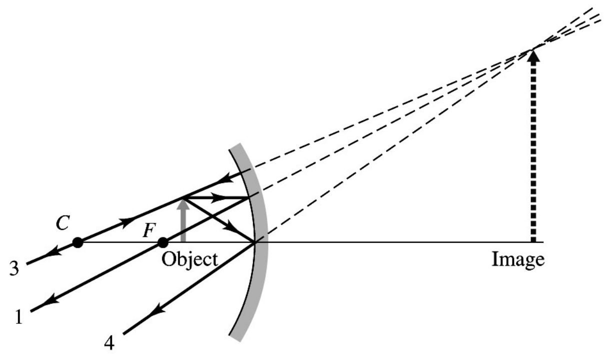

Figure 34.11

34.12. IDENTIFY and SET UP: For a spherical mirror, we have $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$, and the magnification is $m=-\frac{s'}{s}$. For a real image, $s' > 0$, so m is negative. The image height is the same as the object height, so $s' = s$.

EXECUTE: Using $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$, with $s' = s$, we have $\frac{1}{f}=\frac{1}{s}+\frac{1}{s}=\frac{2}{s}=\frac{1}{18.0\text{ cm}}$, so $s = 36.0$ cm.

EVALUATE: The radius of curvature of the mirror is $R = 2f = 2(18.0\text{ cm}) = 36.0$ cm, which is the same as s. Therefore the object is at the center of curvature of the concave mirror.

34.13. IDENTIFY: $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ and $m=\frac{y'}{y}=-\frac{s'}{s}$.

SET UP: $m=+2.00$ and $s=1.25$ cm. An erect image must be virtual.

EXECUTE: **(a)** $s'=\frac{sf}{s-f}$ and $m=-\frac{f}{s-f}$. For a concave mirror, m can be larger than 1.00. For a convex mirror, $|f|=-f$ so $m=+\frac{|f|}{s+|f|}$ and m is always less than 1.00. The mirror must be concave $(f>0)$.

(b) $\frac{1}{f}=\frac{s'+s}{ss'}$. $f=\frac{ss'}{s+s'}$. $m=-\frac{s'}{s}=+2.00$ and $s'=-2.00s$. $f=\frac{s(-2.00s)}{s-2.00s}=+2.00s=+2.50$ cm. $R=2f=+5.00$ cm.

(c) The principal-ray diagram is drawn in Figure 34.13.

EVALUATE: The principal-ray diagram agrees with the description from the equations.

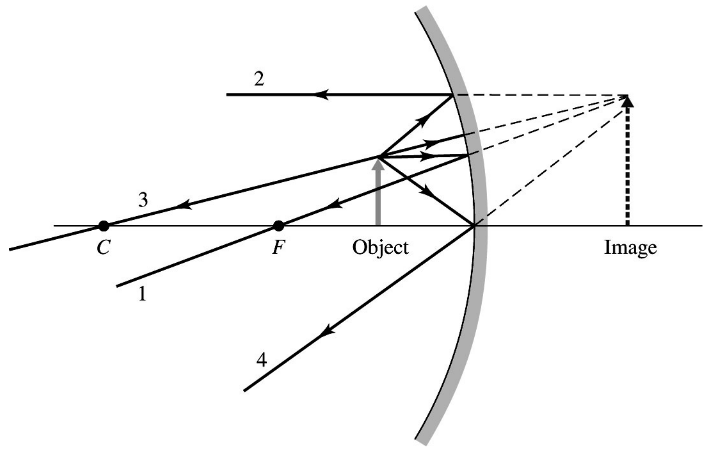

Figure 34.13

34.14. **IDENTIFY** and **SET UP:** For a spherical mirror, we have $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$, and the magnification is $m=-\frac{s'}{s}$. For a convex mirror, the image is virtual, so $s' < 0$, so m is positive. The image height is $\frac{1}{2}$ the same as the object height, so $m = +\frac{1}{2}$. Therefore $+\frac{1}{2}=-\frac{s'}{s}$, which gives $s' = -s/2$.

EXECUTE: Using $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$, we have $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}=\frac{1}{s}-\frac{2}{s}=-\frac{1}{s}=\frac{1}{-12.0\text{ cm}}$, so $s = +12.0$ cm.

EVALUATE: $s' = -s/2 = -6.00$ cm, so the image is virtual, erect, and 6.0 cm from the vertex of the mirror on the side opposite the object.

34.15. **IDENTIFY:** In part (a), the shell is a concave mirror, but in (b) it is a convex mirror. The magnitude of its focal length is the same in both cases, but the sign reverses.

SET UP: For the orientation of the shell shown in the figure in the problem, $R = +12.0$ cm. When the glass is reversed, so the seed faces a convex surface, $R = -12.0$ cm. $\frac{1}{s}+\frac{1}{s'}=\frac{2}{R}$ and $m=\frac{y'}{y}=-\frac{s'}{s}$.

EXECUTE: **(a)** $R = +12.0$ cm. $\frac{1}{s'}=\frac{2}{R}-\frac{1}{s}=\frac{2s-R}{Rs}$ and $s'=\frac{Rs}{2s-R}=\frac{(12.0\text{ cm})(15.0\text{ cm})}{30.0\text{ cm}-12.0\text{ cm}}=+10.0$ cm.

$m=-\frac{s'}{s}=-\frac{10.0\text{ cm}}{15.0\text{ cm}}=-0.667$. $y'=my=-2.20$ mm. The image is 10.0 cm to the left of the shell vertex and is 2.20 mm tall.

(b) $R=-12.0$ cm. $s'=\frac{(-12.0\text{ cm})(15.0\text{ cm})}{30.0\text{ cm}+12.0\text{ cm}}=-4.29$ cm. $m=-\frac{-4.29\text{ cm}}{15.0\text{ cm}}=+0.286$.

$y'=my=0.944$ mm. The image is 4.29 cm to the right of the shell vertex and is 0.944 mm tall.

EVALUATE: In (a), $s > R/2$ and the mirror is concave, so the image is real. In (b) the image is virtual because a convex mirror always forms a virtual image.

34.16. **IDENTIFY:** We have a concave mirror.

SET UP: $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}$, $m=-s'/s$, $f = R/2$. We want the radius of curvature R.

EXECUTE: Since $R = 2f$, we need to find f. First use the magnification. For this mirror, $m = -h_i/h_o$ $= -(2.50\text{ cm})/(0.600\text{ cm}) = -4.167$. Using $m = -s'/s$, we have $-4.167 = -s'/s$, so $s' = 4.167s =$ $(4.167)(24.0\text{ cm}) = 100\text{ cm}$. Now find f. $\dfrac{1}{f} = \dfrac{1}{s} + \dfrac{1}{s'}$ $= 1/(24.0\text{ cm}) + 1/(100\text{ cm})$. $f = 19.4$ cm. Finally R $= 2f = 38.7$ cm.

EVALUATE: The image is on the same side of the mirror as the object and is real.

34.17. **IDENTIFY:** A spoon forms a concave mirror.

SET UP: $\dfrac{1}{f} = \dfrac{1}{s} + \dfrac{1}{s'}$, $m = -s'/s$, $f = R/2$.

EXECUTE: **(a)** Upside down.
(b) Real image.
(c) Estimate: Height = 22 cm.
(d) Estimate: Image height ≈ 2 cm.
(e) $m = -h_{\text{image}}/h_{\text{object}} = -(2\text{ cm})/(22\text{ cm}) = -0.09$.
(f) We want R. First find f and then use $R = 2f$. $\dfrac{1}{f} = \dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{25\text{ cm}} + \dfrac{1}{s'}$. $m = -s'/s = -0.09$. This gives $s' = (0.09)(25\text{ cm}) = 2.3$ cm. $\dfrac{1}{f} = \dfrac{1}{25\text{ cm}} + \dfrac{1}{2.3\text{ cm}}$. $f = 2.1$ cm. $R = 2(2.1\text{ cm}) \approx 4$ cm.
(g) Image is right-side up.
(h) Virtual.

EVALUATE: This is a easy way to get fairly reasonable results.

34.18. **IDENTIFY:** The surface is flat so $R \to \infty$ and $\dfrac{n_a}{s} + \dfrac{n_b}{s'} = 0$.

SET UP: The light travels from the fish to the eye, so $n_a = 1.333$ and $n_b = 1.00$. When the fish is viewed, $s = 7.0$ cm. The fish is $20.0\text{ cm} - 7.0\text{ cm} = 13.0\text{ cm}$ above the mirror, so the image of the fish is 13.0 cm below the mirror and $20.0\text{ cm} + 13.0\text{ cm} = 33.0\text{ cm}$ below the surface of the water. When the image is viewed, $s = 33.0$ cm.

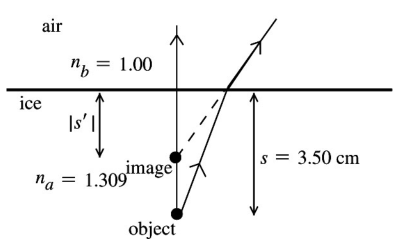
EXECUTE: **(a)** $s' = -\left(\dfrac{n_b}{n_a}\right)s = -\left(\dfrac{1.00}{1.333}\right)(7.0\text{ cm}) = -5.25\text{ cm}$. The apparent depth is 5.25 cm.

(b) $s' = -\left(\dfrac{n_b}{n_a}\right)s = -\left(\dfrac{1.00}{1.333}\right)(33.0\text{ cm}) = -24.8\text{ cm}$. The apparent depth of the image of the fish in the mirror is 24.8 cm.

EVALUATE: In each case the apparent depth is less than the actual depth of what is being viewed.

34.19. **IDENTIFY:** Apply $\dfrac{n_a}{s} + \dfrac{n_b}{s'} = \dfrac{n_b - n_a}{R}$, with $R \to \infty$. $|s'|$ is the apparent depth.

SET UP: The image and object are shown in Figure 34.19.



$\dfrac{n_a}{s} + \dfrac{n_b}{s'} = \dfrac{n_b - n_a}{R}$;
$R \to \infty$ (flat surface), so
$\dfrac{n_a}{s} + \dfrac{n_b}{s'} = 0$.

Figure 34.19

EXECUTE: $s' = -\dfrac{n_b s}{n_a} = -\dfrac{(1.00)(3.50 \text{ cm})}{1.309} = -2.67 \text{ cm}.$

The apparent depth is 2.67 cm.

EVALUATE: When the light goes from ice to air (larger to smaller n), it is bent away from the normal and the virtual image is closer to the surface than the object is.

34.20. **IDENTIFY:** The concave end of a glass rod forms an image inside the glass of an outside object.

SET UP: $\dfrac{n_a}{s} + \dfrac{n_b}{s'} = \dfrac{n_b - n_a}{R}$, $R = -15.0$ cm (concave surface), a is the air and b is the glass. We want the image location s'.

EXECUTE: The distant object is very far away, so $s = \infty$. This gives

$s' = \dfrac{Rn_b}{n_b - n_a} = \dfrac{(-15.0 \text{ cm})(1.50)}{1.50 - 1.00} = -4.50 \text{ cm}.$ Since s' is negative the image is in the air.

EVALUATE: This image has been formed by *refraction*, not reflection.

34.21. **IDENTIFY:** Think of the surface of the water as a section of a sphere having an infinite radius of curvature.

SET UP: $\dfrac{n_a}{s} + \dfrac{n_b}{s'} = 0.$ $n_a = 1.00.$ $n_b = 1.333.$

EXECUTE: The image is $5.20 \text{ m} - 0.80 \text{ m} = 4.40 \text{ m}$ above the surface of the water, so $s' = -4.40$ m.

$s = -\dfrac{n_a}{n_b}s' = -\left(\dfrac{1.00}{1.333}\right)(-4.40 \text{ m}) = +3.30 \text{ m}.$

EVALUATE: The diving board is closer to the water than it looks to the swimmer.

34.22. **IDENTIFY:** Think of the surface of the water as a section of a sphere having an infinite radius of curvature.

SET UP: $\dfrac{n_a}{s} + \dfrac{n_b}{s'} = 0.$ $n_a = 1.333.$ $n_b = 1.00.$

EXECUTE: The image is 4.00 m below surface of the water, so $s' = -4.00$ m.

$s = -\dfrac{n_a}{n_b}s' = -\left(\dfrac{1.333}{1.00}\right)(-4.00 \text{ m}) = 5.33 \text{ m}.$

EVALUATE: The water is 1.33 m deeper than it appears to the person.

34.23. **IDENTIFY:** $\dfrac{n_a}{s} + \dfrac{n_b}{s'} = \dfrac{n_b - n_a}{R}.$ $m = -\dfrac{n_a s'}{n_b s}.$ Light comes from the fish to the person's eye.

SET UP: $R = -14.0$ cm. $s = +14.0$ cm. $n_a = 1.333$ (water). $n_b = 1.00$ (air). Figure 34.23 shows the object and the refracting surface.

EXECUTE: **(a)** $\dfrac{1.333}{14.0 \text{ cm}} + \dfrac{1.00}{s'} = \dfrac{1.00 - 1.333}{-14.0 \text{ cm}}.$ $s' = -14.0$ cm. $m = -\dfrac{(1.333)(-14.0 \text{ cm})}{(1.00)(14.0 \text{ cm})} = +1.33.$

The fish's image is 14.0 cm to the left of the bowl surface so is at the center of the bowl and the magnification is 1.33.

(b) The focal point is at the image location when $s \to \infty$. $\dfrac{n_b}{s'} = \dfrac{n_b - n_a}{R}.$ $n_a = 1.00.$ $n_b = 1.333.$

$R = +14.0$ cm. $\dfrac{1.333}{s'} = \dfrac{1.333 - 1.00}{14.0 \text{ cm}}.$ $s' = +56.0$ cm. s' is greater than the diameter of the bowl, so the surface facing the sunlight does not focus the sunlight to a point inside the bowl. The focal point is outside the bowl and there is no danger to the fish.

EVALUATE: In part (b) the rays refract when they exit the bowl back into the air so the image we calculated is not the final image.

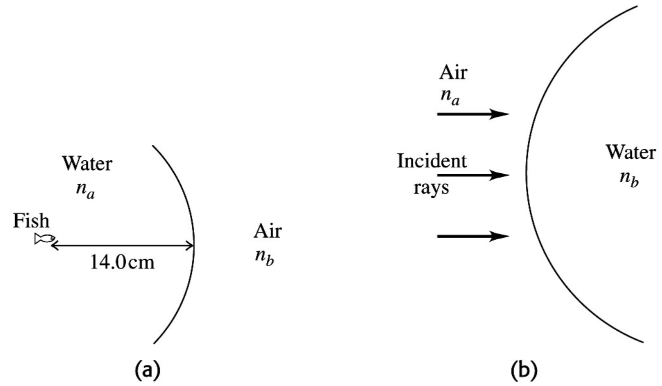


Figure 34.23

34.24. IDENTIFY: Apply $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$.

SET UP: For a convex surface, $R>0$. $R=+3.00$ cm. $n_a=1.00$, $n_b=1.60$.

EXECUTE: **(a)** $s\to\infty$. $\frac{n_b}{s'}=\frac{n_b-n_a}{R}$. $s'=\left(\frac{n_b}{n_b-n_a}\right)R=\left(\frac{1.60}{1.60-1.00}\right)(+3.00\text{ cm})=+8.00\text{ cm}$. The image is 8.00 cm to the right of the vertex.

(b) $s=12.0$ cm. $\frac{1.00}{12.0\text{ cm}}+\frac{1.60}{s'}=\frac{1.60-1.00}{3.00\text{ cm}}$. $s'=+13.7$ cm. The image is 13.7 cm to the right of the vertex.

(c) $s=2.00$ cm. $\frac{1.00}{2.00\text{ cm}}+\frac{1.60}{s'}=\frac{1.60-1.00}{3.00\text{ cm}}$. $s'=-5.33$ cm. The image is 5.33 cm to the left of the vertex.

EVALUATE: The image can be either real $(s'>0)$ or virtual $(s'<0)$, depending on the distance of the object from the refracting surface.

34.25. IDENTIFY: The hemispherical glass surface forms an image by refraction. The location of this image depends on the curvature of the surface and the indices of refraction of the glass and oil.

SET UP: The image and object distances are related to the indices of refraction and the radius of curvature by the equation $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$.

EXECUTE: $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}\Rightarrow\frac{1.45}{s}+\frac{1.60}{1.20\text{ m}}=\frac{0.15}{0.0300\text{ m}}\Rightarrow s=39.5\text{ cm}$.

EVALUATE: The presence of the oil changes the location of the image.

34.26. IDENTIFY: $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$. $m=-\frac{n_a s'}{n_b s}$.

SET UP: $R=+4.00$ cm. $n_a=1.00$. $n_b=1.60$. $s=24.0$ cm.

EXECUTE: $\frac{1}{24.0\text{ cm}}+\frac{1.60}{s'}=\frac{1.60-1.00}{4.00\text{ cm}}$. $s'=+14.8$ cm. $m=-\frac{(1.00)(14.8\text{ cm})}{(1.60)(24.0\text{ cm})}=-0.385$.

$|y'|=|m||y|=(0.385)(1.50\text{ mm})=0.578\text{ mm}$. The image is 14.8 cm to the right of the vertex and is 0.578 mm tall. $m<0$, so the image is inverted.

EVALUATE: The image is real.

34.27. **IDENTIFY:** We have image formation by a spherical mirror.

SET UP: $\frac{1}{f} = \frac{1}{s} + \frac{1}{s'}$, $m = -s'/s$, $R = 2f$.

EXECUTE: **(a)** We want R and h_{image} if the image is real. If the image is real, the mirror must be concave. $\frac{1}{f} = \frac{1}{s} + \frac{1}{s'}$ = 1/(20.0 cm) + 1/(60.0 cm). f = 15.0 cm, so $R = 2f$ = 30.0 cm. $m = -s'/s$ = –(60.0 cm)/(20.0 cm) = –3.00. h_{image} = (3.00)(3.20 mm) = 9.60 mm, and it is inverted.

(b) Same as (a) except the image is virtual. In this case, s' = –60.0 cm.

$\frac{1}{f} = \frac{1}{s} + \frac{1}{s'}$ = 1/(20.0 cm) + 1/(–60.0 cm). f = +30.0 cm, so $R = 2f$ = 60.0 cm.

$m = -s'/s$ = –(–60.0 cm)/(20.0 cm) = +3.00. h_{image} = (3.00)(3.20 mm) = 9.60 mm, and it is upright.

EVALUATE: We get the same magnitude magnification in both cases because s and s' have the same magnitudes in both cases, but they differ in sign.

34.28. **IDENTIFY:** We are trying to find the focal length of a converging lens.

SET UP: Since the graph plots $1/h'$ versus s, we need to relate these quantities so we can interpret the graph. $m = -s'/s$, $m = h'/h$, $\frac{1}{f} = \frac{1}{s} + \frac{1}{s'}$. We only need the magnitude because only magnitudes are on the graph.

EXECUTE: $h' = mh = (s'/s)h$, so $\frac{1}{h'} = \frac{s}{hs'} = \frac{s}{h} \cdot \frac{1}{s'}$. Using $\frac{1}{s'} = \frac{1}{f} - \frac{1}{s}$, we get $\frac{1}{h'} = \frac{s}{h}\left(\frac{1}{f} - \frac{1}{s}\right) = \frac{s}{hf} - \frac{1}{h}$.

Therefore a graph of $1/h'$ versus s should be a straight line having slope equal to $1/hf$, so $f = \frac{1}{h(\text{slope})}$.

$f = 1/[(4.00 \text{ mm})(0.208 \text{ cm}^{-2})] = 12.0$ cm.

EVALUATE: Since only the heights were measured, we used only the magnitude of the magnification.

34.29. **IDENTIFY:** Use the lensmaker's equation $\frac{1}{f} = (n-1)\left(\frac{1}{R_1} - \frac{1}{R_2}\right)$ to calculate f. Then apply the thin-lens equation $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$ and $m = \frac{y'}{y} = -\frac{s'}{s}$.

SET UP: $R_1 \to \infty$. $R_2 = -13.0$ cm. If the lens is reversed, $R_1 = +13.0$ cm and $R_2 \to \infty$.

EXECUTE: **(a)** $\frac{1}{f} = (0.70)\left(\frac{1}{\infty} - \frac{1}{-13.0 \text{ cm}}\right) = \frac{0.70}{13.0 \text{ cm}}$ and $f = 18.6$ cm. $\frac{1}{s'} = \frac{1}{f} - \frac{1}{s} = \frac{s-f}{sf}$.

$s' = \frac{sf}{s-f} = \frac{(22.5 \text{ cm})(18.6 \text{ cm})}{22.5 \text{ cm} - 18.6 \text{ cm}} = 107$ cm. $m = -\frac{s'}{s} = -\frac{107 \text{ cm}}{22.5 \text{ cm}} = -4.76$.

$y' = my = (-4.76)(3.75 \text{ mm}) = -17.8$ mm. The image is 107 cm to the right of the lens and is 17.8 mm tall. The image is real and inverted.

(b) $\frac{1}{f} = (n-1)\left(\frac{1}{13.0 \text{ cm}} - \frac{1}{\infty}\right)$ and $f = 18.6$ cm. The image is the same as in part (a).

EVALUATE: Reversing a lens does not change the focal length of the lens.

34.30. **IDENTIFY:** $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$. The sign of f determines whether the lens is converging or diverging.

SET UP: $s = 16.0$ cm. $s' = -12.0$ cm.

EXECUTE: **(a)** $f = \frac{ss'}{s+s'} = \frac{(16.0 \text{ cm})(-12.0 \text{ cm})}{16.0 \text{ cm} + (-12.0 \text{ cm})} = -48.0$ cm. $f < 0$ and the lens is diverging.

(b) $m = -\dfrac{s'}{s} = -\dfrac{-12.0\text{ cm}}{16.0\text{ cm}} = +0.750.\ |y'| = |m|\, y = (0.750)(8.50\text{ mm}) = 6.38\text{ mm}.$ $m > 0$ and the image is erect.

(c) The principal-ray diagram is sketched in Figure 34.30.

EVALUATE: A diverging lens always forms an image that is virtual, erect, and reduced in size.

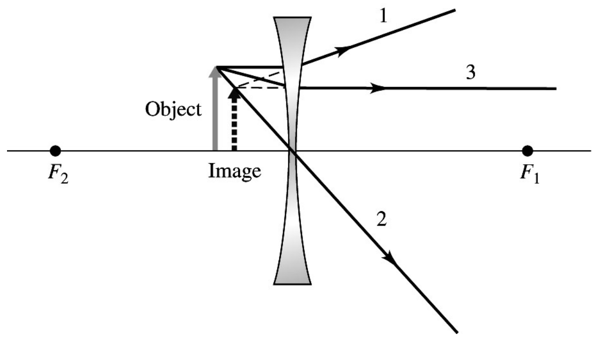

Figure 34.30

34.31. **IDENTIFY:** Use the lensmaker's equation and the thin-lens equation.

SET UP: Combine the lensmaker's equation and the thin-lens equation to get $s = 14.2\text{ cm}: m = -\dfrac{s'}{s} = -\dfrac{14.2}{3.80} = -3.74.$ and use the fact that the magnification of the lens is $m = -\dfrac{s'}{s}.$

EXECUTE: **(a)** $\dfrac{1}{s} + \dfrac{1}{s'} = (n-1)\left(\dfrac{1}{R_1} - \dfrac{1}{R_2}\right) \Rightarrow \dfrac{1}{24.0\text{ cm}} + \dfrac{1}{s'} = (1.52-1)\left(\dfrac{1}{-7.00\text{ cm}} - \dfrac{1}{-4.00\text{ cm}}\right)$

$\Rightarrow s' = 71.2\text{ cm},$ to the right of the lens.

(b) $m = -\dfrac{s'}{s} = -\dfrac{71.2\text{ cm}}{24.0\text{ cm}} = -2.97.$

EVALUATE: Since the magnification is negative, the image is inverted.

34.32. **IDENTIFY:** Apply $m = \dfrac{y'}{y} = -\dfrac{s'}{s}$ to relate s' and s and then use $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}.$

SET UP: Since the image is inverted, $y' < 0$ and $m < 0.$

EXECUTE: $m = \dfrac{y'}{y} = \dfrac{-4.50\text{ cm}}{3.20\text{ cm}} = -1.406.$ $m = -\dfrac{s'}{s}$ gives $s' = +1.406s.$ $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$ gives $\dfrac{1}{s} + \dfrac{1}{1.406s} = \dfrac{1}{70.0\text{ cm}}$ so $s = 119.8\text{ cm},$ which rounds to 120 cm. $s' = (1.406)(119.8\text{ cm}) = 168\text{ cm}.$ The object is 120 cm to the left of the lens. The image is 168 cm to the right of the lens and is real.

EVALUATE: For a single lens an inverted image is always real.

34.33. **IDENTIFY:** The thin-lens equation applies in this case.

SET UP: The thin-lens equation is $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f},$ and the magnification is $m = -\dfrac{s'}{s} = \dfrac{y'}{y}.$

EXECUTE: $m = \dfrac{y'}{y} = \dfrac{34.0\text{ mm}}{8.00\text{ mm}} = 4.25 = -\dfrac{s'}{s} = -\dfrac{-12.0\text{ cm}}{s} \Rightarrow s = 2.82\text{ cm}.$ The thin-lens equation gives $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f} \Rightarrow f = 3.69\text{ cm}.$

EVALUATE: Since the focal length is positive, this is a converging lens. The image distance is negative because the object is inside the focal point of the lens.

34.34. **IDENTIFY:** Apply $m = -\dfrac{s'}{s}$ to relate s and s'. Then use $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$.

SET UP: Since the image is to the right of the lens, $s' > 0$. $s' + s = 6.00$ m.

EXECUTE: **(a)** $s' = 80.0s$ and $s + s' = 6.00$ m gives $81.00s = 6.00$ m and $s = 0.0741$ m. $s' = 5.93$ m.

(b) The image is inverted since both the image and object are real $(s' > 0, s > 0)$.

(c) $\dfrac{1}{f} = \dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{0.0741\text{ m}} + \dfrac{1}{5.93\text{ m}} \Rightarrow f = 0.0732$ m, and the lens is converging.

EVALUATE: The object is close to the lens and the image is much farther from the lens. This is typical for slide projectors.

34.35. **IDENTIFY:** Apply $\dfrac{1}{f} = (n-1)\left(\dfrac{1}{R_1} - \dfrac{1}{R_2}\right)$.

SET UP: For a distant object the image is at the focal point of the lens. Therefore, $f = 1.87$ cm. For the double-convex lens, $R_1 = +R$ and $R_2 = -R$, where $R = 2.50$ cm.

EXECUTE: $\dfrac{1}{f} = (n-1)\left(\dfrac{1}{R} - \dfrac{1}{-R}\right) = \dfrac{2(n-1)}{R}$. $n = \dfrac{R}{2f} + 1 = \dfrac{2.50\text{ cm}}{2(1.87\text{ cm})} + 1 = 1.67$.

EVALUATE: $f > 0$ and the lens is converging. A double-convex lens surrounded by air is always converging.

34.36. **IDENTIFY:** We know the focal length and magnification and are asked to find the locations of the object and image.

SET UP: $m = \dfrac{y'}{y} = -\dfrac{s'}{s}$. Since the image is erect, $y' > 0$ and $m > 0$. $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$.

EXECUTE: $m = \dfrac{y'}{y} = \dfrac{1.30\text{ cm}}{0.400\text{ cm}} = +3.25$. $0.375t = 0.30$ cm gives $s' = -3.25s$. $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$ gives $\dfrac{1}{s} + \dfrac{1}{-3.25s} = \dfrac{1}{9.00\text{ cm}}$ so $s = 6.23$ cm. $s' = -(3.25)(6.23\text{ cm}) = -20.2$ cm. The object is 6.23 cm to the left of the lens. The image is 20.2 cm to the left of the lens and is virtual.

EVALUATE: The image is virtual because the object distance is less than the focal length.

34.37. **IDENTIFY:** This problem involves the lensmaker's equation and a thin lens.

SET UP: $\dfrac{1}{f} = \dfrac{1}{s} + \dfrac{1}{s'}$, $m = -s'/s$, $\dfrac{1}{f} = (n-1)\left(\dfrac{1}{R_1} - \dfrac{1}{R_2}\right)$. We use $R_1 = \infty$ and want the height h' of the image.

EXECUTE: First find the focal length. $\dfrac{1}{f} = (n-1)\left(\dfrac{1}{R_1} - \dfrac{1}{R_2}\right) = (1.50-1)\left(0 - \dfrac{1}{-20.0\text{ cm}}\right)$. This gives f = 40.0 cm. Now use $\dfrac{1}{f} = \dfrac{1}{s} + \dfrac{1}{s'}$ and $m = -s'/s$ to find h'.

Get s': $\dfrac{1}{s'} = \dfrac{1}{f} - \dfrac{1}{s}$ = 1/(40.0 cm) – 1/(20.0 cm), so s' = –40.0 cm.

Now find m: $m = -s'/s$ = –(–40.0 cm)/(20.0 cm) = + 2.00.

$h' = |m|h$ = (2.00)(6.00 mm) = 12.0 mm.

EVALUATE: The image is erect and virtual.

34.38. **IDENTIFY:** Apply the lensmaker's formula to calculate the radii of the surfaces.

SET UP: $\dfrac{1}{f} = (n-1)\left(\dfrac{1}{R_1} - \dfrac{1}{R_2}\right)$, where n = 1.55 and f = 20.0 cm.

EXECUTE: Since $f > 0$ we choose $R_1 = R$ and $R_2 = -R$, where R is the magnitude of the radius of curvature. Thus we have $\dfrac{1}{f} = (n-1)\left(\dfrac{1}{R} - \dfrac{1}{-R}\right) = \dfrac{2(n-1)}{R}$. Solving for R we obtain $R = 2(n-1)f = 2(1.55-1)(20.0\text{ cm}) = 22\text{ cm}.$

EVALUATE: For identical convex surfaces, the relation between f and R is $f = \dfrac{1}{n-1} \cdot \dfrac{R}{2}$. This is reminiscent of the relation for spherical mirrors, which is $f = \dfrac{R}{2}$.

34.39. IDENTIFY: This problem involves the lensmaker's equation and a thin lens.

SET UP: $\dfrac{1}{f} = (n-1)\left(\dfrac{1}{R_1} - \dfrac{1}{R_2}\right)$. One side of the lens is flat, and we want the radius R of the curved side. For the flat side, $R_2 = \infty$.

EXECUTE: $\dfrac{1}{f} = (n-1)\left(\dfrac{1}{R_1} - \dfrac{1}{R_2}\right) = (n-1)\left(\dfrac{1}{R} - \dfrac{1}{\infty}\right) = \dfrac{n-1}{R}$. Solving for R gives $R = (n-1)f =$ $(1.50 - 1)(-24.0\text{ cm}) = -12\text{ cm}.$

EVALUATE: R should be negative because the center of curvature for the first surface is on the side of the incoming light, and this agrees with our result. Also f is negative for diverging lenses, as we have found.

34.40. IDENTIFY: Apply $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$ and $m = \dfrac{y'}{y} = -\dfrac{s'}{s}$.

SET UP: $f = +12.0\text{ cm}$ and $s' = -17.0\text{ cm}.$

EXECUTE: $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f} \Rightarrow \dfrac{1}{s} = \dfrac{1}{12.0\text{ cm}} - \dfrac{1}{-17.0\text{ cm}} \Rightarrow s = 7.0\text{ cm}.$

$m = -\dfrac{s'}{s} = -\dfrac{(-17.0)}{7.0} = +2.4 \Rightarrow y = \dfrac{y'}{m} = \dfrac{0.800\text{ cm}}{+2.4} = +0.34\text{ cm},$ so the object is 0.34 cm tall, erect, same side as the image. The principal-ray diagram is sketched in Figure 34.40. The image is erect.

EVALUATE: When the object is inside the focal point, a converging lens forms a virtual, enlarged image.

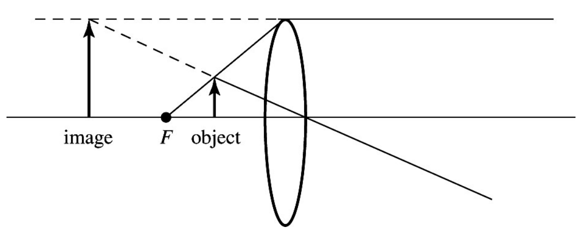

Figure 34.40

34.41. IDENTIFY: Use $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$ to calculate the object distance s. m calculated from $m = -\dfrac{s'}{s}$ determines the size and orientation of the image.

SET UP: $f = -48.0\text{ cm}.$ Virtual image 17.0 cm from lens so $s' = -17.0\text{ cm}.$

EXECUTE: $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$, so $\dfrac{1}{s} = \dfrac{1}{f} - \dfrac{1}{s'} = \dfrac{s'-f}{s'f}$.

$$s = \frac{s'f}{s'-f} = \frac{(-17.0\text{ cm})(-48.0\text{ cm})}{-17.0\text{ cm} - (-48.0\text{ cm})} = +26.3\text{ cm}.$$

$$m = -\frac{s'}{s} = -\frac{-17.0\text{ cm}}{+26.3\text{ cm}} = +0.646.$$

$$m = \frac{y'}{y} \text{ so } |y| = \frac{|y'|}{|m|} = \frac{8.00\text{ mm}}{0.646} = 12.4\text{ mm}.$$

The principal-ray diagram is sketched in Figure 34.41.

EVALUATE: Virtual image, real object $(s > 0)$ so image and object are on same side of lens. $m > 0$ so image is erect with respect to the object. The height of the object is 12.4 mm.

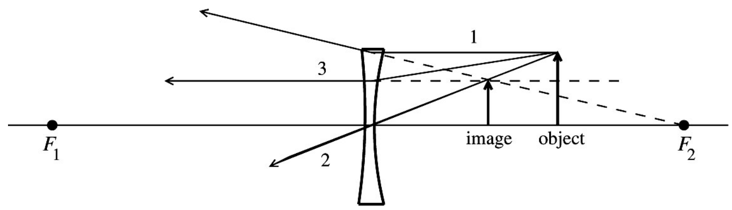

Figure 34.41

34.42. IDENTIFY: Apply $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$.

SET UP: The sign of f determines whether the lens is converging or diverging. $s = 16.0$ cm. $s' = +36.0$ cm. Use $m = -\frac{s'}{s}$ to find the size and orientation of the image.

EXECUTE: **(a)** $f = \frac{ss'}{s+s'} = \frac{(16.0\text{ cm})(36.0\text{ cm})}{16.0\text{ cm} + 36.0\text{ cm}} = 11.1\text{ cm}.$ $f > 0$ and the lens is converging.

(b) $m = -\frac{s'}{s} = -\frac{36.0\text{ cm}}{16.0\text{ cm}} = -2.25.$ $|y'| = |m|\, y = (2.25)(8.00\text{ mm}) = 18.0\text{ mm}.$ $m < 0$ so the image is inverted.

(c) The principal-ray diagram is sketched in Figure 34.42.

EVALUATE: The image is real so the lens must be converging.

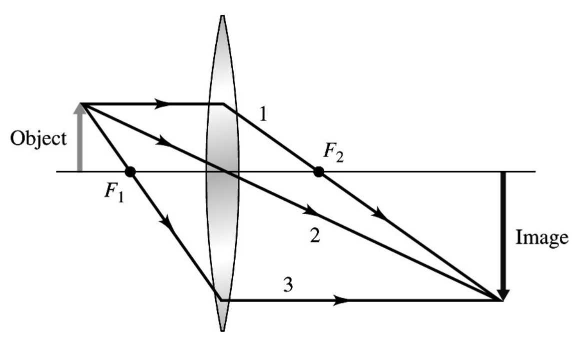

Figure 34.42

34.43. IDENTIFY: The first lens forms an image that is then the object for the second lens.

SET UP: Apply $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$ to each lens. $m_1 = \frac{y_1'}{y_1}$ and $m_2 = \frac{y_2'}{y_2}$.

EXECUTE: **(a)** Lens 1: $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ gives $s_1'=\frac{s_1f_1}{s_1-f_1}=\frac{(50.0\text{ cm})(40.0\text{ cm})}{50.0\text{ cm}-40.0\text{ cm}}=+200\text{ cm}.$

$m_1=-\frac{s_1'}{s_1}=-\frac{200\text{ cm}}{50\text{ cm}}=-4.00.$ $y_1'=m_1y_1=(-4.00)(1.20\text{ cm})=-4.80\text{ cm}.$ The image I_1 is 200 cm to the right of lens 1, is 4.80 cm tall and is inverted.

(b) Lens 2: $y_2=-4.80$ cm. The image I_1 is $300\text{ cm}-200\text{ cm}=100\text{ cm}$ to the left of lens 2, so $s_2=+100\text{ cm}.$ $s_2'=\frac{s_2f_2}{s_2-f_2}=\frac{(100\text{ cm})(60.0\text{ cm})}{100\text{ cm}-60.0\text{ cm}}=+150\text{ cm}.$ $m_2=-\frac{s_2'}{s_2}=-\frac{150\text{ cm}}{100\text{ cm}}=-1.50.$

$y_2'=m_2y_2=(-1.50)(-4.80\text{ cm})=+7.20\text{ cm}.$ The image is 150 cm to the right of the second lens, is 7.20 cm tall, and is erect with respect to the original object.

EVALUATE: The overall magnification of the lens combination is $m_{\text{tot}}=m_1m_2$.

34.44. **IDENTIFY:** The first lens forms an image that is then the object for the second lens. We follow the same general procedure as in Problem 34.43.

SET UP: Apply $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ to each lens. $m_1=\frac{y_1'}{y_1}$ and $m_2=\frac{y_2'}{y_2}$. For a diverging lens, $f<0$.

EXECUTE: **(a)** $f_1=+40.0$ cm. I_1 is the same as in Problem 34.41. For lens 2,

$s_2'=\frac{s_2f_2}{s_2-f_2}=\frac{(100\text{ cm})(-60.0\text{ cm})}{100\text{ cm}-(-60.0\text{ cm})}=-37.5\text{ cm}.$ $m_2=-\frac{s_2'}{s_2}=-\frac{-37.5\text{ cm}}{100\text{ cm}}=+0.375.$

$y_2'=m_2y_2=(+0.375)(-4.80\text{ cm})=-1.80\text{ cm}.$ The final image is 37.5 cm to the left of the second lens (262.5 cm to the right of the first lens). The final image is inverted and is 1.80 cm tall.

(b) $f_1=-40.0$ cm. $s_1'=\frac{s_1f_1}{s_1-f_1}=\frac{(50.0\text{ cm})(-40.0\text{ cm})}{50.0\text{ cm}-(-40.0\text{ cm})}=-22.2\text{ cm}.$ $m_1=-\frac{s_1'}{s_1}=-\frac{-22.2\text{ cm}}{50.0\text{ cm}}=+0.444.$

$y_1'=m_1y_1=(0.444)(1.20\text{ cm})=0.533\text{ cm}.$ The image I_1 is 22.2 cm to the left of lens 1 so is $22.2\text{ cm}+300\text{ cm}=322.2\text{ cm}$ to the left of lens 2 and $s_2=+322.2\text{ cm}.$ $y_2=y_1'=0.533\text{ cm}.$

$s_2'=\frac{s_2f_2}{s_2-f_2}=\frac{(322.2\text{ cm})(60.0\text{ cm})}{322.2\text{ cm}-60.0\text{ cm}}=+73.7\text{ cm}.$ $m_2=-\frac{s_2'}{s_2}=-\frac{73.7\text{ cm}}{322.2\text{ cm}}=-0.229.$

$y_2'=m_2y_2=(-0.229)(0.533\text{ cm})=-0.122\text{ cm}.$ The final image is 73.7 cm to the right of the second lens, is inverted and is 0.122 cm tall.

(c) $f_1=-40.0$ cm. $f_2=-60.0$ cm. $\frac{f-f_0}{f_0}=-0.02\Rightarrow\frac{f}{f_0}=0.98$ so $2-\frac{1}{\cos\theta}=0.98.$ is as calculated in part (b). $s_2'=\frac{s_2f_2}{s_2-f_2}=\frac{(322.2\text{ cm})(-60.0\text{ cm})}{322.2\text{ cm}-(-60.0\text{ cm})}=-50.6\text{ cm}.$ $m_2=-\frac{s_2'}{s_2}=-\frac{-50.6\text{ cm}}{322.2\text{ cm}}=+0.157.$

$y_2'=m_2y_2=(0.157)(0.533\text{ cm})=0.0837\text{ cm}.$ The final image is 50.6 cm to the left of the second lens (249.4 cm to the right of the first lens), is upright and is 0.0837 cm tall.

EVALUATE: The overall magnification of the lens combination is $m_{\text{tot}}=m_1m_2$.

34.45. **IDENTIFY:** The first lens forms an image that is then the object for the second lens. We follow the same general procedure as in Problem 34.43.

SET UP: $m_{\text{tot}}=m_1m_2$. $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ gives $s'=\frac{sf}{s-f}$.

EXECUTE: **(a)** Lens 1: $f_1=-12.0$ cm, $s_1=20.0$ cm. $s'=\frac{(20.0\text{ cm})(-12.0\text{ cm})}{20.0\text{ cm}+12.0\text{ cm}}=-7.5\text{ cm}.$

$m_1=-\frac{s_1'}{s_1}=-\frac{-7.5\text{ cm}}{20.0\text{ cm}}=+0.375.$

Lens 2: The image of lens 1 is 7.5 cm to the left of lens 1 so is $7.5\text{ cm} + 9.00\text{ cm} = 16.5\text{ cm}$ to the left of lens 2. $s_2 = +16.5\text{ cm}$. $f_2 = +12.0\text{ cm}$. $s_2' = \dfrac{(16.5\text{ cm})(12.0\text{ cm})}{16.5\text{ cm} - 12.0\text{ cm}} = 44.0\text{ cm}$.

$m_2 = -\dfrac{s_2'}{s_2} = -\dfrac{44.0\text{ cm}}{16.5\text{ cm}} = -2.67$. The final image is 44.0 cm to the right of lens 2 so is 53.0 cm to the right of the first lens.

(b) $s_2' > 0$ so the final image is real.

(c) $m_{\text{tot}} = m_1 m_2 = (+0.375)(-2.67) = -1.00$. The image is 2.50 mm tall and is inverted.

EVALUATE: The light travels through the lenses in the direction from left to right. A real image for the second lens is to the right of that lens and a virtual image is to the left of the second lens.

34.46. IDENTIFY: We have a diverging lens.

SET UP: $\dfrac{1}{f} = \dfrac{1}{s} + \dfrac{1}{s'}$, $m = -s'/s$. We want *f* and the image height.

EXECUTE: **(a)** The image is to the left of the lens because a diverging lens forms a virtual image on the object side of the lens.

(b) $\dfrac{1}{s} = \dfrac{1}{f} - \dfrac{1}{s'}$ = 1/–25.0 cm) – 1/(–18.0 cm). s = 64.3 cm.

(c) $|m| = s'/s$ = (18.0 cm)/(64.3 cm) = 0.280. $|m| < 1$, so the image is shorter than the object.

EVALUATE: The image is virtual and upright but shorter than the object.

34.47. IDENTIFY: We have a thin converging lens.

SET UP: $\dfrac{1}{f} = \dfrac{1}{s} + \dfrac{1}{s'}$, $m = -s'/s$. We want the image location and the height of the image.

EXECUTE: **(a)** Eq. (34.16): $\dfrac{1}{f} = \dfrac{1}{s} + \dfrac{1}{s'}$. $s = 2f/3$, so $\dfrac{1}{s'} = \dfrac{1}{f} - \dfrac{1}{2f/3} = \dfrac{1}{f}\left(1 - \dfrac{3}{2}\right) = -\dfrac{1}{2f}$, so $s' = -2f$.

Since s' is negative, the image is *virtual* and to the *left* of the lens.

(b) $|m| = h'/h = s'/s = \dfrac{2f}{2f/3} = 3$. So $h' = 3h$. $m = -s'/s$ and s' is negative, so *m* is positive. Therefore the image is *upright.*

EVALUATE: Looking at Fig. 34.37 in the text, we see that our results agree with that figure.

34.48. IDENTIFY: We have a thin lens.

SET UP: $\dfrac{1}{f} = \dfrac{1}{s} + \dfrac{1}{s'}$, $m = -s'/s$. We want *f.*

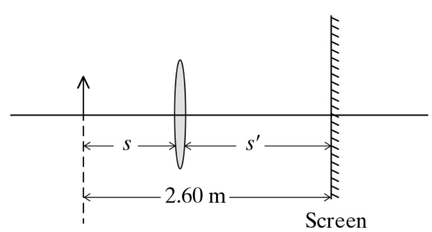

Figure 34.48

EXECUTE: **(a)** The image is on the outgoing side of the lens and is real, so it must be *inverted*. $m = -s'/s$ is negative because s' is positive.

(b) $m = -s'/s = -h'/h = -2.50$, so $s' = 2.50s$. From Fig. 34.38, we see that $s + s' = 2.60$ m. Therefore s + (2.50s) = 2.60 m, so s = 74.29 cm. Thus s' = (2.50)(74.29 cm) = 185.7 cm. $\frac{1}{f} = \frac{1}{s} + \frac{1}{s'}$ = 1/(74.29 cm) + 1/(185.7 cm), so f = +53.1 cm. Since f is positive, the lens is *converging*.

EVALUATE: The lens would have to form a real image for it to be viewed on a screen. Only a converging lens will do that if used alone.

34.49. **IDENTIFY:** Apply $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$ and $m = \frac{y'}{y} = -\frac{s'}{s}$.

SET UP: $s = 3.90$ m. $f = 0.085$ m.

EXECUTE: $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f} \Rightarrow \frac{1}{3.90\text{ m}} + \frac{1}{s'} = \frac{1}{0.085\text{ m}} \Rightarrow s' = 0.0869$ m.

$y' = -\frac{s'}{s}y = -\frac{0.0869}{3.90}1750\text{ mm} = -39.0\text{ mm}$, so it will not fit on the 24-mm$\times$36-mm sensor.

EVALUATE: The image is just outside the focal point and $s' \approx f$. To have $|y'| = 36$ mm, so that the image will fit on the sensor, $s = -\frac{s'y}{y'} \approx -\frac{(0.085\text{ m})(1.75\text{ m})}{-0.036\text{ m}} = 4.1$ m. The person would need to stand about 4.1 m from the lens.

34.50. **IDENTIFY:** The projector lens can be modeled as a thin lens.

SET UP: The thin-lens equation is $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$, and the magnification of the lens is $m = -\frac{s'}{s}$.

EXECUTE: **(a)** $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f} \Rightarrow \frac{1}{f} = \frac{1}{0.150\text{ m}} + \frac{1}{9.00\text{ m}} \Rightarrow f = 147.5$ mm, so use a $f = 148$ mm lens.

(b) $m = -\frac{s'}{s} \Rightarrow |m| = 60 \Rightarrow$ Area $= 1.44\text{ m} \times 2.16\text{ m}$.

EVALUATE: The lens must produce a real image to be viewed on the screen. Since the magnification comes out negative, the slides to be viewed must be placed upside down in the tray.

34.51. **IDENTIFY:** Apply $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$ to each lens. The image of the first lens serves as the object for the second lens.

SET UP: For a distant object, $s \to \infty$.

EXECUTE: **(a)** $s_1 = \infty \Rightarrow s_1' = f_1 = 12$ cm to the right of the converging lens.

(b) $s_2 = 4.0\text{ cm} - 12\text{ cm} = -8\text{ cm}$.

(c) $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f} \Rightarrow \frac{1}{-8\text{ cm}} + \frac{1}{s_2'} = \frac{1}{-12\text{ cm}} \Rightarrow s_2' = 24$ cm, to the right of the diverging lens. This result agrees with Fig. 34.43a.

(d) $s_1 = \infty \Rightarrow s_1' = f_1 = 12$ cm to the right of the converging lens. $s_2 = 8.0\text{ cm} - 12\text{ cm} = -4\text{ cm}$.

$\frac{1}{s} + \frac{1}{s'} = \frac{1}{f} \Rightarrow \frac{1}{-4\text{ cm}} + \frac{1}{s_2'} = \frac{1}{-12\text{ cm}} \Rightarrow s_2' = 6$ cm to the right of the diverging lens. This result agrees with Fig. 34.43b.

EVALUATE: In each case the image of the first lens serves as a virtual object for the second lens, and $s_2 < 0$.

34.52. **IDENTIFY:** Apply $\frac{n_a}{s} + \frac{n_b}{s'} = \frac{n_b - n_a}{R}$.

SET UP: $n_a = 1.00$, $n_b = 1.40$. $s = 40.0$ cm, $s' = 2.60$ cm.

EXECUTE: $\dfrac{1}{40.0\text{ cm}}+\dfrac{1.40}{2.60\text{ cm}}=\dfrac{0.40}{R}$ and $R=0.710$ cm.

EVALUATE: The cornea presents a convex surface to the object, so $R>0$.

34.53. **(a) IDENTIFY:** The purpose of the corrective lens is to take an object 25 cm from the eye and form a virtual image at the eye's near point. Use $\dfrac{1}{s}+\dfrac{1}{s'}=\dfrac{1}{f}$ to solve for the image distance when the object distance is 25 cm.

SET UP: $\dfrac{1}{f}=+2.75$ diopters means $f=+\dfrac{1}{2.75}\text{ m}=+0.3636\text{ m}$ (converging lens)

$f=36.36$ cm; $s=25$ cm; $s'=?$

EXECUTE: $\dfrac{1}{s}+\dfrac{1}{s'}=\dfrac{1}{f}$ so

$$s'=\frac{sf}{s-f}=\frac{(25\text{ cm})(36.36\text{ cm})}{25\text{ cm}-36.36\text{ cm}}=-80.0\text{ cm}.$$

The eye's near point is 80.0 cm from the eye.

(b) IDENTIFY: The purpose of the corrective lens is to take an object at infinity and form a virtual image of it at the eye's far point. Use $\dfrac{1}{s}+\dfrac{1}{s'}=\dfrac{1}{f}$ to solve for the image distance when the object is at infinity.

SET UP: $\dfrac{1}{f}=-1.30$ diopters means $f=-\dfrac{1}{1.30}\text{ m}=-0.7692\text{ m}$ (diverging lens).

$f=-76.92$ cm; $s=\infty$; $s'=?$

EXECUTE: $\dfrac{1}{s}+\dfrac{1}{s'}=\dfrac{1}{f}$ and $s=\infty$ says $\dfrac{1}{s'}=\dfrac{1}{f}$ and $s'=f=-76.9$ cm. The eye's far point is 76.9 cm from the eye.

EVALUATE: In each case a virtual image is formed by the lens. The eye views this virtual image instead of the object. The object is at a distance where the eye can't focus on it, but the virtual image is at a distance where the eye can focus.

34.54. **IDENTIFY** and **SET UP:** For an object 25.0 cm from the eye, the corrective lens forms a virtual image at the near point of the eye. $\dfrac{1}{s}+\dfrac{1}{s'}=\dfrac{1}{f}$. $P(\text{in diopters})=1/f$ (in m).

EXECUTE: **(a)** The person is farsighted.

(b) A converging lens is needed.

(c) $\dfrac{1}{s}+\dfrac{1}{s'}=\dfrac{1}{f}$. $f=\dfrac{ss'}{s+s'}=\dfrac{(25.0\text{ cm})(-45.0\text{ cm})}{25.0\text{ cm}-45.0\text{ cm}}=+56.2$ cm. The power is $\dfrac{1}{0.562\text{ m}}=+1.78$ diopters.

EVALUATE: The object is inside the focal point of the lens, so it forms a virtual image.

34.55. **IDENTIFY** and **SET UP:** For an object 25.0 cm from the eye, the corrective lens forms a virtual image at the near point of the eye. The distances from the corrective lens are $s=23.0$ cm and $s'=-43.0$ cm. $\dfrac{1}{s}+\dfrac{1}{s'}=\dfrac{1}{f}$. $P(\text{in diopters})=1/f$ (in m).

EXECUTE: Solving $\dfrac{1}{s}+\dfrac{1}{s'}=\dfrac{1}{f}$ for f gives $f=\dfrac{ss'}{s+s'}=\dfrac{(23.0\text{ cm})(-43.0\text{ cm})}{23.0\text{ cm}-43.0\text{ cm}}=+49.4$ cm. The power is $\dfrac{1}{0.494\text{ m}}=2.02$ diopters.

EVALUATE: In Problem 34.54 the contact lenses have power 1.78 diopters. The power of the lenses is different for ordinary glasses versus contact lenses.

34.56. **IDENTIFY** and **SET UP:** For an object very far from the eye, the corrective lens forms a virtual image at the far point of the eye. $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$. $P(\text{in diopters}) = 1/f\,(\text{in m})$.

EXECUTE: **(a)** The person is nearsighted.

(b) A diverging lens is needed.

(c) In $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$, $s \to \infty$, so $f = s' = -75.0$ cm. The power is $\frac{1}{-0.750\text{ m}} = -1.33$ diopters.

EVALUATE: A diverging lens is needed to form a virtual image of a distant object. A converging lens could not do this since distant objects cannot be inside its focal point.

34.57. **IDENTIFY:** We are dealing with the eye and want to find her far point and near point.

SET UP: For distant vision (upper half of the lens), f = 1/(–0.500 diopters) = –2.00 m = –200 cm. For close vision (lower half of the lens), f = 1/(+2.00 diopters) = 0.500 m = 50.0 cm. $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}$.

EXECUTE: **(a)** Far point: A very distant object (i.e., at infinity) is placed at her far point. $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}$, so $\frac{1}{-200\text{ cm}} = \frac{1}{\infty}+\frac{1}{s'}$, so s' = –200 cm. The image is 200 cm in front of the glasses, which is 202 cm in front of her eye. So her far point is 202 cm from her eye.

Near point: An object at 25 cm from her eye (23 cm from the glasses) is placed at her near point. $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}$ gives $\frac{1}{50.0\text{ cm}}=\frac{1}{23\text{ cm}}+\frac{1}{s'}$, so s' = –42.6 cm. The image is 42.6 cm in front of the glasses, which is 44.6 cm from her eye. So her near point is at 44.6 cm.

(b) The image for the closest object she can see will be at her near point, which is 42.6 cm from the lens. $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}$ gives $\frac{1}{-200\text{ cm}}=\frac{1}{s}+\frac{1}{-42.6\text{ cm}}$, s = 54.1 cm. The distance from her eye is 56.1 cm.

EVALUATE: Without glasses this woman can clearly see objects between 44.6 cm and 202 cm from her eye. A typical person with excellent vision can see between 25 cm and infinity.

34.58. **IDENTIFY:** When the object is at the focal point, $M = \frac{25.0\text{ cm}}{f}$. In part (b), apply $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ to calculate s for $s' = -25.0$ cm.

SET UP: Our calculation assumes the near point is 25.0 cm from the eye.

EXECUTE: **(a)** Angular magnification $M = \frac{25.0\text{ cm}}{f} = \frac{25.0\text{ cm}}{6.00\text{ cm}} = 4.17$.

(b) $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f} \Rightarrow \frac{1}{s}+\frac{1}{-25.0\text{ cm}}=\frac{1}{6.00\text{ cm}} \Rightarrow s = 4.84$ cm.

EVALUATE: In part (b), $\theta' = \frac{y}{s}$, $\theta = \frac{y}{25.0\text{ cm}}$, and $M = \frac{25.0\text{ cm}}{s} = \frac{25.0\text{ cm}}{4.84\text{ cm}} = 5.17$. M is greater when the image is at the near point than when the image is at infinity.

34.59. **IDENTIFY:** Use $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ and $m = \frac{y'}{y} = -\frac{s'}{s}$ to calculate s and y'.

SET UP: $f = 8.00$ cm; $s' = -25.0$ cm; $s = ?$

EXECUTE: **(a)** $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$, so $\frac{1}{s}=\frac{1}{f}-\frac{1}{s'}=\frac{s'-f}{s'f}$.

$$s=\frac{s'f}{s'-f}=\frac{(-25.0\text{ cm})(+8.00\text{ cm})}{-25.0\text{ cm}-8.00\text{ cm}}=+6.06\text{ cm}.$$

(b) $m=-\frac{s'}{s}=-\frac{-25.0\text{ cm}}{6.06\text{ cm}}=+4.125.$

$|m|=\frac{|y'|}{|y|}$ so $|y'|=|m||y|=(4.125)(1.00\text{ mm})=4.12\text{ mm}.$

EVALUATE: The lens allows the object to be much closer to the eye than the near point. The lens allows the eye to view an image at the near point rather than the object.

34.60. **IDENTIFY:** For a thin lens, $-\frac{s'}{s}=\frac{y'}{y}$, so $\left|\frac{y'}{s'}\right|=\left|\frac{y}{s}\right|$, and the angular size of the image equals the angular size of the object.

SET UP: The object has angular size $\theta=\frac{y}{f}$, with θ in radians.

EXECUTE: $\theta=\frac{y}{f}\Rightarrow f=\frac{y}{\theta}=\frac{2.00\text{ mm}}{0.032\text{ rad}}=62.5\text{ mm}=6.25\text{ cm}$, which rounds to 6.3 cm.

EVALUATE: If the insect were at the near point of a normal human eye, its angular size would be $\frac{2.00\text{ mm}}{250\text{ mm}}=0.0080\text{ rad}.$

34.61. **(a) IDENTIFY** and **SET UP:** Use $M=-\frac{f_1}{f_2}$, with $f_1=95.0\text{ cm}$ (objective) and $f_2=15.0\text{ cm}$ (eyepiece).

EXECUTE: $M=-\frac{f_1}{f_2}=-\frac{95.0\text{ cm}}{15.0\text{ cm}}=-6.33.$

(b) IDENTIFY: Use $m=\frac{y'}{y}=-\frac{s'}{s}$ to calculate y'.

SET UP: $s=3.00\times10^3\text{ m}.$
$s'=f_1=95.0\text{ cm}$ (since s is very large, $s'\approx f$).

EXECUTE: $m=-\frac{s'}{s}=-\frac{0.950\text{ m}}{3.00\times10^3\text{ m}}=-3.167\times10^{-4}.$

$|y'|=|m||y|=(3.167\times10^{-4})(60.0\text{ m})=0.0190\text{ m}=1.90\text{ cm}.$

(c) IDENTIFY and **SET UP:** Use $M=\frac{\theta'}{\theta}$ and the angular magnification M obtained in part (a) to calculate θ'. The angular size θ of the image formed by the objective (object for the eyepiece) is its height divided by its distance from the objective.

EXECUTE: The angular size of the object for the eyepiece is $\theta=\frac{0.0190\text{ m}}{0.950\text{ m}}=0.0200\text{ rad}.$

(Note that this is also the angular size of the object for the objective: $\theta=\frac{60.0\text{ m}}{3.00\times10^3\text{ m}}=0.0200\text{ rad}.$ For a thin lens the object and image have the same angular size and the image of the objective is the object for the eyepiece.) $M=\frac{\theta'}{\theta}$, so the angular size of the image is $\theta'=M\theta=-(6.33)(0.0200\text{ rad})=$ -0.127 rad. (The minus sign shows that the final image is inverted.)

EVALUATE: The lateral magnification of the objective is small; the image it forms is much smaller than the object. But the total angular magnification is larger than 1.00; the angular size of the final image viewed by the eye is 6.33 times larger than the angular size of the original object, as viewed by the unaided eye.

34.62. **IDENTIFY:** For a telescope, $M = -\dfrac{f_1}{f_2}$.

SET UP: $f_2 = 9.0$ cm. The distance between the two lenses equals $f_1 + f_2$.

EXECUTE: $f_1 + f_2 = 1.20 \text{ m} \Rightarrow f_1 = 1.20 \text{ m} - 0.0900 \text{ m} = 1.11 \text{ m}$. $M = -\dfrac{f_1}{f_2} = -\dfrac{111 \text{ cm}}{9.00 \text{ cm}} = -12.3$.

EVALUATE: For a telescope, $f_1 \gg f_2$.

34.63. **IDENTIFY:** $f = R/2$ and $M = -\dfrac{f_1}{f_2}$.

SET UP: For object and image both at infinity, $f_1 + f_2$ equals the distance *d* between the eyepiece and the mirror vertex. $f_2 = 1.10$ cm. $R_1 = 1.30$ m.

EXECUTE: **(a)** $f_1 = \dfrac{R_1}{2} = 0.650 \text{ m} \Rightarrow d = f_1 + f_2 = 0.661 \text{ m}$.

(b) $|M| = \dfrac{f_1}{f_2} = \dfrac{0.650 \text{ m}}{0.011 \text{ m}} = 59.1$.

EVALUATE: For a telescope, $m = -\dfrac{s'}{s} = -\dfrac{-3.00 \text{ cm}}{8.00 \text{ cm}} = +0.375$.

34.64. **IDENTIFY:** This is a compound microscope.

SET UP: $\dfrac{1}{f} = \dfrac{1}{s} + \dfrac{1}{s'}$, $m_1 = -s'/s$, $M_2 = (25 \text{ cm})/f_2$, $M = m_1 M_2$. Fig. 34.64 shows the arrangement of the lenses. I_2 is at infinity, so I_1 is at F_2.

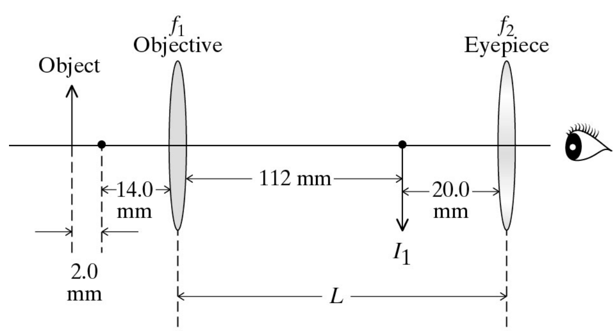

Figure 34.64

EXECUTE: **(a)** We want the length L. First image (I–$_1$): $\dfrac{1}{f_1} = \dfrac{1}{s_1} + \dfrac{1}{s_1'}$. $\dfrac{1}{14.0 \text{ mm}} = \dfrac{1}{16.0 \text{ mm}} + \dfrac{1}{s_1'}$.

$s_1' = 112$ mm. $m_1 = -s_1'/s_1 = -(112 \text{ mm})/(16 \text{ mm}) = -7.00$.

Second image (I–$_2$): $s_2' = \infty$. $\dfrac{1}{f_2} = \dfrac{1}{s_2} + \dfrac{1}{s_2'} = \dfrac{1}{s_2}$, so $s_2 = f_2 = 20.0$ mm.

$M_2 = (25 \text{ cm})/f_2 = (250 \text{ mm})/(20.0 \text{ mm}) = 12.5$. $L = 112 \text{ mm} + 20.0 \text{ mm} = 132$ mm.

(b) We want the magnification. $M = m_1 M_2$. $m_1 = -s_1'/s_1 = -(112 \text{ mm})/(16 \text{ mm}) = -7.00$. Therefore $M = (-7.00)(250 \text{ mm})/(20 \text{ mm}) = -87.5$.

(c) If we use $s_1 \approx f_1$, we have $M = -[(112\text{ mm})/(14.0\text{ mm})][(250\text{ mm})/(20.0\text{ mm})] = -100$. The percent difference is $(100 - 87.5)/(87.5) = 0.143 = 14.3\%$.

EVALUATE: Using $f_1 \approx s_1$ is convenient, but as we have seen, doing so can lead to significant error compared to the true magnification.

34.65. **IDENTIFY:** We have a compound microscope.

SET UP: $\dfrac{1}{f} = \dfrac{1}{s} + \dfrac{1}{s'}$, $m_1 = -s'/s$, $M_2 = (25\text{ cm})/f_2$, $M = m_1 M_2$. Fig. 34.65 shows the arrangement of the lenses. I_2 is at infinity, so I_1 is at F_2. We want f_1.

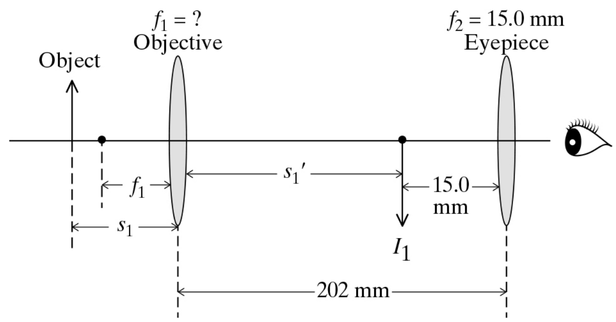

Figure 34.65

EXECUTE: From the figure, we see that $s_1' = 202\text{ mm} - 15.0\text{ mm} = 187\text{ mm}$. Use $\dfrac{1}{f_1} = \dfrac{1}{s_1} + \dfrac{1}{s_1'}$.

$\dfrac{1}{f_1} = \dfrac{1}{s_1} + \dfrac{1}{187\text{ mm}}$. Use $M = m_1 M_2$ to find s_1. $M = m_1 M_2 = -\dfrac{s_1'}{s_1}\dfrac{25\text{ cm}}{f_2}$. $178 = \dfrac{187\text{ mm}}{s_1}\left(\dfrac{250\text{ mm}}{15.0\text{ mm}}\right)$, so $1/s_1 = 0.05711\text{ mm}^{-1}$. Use this result in the lens equation. $\dfrac{1}{f_1} = 005711\text{ mm}^{-1} + \dfrac{1}{187\text{ mm}}$. $f_1 = 16.0$ mm.

EVALUATE: If we had used the approximation $s_1 \approx f_1$, the magnification we would have calculated would have been $M = -\dfrac{s_1'}{s_1}\dfrac{25\text{ cm}}{f_2} = \dfrac{187\text{ mm}}{16.0\text{ mm}}\left(\dfrac{250\text{ mm}}{15.0\text{ mm}}\right) = -195$, which is significantly different from the true magnification of -178.

34.66. **IDENTIFY:** Combine $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{2}{R}$ and $m = -\dfrac{s'}{s}$.

SET UP: $m = +2.50$. $R > 0$.

EXECUTE: $m = -\dfrac{s'}{s} = +2.50$. $s' = -2.50s$. $\dfrac{1}{s} + \dfrac{1}{-2.50s} = \dfrac{2}{R}$. $\dfrac{0.600}{s} = \dfrac{2}{R}$ and $s = 0.300R$.

$s' = -2.50s = (-2.50)(0.300R) = -0.750R$. The object is a distance of $0.300R$ in front of the mirror and the image is a distance of $0.750R$ behind the mirror.

EVALUATE: For a single mirror an erect image is always virtual.

34.67. **IDENTIFY:** We are given the image distance, the image height, and the object height. Use $m = -\dfrac{s'}{s}$ to calculate the object distance s. Then use $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{2}{R}$ to calculate R.

SET UP: The image is to be formed on screen so it is a real image; $s' > 0$. The mirror-to-screen distance is 8.00 m, so $s' = +800$ cm. $m = -\dfrac{s'}{s} < 0$ since both s and s' are positive.

EXECUTE: **(a)** $|m| = \dfrac{|y'|}{|y|} = \dfrac{24.0\text{ cm}}{0.600\text{ cm}} = 40.0$, so $m = -40.0$. Then $m = -\dfrac{s'}{s}$ gives

$s = -\dfrac{s'}{m} = -\dfrac{800\text{ cm}}{-40.0} = +20.0\text{ cm}.$

(b) $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{2}{R}$, so $\dfrac{2}{R} = \dfrac{s+s'}{ss'}$. $R = 2\left(\dfrac{ss'}{s+s'}\right) = 2\left(\dfrac{(20.0\text{ cm})(800\text{ cm})}{20.0\text{ cm} + 800\text{ cm}}\right) = 39.0\text{ cm}.$

EVALUATE: R is calculated to be positive, which is correct for a concave mirror. Also, in part (a) s is calculated to be positive, as it should be for a real object.

34.68. **IDENTIFY:** Apply $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{2}{R}$ and $m = -\dfrac{s'}{s}$.

SET UP: Since the image is projected onto the wall it is real and $s' > 0$. $m = -\dfrac{s'}{s}$ so m is negative and $m = -3.50$. The object, mirror and wall are sketched in Figure 34.68. This sketch shows that $s' - s = 3.00$ m = 300 cm.

EXECUTE: $m = -3.50 = -\dfrac{s'}{s}$ so $s' = 3.50s$. $s' - s = 3.50s - s = 300\text{ cm}$ so $s = 120\text{ cm}$.

$s' = 300\text{ cm} + 120\text{ cm} = 420\text{ cm}$. The mirror should be 4.20 m from the wall. $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{2}{R}$.

$\dfrac{1}{120\text{ cm}} + \dfrac{1}{420\text{ cm}} = \dfrac{2}{R}$. $R = 187\text{ cm} = 1.87\text{ m}.$

EVALUATE: The focal length of the mirror is $f = R/2 = 93.5\text{ cm}$ and $s > f$, as it must if the image is to be real.

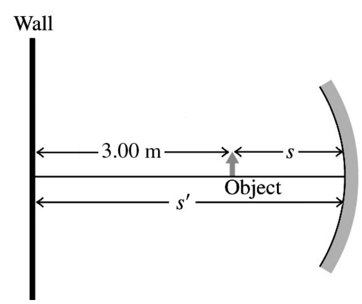

Figure 34.68

34.69. **IDENTIFY:** Since the truck is moving toward the mirror, its image will also be moving toward the mirror.

SET UP: The equation relating the object and image distances to the focal length of a spherical mirror is $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$, where $f = R/2$.

EXECUTE: Since the mirror is convex, $f = R/2 = (-1.50\text{ m})/2 = -0.75\text{ m}$. Applying the equation for a spherical mirror gives $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f} \Rightarrow s' = \dfrac{fs}{s-f}$. Using the chain rule from calculus and the fact that $v = ds/dt$, we have $v' = \dfrac{ds'}{dt} = \dfrac{ds'}{ds}\dfrac{ds}{dt} = v\dfrac{f^2}{(s-f)^2}$. Solving for v gives

$v = v'\left(\dfrac{s-f}{f}\right)^2 = (1.9\text{ m/s})\left[\dfrac{2.0\text{ m} - (-0.75\text{ m})}{-0.75\text{ m}}\right]^2 = 25.5\text{ m/s}$. This is the velocity of the truck relative to the mirror, so the truck is approaching the mirror at 25.5 m/s. You are traveling at 25 m/s, so the truck must be traveling at $25 \text{ m/s} + 25.5 \text{ m/s} = 51 \text{ m/s}$ relative to the highway.

EVALUATE: Even though the truck and car are moving at constant speed, the image of the truck is *not* moving at constant speed because its location depends on the distance from the mirror to the truck.

34.70. IDENTIFY: Apply $\dfrac{n_a}{s} + \dfrac{n_b}{s'} = \dfrac{n_b - n_a}{R}$, with $R \to \infty$ since the surfaces are flat.

SET UP: The image formed by the first interface serves as the object for the second interface.

EXECUTE: For the water-benzene interface, we get the apparent water depth:

$\dfrac{n_a}{s} + \dfrac{n_b}{s'} = 0 \Rightarrow \dfrac{1.33}{5.70 \text{ cm}} + \dfrac{1.50}{s'} = 0 \Rightarrow s' = -6.429 \text{ cm}$. For the benzene-air interface, we get the total apparent distance to the bottom: $\dfrac{n_a}{s} + \dfrac{n_b}{s'} = 0 \Rightarrow \dfrac{1.50}{(6.429 \text{ cm} + 4.20 \text{ cm})} + \dfrac{1}{s'} = 0 \Rightarrow s' = -7.09 \text{ cm}$.

EVALUATE: At the water-benzene interface the light refracts into material of greater refractive index but at the benzene-air interface it refracts into material of smaller refractive index. The overall effect is that the apparent depth is less than the actual depth.

34.71. IDENTIFY: Apply $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$ to calculate s' and then use $m = -\dfrac{s'}{s} = \dfrac{y'}{y}$ to find the height of the image.

SET UP: For a convex mirror, $R < 0$, so $R = -18.0 \text{ cm}$ and $f = \dfrac{R}{2} = -9.00 \text{ cm}$.

EXECUTE: **(a)** $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$. $s' = \dfrac{sf}{s-f} = \dfrac{(900 \text{ cm})(-9.00 \text{ cm})}{900 \text{ cm} - (-9.00 \text{ cm})} = -8.91 \text{ cm}$.

$m = -\dfrac{s'}{s} = -\dfrac{-8.91 \text{ cm}}{900 \text{ cm}} = 9.90 \times 10^{-3}$. $|y'| = |m|\, y = (9.90 \times 10^{-3})(1.5 \text{ m}) = 0.0149 \text{ m} = 1.49 \text{ cm}$.

(b) The height of the image is much less than the height of the car, so the car appears to be farther away than its actual distance.

EVALUATE: A plane mirror would form an image the same size as the car. Since the image formed by the convex mirror is smaller than the car, the car appears to be farther away compared to what it would appear using a plane mirror.

34.72. IDENTIFY: Apply $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$ and the concept of principal rays.

SET UP: $s = 10.0 \text{ cm}$. If extended backward the ray comes from a point on the optic axis 18.0 cm from the lens and the ray is parallel to the optic axis after it passes through the lens.

EXECUTE: **(a)** The ray is bent toward the optic axis by the lens so the lens is converging.

(b) The ray is parallel to the optic axis after it passes through the lens so it comes from the focal point; $f = 18.0 \text{ cm}$.

(c) The principal-ray diagram is drawn in Figure 34.72. The diagram shows that the image is 22.5 cm to the left of the lens.

(d) $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$ gives $s' = \dfrac{sf}{s-f} = \dfrac{(10.0 \text{ cm})(18.0 \text{ cm})}{10.0 \text{ cm} - 18.0 \text{ cm}} = -22.5 \text{ cm}$. The calculated image position agrees with the principal-ray diagram.

EVALUATE: The image is virtual. A converging lens produces a virtual image when the object is inside the focal point.

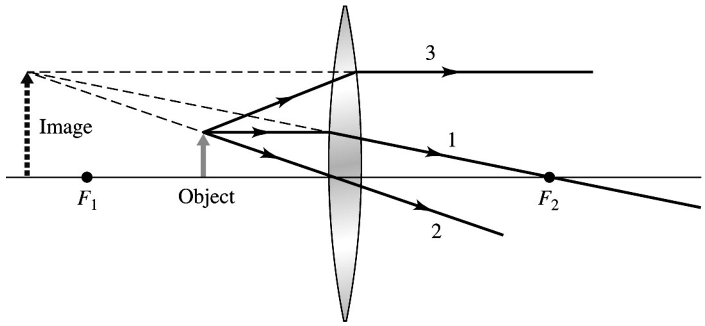

Figure 34.72

34.73. IDENTIFY and **SET UP:** Rays that pass through the hole are undeflected. All other rays are blocked. $m = -\dfrac{s'}{s}$.

EXECUTE: (a) The ray diagram is drawn in Figure 34.73. The ray shown is the only ray from the top of the object that reaches the film, so this ray passes through the top of the image. An inverted image is formed on the far side of the box, no matter how far this side is from the pinhole and no matter how far the object is from the pinhole.

(b) $s = 1.5\text{ m}$. $s' = 20.0\text{ cm}$. $m = -\dfrac{s'}{s} = -\dfrac{20.0\text{ cm}}{150\text{ cm}} = -0.133$. $y' = my = (-0.133)(18\text{ cm}) = -2.4\text{ cm}$.

The image is 2.4 cm tall.

EVALUATE: A defect of this camera is that not much light energy passes through the small hole each second, so long exposure times are required.

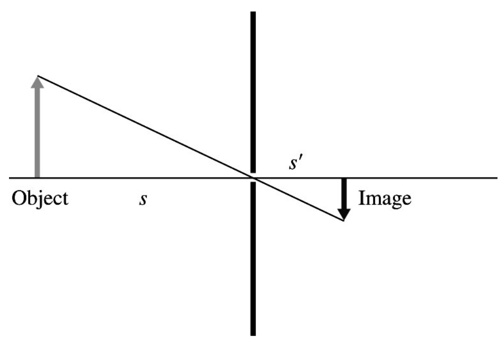

Figure 34.73

34.74. IDENTIFY: We have a combination of two thin lenses.

SET UP: $\dfrac{1}{f} = \dfrac{1}{s} + \dfrac{1}{s'}$, $m = -s'/s$, $M = m_1 m_2$. Fig. 34.74 shows the arrangement of the lenses. The first lens L_1 forms an image I_1 which is then the object for the second lens L_2, and L_2 forms the final image I_2. We want f_2 and the distance between the object and the final image I_2.

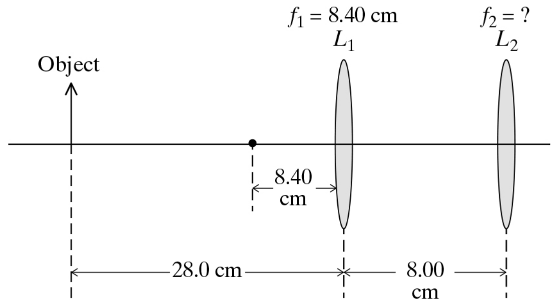

Figure 34.74

EXECUTE: **(a)** We want f_2. Locate the image formed by lens L_1. $\frac{1}{f} = \frac{1}{s} + \frac{1}{s'}$ gives $\frac{1}{8.40 \text{ cm}} = \frac{1}{28.0 \text{ cm}} + \frac{1}{s'}$, so $s' = 12.0$ cm. $m_1 = -s_1'/s_1 = -(12.0 \text{ cm})/(28.0 \text{ cm}) = -0.4286$. Now look at lens L_2. I_1 is (or would be) formed 4.00 cm to the right of L_2. Thus it is a *virtual object* for that lens (see Fig. 34.37(f) in the textbook). So $s_2 = -4.00$ cm for L_2. $m_2 = -s_2'/s_2$, so $M = m_{-1}m_2 = (-0.4286)\left(-\frac{s_2'}{s_2}\right)$.

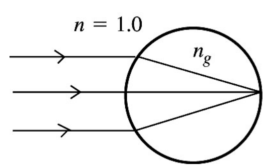
We also know that $M = -h_2/h = -(5.60 \text{ mm})/(4.00 \text{ mm}) = -1.40$. Use this and our latest result to find s_2'.
$-1.40 = (-0.4286)\left(-\frac{s_2'}{-4.00 \text{ cm}}\right)$, so $s_2' = +13.07$ cm. Now get f_2. $\frac{1}{f_2} = \frac{1}{-4.00 \text{ cm}} + \frac{1}{13.07 \text{ cm}}$, so $f_2 = -5.76$ cm.

(b) $s_2' = +13.1$ cm, so I_2 is 13.1 cm to the right of L_2. The object is 28.0 cm + 8.00 cm = 36.0 cm to the left of L_2, so the distance between the object and the final image is 36.0 cm + 13.1 cm = 49.1 cm.

EVALUATE: Careful of virtual objects: for them the object distance is *negative*.

34.75. **IDENTIFY:** Apply $\frac{n_a}{s} + \frac{n_b}{s'} = \frac{n_b - n_a}{R}$ to the image formed by refraction at the front surface of the sphere.

SET UP: Let n_g be the index of refraction of the glass. The image formation is shown in Figure 34.75.



$s = \infty$.
$s' = +2r$, where r is the radius of the sphere.
$n_a = 1.00, n_b = n_g, R = +r$.

Figure 34.75

EXECUTE: $\frac{1}{\infty} + \frac{n_g}{2r} = \frac{n_g - 1.00}{r}$.

$\frac{n_g}{2r} = \frac{n_g}{r} - \frac{1}{r}$; $\frac{n_g}{2r} = \frac{1}{r}$ and $n_g = 2.00$.

EVALUATE: The required refractive index of the glass does not depend on the radius of the sphere.

34.76. **IDENTIFY:** This problem involves the lateral magnification by a curved surface.

SET UP: Eq. (343.11): $\frac{n_a}{s} + \frac{n_b}{s'} = \frac{n_b - n_a}{R}$, Eq. (34.12): $m = -\frac{n_a s'}{n_b s}$. a is water and b is air.

EXECUTE: **(a)** Yes, it widens.

(b) Estimate: Lateral magnification is about 1 ½ = 1.5.

(c) We want m. $n_a = n$ (water) and $n_b = 1$ (air). Eqs. (34.11) and (34.12) become $\frac{n}{s}+\frac{1}{s'}=\frac{1-n}{R}$ and $m=-\frac{ns'}{s}$. Because R is negative for the glass, we can write the first equation as $\frac{n}{s}+\frac{1}{s'}=\frac{n-1}{|R|}$.

Combine these equations and solve for m, giving $m=\dfrac{1}{1-\frac{s}{|R|}(1-1/n)}$.

(d) We want n. Since the image is at the back of the glass, $s = 2|R|$. Combining this with the result of part (c) gives $m=\dfrac{1}{1+2(1-1/n)}$. Solve for n: $n=\dfrac{2}{1+1/m}$.

(e) $n=\dfrac{2}{1+1/m}=\dfrac{2}{1+1/1.5}=1.2.$

EVALUATE: This result is reasonably close to $n = 1.33$ considering the rough estimates involved.

34.77. **IDENTIFY:** We know the magnitude of the focal length is 35.0 cm and that it produces an image that is twice the height of the object. In part (a) the image is real, and in part (b) it is virtual. In each case we want to know the distance from the object to the lens and if the lens is converging or diverging. The thin-lens formula applies in both cases.

SET UP: Apply $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ with $f=\pm 35.0$ cm. We know that the magnification is $m=-\frac{s'}{s}$.

EXECUTE: **(a)** We want the size of the image to be twice that of the object, so we must have $m=\pm 2$. Since the image is real we know that $s'>0$, which implies that $m=-2=-\frac{s'}{s}$. Thus we conclude that $s'=2s$. Now we can determine the location of the object: $\frac{1}{s}+\frac{1}{s'}=\frac{1}{s}+\frac{1}{2s}=\frac{3}{2s}=\frac{1}{f}$. Solving for s we get $s=\frac{3}{2}f$. Since we know that $s>0$ we must have that $f=+35.0$ cm, and thus $s=\frac{3}{2}f=\frac{3}{2}(35.0\text{ cm})=$ 52.5 cm. The lens is a converging lens, and the object must be placed 52.5 cm in front of the lens.

(b) We again want the image to be twice the size as the object; however, in this case we have a virtual image so $s'<0$ and $m=+2=-\frac{s'}{s}$. Thus, we have $s'=-2s$. Now we can determine the location of the object: $\frac{1}{s}+\frac{1}{s'}=\frac{1}{s}+\frac{1}{-2s}=\frac{1}{2s}=\frac{1}{f}$. Solving for s we obtain $s=\frac{1}{2}f$. Since we know that $s>0$ we must have that $f=+35.0$ cm and thus $s=\frac{1}{2}(35.0\text{ cm})=17.5$ cm. The lens is a converging lens, and the object must be placed 17.5 cm in front of the lens.

EVALUATE: For a diverging lens we have $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}<0$. This can only occur if $\frac{1}{s'}$ is negative and larger in magnitude than $\frac{1}{s}$. Thus we have $|m|=\left|-\frac{s'}{s}\right|<1$. It follows that the image is always smaller than the object for a diverging lens. In this exercise $|m|=2>1$, so only a converging lens will work.

34.78. **IDENTIFY:** The lens forms an image of the object. That image (I_1) is reflected in the plane mirror, and its image (I_2) is just as far behind the mirror as I_1 is in front of the mirror. The image I_2 in the mirror then acts as the object for the lens which forms an image I_3 on the screen.

SET UP: The thin-lens equation, $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$, applies to the lens.

EXECUTE: **(a)** Figure 34.78 shows the arrangement of the screen, object, lens, and mirror.

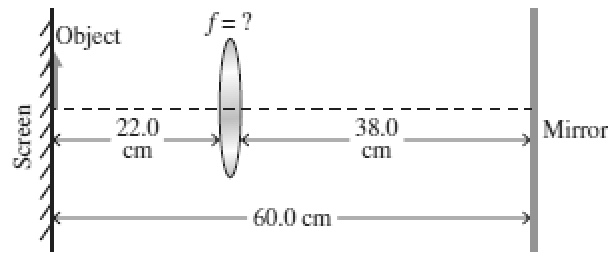


Figure 34.78

(b) First image formed by the lens (I_1) : Apply $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ at the lens. The object distance s is 22.0 cm.

$$\frac{1}{22.0\text{ cm}}+\frac{1}{s'}=\frac{1}{f}. \qquad \text{Eq. (1)}$$

Image I_2 in the mirror : The image I_1 is a distance s' from the lens, so its distance from the mirror is 38.0 cm $-\ s'$. So its image I_2 in the mirror is a distance 38.0 cm $-\ s'$ behind the mirror.

Second image formed by the lens (I_3) : I_2 serves as the object for the lens, and its distance s from the lens is

s = 38.0 cm + (38.0 cm $-\ s'$) = 76.0 cm $-\ s'$. The lens forms the image I_3 on the screen, so the image distance is s' = 22.0 cm. Applying the thin-lens equation again gives

$$\frac{1}{76.0\text{ cm}-s'}+\frac{1}{22.0\text{ cm}}=\frac{1}{f}. \qquad \text{Eq. (2)}$$

Equating the two expressions for $1/f$ from Equations (1) and (2) gives

$\frac{1}{22.0\text{ cm}}+\frac{1}{s'}=\frac{1}{76.0\text{ cm}-s'}+\frac{1}{22.0\text{ cm}}$, which simplifies to $\frac{1}{s'}=\frac{1}{76.0\text{ cm}-s'}$. Solving for s' gives s' = 38.0 cm. Putting this into Eq. (1) gives $\frac{1}{f}=\frac{1}{22.0\text{ cm}}+\frac{1}{38.0\text{ cm}}$, so f = 13.9 cm.

EVALUATE: The image I_1 is *at* the mirror.

34.79. **IDENTIFY:** We know that the image is real, is 214 cm from the *object* (*not* from the lens), and is 5/3 times the height of the object. We want to find the type of lens and its focal length. The thin-lens equation applies.

SET UP: Apply $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ with the conditions that $s + s'$ = ±214 cm and $m=-\frac{s'}{s}$.

EXECUTE: Since the size of the image is greater than the size of the object, we know that the image must be farther from the lens than the object. This implies that the focal length of the lens is positive and the lens is converging. We know that the image is real, so $s'>0$. In this case we have $s+s'=+214$ cm and $m = -\dfrac{s'}{s} = -\dfrac{5}{3}$. Thus, we may write $s' = \frac{5}{3}s$ and $s + s' = \frac{8}{3}s = +214$ cm. Solving for s and s' we obtain $s = 80.25$ cm and $s' = 133.75$ cm. This gives $f = \dfrac{ss'}{s+s'} = \dfrac{(80.25\text{ cm})(133.75\text{ cm})}{214\text{ cm}} = 50.2$ cm.

EVALUATE: For a diverging lens we have $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f} < 0$. This can only occur if $\dfrac{1}{s'}$ is negative and larger in magnitude than $\dfrac{1}{s}$. Thus we have $|m| = \left|-\dfrac{s'}{s}\right| < 1$. It follows that the image is always smaller than the object for a diverging lens. In this exercise $|m| = \dfrac{5}{3} > 1$, so only a converging lens will work.

34.80. IDENTIFY: Apply $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$ and $m = \dfrac{y'}{y} = -\dfrac{s'}{s}$. The type of lens determines the sign of *f*. The sign of s' determines whether the image is real or virtual.

SET UP: $s = +8.00$ cm. $s' = -3.00$ cm. s' is negative because the image is on the same side of the lens as the object.

EXECUTE: **(a)** $\dfrac{1}{f} = \dfrac{s+s'}{ss'}$ and $f = \dfrac{ss'}{s+s'} = \dfrac{(8.00\text{ cm})(-3.00\text{ cm})}{8.00\text{ cm} - 3.00\text{ cm}} = -4.80$ cm. *f* is negative so the lens is diverging.

(b) $m = -\dfrac{s'}{s} = -\dfrac{-3.00\text{ cm}}{8.00\text{ cm}} = +0.375$. $y' = my = (0.375)(6.50\text{ mm}) = 2.44$ mm. $s' < 0$ and the image is virtual.

EVALUATE: A converging lens can also form a virtual image, if the object distance is less than the focal length. But in that case $|s'| > s$ and the image would be farther from the lens than the object is.

34.81. IDENTIFY: $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$. The type of lens determines the sign of *f*. $m = \dfrac{y'}{y} = -\dfrac{s'}{s}$. The sign of s' depends on whether the image is real or virtual. $s = 16.0$ cm.

SET UP: $s' = -22.0$ cm; s' is negative because the image is on the same side of the lens as the object.

EXECUTE: **(a)** $\dfrac{1}{f} = \dfrac{s+s'}{ss'}$ and $f = \dfrac{ss'}{s+s'} = \dfrac{(16.0\text{ cm})(-22.0\text{ cm})}{16.0\text{ cm} - 22.0\text{ cm}} = +58.7$ cm. *f* is positive so the lens is converging.

(b) $m = -\dfrac{s'}{s} = -\dfrac{-22.0\text{ cm}}{16.0\text{ cm}} = 1.38$. $y' = my = (1.38)(3.25\text{ mm}) = 4.48$ mm. $s' < 0$ and the image is virtual.

EVALUATE: A converging lens forms a virtual image when the object is closer to the lens than the focal point.

34.82. IDENTIFY: Apply $\dfrac{n_a}{s} + \dfrac{n_b}{s'} = \dfrac{n_b - n_a}{R}$. Use the image distance when viewed from the flat end to determine the refractive index *n* of the rod.

SET UP: When viewing from the flat end, $n_a = n$, $n_b = 1.00$ and $R \to \infty$. When viewing from the curved end, $n_a = n$, $n_b = 1.00$, and $R = -10.0$ cm.

EXECUTE: When viewed from the flat end of the rod:

$$\frac{n_a}{s} + \frac{n_b}{s'} = 0 \Rightarrow \frac{n}{15.0\text{ cm}} + \frac{1}{-8.20\text{ cm}} = 0 \Rightarrow n = \frac{15.0}{8.20} = 1.829.$$

When viewed from the curved end of the rod:

$$\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}\Rightarrow\frac{n}{s}+\frac{1}{s'}=\frac{1-n}{R}\Rightarrow\frac{1.829}{15.0\text{ cm}}+\frac{1}{s'}=\frac{-0.829}{-10.0\text{ cm}},\text{ so } s'=-25.6\text{ cm}.$$

The image is 25.6 cm within the rod from the curved end.

EVALUATE: In each case the image is virtual and on the same side of the surface as the object.

34.83. IDENTIFY: The image formed by refraction at the surface of the eye is located by $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$.

SET UP: $n_a=1.00$, $n_b=1.35$. $R>0$. For a distant object, $s\approx\infty$ and $\frac{1}{s}\approx 0$.

EXECUTE: **(a)** $s\approx\infty$ and $s'=2.5$ cm: $\frac{1.35}{2.5\text{ cm}}=\frac{1.35-1.00}{R}$ and $R=0.648\text{ cm}=6.48\text{ mm}$.

(b) $R=0.648$ cm and $s=25$ cm: $\frac{1.00}{25\text{ cm}}+\frac{1.35}{s'}=\frac{1.35-1.00}{0.648}$. $\frac{1.35}{s'}=0.500$ and $s'=2.70\text{ cm}=27.0\text{ mm}$. The image is formed behind the retina.

(c) Calculate s' for $s\approx\infty$ and $R=0.50$ cm: $\frac{1.35}{s'}=\frac{1.35-1.00}{0.50\text{ cm}}$. $s'=1.93\text{ cm}=19.3\text{ mm}$. The image is formed in front of the retina.

EVALUATE: The cornea alone cannot achieve focus of both close and distant objects.

34.84. IDENTIFY and SET UP: Use the lensmaker's equation $\frac{1}{f}=(n-1)\left(\frac{1}{R_1}-\frac{1}{R_2}\right)$ to calculate the focal length of the lenses. The image formed by the first lens serves at the object for the second lens. $m_{\text{tot}}=m_1m_2$. The thin-lens formula $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ gives $s'=\frac{sf}{s-f}$.

EXECUTE: **(a)** $\frac{1}{f}=(0.60)\left(\frac{1}{12.0\text{ cm}}-\frac{1}{28.0\text{ cm}}\right)$ and $f=+35.0$ cm.

<u>Lens 1:</u> $f_1=+35.0$ cm. $s_1=+45.0$ cm. $s_1'=\frac{s_1f_1}{s_1-f_1}=\frac{(45.0\text{ cm})(35.0\text{ cm})}{45.0\text{ cm}-35.0\text{ cm}}=+158\text{ cm}.$

$m_1=-\frac{s_1'}{s_1}=-\frac{158\text{ cm}}{45.0\text{ cm}}=-3.51$. $|y_1'|=|m_1|y_1=(3.51)(5.00\text{ mm})=17.6\text{ mm}$. The image of the first lens is 158 cm to the right of lens 1 and is 17.6 mm tall.

(b) The image of lens 1 is $315\text{ cm}-158\text{ cm}=157\text{ cm}$ to the left of lens 2. $f_2=+35.0$ cm.

$s_2=+157$ cm. $s_2'=\frac{s_2f_2}{s_2-f_2}=\frac{(157\text{ cm})(35.0\text{ cm})}{157\text{ cm}-35.0\text{ cm}}=+45.0\text{ cm}$. $m_2=-\frac{s_2'}{s_2}=-\frac{45.0\text{ cm}}{157\text{ cm}}=-0.287$.

$m_{\text{tot}}=m_1m_2=(-3.51)(-0.287)=+1.00$. The final image is 45.0 cm to the right of lens 2. The final image is 5.00 mm tall. $m_{\text{tot}}>0$ and the final image is erect.

EVALUATE: The final image is real. It is erect because each lens produces an inversion of the image, and two inversions return the image to the orientation of the object.

34.85. IDENTIFY: We are dealing with the image formed by a spherical refracting surface.

SET UP: $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$, $m=-\frac{n_as'}{n_bs}$. The object is in the liquid and the image is formed in air, so a is the liquid ($n_a=n=1.627$), b is air ($n_b=1.00$). Using these symbols, the equations become $\frac{n}{s}+\frac{1}{s'}=\frac{1-n}{R}$ and $m=-\frac{ns'}{s}$. Refer to Fig. P34.85 with the problem in the textbook.

EXECUTE: **(a)** We want the minimum *H*. For the device to function, s' must be positive to form a real image in the air. So $+\frac{1}{s'} = \frac{1-n}{R} - \frac{n}{s} = \frac{1-1.627}{-2.50 \text{ cm}} - \frac{1.627}{s} \geq 0.$ For the limit, we used the equality, which gives $s = 6.49$ cm. If *s* is less than this value, s' is negative, so this is the *minimum* height *H*.

(b) We want the range of object distances. s' varies from 50.0 cm to 1.00 m.

For s' = 50.0 cm: $\frac{1.627}{s} + \frac{1}{50.0 \text{ cm}} = \frac{1-1.627}{-2.50 \text{ cm}} = 0.2508 \text{ cm}^{-1},$ so s = 7.05 cm.

For s' = 1.00 m: The same procedure gives s = 6.76 cm.

Therefore the range is 6.76 cm $\leq s \leq$ 7.05 cm.

(c) We want s'. The object is halfway between the extremes in (b), so s = 6.90 cm. Using $\frac{n}{s} + \frac{1}{s'} = \frac{1-n}{R}$ gives $\frac{1}{s'} = 0.2508 \text{ cm}^{-1} - \frac{1.627}{6.90 \text{ cm}}$, so s' = 66.2 cm.

(d) We want the velocity of the image when s = 6.90 cm (at which time s' = 66.2 cm). The velocity of the image is ds'/dt. Take the time derivative of $\frac{n}{s} + \frac{1}{s'} = \frac{1-n}{R}$, which gives $\frac{ds'}{dt} = -n\left(\frac{s'}{s}\right)\frac{ds}{dt}.$ We know that $s = A\sin\omega t,$ so $ds/dt = \omega A\cos\omega t,$ which gives $\frac{ds'}{dt} = -n\left(\frac{s'}{s}\right)\omega A\cos\omega t.$ The motion varies between 6.76 cm and 7.05 cm, so the amplitude is 0.145 cm. Using $\omega = 2\pi f$ and the numerical quantities gives $\frac{ds'}{dt} = -(1.627)\left(\frac{66.2 \text{ cm}}{6.90 \text{ cm}}\right)(2\pi \text{ Hz})(0.145 \text{ cm})\cos\omega t.$ When the object is at its midpoint, $\sin\omega t = 0$, so its velocity is –1.36 m/s in the vertical direction.

(d) We want the maximum diameter of the image. $|m| = \frac{ns'}{s}.$ *m* is a maximum when s' is greatest and *s* is least. The maximum s' is 1.00 m, at which time s = 6.76 cm (from (b)), so

$$h'_{\text{max}} = hm_{\text{max}} = h\frac{ns'}{s} = (1.00 \text{ cm})(1.627)\left(\frac{100 \text{ cm}}{6.76 \text{ cm}}\right) = 24.1 \text{ cm}.$$

EVALUATE: A very small amplitude for the object motion produces a much larger amplitude for the image motion.

34.86. **IDENTIFY:** Apply $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$ and $m = -\frac{s'}{s}.$

SET UP: $s + s' = 22.0$ cm.

EXECUTE: **(a)** $\frac{1}{22.0 \text{ cm} - s'} + \frac{1}{s'} = \frac{1}{3.00 \text{ cm}}.$ $(s')^2 - (22.0 \text{ cm})s' + 66.0 \text{ cm}^2 = 0$ so $s' = 18.42$ cm or 3.58 cm. $s = 3.58$ cm or 18.42 cm, so the lens must either be 3.58 cm or 18.4 cm from the object.

(b) $s = 3.58$ cm and s' = 18.42 cm gives $m = -\frac{s'}{s} = -\frac{18.42}{3.58} = -5.15.$

$s = 18.42$ cm and s' = 3.58 cm gives $m = -\frac{s'}{s} = -\frac{3.58}{18.42} = -0.914.$

EVALUATE: Since the image is projected onto the screen, the image is real and s' is positive. We assumed this when we wrote the condition $s + s' = 22.0$ cm.

34.87. **IDENTIFY** and **SET UP:** The person's eye cannot focus on anything closer than 85.0 cm. The problem asks us to find the location of an object such that his old lenses produce a virtual image 85.0 cm from his eye. $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}.$ $P(\text{in diopters}) = 1/f\,(\text{in m}).$

EXECUTE: (a) $\dfrac{1}{f} = 2.25$ diopters so $f = 44.4$ cm. The image is 85.0 cm from his eye so is 83.0 cm from the eyeglass lens. Solving $\dfrac{1}{s}+\dfrac{1}{s'}=\dfrac{1}{f}$ for s gives $s = \dfrac{s'f}{s'-f} = \dfrac{(-83.0\text{ cm})(44.4\text{ cm})}{-83.0\text{ cm} - 44.4\text{ cm}} = +28.9$ cm.
The object is 28.9 cm from the eyeglasses so is 30.9 cm from his eyes.

(b) Now $s' = -85.0$ cm. $s = \dfrac{s'f}{s'-f} = \dfrac{(-85.0\text{ cm})(44.4\text{ cm})}{-85.0\text{ cm} - 44.4\text{ cm}} = +29.2$ cm.

EVALUATE: The old glasses allow him to focus on objects as close as about 30 cm from his eyes. This is much better than a closest distance of 85 cm with no glasses, but his current glasses probably allow him to focus as close as 25 cm.

34.88. IDENTIFY and SET UP: The thin-lens equation, $\dfrac{1}{s}+\dfrac{1}{s'}=\dfrac{1}{f}$, applies. The lens forms an image of the object on the screen, so the distance from the lens to the screen is the image distance s'. The distance from the object to the lens is s, so $s + s' = d$.

EXECUTE: We combine $\dfrac{1}{s}+\dfrac{1}{s'}=\dfrac{1}{f}$ and $s + s' = d$ to solve for d.

$s + s' = d \quad \rightarrow \quad s' = d - s.$

$\dfrac{1}{s}+\dfrac{1}{s'}=\dfrac{1}{f} \quad \rightarrow \quad s' = \dfrac{sf}{s-f} \quad \rightarrow \quad d - s = \dfrac{sf}{s-f}.$

$ds - s^2 - df + sf = sf \quad \rightarrow \quad s^2 - ds + df = 0 \quad \rightarrow \quad s = \dfrac{1}{2}(d \pm \sqrt{d^2 - 4df}).$

If $4df > d^2$, there is no real solution, so we must have $d^2 \geq 4df$. The smallest that d can be is if $d^2 = 4df$, in which case $d = 4f$.

EVALUATE: Larger values of d are possible, but we want only the smallest one.

34.89. IDENTIFY: $\dfrac{1}{s}+\dfrac{1}{s'}=\dfrac{1}{f}$ gives $s' = \dfrac{sf}{s-f}$, for both the mirror and the lens.

SET UP: For the second image, the image formed by the mirror serves as the object for the lens. For the mirror, $f_{\text{m}} = +10.0$ cm. For the lens, $f = 32.0$ cm. The center of curvature of the mirror is $R = 2f_{\text{m}} = 20.0$ cm to the right of the mirror vertex.

EXECUTE: (a) The principal-ray diagrams from the two images are sketched in Figure 34.89. In Figure 34.89b, only the image formed by the mirror is shown. This image is at the location of the candle so the principal-ray diagram that shows the image formation when the image of the mirror serves as the object for the lens is analogous to that in Figure 34.89a and is not drawn.

(b) Image formed by the light that passes directly through the lens: The candle is 85.0 cm to the left of the lens. $s' = \dfrac{sf}{s-f} = \dfrac{(85.0\text{ cm})(32.0\text{ cm})}{85.0\text{ cm} - 32.0\text{ cm}} = +51.3$ cm. $m = -\dfrac{s'}{s} = -\dfrac{51.3\text{ cm}}{85.0\text{ cm}} = -0.604$. This image is 51.3 cm to the right of the lens. $s' > 0$ so the image is real. $m < 0$ so the image is inverted. Image formed by the light that first reflects off the mirror: First consider the image formed by the mirror. The candle is 20.0 cm to the right of the mirror, so $s = +20.0$ cm.

$s' = \dfrac{sf}{s-f} = \dfrac{(20.0\text{ cm})(10.0\text{ cm})}{20.0\text{ cm} - 10.0\text{ cm}} = 20.0$ cm. $m_1 = -\dfrac{s_1'}{s_1} = -\dfrac{20.0\text{ cm}}{20.0\text{ cm}} = -1.00$. The image formed by the mirror is at the location of the candle, so $s_2 = +85.0$ cm and $s_2' = 51.3$ cm. $m_2 = -0.604$.

$m_{\text{tot}} = m_1 m_2 = (-1.00)(-0.604) = 0.604$. The second image is 51.3 cm to the right of the lens. $s_2' > 0$, so the final image is real. $m_{\text{tot}} > 0$, so the final image is erect.

EVALUATE: The two images are at the same place. They are the same size. One is erect and one is inverted.

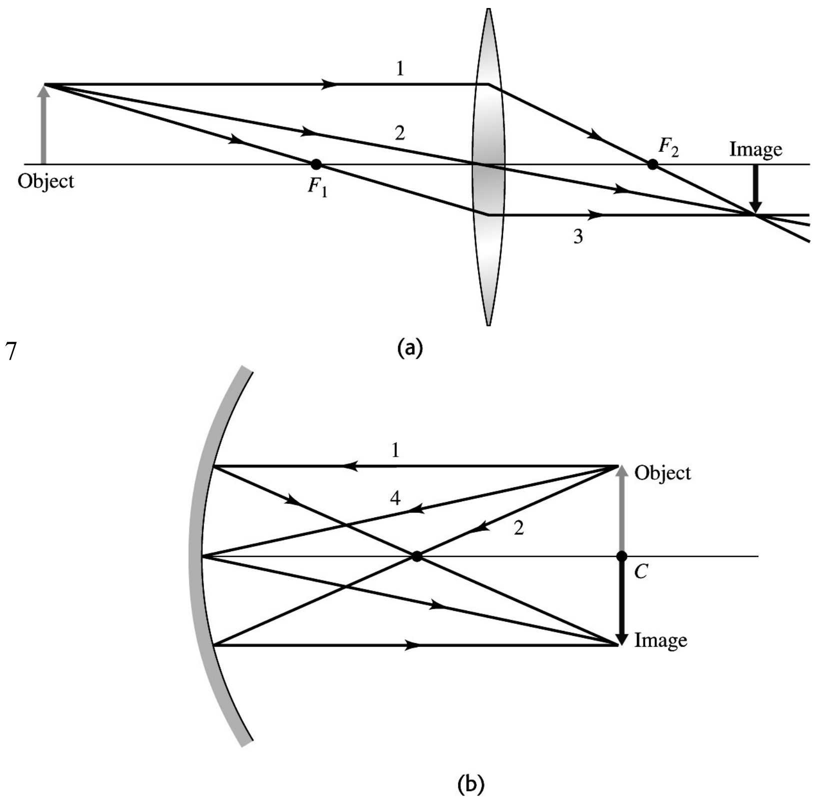

Figure 34.89

34.90. IDENTIFY: Apply $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ to each lens. The image formed by the first lens serves as the object for the second lens. The focal length of the lens combination is defined by $\frac{1}{s_1}+\frac{1}{s_2'}=\frac{1}{f}$. In part (b) use $\frac{1}{f}=(n-1)\left(\frac{1}{R_1}-\frac{1}{R_2}\right)$ to calculate f for the meniscus lens and for the CCl_4, treated as a thin lens.

SET UP: With two lenses of different focal length in contact, the image distance from the first lens becomes exactly minus the object distance for the second lens.

EXECUTE: **(a)** $\frac{1}{s_1}+\frac{1}{s_1'}=\frac{1}{f_1}\Rightarrow\frac{1}{s_1'}=\frac{1}{f_1}-\frac{1}{s_1}$ and $\frac{1}{s_2}+\frac{1}{s_2'}=\frac{1}{-s_1'}+\frac{1}{s_2'}=\left(\frac{1}{s_1}-\frac{1}{f_1}\right)+\frac{1}{s_2'}=\frac{1}{f_2}$. But overall for the lens system, $\frac{1}{s_1}+\frac{1}{s_2'}=\frac{1}{f}\Rightarrow\frac{1}{f}=\frac{1}{f_2}+\frac{1}{f_1}$.

(b) With carbon tetrachloride sitting in a meniscus lens, we have two lenses in contact. All we need in order to calculate the system's focal length is calculate the individual focal lengths, and then use the formula from part (a). For the meniscus lens

$$\frac{1}{f_m}=(n_b-n_a)\left(\frac{1}{R_1}-\frac{1}{R_2}\right)=(0.55)\left(\frac{1}{4.50\text{ cm}}-\frac{1}{9.00\text{ cm}}\right)=0.061\text{ cm}^{-1}\text{ and }f_m=16.4\text{ cm}.$$

For the CCl_4: $\dfrac{1}{f_w} = (n_b - n_a)\left(\dfrac{1}{R_1} - \dfrac{1}{R_2}\right) = (0.46)\left(\dfrac{1}{9.00\text{ cm}} - \dfrac{1}{\infty}\right) = 0.051\text{ cm}^{-1}$ and $f_w = 19.6$ cm.

$\dfrac{1}{f} = \dfrac{1}{f_w} + \dfrac{1}{f_m} = 0.112\text{ cm}^{-1}$ and $f = 8.93$ cm.

EVALUATE: $f = \dfrac{f_1 f_2}{f_1 + f_2}$, so f for the combination is less than either f_1 or f_2.

34.91. **IDENTIFY:** Apply $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$.

SET UP: The image formed by the converging lens is 30.0 cm from the converging lens, and becomes a virtual object for the diverging lens at a position 15.0 cm to the right of the diverging lens. The final image is projected $15\text{ cm} + 19.2\text{ cm} = 34.2\text{ cm}$ from the diverging lens.

EXECUTE: $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f} \Rightarrow \dfrac{1}{-15.0\text{ cm}} + \dfrac{1}{34.2\text{ cm}} = \dfrac{1}{f} \Rightarrow f = -26.7$ cm.

EVALUATE: Our calculation yields a negative value of f, which should be the case for a diverging lens.

34.92. **IDENTIFY:** Start with the two formulas right after the beginning of the section in the textbook on the lensmaker's equation: $\dfrac{n_a}{s_1} + \dfrac{n_b}{s_1'} = \dfrac{n_b - n_a}{R_1}$ and $\dfrac{n_b}{s_2} + \dfrac{n_c}{s_2'} = \dfrac{n_c - n_b}{R_2}$.

SET UP: The lens is surrounded by a liquid, so $n_a = n_c = n_{liq}$ and $n_b = n$ (for the lens), and $s_2 = -s_1'$.

EXECUTE: **(a)** Putting in the quantities indicated above, the two starting equations become $\dfrac{n_{liq}}{s_1} + \dfrac{n}{-s_2} = \dfrac{n - n_{liq}}{R_1}$ and $\dfrac{n}{s_2} + \dfrac{n_{liq}}{s_2'} = \dfrac{n_{liq} - n}{R_2}$. Add these two equations to eliminate n/s_2, giving $\dfrac{n_{liq}}{s_1} + \dfrac{n_{liq}}{s_2'} = (n - n_{liq})\left(\dfrac{1}{R_1} - \dfrac{1}{R_2}\right)$. Dividing by n_{liq} gives $\dfrac{1}{s_1} + \dfrac{1}{s_2'} = \left(\dfrac{n}{n_{liq}} - 1\right)\left(\dfrac{1}{R_1} - \dfrac{1}{R_2}\right)$, which gives $\dfrac{1}{s_1} + \dfrac{1}{s_2'} = \left(\dfrac{n}{n_{liq}} - 1\right)\left(\dfrac{1}{R_1} - \dfrac{1}{R_2}\right)$. Therefore $\dfrac{1}{f_{liq}} = \left(\dfrac{n}{n_{liq}} - 1\right)\left(\dfrac{1}{R_1} - \dfrac{1}{R_2}\right)$, where f_{liq} is the focal length of the lens when it is immersed in the liquid.

(b) Take the ratio of $1/f_{liq}$ to $1/f_{air}$: $\dfrac{\dfrac{1}{f_{liq}}}{\dfrac{1}{f_{air}}} = \dfrac{\left(\dfrac{n}{n_{liq}} - 1\right)\left(\dfrac{1}{R_1} - \dfrac{1}{R_2}\right)}{(n-1)\left(\dfrac{1}{R_1} - \dfrac{1}{R_2}\right)}$. Now solve for f_{liq}, giving $f_{liq} = f_{air}\left(\dfrac{n-1}{n/n_{liq} - 1}\right) = (18.0\text{ cm})\left(\dfrac{1.60 - 1}{1.60/1.42 - 1}\right) = +85.2$ cm.

EVALUATE: In part (b) we saw that immersing a lens in a liquid can change its focal length considerably. But even more extreme behavior can result. If the "liquid" is air, $\dfrac{1}{f_{air}} = (n-1)\left(\dfrac{1}{R_1} - \dfrac{1}{R_2}\right)$, and the factor $(n - 1)$ is always positive. But if the liquid has an index of refraction greater than that of the lens material, then $n/n_{liq} < 1$, so the factor $(n/n_{liq} - 1)$ is negative. This means that f changes sign from what it was in air. In other words, submerging a converging lens in a liquid can turn it into a diverging lens, and vice versa!

34.93. **IDENTIFY:** The spherical mirror forms an image of the object. It forms another image when the image of the plane mirror serves as an object.

SET UP: For the convex mirror $f = -24.0$ cm. The image formed by the plane mirror is 10.0 cm to the right of the plane mirror, so is $20.0\text{ cm} + 10.0\text{ cm} = 30.0\text{ cm}$ from the vertex of the spherical mirror.

EXECUTE: The first image formed by the spherical mirror is the one where the light immediately strikes its surface, without bouncing from the plane mirror.

$\frac{1}{s}+\frac{1}{s'}=\frac{1}{f} \Rightarrow \frac{1}{10.0\text{ cm}}+\frac{1}{s'}=\frac{1}{-24.0\text{ cm}} \Rightarrow s' = -7.06$ cm, and the image height is

$y' = -\frac{s'}{s}y = -\frac{-7.06}{10.0}(0.250\text{ cm}) = 0.177$ cm.

The image of the object formed by the plane mirror is located 30.0 cm from the vertex of the spherical mirror. $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f} \Rightarrow \frac{1}{30.0\text{ cm}}+\frac{1}{s'}=\frac{1}{-24.0\text{ cm}} \Rightarrow s' = -13.3$ cm and the image height is

$y' = -\frac{s'}{s}y = -\frac{-13.3}{30.0}(0.250\text{ cm}) = 0.111$ cm.

EVALUATE: Other images are formed by additional reflections from the two mirrors.

34.94. **IDENTIFY:** The smallest image we can resolve occurs when the image is the size of a retinal cell.

SET UP: $m = -\frac{s'}{s} = \frac{y'}{y}$. $s' = 2.50$ cm.

$|y'| = 5.0\ \mu\text{m}$. The angle subtended (in radians) is height divided by distance from the eye.

EXECUTE: **(a)** $m = -\frac{s'}{s} = -\frac{2.50\text{ cm}}{25\text{ cm}} = -0.10$. $y = \left|\frac{y'}{m}\right| = \frac{5.0\ \mu\text{m}}{0.10} = 50\ \mu\text{m}$.

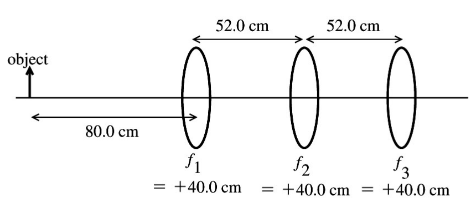
(b) $\theta = \frac{y}{s} = \frac{50\ \mu\text{m}}{25\text{ cm}} = \frac{50\times10^{-6}\text{ m}}{25\times10^{-2}\text{ m}} = 2.0\times10^{-4}\text{ rad} = 0.0115° = 0.69\text{ min}$. This is only a bit smaller than the typical experimental value of 1.0 min.

EVALUATE: The angle subtended by the object equals the angular size of the image,

$\frac{|y'|}{s'} = \frac{5.0\times10^{-6}\text{ m}}{2.50\times10^{-2}\text{ m}} = 2.0\times10^{-4}$ rad.

34.95. **IDENTIFY:** Apply the thin-lens equation to calculate the image distance for each lens. The image formed by the first lens serves as the object for the second lens, and the image formed by the second lens serves as the object for the third lens.

SET UP: The positions of the object and lenses are shown in Figure 34.95.



$\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$.

$\frac{1}{s'}=\frac{1}{f}-\frac{1}{s}=\frac{s-f}{sf}$.

$s'=\frac{sf}{s-f}$.

Figure 34.95

EXECUTE: Lens #1:
$s = +80.0$ cm; $f = +40.0$ cm.

$$s' = \frac{sf}{s-f} = \frac{(+80.0\text{ cm})(+40.0\text{ cm})}{+80.0\text{ cm} - 40.0\text{ cm}} = +80.0\text{ cm}.$$

The image formed by the first lens is 80.0 cm to the right of the first lens, so it is $80.0\text{ cm} - 52.0\text{ cm} = 28.0\text{ cm}$ to the right of the second lens.

Lens #2:
$s = -28.0$ cm; $f = +40.0$ cm.

$$s' = \frac{sf}{s-f} = \frac{(-28.0\text{ cm})(+40.0\text{ cm})}{-28.0\text{ cm} - 40.0\text{ cm}} = +16.47\text{ cm}.$$

The image formed by the second lens is 16.47 cm to the right of the second lens, so it is $52.0\text{ cm} - 16.47\text{ cm} = 35.53\text{ cm}$ to the left of the third lens.

Lens #3:
$s = +35.53$ cm; $f = +40.0$ cm.

$$s' = \frac{sf}{s-f} = \frac{(+35.53\text{ cm})(+40.0\text{ cm})}{+35.53\text{ cm} - 40.0\text{ cm}} = -318\text{ cm}.$$

The final image is 318 cm to the left of the third lens, so it is $318\text{ cm} - 52\text{ cm} - 52\text{ cm} - 80\text{ cm} = 134\text{ cm}$ to the left of the object.

EVALUATE: We used the separation between the lenses and the sign conventions for s and s' to determine the object distances for the second and third lenses. The final image is virtual since the final s' is negative.

34.96. **IDENTIFY:** Apply $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$ and calculate s' for each s.

SET UP: $f = 90$ mm.

EXECUTE: $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f} \Rightarrow \frac{1}{1300\text{ mm}} + \frac{1}{s'} = \frac{1}{90\text{ mm}} \Rightarrow s' = 96.7$ mm.

$\frac{1}{s} + \frac{1}{s'} = \frac{1}{f} \Rightarrow \frac{1}{6500\text{ mm}} + \frac{1}{s'} = \frac{1}{90\text{ mm}} \Rightarrow s' = 91.3$ mm.

$\Rightarrow \Delta s' = 96.7\text{ mm} - 91.3\text{ mm} = 5.4$ mm toward the sensor.

EVALUATE: $s' = \frac{sf}{s-f}$. For $f > 0$ and $s > f$, s' decreases as s increases.

34.97. **IDENTIFY:** Apply $\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$. The near point is at infinity, so that is where the image must be formed for any objects that are close.

SET UP: The power in diopters equals $\frac{1}{f}$, with f in meters.

EXECUTE: $\frac{1}{f} = \frac{1}{s} + \frac{1}{s'} = \frac{1}{24\text{ cm}} + \frac{1}{-\infty} = \frac{1}{0.24\text{ m}} = 4.17$ diopters.

EVALUATE: To focus on closer objects, the power must be increased.

34.98. **IDENTIFY:** Apply $\frac{n_a}{s} + \frac{n_b}{s'} = \frac{n_b - n_a}{R}$.

SET UP: $n_a = 1.00$, $n_b = 1.40$.

EXECUTE: $\frac{1}{36.0\text{ cm}} + \frac{1.40}{s'} = \frac{0.40}{0.75\text{ cm}} \Rightarrow s' = 2.77$ cm.

EVALUATE: This distance is greater than for the normal eye, which has a cornea vertex to retina distance of about 2.6 cm.

34.99. IDENTIFY: Use similar triangles in Figure P34.99 in the textbook and $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ to derive the expressions called for in the problem.

(a) SET UP: The effect of the converging lens on the ray bundle is sketched in Figure 34.99a.

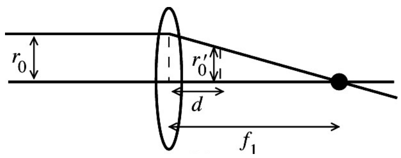


Figure 34.99a

EXECUTE: From similar triangles in Figure 34.99a, $\frac{r_0}{f_1}=\frac{r_0'}{f_1-d}$.

Thus $r_0'=\left(\frac{f_1-d}{f_1}\right)r_0$, as was to be shown.

(b) SET UP: The image at the focal point of the first lens, a distance f_1 to the right of the first lens, serves as the object for the second lens. The image is a distance f_1-d to the right of the second lens, so $s_2=-(f_1-d)=d-f_1$.

EXECUTE: $s_2'=\frac{s_2f_2}{s_2-f_2}=\frac{(d-f_1)f_2}{d-f_1-f_2}$.

$f_2<0$ so $|f_2|=-f_2$ and $s_2'=\frac{(f_1-d)|f_2|}{|f_2|-f_1+d}$, as was to be shown.

(c) SET UP: The effect of the diverging lens on the ray bundle is sketched in Figure 34.99b.

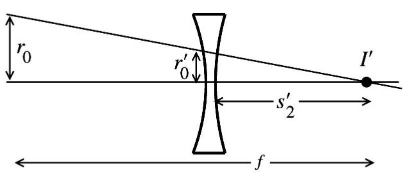

Figure 34.99b

EXECUTE: From similar triangles in the sketch, $\frac{r_0}{f}=\frac{r_0'}{s_2'}$.

Thus $\frac{r_0}{r_0'}=\frac{f}{s_2'}$.

From the results of part (a), $\frac{r_0}{r_0'}=\frac{f_1}{f_1-d}$. Combining the two results gives $\frac{f_1}{f_1-d}=\frac{f}{s_2'}$.

$f=s_2'\left(\frac{f_1}{f_1-d}\right)=\frac{(f_1-d)|f_2|f_1}{(|f_2|-f_1+d)(f_1-d)}=\frac{f_1|f_2|}{|f_2|-f_1+d}$, as was to be shown.

(d) SET UP: Put the numerical values into the expression derived in part (c).

EXECUTE: $f=\frac{f_1|f_2|}{|f_2|-f_1+d}$.

$f_1=12.0\text{ cm}$, $|f_2|=18.0\text{ cm}$, so $f=\frac{216\text{ cm}^2}{6.0\text{ cm}+d}$.

$d=0$ gives $f=36.0\text{ cm}$; maximum f.

$d = 4.0$ cm gives $f = 21.6$ cm; minimum f.

$f = 30.0$ cm says $30.0\text{ cm} = \dfrac{216\text{ cm}^2}{6.0\text{ cm} + d}$.

$6.0\text{ cm} + d = 7.2$ cm and $d = 1.2$ cm.

EVALUATE: Changing d produces a range of effective focal lengths. The effective focal length can be both smaller and larger than $f_1 + |f_2|$.

34.100. **IDENTIFY:** For u and u' as defined in Figure P34.100 in the textbook, $M = \dfrac{u'}{u}$.

SET UP: f_2 is negative. From Figure P34.100 in the textbook, the length of the telescope is $f_1 + f_2$, since f_2 is negative.

EXECUTE: **(a)** From the figure, $u = \dfrac{y}{f_1}$ and $u' = \dfrac{y}{|f_2|} = -\dfrac{y}{f_2}$. The angular magnification is

$M = \dfrac{u'}{u} = -\dfrac{f_1}{f_2}$.

(b) $M = -\dfrac{f_1}{f_2} \Rightarrow f_2 = -\dfrac{f_1}{M} = -\dfrac{95.0\text{ cm}}{6.33} = -15.0\text{ cm}$.

(c) The length of the telescope is $95.0\text{ cm} - 15.0\text{ cm} = 80.0\text{ cm}$, compared to the length of 110 cm for the telescope in Exercise 34.61.

EVALUATE: An advantage of this construction is that the telescope is somewhat shorter.

34.101. **IDENTIFY:** The thin-lens formula applies. The converging lens forms a real image on its right side. This image acts as the object for the diverging lens. The image formed by the converging lens is on the right side of the diverging lens, so this image acts as a *virtual object* for the diverging lens and its object distance is *negative*.

SET UP: Apply $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$ in each case. $m = -\dfrac{s'}{s}$. The total magnification of two lenses is $m_{\text{tot}} = m_1 m_2$.

EXECUTE: **(a)** For the first trial on the diverging lens, we have
s = 20.0 cm – 29.7 cm = –9.7 cm and s' = 42.8 cm – 20.0 cm = 22.8 cm.

$$\frac{1}{f} = \frac{1}{s} + \frac{1}{s'} = \frac{1}{-9.7\text{ cm}} + \frac{1}{22.8\text{ cm}} \quad \rightarrow \quad f = -16.88\text{ cm}.$$

For the second trial on the diverging lens, we have
s = 25.0 cm – 29.7 cm = –4.7 cm and s' = 31.6 cm – 25.0 cm = 6.6 cm.

$$\frac{1}{f} = \frac{1}{s} + \frac{1}{s'} = \frac{1}{-4.7\text{ cm}} + \frac{1}{6.6\text{ cm}} \quad \rightarrow \quad f = -16.33\text{ cm}.$$

Taking the average of the focal lengths, we get f_{av} = (–16.88 cm – 16.33 cm)/2 = –16.6 cm.

(b) The total magnification is $m_{\text{tot}} = m_1 m_2$. The converging lens does not move during the two trials, so m_1 is the same for both of them. But m_2 does change.

At 20.0 cm: $m = -\dfrac{s'}{s}$ = –(22.8 cm)/(–9.7 cm) = +2.35.

At 25.0 cm: $m = -\dfrac{s'}{s}$ = –(6.6 cm)/(–4.7 cm) = +1.40.

The magnification is greater when the lens is at 20.0 cm.

EVALUATE: This is a case where a diverging lens can form a real image, but only when it is used in conjunction with one or more other lenses.

34.102. IDENTIFY and SET UP: The formulas $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ and $m=-\frac{s'}{s}$ both apply for the mirror.

EXECUTE: **(a)** Combining the two formula above and eliminating s' gives $s=f-f\left(\frac{1}{m}\right)$. Therefore a graph of s versus $1/m$ should be a straight line having a slope equal to $-f$.

(b) Using the points (–1.8, 70 cm) and (–0.2, 30 cm) on the graph, we calculate the slope to be

slope = $\frac{30\text{ cm} - 70\text{ cm}}{-0.2+1.8} = -25\text{ cm} = -f$, so f = 25 cm.

(c) The image is inverted, so the magnification is negative. The image is twice as high as the object, so the magnification has magnitude 2. Combining these conditions tells us that $m = -2$, so $1/m = -1/2$. Using our equation, we have s = 25 cm – (25 cm)(–1/2) = 37.5 cm.

(d) Since m is negative, we can write our formula for s as $s=f+f\left(\frac{1}{|m|}\right)$. To increase the size of the image, we must increase the magnitude of the magnification, which means we must decrease $1/|m|$. To do this, we must make s smaller, so we must move the object *closer* to the mirror. If we want m to be –3, our equation for s gives us s = 25 cm – 24 cm (–1/3) = 33.3 cm. This result agrees with our reasoning that we must move the object closer to the mirror.

(e) As $s \to 25$ cm, the object is approaching the focal point of the mirror, so $s' \to \infty$. Therefore $m=-\frac{s'}{s} \to \infty$, so $1/m \to 0$.

(f) When $s < 25$ cm and $m > 0$, the image distance is negative, so the image is virtual and therefore cannot be seen on a screen. Only real images can be focused on a screen.

EVALUATE: According to our equation $s=f-f\left(\frac{1}{m}\right)$ in (a), as $1/m \to 0$, $s \to f$. By extending our graph downward and to the left, we see that s does approach 25 cm as $1/m$ approaches zero, so 25 cm should be the focal length. This agrees with our result in (b).

34.103. IDENTIFY and SET UP: We measure s and s'. The equation $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$ applies. In this case, n_a = 1.00 for air and $n_b = n$.

EXECUTE: **(a)** In this case, the equation $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$ becomes $\frac{1}{s}+\frac{n}{s'}=\frac{n-1}{R}$. Solving for $1/s'$ gives $\frac{1}{s'}=\frac{n-1}{nR}-\frac{1}{n}\cdot\frac{1}{s}$. Therefore a graph of $1/s'$ versus $1/s$ should be a straight line having slope equal to $-1/n$ and a y-intercept equal to $(n-1)/nR$. Figure 34.103 shows the graph of the data from the table in the problem.

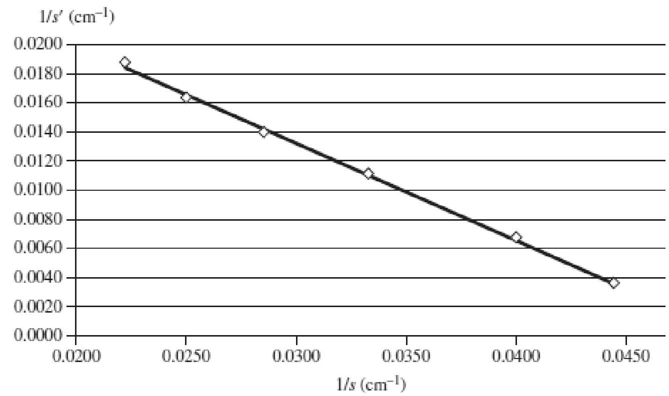

Figure 34.103

(b) The equation of the best-fit graph of the data is $\frac{1}{s'} = -(0.6666)\frac{1}{s} + 0.0333\text{ cm}^{-1}$. From this we have

slope = –1/n $\rightarrow$ n = –1/(slope) = –1/(–0.6666) = 1.50.

Using the y-intercept, we have y-intercept = (n – 1)/nR. Solving for R gives

$R = (n-1)/[n(y\text{-intercept})] = (1.50-1)/[(1.50)(0.03333\text{ cm}^{-1})] = 10.0\text{ cm}$.

(c) Using our equation from the graph $\frac{1}{s'} = -(0.6666)\frac{1}{s} + 0.0333\text{ cm}^{-1}$, we have

$$\frac{1}{s'} = -(0.6666)\frac{1}{15.0\text{ cm}} + 0.0333\text{ cm}^{-1} \quad \rightarrow \quad s' = -90\text{ cm}.$$

The image is 90 cm in front of the glass and is virtual.

EVALUATE: An index of refraction of n = 1.50 for glass is very reasonable.

34.104. **IDENTIFY:** We are dealing with a parabolic mirror.

SET UP and **EXECUTE:** Refer to Fig. P34.104 with the problem in the textbook. **(a)** We want the slope at $x = r$. $y = ax^2$, so the slope is $dy/dx = 2ax$. At $x = r$, the slope is $2ar$.

(b) We want the slope of the dashed line at $x = r$. If two lines are perpendicular, we know from analytic geometry their slopes m_1 and m_2 are related by $m_1m_2 = -1$. So $m_2 = -\frac{1}{m_1} = -\frac{1}{2ar}$.

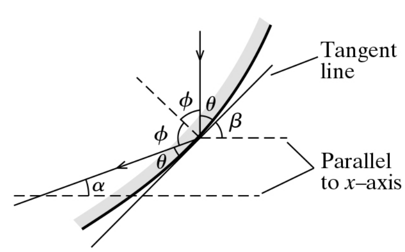

Figure 34.104

(c) We want to find ϕ. See Fig. 34.104 for the geometry. We have drawn the tangent line to the curve. The two horizontal dashed lines are parallel to the x-axis, so $\tan\beta$ is the slope of the tangent line. The tangent line is perpendicular to the normal, so $\phi + \theta = 90°$. The x- and y-axes are perpendicular to each other, so $\theta + \beta = 90°$. Therefore $\phi = \beta$, so $\tan\phi$ is the slope of the tangent line. Thus $\tan\phi = 2ar$, which gives $\phi = \arctan(2ar)$.

(d) We want α. Refer to Fig. 34.104. In the triangle involving α, the obtuse angle is $180° - \beta$. The sum of the angles in a triangle is 180°, so $\alpha + \theta + (180° - \beta) = 180°$, which means that $\alpha + \theta - \beta) = 0°$. From part (c), we have $\theta = 90° - \beta$, so $\alpha = 2\beta - 90°$. But $\beta = \phi$, so $\alpha = 2\phi - 90°$.

(e) We want b. $\tan\alpha = b/r$ and $\tan\alpha = \tan(2\phi - 90°) = -\cot 2\phi$. Equating gives $\cot 2\phi = -b/r$. Using the identity $\cot 2\phi = \dfrac{\cot^2\phi - 1}{2\cot\phi}$, we have $\dfrac{\cot^2\phi - 1}{2\cot\phi} = -\dfrac{b}{r}$. Rearranging gives $-\dfrac{2b}{r} = -\tan\phi + \dfrac{1}{\tan\phi}$. But $\tan\phi$ is the slope of the graph at $x = r$, which is $2ar$, so we have $\dfrac{2b}{r} = 2ar - \dfrac{1}{2ar}$. Solving for b gives $b = ar^2 - \dfrac{1}{4a}$.

(f) We want f. Refer to Fig. P34.104 in the textbook. At $x = r$, $y = ar^2$ and $f + b = y = ar^2$. Using b from part (e) gives $f + \left(ar^2 - \dfrac{1}{4a}\right) = ar^2$. Solving for f gives $f = 1/4a$.

EVALUATE: Since f is independent of r, it has this value for *all r*. This means that all rays go to the same point, so there is no spherical aberration.

34.105. IDENTIFY: The distance between image and object can be calculated by taking the derivative of the separation distance and minimizing it.

SET UP: For a real image $s' > 0$ and the distance between the object and the image is $D = s + s'$. For a real image must have $s > f$.

EXECUTE: **(a)** $D = s + s'$ but $s' = \dfrac{sf}{s-f} \Rightarrow D = s + \dfrac{sf}{s-f} = \dfrac{s^2}{s-f}$.

$\dfrac{dD}{ds} = \dfrac{d}{ds}\left(\dfrac{s^2}{s-f}\right) = \dfrac{2s}{s-f} - \dfrac{s^2}{(s-f)^2} = \dfrac{s^2 - 2sf}{(s-f)^2} = 0$. $s^2 - 2sf = 0$. $s(s-2f) = 0$. $s = 2f$ is the solution for which $s > f$. For $s = 2f$, $s' = 2f$. Therefore, the minimum separation is $2f + 2f = 4f$.

(b) A graph of D/f versus s/f is sketched in Figure 34.105. Note that the minimum does occur for $D = 4f$.

EVALUATE: If, for example, $s = 3f/2$, then $s' = 3f$ and $D = s + s' = 4.5f$, greater than the minimum value.

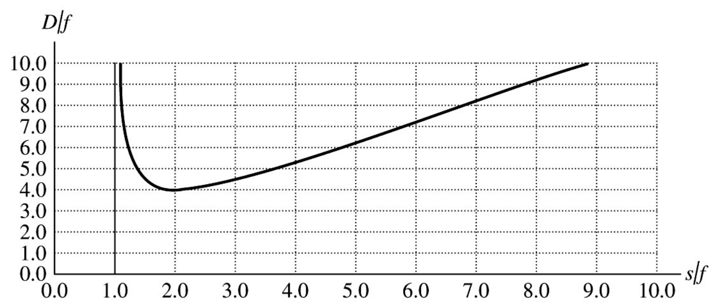

Figure 34.105

34.106. IDENTIFY: Use $\dfrac{1}{s} + \dfrac{1}{s'} = \dfrac{1}{f}$ to calculate s' (the distance of each point from the lens), for points A, B, and C.

SET UP: The object and lens are shown in Figure 34.106a.

EXECUTE: **(a)** For point C: $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f} \Rightarrow \frac{1}{45.0\text{ cm}}+\frac{1}{s'}=\frac{1}{20.0\text{ cm}} \Rightarrow s'=36.0\text{ cm}.$

$y'=-\frac{s'}{s}y=-\frac{36.0}{45.0}(15.0\text{ cm})=-12.0\text{ cm},$ so the image of point C is 36.0 cm to the right of the lens, and 12.0 cm below the axis.

For point A: $s=45.0\text{ cm}+(8.00\text{ cm})(\cos 45°)=50.7\text{ cm}.$

$\frac{1}{s}+\frac{1}{s'}=\frac{1}{f} \Rightarrow \frac{1}{50.7\text{ cm}}+\frac{1}{s'}=\frac{1}{20.0\text{ cm}} \Rightarrow s'=33.0\text{ cm}.$

$y'=-\frac{s'}{s}y=-\frac{33.0}{45.0}[15.0\text{ cm}-(8.00\text{ cm})(\sin 45°)]=-6.10\text{ cm},$ so the image of point A is 33.0 cm to the right of the lens, and 6.10 cm below the axis.

For point B: $s=45.0\text{ cm}-(8.00\text{ cm})(\cos 45°)=39.3\text{ cm}.$

$\frac{1}{s}+\frac{1}{s'}=\frac{1}{f} \Rightarrow \frac{1}{39.3\text{ cm}}+\frac{1}{s'}=\frac{1}{20.0\text{ cm}} \Rightarrow s'=40.7\text{ cm}.$

$y'=-\frac{s'}{s}y=-\frac{40.7}{39.3}[15.0\text{ cm}+(8.00\text{ cm})(\sin 45°)]=-21.4\text{ cm},$ so the image of point B is 40.7 cm to the right of the lens, and 21.4 cm below the axis. The image is shown in Figure 34.106b.

(b) The length of the pencil is the distance from point A to B:

$L=\sqrt{(x_A-x_B)^2+(y_A-y_B)^2}=\sqrt{(33.0\text{ cm}-40.7\text{ cm})^2+(6.10\text{ cm}-21.4\text{ cm})^2}=17.1\text{ cm}$

EVALUATE: The image is below the optic axis and is larger than the object.

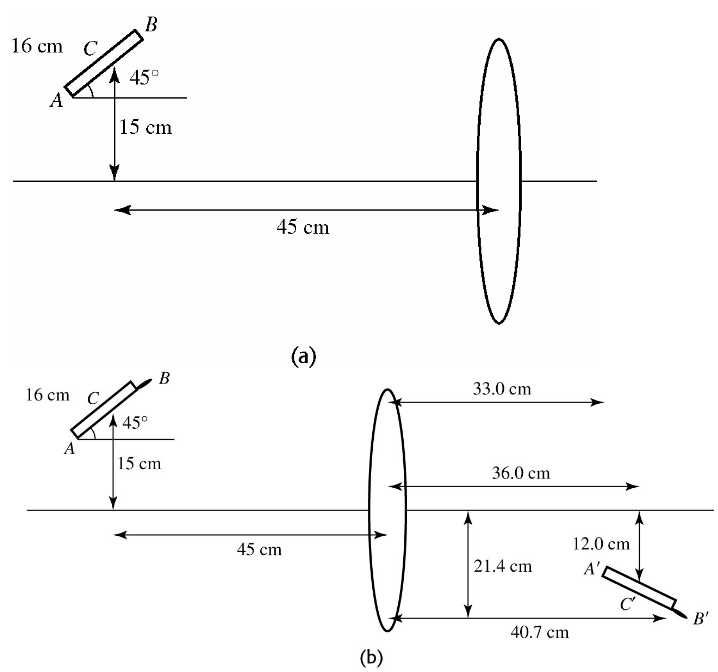

Figure 34.106

34.107. **IDENTIFY:** Apply $\frac{n_a}{s}+\frac{n_b}{s'}=\frac{n_b-n_a}{R}$ to refraction at the cornea to find where the object for the cornea must be in order for the image to be at the retina. Then use $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ to calculate *f* so that the lens produces an image of a distant object at this point.

SET UP: For refraction at the cornea, $n_a=1.333$ and $n_b=1.40$. The distance from the cornea to the retina in this model of the eye is 2.60 cm. From Problem 34.52, $R=0.710$ cm.

EXECUTE: **(a)** People with normal vision cannot focus on distant objects under water because the image is unable to be focused in a short enough distance to form on the retina. Equivalently, the radius of curvature of the normal eye is about five or six times too great for focusing at the retina to occur.

(b) When introducing glasses, let's first consider what happens at the eye:

$\frac{n_a}{s_2}+\frac{n_b}{s_2'}=\frac{n_b-n_a}{R}\Rightarrow\frac{1.333}{s_2}+\frac{1.40}{2.6\text{ cm}}=\frac{0.067}{0.71\text{ cm}}\Rightarrow s_2=-3.00\text{ cm}$. That is, the object for the cornea must be 3.00 cm behind the cornea. Now, assume the glasses are 2.00 cm in front of the eye, so $s_1'=2.00\text{ cm}+|s_2|=5.00\text{ cm}$. $\frac{1}{s_1}+\frac{1}{s_1'}=\frac{1}{f_1'}$ gives $\frac{1}{\infty}+\frac{1}{5.00\text{ cm}}=\frac{1}{f_1'}$ and $f_1'=5.00\text{ cm}$. This is the focal length in water, but to get it in air, we use the formula from Problem 34.92:

$$f_1=f_1'\left[\frac{n-n_{\text{liq}}}{n_{\text{liq}}(n-1)}\right]=(5.00\text{ cm})\left[\frac{1.62-1.333}{1.333(1.62-1)}\right]=1.74\text{ cm}.$$

EVALUATE: A converging lens is needed.

34.108. **IDENTIFY** and **SET UP:** Apply the thin-lens formula $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ to the eye and calculate s' in both cases. The focal length stays the same.

EXECUTE: At 10 cm: $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}=\frac{1}{10\text{ cm}}+\frac{1}{0.8\text{ cm}}$. At 15 cm: $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}=\frac{1}{15\text{ cm}}+\frac{1}{s'}$. Equate the two expressions for 1/*f* and solve for s'.

$$\frac{1}{15\text{ cm}}+\frac{1}{s'}=\frac{1}{10\text{ cm}}+\frac{1}{0.8\text{ cm}}\quad\rightarrow\ s'=0.779\text{ cm}.$$

The distance the lens must move is 0.8 cm – 0.779 cm = 0.021 cm ≈ 0.02 cm, which is choice (a).

EVALUATE: This is a very small distance to move, but the eye of a frog is also very small, so the result seems plausible.

34.109. **IDENTIFY** and **SET UP:** Apply the thin-lens formula $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$ to the eye. The lens power in diopters is 1/*f* (in m). For the corrected eye, the image is at infinity, and it would take –6.0 D to correct the frog's vision so it could see at infinity.

EXECUTE: Using $\frac{1}{f}=\frac{1}{s}+\frac{1}{s'}$ gives $-6.0\text{ m}^{-1}=1/s+1/\infty=1/s$, so $s=0.17$ m = 17 cm, which makes choice (d) the correct one.

EVALUATE: It is reasonable for a fog to see clearly up to only 17 cm since its food consists of insects, which must be fairly close to get caught.

34.110. IDENTIFY and SET UP: Apply Snell's law, $n_a \sin\theta_a = n_b \sin\theta_b$, at the cornea.

EXECUTE: From $n_a \sin\theta_a = n_b \sin\theta_b$, we have $\sin\theta_b = (n_b/n_a)\sin\theta_a$. When n_a and n_b are closer to each other, θ_b is closer to θ_a, so less refraction occurs at the cornea. This will be the case when a frog goes under water, since the refractive index of water (1.33) is closer to that of the cornea than is the refractive index of air, which is 1.00. Therefore choice (b) is correct.

EVALUATE: Frogs must adapt when they go under water. They are probably better hunters there and are better able to spot predators.

34.111. IDENTIFY and SET UP: Apply the thin-lens formula $\dfrac{1}{s}+\dfrac{1}{s'}=\dfrac{1}{f}$ to the eye. The lens power in diopters is D = 1/*f* (in m).

EXECUTE: Since *D* = 1/*f* (in m), the larger |D| the smaller *s*. So the frog with the –15-D lens could focus at a shorter distance than the frog with the –9-D lens, which is choice (b).

EVALUATE: The lens would not move the same distance with the –15-D lens as with the 9-D lens.

35

GEOMETRIC OPTICS

VP35.2.1. **IDENTIFY:** This problem is about double-slit interference of light.

SET UP: Constructive interference: $d\sin\theta_m = m\lambda$, for small angles: $y_m = R\dfrac{m\lambda}{d}$.

EXECUTE: **(a)** We want λ. For small angles we can use $y_m = R\dfrac{m\lambda}{d}$. Solve for λ_2.

$$\lambda_2 = \frac{y_2 d}{2R} = \frac{(11.4\text{ mm})(0.180\text{ mm})}{2(1500\text{ mm})} = 684\text{ nm.}$$

(b) We want the distance to the $m = -3$ fringe. This will be the same as the distance to the $m = +3$ fringe, so we can ignore the minus sign. $\dfrac{y_3}{y_2} = \dfrac{R(3\lambda/d)}{R(2\lambda/d)} = \dfrac{3}{2}$. $y_3 = (3/2)y_{-2} = (3/3)(11.4\text{ mm}) = 17.1\text{ mm}$.

EVALUATE: The small-angle approximation works only fairly close to the central maximum where bright fringes are evenly spaced.

VP35.2.2. **IDENTIFY:** This problem deals with the interference of radiowaves from two sources.

SET UP: Maxima occur when $d\sin\theta_m = m\lambda$, minima occur when $d\sin\theta_m = \left(m + \dfrac{1}{2}\right)\lambda$, $f\lambda = c$. We want the angles to the maxima and minima.

EXECUTE: **(a)** Maxima: First find λ: $\lambda = c/f = c/(1.05\text{ MHz}) = 285.7$ m. Now use $d\sin\theta_m = m\lambda$, $m = 0, \pm1, \pm2, \ldots$ Solve for $\sin\theta_m$, giving $\sin\theta_m = \dfrac{m\lambda}{d} = m\left(\dfrac{285.7\text{ m}}{810\text{ m}}\right) = 0.3527m$.

$m = 0$: $\sin\theta_0 = 0 \rightarrow \theta_0 = 0°$

$m = 1$: $\sin\theta_1 = (0.3527)(1) = 0.3527 \rightarrow \theta_1 = 20.7°$

$m = 2$: $\sin\theta_2 = (0.3527)(2) = 0.7021 \rightarrow \theta_2 = 44.9°$

$m = 3$: $\sin\theta_3 = (0.3527)(3) = 1.06 \rightarrow$ not possible

(b) Maxima: Use $d\sin\theta_m = \left(m + \dfrac{1}{2}\right)\lambda$, $m = 0, 1, 2, \ldots$

$m = 0$: $\sin\theta_0 = (0.3527)(0.500) = 0.1764 \rightarrow \theta_0 = 10.2°$

$m = 1$: $\sin\theta_1 = (0.3527)(1.5) = 0.5291 \rightarrow \theta_1 = 31.9°$

$m = 2$: $\sin\theta_2 = (0.3527)(2.5) = 0.8818 \rightarrow \theta_2 = 61.9°$

$m = 3$: $\sin\theta_3 = (0.3527)(3.5) = 1.23 \rightarrow$ not possible

EVALUATE: The minima are between the maxima, but not midway between them.

VP35.2.3. **IDENTIFY:** We have double slit interference.

SET UP: $y_m = R\dfrac{m\lambda}{d}$.

EXECUTE: **(a)** We want d. Solve $y_m = R\dfrac{m\lambda}{d}$ for d. $d = \dfrac{m\lambda R}{y_m} = \dfrac{3(685 \text{ nm})(2100 \text{ mm})}{9.15 \text{ mm}} = 0.472$ mm.

(b) We want y. $\dfrac{y_g}{y_r} = \dfrac{R\dfrac{m\lambda_g}{d}}{R\dfrac{m\lambda_r}{d}} = \dfrac{\lambda_g}{\lambda_r} = \dfrac{515 \text{ nm}}{685 \text{ nm}} = 0.7518$, so y_g = (9.15 mm)(0.7518) = 6.88 mm.

EVALUATE: Since $y \propto \lambda$, as λ decreases, the bright fringes get closer together, which agrees with our result in part (b).

VP35.2.4. **IDENTIFY:** We have double slit interference.

SET UP: $d\sin\theta_m = m\lambda$ (bright fringes), $d\sin\theta_m = \left(m + \dfrac{1}{2}\right)\lambda$ (dark spots).

EXECUTE: **(a)** We want λ. $\lambda = \dfrac{d\sin\theta_m}{m} = \dfrac{(0.370 \text{ mm})\sin(0.407°)}{4} = 657$ nm.

(b) We want θ_2 for a dark spot. $\sin\theta_2 = \dfrac{\left(2 + \dfrac{1}{2}\right)\lambda}{d} = \dfrac{(2.5)(657 \text{ nm})}{0.370 \text{ mm}}$. θ_2 = 0.254°.

EVALUATE: The bright (and dark) spots are equally spaced for small angles but not for large ones.

VP35.3.1. **IDENTIFY:** This problem is about the intensity of a two-source interference pattern.

SET UP: $I = I_0\cos^2(\phi/2)$, $\phi/2 = \pi d\sin\theta/\lambda$, $f\lambda = c$.

EXECUTE: **(a)** We want I. First find λ. $\lambda = c/f$ = c/(59.3 MHz) = 5.059 m. $\phi/2 = \pi d\sin\theta/\lambda$ = π(13.0 m)(sin 5.00°)/(5.059 m) = 0.7036 rad = 40.313°. Now use $I = I_0\cos^2(\phi/2)$ to find the intensity. $I = I_0\cos^2(\phi/2)$ = (0.0330 W/m^2) cos^2(40.313°) = = 0.0192 W/m^2.

(b) We want $\theta_{\min}$. $I = I_0\cos^2(\phi/2) = \dfrac{I_0}{2}$, so $\cos(\phi/2) = 1/\sqrt{2}$. $\phi/2$ = 45.0° = π/4 rad. $\phi/2 = \pi d\sin\theta/\lambda$ = π/4, so $\sin\theta = \lambda/4d =$ (5.059 m)/[4(13.0 m)] = 0.09729. $\theta_{\min}$ = 5.58°.

EVALUATE: At 5.00° I = 0.0192 W/m^2, which is a little more than I_0/2. So at a slightly larger angle I will equal I_0/2. This agrees with our result because we found θ = 5.58° for $I = I_0/2$.

VP35.3.2. **IDENTIFY:** This problem is about the intensity of a double-slit interference pattern.

SET UP: $I = I_0\cos^2(\phi/2)$, $\phi/2 = \pi d\sin\theta/\lambda$, for small angles $y_m = R\dfrac{m\lambda}{d}$

EXECUTE: **(a)** We want I. For small angles $\sin\theta \approx \tan\theta \approx \dfrac{y}{R}$, so $\dfrac{\phi}{2} = \dfrac{\pi d\sin\theta}{\lambda} \approx \dfrac{\pi dy}{\lambda R}$

$= \dfrac{\pi(0.230 \text{ mm})(6.50 \text{ mm})}{(655 \text{ nm})(1.75 \text{ m})} = 4.0974$ rad = 234.8°. $I = I_0\cos^2(\phi/2)$ = (0.520 W/m^2) cos^2(234.8°) = 0.173 W/m^2.

(b) We want y. $I = I_0\cos^2(\phi/2) = \dfrac{I_0}{4}$, $\cos(\phi/2) = 1/2$, so $\phi/2$ = 60° = π/3 rad. Therefore $\dfrac{\phi}{2} = \dfrac{\pi}{3} \approx \dfrac{\pi dy}{\lambda R}$, which gives $y = \dfrac{\lambda R}{3d} = \dfrac{(655 \text{ nm})(1.75 \text{ m})}{3(0.230 \text{ mm})} = 1.66$ mm.

EVALUATE: We must be careful to convert angles in radians to degrees to use most calculators.

VP35.3.3. **IDENTIFY:** This problem involves the intensity of the interference pattern of two sources of radiowaves.

SET UP: $I = I_0 \cos^2(\phi/2)$, $\phi/2 = \pi d \sin\theta/\lambda$.

EXECUTE: **(a)** We want λ. Use $I = I_0 \cos^2(\phi/2)$ and $\phi/2 = \pi d \sin\theta/\lambda$ to find ϕ and then use that to find λ. At 6.00° we have 0.0303 W/m^2 = (0.0540 W/m^2) cos^2(ϕ/2). ϕ/2 = 41.49° = 0.7241 rad. Now get λ: $\phi/2 = \pi d \sin\theta/\lambda$ gives $\lambda = \dfrac{\pi d \sin\theta}{\phi/2} = \dfrac{\pi(8.00\text{ m})\sin(6.00°)}{0.7241\text{ rad}} = 3.63\text{ m}.$

(b) We want I at θ = 12.0°. $\phi/2 = \pi d \sin\theta/\lambda$ = π(8.00 m)(sin 12.0°)/(3.63 m) = 1.440 rad = 8253°.

$I = I_0 \cos^2(\phi/2)$ = (0.0540 W/m^2) cos^2(82.53°) = 9.14×10^{-4} W/m^2.

EVALUATE: It would not be good to use the small-angle approximation in this case with θ = 12°.

VP35.3.4. **IDENTIFY:** This problem is about the intensity of a two-slit interference pattern.

SET UP: $I = I_0 \cos^2(\phi/2)$, $\phi/2 = \pi d \sin\theta/\lambda$, $\sin\theta \approx y/R$ (small-angle approximation).

EXECUTE: **(a)** We want λ. First find ϕ/2, then use it to find p using $\sin\theta \approx y/R$. $I = I_0 \cos^2(\phi/2)$ gives 0.0900I_0 = I_0 cos^2(ϕ /), so ϕ /2 = 72.54° = 1.266 rad. Now use $\phi/2 = \pi d \sin\theta/\lambda$ and solve for λ using $\sin\theta \approx y/R$. $\lambda = \dfrac{\pi d(y/R)}{\phi/2} = \dfrac{\pi(0.110\text{ mm})(10.5\text{ mm})/(5.00\text{ m})}{1.266\text{ rad}} = 573\text{ nm}.$

(b) We want y. Find $\phi/2$: 0.300I_0 = I_0 cos^2 $\phi/2$ gives $\phi/2$ = 56.79° = 0.9918 rad. Now find y. Since y will be less than 10.5 mm, we can use the small-angle approximation. Solve $\phi/2 = \pi d \sin\theta/\lambda$ for y using $\sin\theta \approx y/R$. $y = \dfrac{\lambda(\phi/2)R}{\pi d}$. Take ratios giving $\dfrac{y_2}{y_1} = \dfrac{\dfrac{\lambda(\phi_2/2)R}{\pi d}}{\dfrac{\lambda(\phi_1/2)R}{\pi d}} = \dfrac{\phi_2/2}{\phi_1/2} = \dfrac{0.9912}{1.266} = 0.7829.$

y_2 = (0.7829)(10.5 mm) = 8.22 mm.

EVALUATE: We find $y_2 < y_1$, as we expect.

VP35.6.1. **IDENTIFY:** This problem is about thin-film interference.

SET UP: Refer to Fig. 35.15 in the textbook. Call h the thickness of the paper and t the thickness at point x. A half-cycle phase shift occurs at reflection at the lower plate. The dark fringes occur at points of destructive interference, for which 2t = $m\lambda$ due to the half-cycle phase shift.

EXECUTE: **(a)** We want h. 2t = $m\lambda$, so t = $m\lambda$/2 (m = 0, 1, 2, …) As in Fig. 35.15 in the textbook, t/x = h/l, so h = lt/x = $l\,m\lambda$/2. The fringes are 1.30 mm apart. The first one is at x = 0, so the next one is at x = 1.30 mm. The m = 1 dark fringe is at t_1 = (1) λ /2 = (565 nm)/2 = 282.5 nm. So $\tan\theta = t_1/x_1 = h/l$, which gives h = lt_1/x_1 = (8.00 cm)(282.5 nm)/(1.30 mm) = 0.0174 mm.

(b) We want the fringe spacing. There is still a half-cycle phase shift at reflection because $n_{\text{glass}} > n_{\text{ethanol}}$, but $\lambda_n = \dfrac{\lambda_0}{n_{\text{ethanol}}}$. The m = 0 fringe is at x = 0. The m = 1 fringe is at x_1 (which we do not know).

2t_1 = $= \dfrac{\lambda_0}{n}$. So $t_1 = \lambda/2n$ = (565 nm)/[2(136)] = 207.7 nm. As before, $t_1/x_1 = h/l$, so $x_{-1} = t_1 l/h$. This gives x_1 = (207.7 nm)(8.00 cm)/(0.0174 mm) = 0.956 mm. This is the distance between the m = 0 fringe and the m = 1 fringe, so it is the fringe spacing.

EVALUATE: The replacement of ethanol for air made significant changes in the fringe pattern because it changed the wavelength of light in the region between the glass plates.

VP35.6.2. **IDENTIFY:** We have thin-film interference.

SET UP: We want to know which wavelengths of visible light have destructive and constructive interference. In both cases there is a half-cycle phase shift during reflection because n_{glass} is greater than both n_{air} and $n_{\text{carbon-tet}}$, so for constructive interference $2t = \left(m + \frac{1}{2}\right)\lambda_m$ and for destructive interference $2t = m\lambda_m$.

EXECUTE: **(a)** Air film. Solve for λ, which gives $\lambda_m = \frac{2t}{m + 1/2}$.

Constructive: Use $2t = \left(m + \frac{1}{2}\right)\lambda_m$.

$m = 0$: $\lambda_0 = 4t$ = 4(146 nm) = 584 nm (not visible)

$m = 1$: λ_1 = 2(146 nm)/1.5 = 194 nm (not visible)

Therefore no visible light interferes constructively.

Destructive: Use $2t = m\lambda_m$.

$m = 1$: $\lambda_1 = 2t = 292$ nm (not visible)

No visible light interferes destructively.

(b) Carbon tetrachloride film. Follow the same procedure as in (a) except $\lambda_n = \frac{\lambda_0}{1.46}$. The results are: No wavelengths interfere constructively, but λ = 426 nm interferes destructively.

EVALUATE: By varying t we could get different wavelengths to interfere.

VP35.6.3. **IDENTIFY:** We have thin-film interference.

SET UP: We want to know which wavelengths of visible light have destructive and constructive interference. In both cases there is a half-cycle phase shift during reflection because n_{plastic} is greater than both n_{air} and n_{ethanol}, so for constructive interference $2t = \left(m + \frac{1}{2}\right)\lambda_m$ and for destructive interference $2t = m\lambda_m$.

EXECUTE: **(a)** Air film. Solve for λ, which gives.

Constructive: Use $2t = \left(m + \frac{1}{2}\right)\lambda_m$.

$m = 0$: $\lambda_0 = 4t$ = 4(185 nm) = 740 nm (visible)

$m = 1$: λ_1 = 2(185 nm)/1.5 = 247 nm (not visible)

Therefore only 740 nm interferes constructively.

Destructive: Use $2t = m\lambda_m$.

$m = 1$: $\lambda_1 = 2t = 370$ nm (not visible)

No visible light interferes destructively.

(b) Carbon tetrachloride film. Follow the same procedure as in (a) except $\lambda_n = \frac{\lambda_0}{1.46}$. The results are: No wavelengths interfere constructively, but λ = 503 nm interferes destructively.

EVALUATE: We are only considering interference of rays reflected off the top and bottom of the gap between the sheets.

VP35.6.4. **IDENTIFY:** We have thin-film interference.

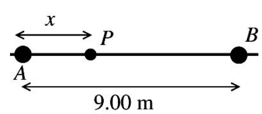
SET UP: There is a half-cycle phase reversal at the upper surface of the grease but not at the lower surface. For constructive interference $2t = \left(m + \frac{1}{2}\right)\lambda_m$, $\lambda_n = \frac{\lambda_0}{n}$.

EXECUTE: **(a)** We want the smallest possible thickness. $2t = \left(m + \frac{1}{2}\right)\lambda_m$. The minimum thickness is for $m = 0$, so $t_{\text{min}} = \lambda/4n_{\text{glass}} =$ (565 nm)/[4(1.60)] = 88.3 nm.

(b) We want the second smallest possible thickness. This is for $m = 1$. $t = \left(1+\frac{1}{2}\right)\frac{\lambda_m}{2} = 265\ \text{nm}.$

EVALUATE: The second smallest thickness is one wavelength (in the grease) greater than the smallest thickness.

35.1. **IDENTIFY:** Use $c = f\lambda$ to calculate the wavelength of the transmitted waves. Compare the difference in the distance from A to P and from B to P. For constructive interference this path difference is an integer multiple of the wavelength.
SET UP: Consider Figure 35.1.



The distance of point P from each coherent source is $r_A = x$ and $r_B = 9.00\ \text{m} - x.$

Figure 35.1

EXECUTE: The path difference is $r_B - r_A = 9.00\ \text{m} - 2x.$

$r_B - r_A = m\lambda,\ m = 0,\ \pm 1, \pm 2,\ \ldots$

$$\lambda = \frac{c}{f} = \frac{2.998\times 10^8\ \text{m/s}}{120\times 10^6\ \text{Hz}} = 2.50\ \text{m}.$$

Thus $9.00\ \text{m} - 2x = m(2.50\ \text{m})$ and $x = \dfrac{9.00\ \text{m} - m(2.50\ \text{m})}{2} = 4.50\ \text{m} - (1.25\ \text{m})m.$ x must lie in the range 0 to 9.00 m since P is said to be between the two antennas.

$m = 0$ gives $x = 4.50\ \text{m}.$
$m = +1$ gives $x = 4.50\ \text{m} - 1.25\ \text{m} = 3.25\ \text{m}.$
$m = +2$ gives $x = 4.50\ \text{m} - 2.50\ \text{m} = 2.00\ \text{m}.$
$m = +3$ gives $x = 4.50\ \text{m} - 3.75\ \text{m} = 0.75\ \text{m}.$
$m = -1$ gives $x = 4.50\ \text{m} + 1.25\ \text{m} = 5.75\ \text{m}.$
$m = -2$ gives $x = 4.50\ \text{m} + 2.50\ \text{m} = 7.00\ \text{m}.$
$m = -3$ gives $x = 4.50\ \text{m} + 3.75\ \text{m} = 8.25\ \text{m}.$

All other values of m give values of x out of the allowed range. Constructive interference will occur for $x = 0.75$ m, 2.00 m, 3.25 m, 4.50 m, 5.75 m, 7.00 m, and 8.25 m.

EVALUATE: Constructive interference occurs at the midpoint between the two sources since that point is the same distance from each source. The other points of constructive interference are symmetrically placed relative to this point.

35.2. **IDENTIFY:** For destructive interference the path difference is $(m+\frac{1}{2})\lambda,\ m = 0, \pm 1, \pm 2, \ldots.$ The longest wavelength is for $m = 0$. For constructive interference the path difference is $m\lambda,\ m = 0, \pm 1, \pm 2, \ldots.$ The longest wavelength is for $m = 1$.
SET UP: The path difference is 120 m.

EXECUTE: **(a)** For destructive interference $\dfrac{\lambda}{2} = 120\ \text{m} \Rightarrow \lambda = 240\ \text{m}.$

(b) The longest wavelength for constructive interference is $\lambda = 120\ \text{m}.$

EVALUATE: The path difference doesn't depend on the distance of point Q from B.

35.3. **IDENTIFY:** If the path difference between the two waves is equal to a whole number of wavelengths, constructive interference occurs, but if it is an odd number of half-wavelengths, destructive interference occurs.
SET UP: We calculate the distance traveled by both waves and subtract them to find the path difference.

EXECUTE: Call P_1 the distance from the right speaker to the observer and P_2 the distance from the left speaker to the observer.

(a) $P_1 = 8.0\text{ m}$ and $P_2 = \sqrt{(6.0\text{ m})^2 + (8.0\text{ m})^2} = 10.0\text{ m}$. The path distance is $\Delta P = P_2 - P_1 = 10.0\text{ m} - 8.0\text{ m} = 2.0\text{ m}$.

(b) The path distance is one wavelength, so constructive interference occurs.

(c) $P_1 = 17.0\text{ m}$ and $P_2 = \sqrt{(6.0\text{ m})^2 + (17.0\text{ m})^2} = 18.0\text{ m}$. The path difference is $18.0\text{ m} - 17.0\text{ m} = 1.0\text{ m}$, which is one-half wavelength, so destructive interference occurs.

EVALUATE: Constructive interference also occurs if the path difference $2\lambda, 3\lambda, 4\lambda,$ etc., and destructive interference occurs if it is $\lambda/2, 3\lambda/2, 5\lambda/2,$ etc.

35.4. IDENTIFY: For constructive interference the path difference d is related to λ by $d = m\lambda,\ m = 0, 1, 2, \dots$ For destructive interference $d = (m + \frac{1}{2})\lambda, m = 0, 1, 2, \dots$

SET UP: $d = 2040\text{ nm}$.

EXECUTE: **(a)** The brightest wavelengths are when constructive interference occurs:

$$d = m\lambda_m \Rightarrow \lambda_m = \frac{d}{m} \Rightarrow \lambda_3 = \frac{2040\text{ nm}}{3} = 680\text{ nm},\ \lambda_4 = \frac{2040\text{ nm}}{4} = 510\text{ nm and } \lambda_5 = \frac{2040\text{ nm}}{5} = 408\text{ nm}.$$

(b) The path-length difference is the same, so the wavelengths are the same as part (a).

(c) $d = (m + \frac{1}{2})\lambda_m$ so $\lambda_m = \dfrac{d}{m + \frac{1}{2}} = \dfrac{2040\text{ nm}}{m + \frac{1}{2}}$. The visible wavelengths are $\lambda_3 = 583\text{ nm}$ and $\lambda_4 = 453\text{ nm}$.

EVALUATE: The wavelengths for destructive interference are between those for constructive interference.

35.5. IDENTIFY: This problem is about interference of electromagnetic waves.

SET UP: For constructive interference, the path difference $r_2 - r_1$ must be equal to $m\lambda$.

EXECUTE: **(a)** How many points have constructive interference? $r_2 - r_1 = m\lambda$. Call x the distance from A, so the distance from B is $40.0\text{ m} - x$. The path difference is $(40.0\text{ m} - x) - x = 40.0\text{ m} - 2x$, so we must have $40.0\ m - 2x = m\lambda$, where $m = 0, 1, 2, \dots$. Therefore $x = 20.0\text{ m} - \dfrac{m\lambda}{2} = 20.0\text{ m} - (350\text{ m})m.$

For $m = 0$, $x = 20.0$ m, which is the midpoint between the speakers. The maximum m for a positive x is $m = 5$, for which $x = 2.50$ m. So there are 5 points between A and the midpoint. There are also 5 points on the other side of the midpoint. The total is therefore 5 + 5 + 1 = 11 points.

(b) The minimum x is for $m = 5$, so $x_{min} = 2.50$ m.

EVALUATE: There are also points at which destructive interference occurs when the path difference is an odd multiple of $\lambda/2$.

35.6. IDENTIFY: We have double-slit interference of light.

SET UP: We want the distance between the $m = 49$ and $m = 50$ maxima. $d\sin\theta_m = m\lambda$ (all angles), $y_m = R\dfrac{m\lambda}{d}$ (small angles), $y_m = R\tan\theta_m$.

EXECUTE: First find the slit spacing d. Near the center we can use $y_m = R\dfrac{m\lambda}{d}$. We know the distance between adjacent fringes, so $\Delta m = 1$. $\Delta y_m = R\dfrac{\Delta m\lambda}{d} = \dfrac{R\lambda}{d}$. Solving for d gives $d = \dfrac{R\lambda}{\Delta y} = (200\text{ cm})$ $(500\text{ nm})/(3.53\text{ cm}) = 2.833\times10^4\text{ nm}$. For the distant fringes (large n) we cannot use the small-angle approximation, so we use $d\sin\theta_m = m\lambda$. $\sin\theta_{49} = 49\lambda/d$ and $\sin\theta_{50} = 50\lambda/d$. Using the known values for d and λ gives $\theta_{49} = 59.87°$ and $\theta_{50} = 61.94°$. Using $y_m = R\tan\theta_m$ with $R = 200$ cm gives $\Delta y = y_{50} - y_{49} = R\left(\tan\theta_{50} - \tan\theta_{49}\right) = 30.6 \text{ cm}$.

EVALUATE: Clearly the small-angle approximation cannot be used for fringes far from the center.

35.7. **IDENTIFY:** The value of y_{20} is much smaller than R and the approximate expression $y_m = R\dfrac{m\lambda}{d}$ is accurate.

SET UP: $y_{20} = 10.6\times10^{-3}$ m.

EXECUTE: $d = \dfrac{20R\lambda}{y_{20}} = \dfrac{(20)(1.20 \text{ m})(502\times10^{-9} \text{ m})}{10.6\times10^{-3} \text{ m}} = 1.14\times10^{-3} \text{ m} = 1.14 \text{ mm}.$

EVALUATE: $\tan\theta_{20} = \dfrac{y_{20}}{R}$ so $\theta_{20} = 0.51°$ and the approximation $\sin\theta_{20} \approx \tan\theta_{20}$ is very accurate.

35.8. **IDENTIFY:** Since the dark fringes are equally spaced, $R \gg y_m$, the angles are small and the dark bands are located by $y_{m+\frac{1}{2}} = R\dfrac{(m+\frac{1}{2})\lambda}{d}$.

SET UP: The separation between adjacent dark bands is $\Delta y = \dfrac{R\lambda}{d}$.

EXECUTE: $\Delta y = \dfrac{R\lambda}{d} \Rightarrow d = \dfrac{R\lambda}{\Delta y} = \dfrac{(1.80 \text{ m})(4.50\times10^{-7} \text{ m})}{3.90\times10^{-3} \text{ m}} = 2.08\times10^{-4} \text{ m} = 0.208 \text{ mm}.$

EVALUATE: When the separation between the slits decreases, the separation between dark fringes increases.

35.9. **IDENTIFY** and **SET UP:** The dark lines correspond to destructive interference and hence are located by $d\sin\theta = (m+\frac{1}{2})\lambda$ so $\sin\theta = \dfrac{(m+\frac{1}{2})\lambda}{d}$, $m = 0, \pm1, \pm2, \ldots$.

Solve for θ that locates the second and third dark lines. Use to find the distance of each of the dark lines from the center of the screen.

EXECUTE: 1st dark line is for $m = 0$.

2nd dark line is for $m = 1$ and $\sin\theta_1 = \dfrac{3\lambda}{2d} = \dfrac{3(500\times10^{-9} \text{ m})}{2(0.450\times10^{-3} \text{m})} = 1.667\times10^{-3}$ and $\theta_1 = 1.667\times10^{-3}$ rad.

3rd dark line is for $m = 2$ and $\sin\theta_2 = \dfrac{5\lambda}{2d} = \dfrac{5(500\times10^{-9} \text{ m})}{2(0.450\times10^{-3} \text{m})} = 2.778\times10^{-3}$ and $\theta_2 = 2.778\times10^{-3}$ rad.

(Note that θ_1 and θ_2 are small so that the approximation $\theta \approx \sin\theta \approx \tan\theta$ is valid.) The distance of each dark line from the center of the central bright band is given by $y_m = R\tan\theta$, where $R = 0.850$ m is the distance to the screen.

$\tan\theta \approx \theta$ so $y_m = R\theta_m$.

$y_1 = R\theta_1 = (0.750 \text{ m})(1.667\times10^{-3} \text{ rad}) = 1.25\times10^{-3} \text{ m}.$

$y_2 = R\theta_2 = (0.750 \text{ m})(2.778\times10^{-3} \text{ rad}) = 2.08\times10^{-3} \text{ m}.$

$\Delta y = y_2 - y_1 = 2.08\times10^{-3} \text{ m} - 1.25\times10^{-3} \text{ m} = 0.83 \text{ mm}.$

EVALUATE: Since θ_1 and θ_2 are very small we could have used $y_m = R\dfrac{m\lambda}{d}$, generalized to destructive interference: $y_m = R(m+\frac{1}{2})\lambda/d$.

35.10. **IDENTIFY:** We have two-slit interference.

SET UP: Bright fringes occur when $d\sin\theta_m = m\lambda$, $f\lambda = c$. We want the distance d between the slits. We can vary the frequency, and we know that $f_m = 5.60\times10^{12}$ Hz and $f_{m+1} = 7.47\times10^{12}$ Hz.

EXECUTE: For the first frequency $d\sin\theta_m = m\lambda = m\dfrac{c}{f_m}$. For the next higher frequency

$d\sin\theta_{m+1} = (m+1)\dfrac{c}{f_{m+1}}$. Both maxima occur at the same place, so $d\sin\theta$ is the same. Thus

$m\dfrac{c}{f_m} = (m+1)\dfrac{c}{f_{m+1}}$. Using the known frequencies gives $m = 3$. Now we can find d. $d\sin\theta_3 = 3\dfrac{c}{f_m}$.

Using $\theta = 60.0°$ and f_m gives $d = 0.186$ mm.

EVALUATE: We cannot use the small-angle approximation for an angle as large as 60°.

35.11. **IDENTIFY:** Bright fringes are located at angles θ given by $d\sin\theta = m\lambda$.

SET UP: The largest value $\sin\theta$ can have is 1.00.

EXECUTE: **(a)** $m = \dfrac{d\sin\theta}{\lambda}$. For $\sin\theta = 1$, $m = \dfrac{d}{\lambda} = \dfrac{0.0116\times10^{-3}\text{ m}}{5.85\times10^{-7}\text{ m}} = 19.8$. Therefore, the largest m for fringes on the screen is $m = 19$. There are $2(19)+1 = 39$ bright fringes, the central one and 19 above and 19 below it.

(b) The most distant fringe has $m = \pm19$. $\sin\theta = m\dfrac{\lambda}{d} = \pm19\left(\dfrac{5.85\times10^{-7}\text{ m}}{0.0116\times10^{-3}\text{ m}}\right) = \pm0.958$ and

$\theta = \pm73.3°$.

EVALUATE: For small θ the spacing Δy between adjacent fringes is constant but this is no longer the case for larger angles.

35.12. **IDENTIFY:** The width of a bright fringe can be defined to be the distance between its two adjacent destructive minima. Assuming the small angle formula for destructive interference $y_m = R\dfrac{(m+\frac{1}{2})\lambda}{d}$.

SET UP: $d = 0.200\times10^{-3}$ m. $R = 4.00$ m.

EXECUTE: The distance between any two successive minima is

$y_{m+1} - y_m = R\dfrac{\lambda}{d} = (4.00\text{ m})\dfrac{(400\times10^{-9}\text{m})}{(0.200\times10^{-3}\text{ m})} = 8.00\text{ mm}$. Thus, the answer to both part (a) and part (b) is that the width is 8.00 mm.

EVALUATE: For small angles, when $y_m << R$, the interference minima are equally spaced.

35.13. **IDENTIFY** and **SET UP:** The dark lines are located by $d\sin\theta = (m+\frac{1}{2})\lambda$. The distance of each line from the center of the screen is given by $y = R\tan\theta$.

EXECUTE: First dark line is for $m = 0$ and $d\sin\theta_1 = \lambda/2$.

$\sin\theta_1 = \dfrac{\lambda}{2d} = \dfrac{550\times10^{-9}\text{ m}}{2(1.80\times10^{-6}\text{ m})} = 0.1528$ and $\theta_1 = 8.789°$. Second dark line is for $m = 1$ and $d\sin\theta_2 = 3\lambda/2$.

$\sin\theta_2 = \dfrac{3\lambda}{2d} = 3\left(\dfrac{550\times10^{-9}\text{ m}}{2(1.80\times10^{-6}\text{ m})}\right) = 0.4583$ and $\theta_2 = 27.28°$.

$y_1 = R\tan\theta_1 = (0.350\text{ m})\tan 8.789° = 0.0541$ m.

$y_2 = R\tan\theta_2 = (0.350\text{ m})\tan 27.28° = 0.1805$ m.

The distance between the lines is $\Delta y = y_2 - y_1 = 0.1805\text{ m} - 0.0541\text{ m} = 0.126\text{ m} = 12.6$ cm.

EVALUATE: $\sin\theta_1 = 0.1528$ and $\tan\theta_1 = 0.1546$. $\sin\theta_2 = 0.4583$ and $\tan\theta_2 = 0.5157$. As the angle increases, $\sin\theta \approx \tan\theta$ becomes a poorer approximation.

35.14. **IDENTIFY:** For small angles: $y_m = R\dfrac{m\lambda}{d}$.

SET UP: First-order means $m = 1$.

EXECUTE: The distance between corresponding bright fringes is

$$\Delta y = \frac{Rm}{d}\Delta\lambda = \frac{(4.00\text{ m})(1)}{(0.300\times10^{-3}\text{ m})}(660-470)\times(10^{-9}\text{ m}) = 2.53\times10^{-3}\text{ m} = 2.53\text{ mm}.$$

EVALUATE: The separation between these fringes for different wavelengths increases when the slit separation decreases.

35.15. **IDENTIFY** and **SET UP:** Use the information given about the bright fringe and $y_m = R\dfrac{m\lambda}{d}$ to find the distance d between the two slits. Then use $d\sin\theta = (m+\frac{1}{2})\lambda,\ m = 0, \pm1, \pm2, \ldots$ and $y = R\tan\theta$ to calculate λ for which there is a first-order dark fringe at this same place on the screen.

EXECUTE: $y_1 = \dfrac{R\lambda_1}{d}$, so $d = \dfrac{R\lambda_1}{y_1} = \dfrac{(3.00\text{ m})(600\times10^{-9}\text{ m})}{4.84\times10^{-3}\text{ m}} = 3.72\times10^{-4}\text{ m}$. ($R$ is much greater than d, so $y_m = R\dfrac{m\lambda}{d}$ is valid.) The dark fringes are located by $d\sin\theta = (m+\frac{1}{2})\lambda,\ m = 0, \pm1, \pm2, \ldots$. The first-order dark fringe is located by $\sin\theta = \lambda_2/2d$, where λ_2 is the wavelength we are seeking.

$$y = R\tan\theta \approx R\sin\theta = \frac{\lambda_2 R}{2d}.$$

We want λ_2 such that $y = y_1$. This gives $\dfrac{R\lambda_1}{d} = \dfrac{R\lambda_2}{2d}$ and $\lambda_2 = 2\lambda_1 = 1200$ nm.

EVALUATE: For $\lambda = 600$ nm the path difference from the two slits to this point on the screen is 600 nm. For this same path difference (point on the screen) the path difference is $\lambda/2$ when $\lambda = 1200$ nm.

35.16. **IDENTIFY:** Bright fringes are located at $y_m = R\dfrac{m\lambda}{d}$, when $y_m \ll R$. Dark fringes are at $d\sin\theta = (m+\frac{1}{2})\lambda$ and $y = R\tan\theta$.

SET UP: $\lambda = \dfrac{c}{f} = \dfrac{3.00\times10^{8}\text{ m/s}}{6.32\times10^{14}\text{ Hz}} = 4.75\times10^{-7}\text{ m}$. For the third bright fringe (not counting the central bright spot), $m = 3$. For the third dark fringe, $m = 2$.

EXECUTE: **(a)** $d = \dfrac{m\lambda R}{y_m} = \dfrac{3(4.75\times10^{-7}\text{ m})(0.850\text{ m})}{0.0311\text{ m}} = 3.89\times10^{-5}\text{ m} = 0.0389\text{ mm}.$

(b) $\sin\theta = (2+\frac{1}{2})\dfrac{\lambda}{d} = (2.5)\left(\dfrac{4.75\times10^{-7}\text{ m}}{3.89\times10^{-5}\text{ m}}\right) = 0.0305$ and $\theta = 1.75°$.

$y = R\tan\theta = (85.0\text{ cm})\tan 1.75° = 2.60\text{ cm}.$

EVALUATE: The third dark fringe is closer to the center of the screen than the third bright fringe on one side of the central bright fringe.

35.17. **IDENTIFY:** Use $I = I_0\cos^2(\phi/2)$ with $\phi = (2\pi/\lambda)(r_2 - r_1)$.

SET UP: ϕ is the phase difference and $(r_2 - r_1)$ is the path difference.

EXECUTE: **(a)** $I = I_0(\cos 30.0°)^2 = 0.750 I_0$.

(b) $60.0° = (\pi/3)$ rad. $(r_2 - r_1) = (\phi/2\pi)\lambda = [(\pi/3)/2\pi]\lambda = \lambda/6 = 80$ nm.

EVALUATE: $\phi = 360°/6$ and $(r_2 - r_1) = \lambda/6.$

35.18. (a) IDENTIFY and **SET UP:** The minima are located at angles θ given by $d\sin\theta = (m+\tfrac{1}{2})\lambda.$ The first minimum corresponds to $m = 0.$ Solve for $\theta.$ Then the distance on the screen is $y = R\tan\theta.$

EXECUTE: $\sin\theta = \dfrac{\lambda}{2d} = \dfrac{660\times10^{-9}\text{ m}}{2(0.260\times10^{-3}\text{ m})} = 1.27\times10^{-3}$ and $\theta = 1.27\times10^{-3}$ rad.

$y = (0.900\text{ m})\tan(1.27\times10^{-3}\text{ rad}) = 1.14\times10^{-3}\text{ m} = 1.14$ mm.

(b) IDENTIFY and **SET UP:** The equation $I = I_0\cos^2\left(\dfrac{\pi dy}{\lambda R}\right)$ gives the intensity *I* as a function of the position *y* on the screen. Set $I = I_0/2$ and solve for *y*.

EXECUTE: $I = \tfrac{1}{2}I_0$ says $\cos^2\left(\dfrac{\pi dy}{\lambda R}\right) = \tfrac{1}{2}.$

$\cos\left(\dfrac{\pi dy}{\lambda R}\right) = \dfrac{1}{\sqrt{2}}$ so $\dfrac{\pi dy}{\lambda R} = \dfrac{\pi}{4}$ rad.

$y = \dfrac{\lambda R}{4d} = \dfrac{(660\times10^{-9}\text{ m})(0.900\text{ m})}{4(0.260\times10^{-3}\text{ m})} = 5.71\times10^{-4}\text{ m} = 0.571$ mm.

EVALUATE: $I = I_0/2$ at a point on the screen midway between where $I = I_0$ and $I = 0.$

35.19. IDENTIFY and **SET UP:** The phase difference ϕ is given by $\phi = (2\pi d/\lambda)\sin\theta.$

EXECUTE: $\phi = [2\pi(0.340\times10^{-3}\text{ m})/(500\times10^{-9}\text{ m})\sin 23.0° = 1670$ rad.

EVALUATE: The *m*th bright fringe occurs when $\phi = 2\pi m,$ so there are a large number of bright fringes within $23.0°$ from the centerline. Note that the equation $\phi = (2\pi d/\lambda)\sin\theta$ gives ϕ in radians.

35.20. IDENTIFY: Light from the two slits interferes on the screen. The bright and dark fringes are very close together compared to the distance between the screen and the slits, so we can use the small-angle approximation. $\phi = \dfrac{2\pi}{\lambda}(r_1 - r_2).$ The intensity is $I = I_0\cos^2\left(\dfrac{\phi}{2}\right).$

SET UP: The intensity is $I = I_0\cos^2\left(\dfrac{\phi}{2}\right).$ $\dfrac{\phi}{2} = \dfrac{\pi d\sin\theta}{\lambda},$ but for small angles $\dfrac{\phi}{2} \approx \dfrac{\pi dy}{R\lambda}.$

EXECUTE: At the first minim, $y = 3.00$ mm and $\phi/2 = \pi/2$. At $y = 2.00$ mm, which is 2/3 of 3.00 mm, $\phi/2 = (2/3)(\pi/2) = \pi/3 = 60°$. Therefore the intensity at $x = 2.00$ mm is

$I = (0.0600\text{ W/m}^2)\cos^2(60°) = 0.0150\text{ W/m}^2.$

(b) Using the same reasoning as in (a), 1.50 mm is $\tfrac{1}{2}$ of 3.00 m, so $\phi/2 = (1/2)(\pi/2) = \pi/4 = 45°$. So

$I = (0.0600\text{ W/m}^2)\cos^2(45°) = 0.0300\text{ W/m}^2.$

EVALUATE: As a check, we could first find λ and then use it to find the intensities. At the first minimum, $\phi/2 = \pi/2 = \pi dy/R\lambda,$ which gives $\lambda = 2dy/R = 5.40\times10^{-4}$ mm. Now use this to calculate the intensities using $I = I_0\cos^2\left(\dfrac{\phi}{2}\right)$ and $\dfrac{\phi}{2} \approx \dfrac{\pi dy}{R\lambda}.$

35.21. **IDENTIFY:** The phase difference ϕ and the path difference $r_1 - r_2$ are related by $\phi = \dfrac{2\pi}{\lambda}(r_1 - r_2)$. The intensity is given by $I = I_0 \cos^2\left(\dfrac{\phi}{2}\right)$.

SET UP: $\lambda = \dfrac{c}{f} = \dfrac{3.00\times 10^8 \text{ m/s}}{1.20\times 10^8 \text{ Hz}} = 2.50 \text{ m}$. When the receiver measures intensity I_0, $\phi = 0$.

EXECUTE: **(a)** $\phi = \dfrac{2\pi}{\lambda}(r_1 - r_2) = \dfrac{2\pi}{2.50 \text{ m}}(1.8 \text{ m}) = 4.52 \text{ rad}$.

(b) $I = I_0 \cos^2\left(\dfrac{\phi}{2}\right) = I_0 \cos^2\left(\dfrac{4.52 \text{ rad}}{2}\right) = 0.404 I_0$.

EVALUATE: $(r_1 - r_2)$ is greater than $\lambda/2$, so one minimum has been passed as the receiver is moved.

35.21. **IDENTIFY:** The phase difference ϕ and the path difference $r_1 - r_2$ are related by $\phi = \dfrac{2\pi}{\lambda}(r_1 - r_2)$. The intensity is given by $I = I_0 \cos^2\left(\dfrac{\phi}{2}\right)$.

SET UP: $\lambda = \dfrac{c}{f} = \dfrac{3.00\times 10^8 \text{ m/s}}{1.20\times 10^8 \text{ Hz}} = 2.50 \text{ m}$. When the receiver measures intensity I_0, $\phi = 0$.

EXECUTE: **(a)** $\phi = \dfrac{2\pi}{\lambda}(r_1 - r_2) = \dfrac{2\pi}{2.50 \text{ m}}(1.8 \text{ m}) = 4.52 \text{ rad}$.

(b) $I = I_0 \cos^2\left(\dfrac{\phi}{2}\right) = I_0 \cos^2\left(\dfrac{4.52 \text{ rad}}{2}\right) = 0.404 I_0$.

EVALUATE: $(r_1 - r_2)$ is greater than $\lambda/2$, so one minimum has been passed as the receiver is moved.

35.22. **IDENTIFY:** We are dealing with thin-film interference with an air film of variable thickness.
SET UP: There is no phase-reversal at the upper air surface, but there is one at the lower air surface because $n_{glass} > n_{air}$. There is constructive interference when $t_1 = 650$ nm, and the next value of t for which constructive interference occurs is $t_2 = 910$ nm. $2t = \left(m + \dfrac{1}{2}\right)\lambda$, $\lambda_n = \dfrac{\lambda_0}{n}$.

EXECUTE: **(a)** We want wavelength of the light in air. Using $2t = \left(m + \dfrac{1}{2}\right)\lambda$ at both thicknesses gives $2t_1 = \left(m + \dfrac{1}{2}\right)\lambda$ and $2t_2 = \left(m + \dfrac{3}{2}\right)\lambda$. Taking t_2/t_1 gives $m = 2$. From this we get $\lambda = 520$ nm.

(b) We want the minimum thickness t_{min}. For the smallest thickness, $2t = \lambda/2$, so $t = \dfrac{\lambda}{4} = 130$ nm.

EVALUATE: Be careful of the half-cycle phase shift when the light reflects off the glass at the bottom of the air film.

35.23. **IDENTIFY:** Consider interference between rays reflected at the upper and lower surfaces of the film. Consider phase difference due to the path difference of $2t$ and any phase differences due to phase changes upon reflection.
SET UP: Consider Figure 35.23.

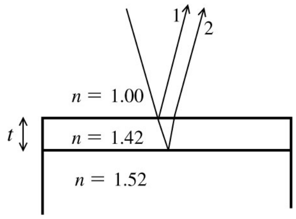


Figure 35.23

Both rays (1) and (2) undergo a $180°$ phase change on reflection, so there is no net phase difference introduced and the condition for destructive interference is $2t = (m+\frac{1}{2})\lambda.$

EXECUTE: $t = \dfrac{(m+\frac{1}{2})\lambda}{2}$; thinnest film says $m = 0$ so $t = \dfrac{\lambda}{4}.$

X and $t = \dfrac{\lambda_0}{4(1.42)} = \dfrac{650\times10^{-9}\text{ m}}{4(1.42)} = 1.14\times10^{-7}\text{ m} = 114\text{ nm}.$

EVALUATE: We compared the path difference to the wavelength in the film, since that is where the path difference occurs.

35.24. **IDENTIFY:** Require destructive interference for light reflected at the front and rear surfaces of the film.
SET UP: At the front surface of the film, light in air $(n = 1.00)$ reflects from the film $(n = 2.62)$ and there is a $180°$ phase shift due to the reflection. At the back surface of the film, light in the film $(n = 2.62)$ reflects from glass $(n = 1.62)$ and there is no phase shift due to reflection. Therefore, there is a net $180°$ phase difference produced by the reflections. The path difference for these two rays is $2t$, where t is the thickness of the film. The wavelength in the film is $\lambda = \dfrac{505\text{ nm}}{2.62}.$

EXECUTE: **(a)** Since the reflection produces a net $180°$ phase difference, destructive interference of the reflected light occurs when $2t = m\lambda.$ $t = m\left(\dfrac{505\text{ nm}}{2[2.62]}\right) = (96.4\text{ nm})m.$ The minimum thickness is 96.4 nm.

(b) The next three thicknesses are for $m = 2, 3$ and 4: 192 nm, 289 nm, and 386 nm.

EVALUATE: The minimum thickness is for $t = \lambda_0/2n.$ Compare this to Problem 35.23, where the minimum thickness for destructive interference is $t = \lambda_0/4n.$

35.25. **IDENTIFY:** The light reflected from the top of the TiO_2 film interferes with the light reflected from the top of the glass surface. These waves are out of phase due to the path difference in the film and the phase differences caused by reflection.

SET UP: There is a π phase change at the TiO_2 surface but none at the glass surface, so for destructive interference the path difference must be $m\lambda$ in the film.

EXECUTE: **(a)** Calling T the thickness of the film gives $2T = m\lambda_0/n,$ which yields $T = m\lambda_0/(2n).$ Substituting the numbers gives

$T = m\text{ (520.0 nm)}/[2(2.62)] = 99.237\text{ nm}.$

T must be greater than 1036 nm, so $m = 11,$ which gives $T = 1091.6\text{ nm},$ since we want to know the minimum thickness to add.

$\Delta T = 1091.6\text{ nm} - 1036\text{ nm} = 55.6\text{ nm}.$

(b) (i) Path difference $= 2T = 2(1092\text{ nm}) = 2184\text{ nm} = 2180\text{ nm}.$

(ii) The wavelength in the film is $\lambda = \lambda_0/n = (520.0\text{ nm})/2.62 = 198.5\text{ nm}.$

Path difference $= (2180\text{ nm})/[(198.5\text{ nm})/\text{wavelength}] = 11.0$ wavelengths.

EVALUATE: Because the path difference in the film is 11.0 wavelengths, the light reflected off the top of the film will be 180° out of phase with the light that traveled through the film and was reflected off the glass due to the phase change at reflection off the top of the film.

35.26. **IDENTIFY:** Consider the phase difference produced by the path difference and by the reflections. For destructive interference the total phase difference is an integer number of half cycles.

SET UP: The reflection at the top surface of the film produces a half-cycle phase shift. There is no phase shift at the reflection at the bottom surface.

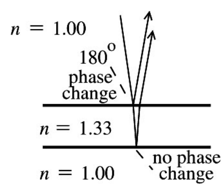
EXECUTE: **(a)** Since there is a half-cycle phase shift at just one of the interfaces, the minimum thickness for constructive interference is $t = \frac{\lambda}{4} = \frac{\lambda_0}{4n} = \frac{550\text{ nm}}{4(1.70)} = 80.9\text{ nm}.$

(b) The next smallest thickness for constructive interference is with another half wavelength thickness added. $t = \frac{3\lambda}{4} = \frac{3\lambda_0}{4n} = \frac{3(550\text{ nm})}{4(1.70)} = 243\text{ nm}.$

EVALUATE: Note that we must compare the path difference to the wavelength in the film.

35.27. **IDENTIFY:** Consider the interference between rays reflected from the two surfaces of the soap film. Strongly reflected means constructive interference. Consider phase difference due to the path difference of $2t$ and any phase difference due to phase changes upon reflection.

SET UP: Consider Figure 35.27.



There is a 180° phase change when the light is reflected from the outside surface of the bubble and no phase change when the light is reflected from the inside surface.

Figure 35.27

EXECUTE: **(a)** The reflections produce a net 180° phase difference and for there to be constructive interference the path difference $2t$ must correspond to a half-integer number of wavelengths to compensate for the $\lambda/2$ shift due to the reflections. Hence the condition for constructive interference is $2t = (m+\frac{1}{2})(\lambda_0/n),\ m = 0, 1, 2, \ldots$ Here λ_0 is the wavelength in air and (λ_0/n) is the wavelength in the bubble, where the path difference occurs.

$$\lambda_0 = \frac{2tn}{m+\frac{1}{2}} = \frac{2(290\text{ nm})(1.33)}{m+\frac{1}{2}} = \frac{771.4\text{ nm}}{m+\frac{1}{2}}$$

for $m = 0, \lambda = 1543$ nm; for $m = 1, \lambda = 514$ nm; for $m = 2, \lambda = 308$ nm;… Only 514 nm is in the visible region; the color for this wavelength is green.

(b) $\lambda_0 = \frac{2tn}{m+\frac{1}{2}} = \frac{2(340\text{ nm})(1.33)}{m+\frac{1}{2}} = \frac{904.4\text{ nm}}{m+\frac{1}{2}}$

for $m = 0, \lambda = 1809$ nm; for $m = 1, \lambda = 603$ nm; for $m = 2, \lambda = 362$ nm;… Only 603 nm is in the visible region; the color for this wavelength is orange.

EVALUATE: The dominant color of the reflected light depends on the thickness of the film. If the bubble has varying thickness at different points, these points will appear to be different colors when the light reflected from the bubble is viewed.

35.28. **IDENTIFY** and **SET UP:** Since the film reflects 575 nm strongly, we must have constructive interference at that wavelength. The light reflected from the air-benzene interface experiences a 180° phase inversion (since $n_{\text{air}} < n_{\text{benzene}}$), but the light reflected from the benzene-water interface does not experience a phase inversion (since $n_{\text{benzene}} > n_{\text{water}}$). Thus, the condition for constructive interference is $2t = m\dfrac{\lambda}{2n}$, where $m = 1,\ 3,\ 5, \ldots$ and $\dfrac{\lambda}{n}$ is the wavelength of the light in the benzene (which is where the path-difference occurs).

EXECUTE: The minimum required thickness occurs when $m = 1$, so $t = \dfrac{\lambda}{4n} = \dfrac{575\text{ nm}}{4(1.50)} = 95.8\text{ nm}.$

EVALUATE: Since the path difference occurs within the benzene, and not within the water, the exact value of the index of refraction of water is not needed (provided we know that $n_{\text{benzene}} > n_{\text{water}}$).

35.29. **IDENTIFY:** Require destructive interference between light reflected from the two points on the disc.

SET UP: Both reflections occur for waves in the plastic substrate reflecting from the reflective coating, so they both have the same phase shift upon reflection and the condition for destructive interference (cancellation) is $2t = (m + \frac{1}{2})\lambda$, where t is the depth of the pit. $\lambda = \dfrac{\lambda_0}{n}$. The minimum pit depth is for $m = 0$.

EXECUTE: $2t = \dfrac{\lambda}{2}$. $t = \dfrac{\lambda}{4} = \dfrac{\lambda_0}{4n} = \dfrac{790\text{ nm}}{4(1.8)} = 110\text{ nm} = 0.11\ \mu\text{m}.$

EVALUATE: The path difference occurs in the plastic substrate and we must compare the wavelength in the substrate to the path difference.

35.30. **IDENTIFY:** Apply $y = m(\lambda/2)$.

SET UP: $m = 818$. Since the fringes move in opposite directions, the two people move the mirror in opposite directions.

EXECUTE: **(a)** For Jan, the total shift was $y_1 = \dfrac{m\lambda_1}{2} = \dfrac{818(6.06\times10^{-7}\text{ m})}{2} = 2.48\times10^{-4}\text{m}.$ For Linda, the total shift was $y_2 = \dfrac{m\lambda_2}{2} = \dfrac{818(5.02\times10^{-7}\text{ m})}{2} = 2.05\times10^{-4}\text{ m}.$

(b) The net displacement of the mirror is the difference of the above values:

$\Delta y = y_1 - y_2 = 0.248\text{ mm} - 0.205\text{ mm} = 0.043\text{ mm}.$

EVALUATE: The person using the larger wavelength moves the mirror the greater distance.

35.31. **IDENTIFY** and **SET UP:** Apply $y = m(\lambda/2)$ and calculate y for $m = 1800$.

EXECUTE: $y = m(\lambda/2) = 1800(633\times10^{-9}\text{ m})/2 = 5.70\times10^{-4}\text{ m} = 0.570\text{ mm}.$

EVALUATE: A small displacement of the mirror corresponds to many wavelengths and a large number of fringes cross the line.

35.32. **IDENTIFY:** This problem involves the interference of waves.

SET UP and **EXECUTE:** **(a)** We want E. $I = \dfrac{1}{2}\epsilon_0 cE_{\text{max}}^2 = P/A.$

$$E = \sqrt{\frac{2I}{\epsilon_0 c}} = \sqrt{\frac{2(100\text{ kW/cm}^2)}{\epsilon_0 c}} = 870\text{ kV/m}.$$

(b) Estimate the phase difference δ . $\dfrac{\delta}{2\pi} = \dfrac{\Delta l}{\lambda}$. The phase difference accumulates with each round trip. There are 280 round trips, each with an up-and-back segment. So the total for Δl is $\Delta l = 2(280)(10^{-18}\text{m})$. Therefore $\delta = 2\pi\dfrac{\Delta l}{\lambda} = \dfrac{2\pi(560\times10^{-18}\text{ m})}{1064\text{ nm}} = 3.3\times10^{-9}\text{ rad}.$

(c) We want $E_{\min}$. Eq. (35.7) gives $E_p = 2E\left|\cos\frac{\phi}{2}\right|$. $\phi = \pi + \delta$, so

$$E_p = 2E\left|\cos\frac{\pi+\delta}{2}\right| = 2E\sin\frac{\delta}{2} \approx 2E\frac{\delta}{2} = E\delta = (870\text{ kV/m})(3.3\times10^{-9}\text{rad}) = 2.9\times10^{-3}\text{V/m}.$$

EVALUATE: The minimum field strength is about 3 mN/C, which is very small.

35.33. **IDENTIFY:** The two scratches are parallel slits, so the light that passes through them produces an interference pattern. However, the light is traveling through a medium (plastic) that is different from air.

SET UP: The central bright fringe is bordered by a dark fringe on each side of it. At these dark fringes, $d\ \sin\theta = \frac{1}{2}\lambda/n$, where n is the refractive index of the plastic.

EXECUTE: First use geometry to find the angles at which the two dark fringes occur. At the first dark fringe $\tan\theta = [(5.82\text{ mm})/2]/(3250\text{ mm})$, giving $\theta = \pm 0.0513°$.

For destructive interference, we have $d\ \sin\theta = \frac{1}{2}\lambda/n$ and

$n = \lambda/(2d\sin\theta) = (632.8\text{ nm})/[2(0.000225\text{ m})(\sin\ 0.0513°)] = 1.57.$

EVALUATE: The wavelength of the light in the plastic is reduced compared to what it would be in air.

35.34. **IDENTIFY:** Consider the interference between light reflected from the top and bottom surfaces of the air film between the lens and the glass plate. Introducing a liquid between the lens and the plate just changes the wavelength from λ_0 to $\frac{\lambda_0}{n}$, where n is the refractive index of the liquid.

SET UP: For maximum intensity, with a net half-cycle phase shift due to reflections, $2t = (m+\frac{1}{2})\lambda$, where λ is the wavelength in the film. $t = R - \sqrt{R^2 - r^2}$.

EXECUTE: $\frac{(2m+1)\lambda}{4} = R - \sqrt{R^2-r^2} \Rightarrow \sqrt{R^2-r^2} = R - \frac{(2m+1)\lambda}{4}$

$$\Rightarrow R^2 - r^2 = R^2 + \left[\frac{(2m+1)\lambda}{4}\right]^2 - \frac{(2m+1)\lambda R}{2} \Rightarrow r = \sqrt{\frac{(2m+1)\lambda R}{2} - \left[\frac{(2m+1)\lambda}{4}\right]^2}$$

$$\Rightarrow r \approx \sqrt{\frac{(2m+1)\lambda R}{2}},\ \text{for } R \gg \lambda.$$

$\lambda = \lambda_0/n$, where λ_0 is the wavelength in air. Therefore, if r_0 is the radius of the third bright ring when air is between the lens and plate, the radius with water between the lens and plate is

$$r = \frac{r_0}{\sqrt{n}} = \frac{0.640\text{ mm}}{\sqrt{1.33}} = 0.555\text{ mm}.$$

EVALUATE: The refractive index of the water is less than that of the glass plate, so the phase changes on reflection are the same as when air is in the space.

35.35. **IDENTIFY** and **SET UP:** Consider the interference of the rays reflected from each side of the film. At the front of the film light in air reflects off the film $(n = 1.432)$ and there is a 180° phase shift. At the back of the film light in the film $(n = 1.432)$ reflects off the glass $(n = 1.62)$ and there is a 180° phase shift. Therefore, the reflections introduce no net phase shift. The path difference is $2t$, where t is the thickness of the film. The wavelength in the film is $\lambda = \frac{\lambda_{\text{air}}}{n}$.

EXECUTE: **(a)** Since there is no net phase difference produced by the reflections, the condition for destructive interference is $2t = (m+\frac{1}{2})\lambda.\ t = (m+\frac{1}{2})\frac{\lambda}{2}$ and the minimum thickness is

$$t = \frac{\lambda}{4} = \frac{\lambda_{\text{air}}}{4n} = \frac{550\text{ nm}}{4(1.432)} = 96.0\text{ nm}.$$

(b) For destructive interference, $2t=(m+\tfrac{1}{2})\dfrac{\lambda_{\text{air}}}{n}$ and $\lambda_{\text{air}}=\dfrac{2tn}{m+\tfrac{1}{2}}=\dfrac{275\text{ nm}}{m+\tfrac{1}{2}}$. $m=0$: $\lambda_{\text{air}}=550$ nm.

$m=1$: $\lambda_{\text{air}}=183$ nm. All other λ_{air} values are shorter. For constructive interference, $2t=m\dfrac{\lambda_{\text{air}}}{n}$ and

$\lambda_{\text{air}}=\dfrac{2tn}{m}=\dfrac{275\text{ nm}}{m}$. For $m=1$, $\lambda_{\text{air}}=275$ nm and all other λ_{air} values are shorter.

EVALUATE: The only visible wavelength in air for which there is destructive interference is 550 nm. There are no visible wavelengths in air for which there is constructive interference.

35.36. **IDENTIFY** and **SET UP:** Consider reflection from either side of the film. **(a)** At the front of the film, light in air $(n=1.00)$ reflects off the film $(n=1.45)$ and there is a 180° phase shift. At the back of the film, light in the film $(n=1.45)$ reflects off the cornea $(n=1.38)$ and there is no phase shift. The reflections produce a net 180° phase difference so the condition for constructive interference is $2t=(m+\tfrac{1}{2})\lambda$, where $\lambda=\dfrac{\lambda_{\text{air}}}{n}$. $t=(m+\tfrac{1}{2})\dfrac{\lambda_{\text{air}}}{2n}$.

EXECUTE: The minimum thickness is for $m=0$, and is given by $t=\dfrac{\lambda_{\text{air}}}{4n}=\dfrac{600\text{ nm}}{4(1.45)}=103$ nm

(103.4 nm with less rounding).

(b) $\lambda_{\text{air}}=\dfrac{2nt}{m+\tfrac{1}{2}}=\dfrac{2(1.45)(103.4\text{ nm})}{m+\tfrac{1}{2}}=\dfrac{300\text{ nm}}{m+\tfrac{1}{2}}$. For $m=0$, $\lambda_{\text{air}}=600$ nm. For $m=1$, $\lambda_{\text{air}}=200$ nm and all other values are smaller. No other visible wavelengths are reinforced. The condition for destructive interference is $2t=m\dfrac{\lambda_{\text{air}}}{n}$. $\lambda=\dfrac{2tn}{m}=\dfrac{300\text{ nm}}{m}$. For $m=1$, $\lambda_{\text{air}}=300$ nm and all other values are shorter. There are no visible wavelengths for which there is destructive interference.

(c) Now both rays have a 180° phase change on reflection and the reflections don't introduce any net phase shift. The expression for constructive interference in parts (a) and (b) now gives destructive interference and the expression in (a) and (b) for destructive interference now gives constructive interference. The only visible wavelength for which there will be destructive interference is 600 nm and there are no visible wavelengths for which there will be constructive interference.

EVALUATE: Changing the net phase shift due to the reflections can convert the interference for a particular thickness from constructive to destructive, and vice versa.

35.37. **IDENTIFY:** The insertion of the metal foil produces a wedge of air, which is an air film of varying thickness. This film causes a path difference between light reflected off the top and bottom of this film.

SET UP: The two sheets of glass are sketched in Figure 35.37. The thickness of the air wedge at a distance x from the line of contact is $t=x\tan\theta$. Consider rays 1 and 2 that are reflected from the top and bottom surfaces, respectively, of the air film. Ray 1 has no phase change when it reflects and ray 2 has a 180° phase change when it reflects, so the reflections introduce a net 180° phase difference. The path difference is $2t$ and the wavelength in the film is $\lambda=\lambda_{\text{air}}$.

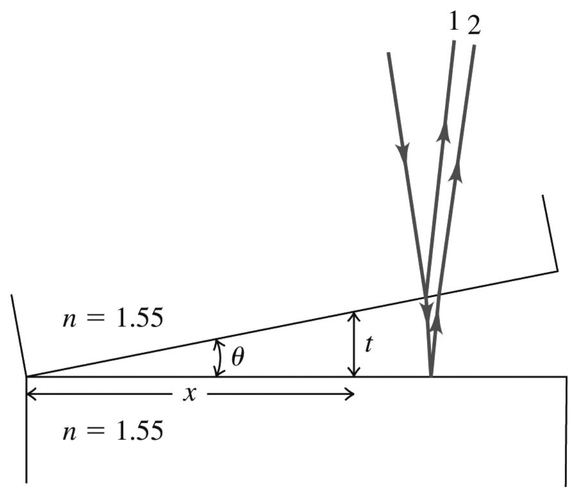


Figure 35.37

EXECUTE: **(a)** Since there is a 180° phase difference from the reflections, the condition for constructive interference is $2t = (m + \frac{1}{2})\lambda$. The positions of first enhancement correspond to $m = 0$ and $2t = \dfrac{\lambda}{2}$. $x\tan\theta = \dfrac{\lambda}{4}$. θ is a constant, so $\dfrac{x_1}{\lambda_1} = \dfrac{x_2}{\lambda_2}$. $x_1 = 1.15$ mm, $\lambda_1 = 400.0$ nm. $x_2 = x_1\left(\dfrac{\lambda_2}{\lambda_1}\right)$. For $\lambda_2 = 550$ nm (green), $x_2 = (1.15\text{ mm})\left(\dfrac{550\text{ nm}}{400\text{ nm}}\right) = 1.58$ mm. For $\lambda_2 = 600$ nm (orange), $x_2 = (1.15\text{ mm})\left(\dfrac{600\text{ nm}}{400\text{ nm}}\right) = 1.72$ mm.

(b) The positions of next enhancement correspond to $m = 1$ and $2t = \dfrac{3\lambda}{2}$. $x\tan\theta = \dfrac{3\lambda}{4}$. The values of x are 3 times what they are in part (a). Violet: 3.45 mm; green: 4.74 mm; orange: 5.16 mm.

(c) $\tan\theta = \dfrac{\lambda}{4x} = \dfrac{400.0\times10^{-9}\text{ m}}{4(1.15\times10^{-3}\text{ m})} = 8.70\times10^{-5}$. $\tan\theta = \dfrac{t_{\text{foil}}}{11.0\text{ cm}}$, so $t_{\text{foil}} = 9.57\times10^{-4}\text{ cm} = 9.57\ \mu\text{m}$.

EVALUATE: The thickness of the foil must be very small to cause these observable interference effects. If it is too thick, the film is no longer a "thin film."

35.38. **IDENTIFY:** We are dealing with two-source interference.

SET UP: For constructive interference $d\sin\theta_m = m\lambda$. $y_m = R\tan\theta_m$. For small angles $y_m = R\dfrac{m\lambda}{d}$.

EXECUTE: **(a)** We want the distance d between slits. The small-angle approximation is justified in this case. Adjacent fringes differ by $\Delta m = 1$, so $\Delta y_m = R\dfrac{\Delta m\lambda}{d} = \dfrac{R\lambda}{d}$. Solving for d gives $d = \dfrac{R\lambda}{\Delta y} =$ (1 m)(650 nm)/(1 cm) = 65 μm.

(b) No. It seems much too small to do at home.

(c) We want the distance between the points of enhanced sound (constructive interference). For sound of frequency 1.0 kHz, $\lambda = v/f$ = (344 m/s)(1.0 kHz) = 0.344 m, d = 40 cm = 0.40 m. We cannot use the small-angle approximation because d is only slightly larger than λ. Using $d\sin\theta_m = m\lambda$ gives $(0.40\text{ m})\sin\theta_1 = 0.344$ m, so $\theta_1 = 59°$. $y_1 = R\tan\theta_1 = (2\text{ m})\tan 59° = 3.3$ m. There is no θ_2 so the distance between the desired points in 3.3 m.

(d) We want d and f so that Δy = 1.75 m. Thus y_1 = 1.75 m, so $\tan\theta_1 = \frac{y_1}{R} = \frac{1.75\text{ m}}{2\text{ m}}$ which gives $\theta_1 = 41°$. Using $d\sin\theta_m = m\lambda$ gives $d\sin 41° = \lambda$. A frequency of 1.0 kHz is easily audible, so we use that which makes λ = 0.344 m. Thus d sin 41° = 0.344 m, so d = 0.52 m = 52 cm.

EVALUATE: **(e)** The 52-cm spacing in part (d) would be easily achieved, and 1.0 kHz is clearly within human hearing.

35.39. **IDENTIFY:** The liquid alters the wavelength of the light and that affects the locations of the interference minima.

SET UP: The interference minima are located by $d\sin\theta = (m+\frac{1}{2})\lambda$. For a liquid with refractive index n, $\lambda_{\text{liq}} = \frac{\lambda_{\text{air}}}{n}$.

EXECUTE: $\frac{\sin\theta}{\lambda} = \frac{(m+\frac{1}{2})}{d} =$ constant, so $\frac{\sin\theta_{\text{air}}}{\lambda_{\text{air}}} = \frac{\sin\theta_{\text{liq}}}{\lambda_{\text{liq}}}$. $\frac{\sin\theta_{\text{air}}}{\lambda_{\text{air}}} = \frac{\sin\theta_{\text{liq}}}{\lambda_{\text{air}}/n}$ and

$$n = \frac{\sin\theta_{\text{air}}}{\sin\theta_{\text{liq}}} = \frac{\sin 35.20°}{\sin 19.46°} = 1.730.$$

EVALUATE: In the liquid the wavelength is shorter and $\sin\theta = (m+\frac{1}{2})\frac{\lambda}{d}$ gives a smaller θ than in air, for the same m.

35.40. **IDENTIFY:** As the brass is heated, thermal expansion will cause the two slits to move farther apart.

SET UP: For destructive interference, $d\ \sin\theta = \lambda/2$. The change in separation due to thermal expansion is $dw = \alpha w_0\, dT$, where w is the distance between the slits.

EXECUTE: The first dark fringe is at d sin $\theta = \lambda/2 \Rightarrow \sin\theta = \lambda/2d$.

Call $d \equiv w$ for these calculations to avoid confusion with the differential. $\sin\theta = \lambda/2w$.

Taking differentials gives $d(\sin\theta) = d(\lambda/2w)$ and $\cos\theta\, d\theta = -\lambda/2\ dw/w^2$. For thermal expansion, $dw = \alpha w_0 dT$, which gives $\cos\theta\, d\theta = -\frac{\lambda}{2}\frac{\alpha w_0 dT}{w_0^2} = -\frac{\lambda\alpha dT}{2w_0}$. Solving for $d\theta$ gives $d\theta = -\frac{\lambda\alpha dT}{2w_0\cos\theta_0}$.

Get λ: $w_0\sin\theta_0 = \lambda/2 \rightarrow \lambda = 2w_0\sin\theta_0$. Substituting this quantity into the equation for $d\theta$ gives

$$d\theta = -\frac{2w_0\sin\theta_0\,\alpha dT}{2w_0\cos\theta_0} = -\tan\theta_0\,\alpha dT.$$

$$d\theta = -\tan(26.6°)(2.0\times10^{-5}\text{ K}^{-1})(115\text{ K}) = -0.001152\text{ rad} = -0.066°.$$

The minus sign tells us that the dark fringes move closer together.

EVALUATE: We can also see that the dark fringes move closer together because $\sin\theta$ is proportional to $1/d$, so as d increases due to expansion, θ decreases.

35.41. **IDENTIFY:** For destructive interference, $d = r_2 - r_1 = (m+\frac{1}{2})\lambda$.

SET UP: $r_2 - r_1 = \sqrt{(200\text{ m})^2 + x^2} - x$.

EXECUTE: $(200\text{ m})^2 + x^2 = x^2 + \left[(m+\frac{1}{2})\lambda\right]^2 + 2x(m+\frac{1}{2})\lambda$.

$x = \frac{20{,}000\text{ m}^2}{(m+\frac{1}{2})\lambda} - \frac{1}{2}(m+\frac{1}{2})\lambda$. The wavelength is calculated by $\lambda = \frac{c}{f} = \frac{3.00\times10^8\text{ m/s}}{5.80\times10^6\text{ Hz}} = 51.7\text{ m}$.

$m = 0: x = 761\text{ m};\ m = 1: x = 219\text{ m};\ m = 2: x = 90.1\text{ m};\ m = 3; x = 20.0\text{ m}.$

EVALUATE: For $m = 3$, $d = 3.5\lambda = 181$ m. The maximum possible path difference is the separation of 200 m between the sources.

35.42. **IDENTIFY:** For destructive interference the net phase difference must be $180°$, which is one-half a period, or $\lambda/2$. Part of this phase difference is due to the fact that the speakers are 1/4 of a period out of phase, and the rest is due to the path difference between the sound from the two speakers.
SET UP: The phase of A is 90° or, $\lambda/4$, ahead of B. At points above the centerline, points are closer to A than to B and the signal from A gains phase relative to B because of the path difference. Destructive interference will occur when $d\sin\theta = (m+\frac{1}{4})\lambda$, $m = 0, 1, 2, \ldots$. At points at an angle θ below the centerline, the signal from B gains phase relative to A because of the phase difference. Destructive interference will occur when $d\sin\theta = (m+\frac{3}{4})\lambda$, $m = 0, 1, 2, \ldots$. $\lambda = \dfrac{v}{f}$.

EXECUTE: $\lambda = \dfrac{340\text{ m/s}}{444\text{ Hz}} = 0.766\text{ m}.$

Points above the centerline: $\sin\theta = (m+\frac{1}{4})\dfrac{\lambda}{d} = (m+\frac{1}{4})\left(\dfrac{0.766\text{ m}}{3.50\text{ m}}\right) = 0.219(m+\frac{1}{4})$. $m=0$: $\theta = 3.14°$;

$m=1$: $\theta = 15.9°$; $m=2$: $\theta = 29.5°$; $m=3$: $\theta = 45.4°$; $m=4$: $\theta = 68.6°$.

Points below the centerline: $\sin\theta = (m+\frac{3}{4})\dfrac{\lambda}{d} = (m+\frac{3}{4})\left(\dfrac{0.766\text{ m}}{3.50\text{ m}}\right) = 0.219(m+\frac{3}{4})$. $m=0$: $\theta = 9.45°$;

$m=1$: $\theta = 22.5°$; $m=2$: $\theta = 37.0°$; $m=3$: $\theta = 55.2°$.

EVALUATE: It is *not* always true that the path difference for destructive interference must be $(m+\frac{1}{2})\lambda$, but it *is* always true that the phase difference must be 180° (or odd multiples of 180°).

35.43. **IDENTIFY** and **SET UP:** Consider interference between rays reflected from the upper and lower surfaces of the film to relate the thickness of the film to the wavelengths for which there is destructive interference. The thermal expansion of the film changes the thickness of the film when the temperature changes.
EXECUTE: For this film on this glass, there is a net $\lambda/2$ phase change due to reflection and the condition for destructive interference is $2t = m(\lambda/n)$, where $n = 1.750$.

Smallest nonzero thickness is given by $t = \lambda/2n$.
At $20.0°\text{C}$, $t_0 = (582.4\text{ nm})/[(2)(1.750)] = 166.4\text{ nm}$.
At $170°\text{C}$, $t = (588.5\text{ nm})/[(2)(1.750)] = 168.1\text{ nm}$.
$t = t_0(1+\alpha\Delta T)$ so
$\alpha = (t-t_0)/(t_0\Delta T) = (1.7\text{ nm})/[(166.4\text{ nm})(150\text{C°})] = 6.8\times10^{-5}(\text{C°})^{-1}$.

EVALUATE: When the film is heated its thickness increases, and it takes a larger wavelength in the film to equal $2t$. The value we calculated for α is the same order of magnitude as those given in Table 17.1.

35.44. **IDENTIFY:** The maximum intensity occurs at all the points of constructive interference. At these points, the path difference between waves from the two transmitters is an integral number of wavelengths.
SET UP: For constructive interference, $\sin\theta = m\lambda/d$.
EXECUTE: **(a)** First find the wavelength of the UHF waves:

$\lambda = c/f = (3.00\times10^8\text{ m/s})/(1575.42\text{ MHz}) = 0.1904\text{ m}$.
For maximum intensity $(\pi d\ \sin\theta)/\lambda = m\pi$, so

$\sin\theta = m\lambda/d = m[(0.1904\text{ m})/(5.18\text{ m})] = 0.03676m$.
The maximum possible m would be for $\theta = 90°$, or $\sin\theta = 1$, so

$m_{\max} = d/\lambda = (5.18\text{ m})/(0.1904\text{ m}) = 27.2$,

which must be ±27 since m is an integer. The total number of maxima is 27 on either side of the central fringe, plus the central fringe, for a total of $27+27+1 = 55$ bright fringes.
(b) Using sin $\theta = m\lambda/d$, where $m = 0, \pm1, \pm2, \text{and} \pm3$, we have

$\sin\theta = m\lambda/d = m[(0.1904\ \text{m})/(5.18\ \text{m})] = 0.03676m.$

$m = 0:\ \sin\theta = 0$, which gives $\theta = 0°$.

$m = \pm1: \sin\theta = \pm(0.03676)(1)$, which gives $\theta = \pm2.11°$.

$m = \pm2: \sin\theta = \pm(0.03676)(2)$, which gives $\theta = \pm4.22°$.

$m = \pm3: \sin\theta = \pm(0.03676)(3)$, which gives $\theta = \pm6.33°$.

(c) $I = I_0\cos^2\left(\dfrac{\pi d\sin\theta}{\lambda}\right) = (2.00\ \text{W/m}^2)\cos^2\left[\dfrac{\pi(5.18\ \text{m})\sin(4.65°)}{0.1904\ \text{m}}\right] = 1.28\ \text{W/m}^2.$

EVALUATE: Notice that $\sin\theta$ increases in integer steps, but θ only increases in integer steps for small θ.

35.45. **IDENTIFY:** Consider the phase difference produced by the path difference and by the reflections.
SET UP: There is just one half-cycle phase change upon reflection, so for constructive interference $2t = (m_1 + \frac{1}{2})\lambda_1 = (m_2 + \frac{1}{2})\lambda_2$, where these wavelengths are in the glass. The two different wavelengths differ by just one m-value, $m_2 = m_1 - 1$.

EXECUTE: $(m_1 + \frac{1}{2})\lambda_1 = (m_1 - \frac{1}{2})\lambda_2 \Rightarrow m_1(\lambda_2 - \lambda_1) = \dfrac{\lambda_1 + \lambda_2}{2} \Rightarrow m_1 = \dfrac{\lambda_1 + \lambda_2}{2(\lambda_2 - \lambda_1)}.$

$m_1 = \dfrac{477.0\ \text{nm} + 540.6\ \text{nm}}{2(540.6\ \text{nm} - 477.0\ \text{nm})} = 8.$ $2t = \left(8 + \dfrac{1}{2}\right)\dfrac{\lambda_{01}}{n} \Rightarrow t = \dfrac{17(477.0\ \text{nm})}{4(1.52)} = 1334\ \text{nm}.$

EVALUATE: Now that we have t we can calculate all the other wavelengths for which there is constructive interference.

35.46. **IDENTIFY:** Light reflected from the top of the coating interferes with light reflected from the bottom of the coating, so we have thin-film interference.
SET UP: For maximum transmission in (a) we want minimum reflection. For minimum transmission in (b) we want maximum reflection. A half-cycle phase shift occurs at the air-coating surface but not at the coating-plastic surface. Thus for minimum reflection we must have $2t = m\dfrac{\lambda_0}{n}$, and for maximum reflection we must have $2t = (m + \frac{1}{2})\dfrac{\lambda_0}{n}$, where t is the thickness of the coating and n is the index of refraction of the coating. We want the thinnest coating possible, so we use m = 1 in (a) and m = 0 in (b).

EXECUTE: **(a)** $2t = m\dfrac{\lambda_0}{n}$ gives $t = m\dfrac{\lambda_0}{2n}$ = (1)(510 nm)/[2(1.65)] = 155 nm.

(b) $2t = (m + \frac{1}{2})\dfrac{\lambda_0}{n}$ gives $t = (m + \frac{1}{2})\dfrac{\lambda_0}{2n}$ = (1/2)(510 nm)/[2(1.65)] = 77.3 nm.

EVALUATE: The thickness in (b) is $\frac{1}{2}$ the thickness in (a) because the path differences differ by a factor of one-half of a wavelength.

35.47. **IDENTIFY** and **SET UP:** At the $m = 3$ bright fringe for the red light there must be destructive interference at this same θ for the other wavelength.
EXECUTE: For constructive interference: $d\sin\theta = m\lambda_1 \Rightarrow d\sin\theta = 3(700\ \text{nm}) = 2100\ \text{nm}$. For destructive interference: $d\sin\theta = (m + \frac{1}{2})\lambda_2 \Rightarrow \lambda_2 = \dfrac{d\sin\theta}{m + \frac{1}{2}} = \dfrac{2100\ \text{nm}}{m + \frac{1}{2}}$. So the possible wavelengths are $\lambda_2 = 600$ nm, for $m = 3$, and $\lambda_2 = 467$ nm, for $m = 4$.

EVALUATE: Both d and θ drop out of the calculation since their combination is just the path difference, which is the same for both types of light.

35.48. **IDENTIFY:** Require constructive interference for the reflection from the top and bottom surfaces of each cytoplasm layer and each guanine layer.

SET UP: At the water (or cytoplasm) to guanine interface, there is a half-cycle phase shift for the reflected light, but there is not one at the guanine to cytoplasm interface. Therefore there will always be one half-cycle phase difference between two neighboring reflected beams, just due to the reflections.

EXECUTE: For the guanine layers:

$$2t_{\rm g} = (m+\tfrac{1}{2})\frac{\lambda}{n_{\rm g}} \Rightarrow \lambda = \frac{2t_{\rm g}n_{\rm g}}{(m+\frac{1}{2})} = \frac{2(74\text{ nm})(1.80)}{(m+\frac{1}{2})} = \frac{266\text{ nm}}{(m+\frac{1}{2})} \Rightarrow \lambda = 533\text{ nm } (m=0).$$

For the cytoplasm layers:

$$2t_{\rm c} = (m+\tfrac{1}{2})\frac{\lambda}{n_{\rm c}} \Rightarrow \lambda = \frac{2t_{\rm c}n_{\rm c}}{(m+\frac{1}{2})} = \frac{2(100\text{ nm})(1.333)}{(m+\frac{1}{2})} = \frac{267\text{ nm}}{(m+\frac{1}{2})} \Rightarrow \lambda = 533\text{ nm } (m=0)\ .$$

(b) By having many layers the reflection is strengthened, because at each interface some more of the transmitted light gets reflected back, increasing the total percentage reflected.

(c) At different angles, the path length in the layers changes (always to a larger value than the normal incidence case). If the path length changes, then so do the wavelengths that will interfere constructively upon reflection.

EVALUATE: The thickness of the guanine and cytoplasm layers are inversely proportional to their refractive indices $\left(\dfrac{100}{74} = \dfrac{1.80}{1.333}\right)$, so both kinds of layers produce constructive interference for the same wavelength in air.

35.49. **IDENTIFY:** Dark fringes occur because the path difference is one-half of a wavelength.

SET UP: At the first dark fringe, $d\sin\theta = \lambda/2$. The intensity at any angle θ is given by $I = I_0\cos^2\left(\dfrac{\pi d\sin\theta}{\lambda}\right)$.

EXECUTE: **(a)** At the first dark fringe, we have $d\sin\theta = \lambda/2$. $d/\lambda = 1/(2\sin 19.0°) = 1.54$.

(b) $I = I_0\cos^2\left(\dfrac{\pi d\sin\theta}{\lambda}\right) = \dfrac{I_0}{10} \Rightarrow \cos\left(\dfrac{\pi d\sin\theta}{\lambda}\right) = \dfrac{1}{\sqrt{10}}$. $\dfrac{\pi d\sin\theta}{\lambda} = \arccos\left(\dfrac{1}{\sqrt{10}}\right) = 71.57° = 1.249$ rad.

Using the result from part (a), that $d/\lambda = 1.54$, we have

$\pi(1.54)\sin\theta = 1.249$. $\sin\theta = 0.2589$, so $\theta = \pm 15.0°$.

EVALUATE: Since the first dark fringes occur at $\pm 19.0°$, it is reasonable that at 15° the intensity is reduced to only $1/10$ of its maximum central value.

35.50. **IDENTIFY:** Light from the two slits interferes on the screen. We can use the small-angle approximation because we are only looking at closely spaced bright fringes near the center of the pattern.

SET UP: For small angles, the bright fringes are at positions on the screen given by $y = R\dfrac{m\lambda}{d}$. R, λ, and *d* are all fixed, and the bright fringes are adjacent ones.

EXECUTE: **(a)** The fringe spacidng is $\Delta y = \dfrac{R\lambda\Delta m}{d}$ and Δm = 1 because the bright fringes are adjacent. This equation can be written as $\Delta y = R\lambda\cdot\dfrac{1}{d}$. From this result, we see that a graph of Δy versus $1/d$ should be a straight line having a slope equal to $R\lambda$.

(b) We use points (9.20 mm^{-1}, 5.0 mm) and (2.00 mm^{-1}, 1.0 mm) to calculate the slope, giving slope = $\dfrac{(5.0-1.0)\text{ mm}}{(9.20-2.00)\text{ mm}^{-1}} = 0.5556\text{ mm}^2$. Since λR = slope, we have

λ = (slope)/R = (0.5556 mm^2)/(900 mm) = 6.2×10^{-4} mm = 6.2×10^{-7} m = 620 nm.

(Answers may vary a bit depending on accuracy in reading the graph.)

EVALUATE: This wavelength is well within the range of visible light. According to Figure 32.4 in the textbook, this light should be yellow-orange.

35.51. **IDENTIFY:** The wave from A travels a longer distance than the wave from B to reach point P, so the two waves will be out of phase when they reach P. For constructive interference, the path difference should be a whole-number multiple of the wavelength.
SET UP: To reach point P, the wave from A travels 240.0 m and the wave from B travels a distance x. The path difference for these two waves is 240.0 m – x. For any wave, $\lambda f = v$. Intensity maxima occur at x = 210.0 m, 216.0 m, and 222.0 m, and there are others.
EXECUTE: **(a)** The distance between adjacent intensity maxima is λ. The three given values of x are 6.0 m apart, so the wavelength must be 6.0 m. The frequency is $f = c/\lambda = c/(6.0\text{ m}) = 5.0\times10^7$ Hz = 50 MHz.
(b) Destructive interference occurs when 240.0 m – $x = (m+\frac{1}{2})\lambda$, which gives

x = 240.0 m – $(m+\frac{1}{2})$ (6.0 m).

The largest x occurs when m = 0, so x = 240.0 m – 3.0 m = 237.0 m.
EVALUATE: According to Figure 32.4 in the textbook, a wave having a wavelength of 6.0 m is in the radiowave region of the electromagnetic spectrum, which is consistent with the fact that you are using short-wave radio antennas.

35.52. **IDENTIFY:** Assume that the glass is horizontal. The light that travels through the glass and reflects off of its lower surface interferes with incident the light that reflects off the upper surface of the glass. The glass behaves like a thin film. A half-cycle phase change occurs at the upper surface but not at the lower surface because $n_{air} < n_{glass}$.
SET UP: For constructive interference with this glass, $2t = (m+\frac{1}{2})\left(\lambda_0/n\right)$.

EXECUTE: **(a)** For the 386-nm light: $2t = (m+\frac{1}{2})$ [(386 nm)/n].

For the 496-nm light: $2t = (m+1+\frac{1}{2})$ [(496 nm)/n] = $(m+\frac{3}{2})$ [(386 nm)/n].

Taking the ratio of these two equations gives

$$\frac{m+\frac{1}{2}}{m+\frac{3}{2}}=\frac{386\text{ nm}}{497\text{ nm}}=1.285.$$

Solving for m gives m = 3. Now find t using the equation for the shorter-wavelength light.
$2t = (3+\frac{1}{2})$ [(386 nm)/(1.40)] $\rightarrow$ t = 620 nm.

(b) Solving $2t = (m+\frac{1}{2})(\lambda_0/n)$ for λ_0 gives $\lambda_0 = 2nt/(m+\frac{1}{2})$. The largest wavelength will be for m = 0, so $\lambda_0 = 2(1.40)(620\text{ nm})/(\frac{1}{2}) = 3470$ nm.

EVALUATE: Visible light is between approximately 400 nm and 700 nm, so the light in (b) is definitely not visible. According to Figure 32.4 in the textbook, it would be in the infrared region of the electromagnetic spectrum.

35.53. **IDENTIFY:** This problem involves the interference of sound waves.
SET UP and **EXECUTE:** Pressure nodes are displacement antinodes, so we have constructive interference at the points in question.
(a) We want the minimum radius r. For the minimum r, a wave traveling straight up and back will interfere with sound just leaving the source. So the path difference is $2r$ and we must have $2r = \lambda$, so $r = \lambda/2$.
(b) We want the number of pressure nodes. At 20°C v = 344 m/s, so $\lambda = v/f$ = 0.1376 m. The path difference is $2\sqrt{r^2+(d/2)^2}-d$, so for constructive interference $2\sqrt{r^2+(d/2)^2}-d=m\lambda$.

m = 0: $2\sqrt{r^2+(d/2)^2}=d \rightarrow r = 0$, which is not possible.

m = 1: $2\sqrt{r^2+(d/2)^2}-d=\lambda$. Square and solve for d. $d=\dfrac{4r^2-\lambda^2}{2\lambda}=84.1$ cm.

$m = 2$: $2\sqrt{r^2 + (d/2)^2} - d = 2\lambda$. $d = \dfrac{4(r^2 - \lambda^2)}{4\lambda} = 31.7$ cm.

$m = 3$: $2\sqrt{r^2 + (d/2)^2} - d = 3\lambda$. $d = \dfrac{4r^2 - 9\lambda^2}{6\lambda} = 9.64$ cm.

For $m \geq 4$ we get negative d. So there are 3 nodes on each side of the source, for a total of 6.

(c) $d = \pm 9.64$ cm, ± 31.7 cm, ± 84.1 cm.

(d) With helium, $v = 999$ m/s, so $\lambda = 0.3996$ m $= 40.0$ cm. Use the results from part (c).

$m = 1$: $d = \dfrac{4r^2 - \lambda^2}{2\lambda} = 11.3$ cm.

$m = 2$: $d = \dfrac{4(r^2 - \lambda^2)}{4\lambda}$ is negative, so not possible.

There are two nodes, at $d = \pm 11.3$ cm from the center.

EVALUATE: From the calculations for $m = 1$, if $\lambda > 4r$ there are no nodes.

35.54. **IDENTIFY:** This problem is about the interference due to three slits.

SET UP: $E_p = E\cos\omega t + E\cos(\omega t + \phi) + E\cos(\omega t - \phi)$.

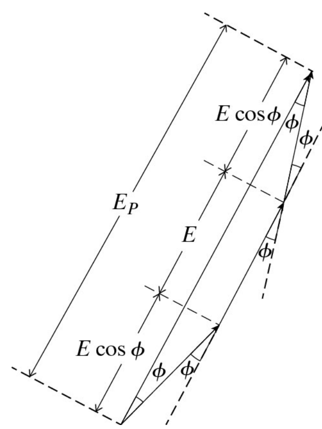

Figure 35.54

EXECUTE: **(a)** We want the amplitude E_p. Using the phasor diagram in Fig. 35.54, we see that $E_p = \cos\phi + E + E\cos\phi = E(1 + 2\cos\phi)$.

(b) We want I at P. $I = \frac{1}{2}\epsilon_0 cE_p^2 = \frac{1}{2}\left[E(1 + 2\cos\phi)\right]^2 \epsilon_0 c = \frac{1}{2}\epsilon_0 cE^2(1 + 2\cos\phi)^2$. The maximum intensity occurs when $\phi = 0$, which gives $I_0 = 9\left(\frac{1}{2}\epsilon_0 cE^2\right)$. Thus $\frac{1}{2}\epsilon_0 cE^2 = \frac{I_0}{9}$. Using this result in our equation for I gives $I = \frac{1}{9}I_0(1 + 2\cos\phi)^2$.

(c) Since $I \propto (1 + 2\cos\phi)^2$, the lesser maxima occur when $\cos\phi = -1$, for $\phi = \pm\pi, \pm 3\pi, \pm 5\pi, \ldots$.

(d) We want I. $I = \frac{1}{9}I_0(1 - 2)^2 = \frac{I_0}{9}$.

(e) We want the dark fringes. Use the result from (b). $I = \frac{1}{9}I_0(1 + 2\cos\phi)^2$. For the minima, $I = 0$, so $\cos\phi = -1/2$, so $\phi = \pm 120°$.

(f) From (c), lesser maxima occur when $\phi = \pm\pi, \pm 3\pi, \ldots$ The nearest to the center is when $\phi = \pm\pi$. $\phi = \pi = \dfrac{2\pi d \sin\theta}{\lambda}$. Using d = 0.200 mm and λ = 650 nm, this gives $\sin\theta = 0.001625$. For small angles, $\sin\theta \approx \tan\theta \approx \theta$. The distance on the screen is $y = R\tan\theta \approx R\theta$ = (1.00 m)(0.001625) = 1.63 mm.

(g) The first absolute maximum away from the center occurs for $\phi = 2\pi$. Using $\phi = 2\pi = \dfrac{2\pi d \sin\theta}{\lambda}$ gives $\sin\theta = 0.00325$. As above $y = R\tan\theta \approx R\theta$, which gives y = 3.25 mm.

EVALUATE: The angles are small near the center, so the first lesser maximum is midway between the central maximum and the first absolute maximum.

35.55. IDENTIFY: There are two effects to be considered: first, the expansion of the rod, and second, the change in the rod's refractive index.

SET UP: $\lambda = \dfrac{\lambda_0}{n}$ and $\Delta n = n_0(2.50\times10^{-5}\ (\text{C}°)^{-1})\Delta T$. $\Delta L = L_0(5.00\times10^{-6}\ (\text{C}°)^{-1})\Delta T$.

EXECUTE: The extra length of rod replaces a little of the air so that the change in the number of wavelengths due to this is given by: $\Delta N_1 = \dfrac{2n_{\text{glass}}\Delta L}{\lambda_0} - \dfrac{2n_{\text{air}}\Delta L}{\lambda_0} = \dfrac{2(n_{\text{glass}}-1)L_0\alpha\Delta T}{\lambda_0}$ and

$$\Delta N_1 = \frac{2(1.48-1)(0.030\text{ m})(5.00\times10^{-6}/\text{C}°)(5.00\text{ C}°)}{5.89\times10^{-7}\text{ m}} = 1.22.$$

The change in the number of wavelengths due to the change in refractive index of the rod is:

$$\Delta N_2 = \frac{2\Delta n_{\text{glass}}L_0}{\lambda_0} = \frac{2(2.50\times10^{-5}/\text{C}°)(5.00\text{ C}°/\text{min})(1.00\text{ min})(0.0300\text{ m})}{5.89\times10^{-7}\text{ m}} = 12.73.$$

So, the total change in the number of wavelengths as the rod expands is
$\Delta N = 12.73 + 1.22 = 14.0$ fringes/minute.

EVALUATE: Both effects increase the number of wavelengths along the length of the rod. Both ΔL and Δn_{glass} are very small and the two effects can be considered separately.

35.56. IDENTIFY: Apply Snell's law to the refraction at the two surfaces of the prism. S_1 and S_2 serve as coherent sources so the fringe spacing is $\Delta y = \dfrac{R\lambda}{d}$, where d is the distance between S_1 and S_2.

SET UP: For small angles, $\sin\theta \approx \theta$, with θ expressed in radians.

EXECUTE: **(a)** Since we can approximate the angles of incidence on the prism as being small, Snell's law tells us that an incident angle of θ on the flat side of the prism enters the prism at an angle of θ/n, where n is the index of refraction of the prism. Similarly on leaving the prism, the in-going angle is $\theta/n - A$ from the normal, and the outgoing angle, relative to the prism, is $n(\theta/n - A)$. So the beam leaving the prism is at an angle of $\theta' = n(\theta/n - A) + A$ from the optical axis. So $\theta - \theta' = (n-1)A$. At the plane of the source S_0, we can calculate the height of one image above the source:

$$\frac{d}{2} = \tan(\theta-\theta')a \approx (\theta-\theta')a = (n-1)Aa \Rightarrow d = 2aA(n-1).$$

(b) To find the spacing of fringes on a screen, we use

$$\Delta y = \frac{R\lambda}{d} = \frac{R\lambda}{2aA(n-1)} = \frac{(2.00\text{ m}+0.200\text{ m})\,(5.00\times10^{-7}\text{ m})}{2(0.200\text{ m})\,(3.50\times10^{-3}\text{ rad})\,(1.50-1.00)} = 1.57\times10^{-3}\text{ m}.$$

EVALUATE: The fringe spacing is proportional to the wavelength of the light. The biprism serves as an alternative to two closely spaced narrow slits.

35.57. **IDENTIFY and SET UP:** Interference occurs when two or more waves combine.
EXECUTE: All of the students now hear the tone, so no interference is occurring. Therefore only one speaker must be on, so the professor must have disconnected one of them. This makes choice (d) correct.
EVALUATE: Turning off one of the speakers would decrease the loudness of the sound, as was observed.

35.58. **IDENTIFY and SET UP:** Constructive interference occurs when a wave crest meets another crest, and descructive interference occurs when a crest meets a trough.
EXECUTE: The students who originally heard a loud tone were at a point of constructive interference, so a crest from one speaker met a crest from the other speaker, and those who originally heard nothing were at points where a crest met a trough. Now the students who originally heard a loud tone hear nothing, so at their point a crest meets a trough. The students who originally heard nothing are not at a point where a crest meets a crest. Since the speakers (and students) have not been moved, their phase relationship has been changed, which is choice (d).
EVALUATE: Since a point of constructive interference was turned into a point of destructive interference by the phase change, the phase change must have been π or 180°, equivalent to one-half a wavelength.

35.59. **IDENTIFY:** Moving one of the speakers increases the distance that its sound must travel to reach the listener. This changes the phase difference in the sound from the two speakers as it reaches the listeners.
SET UP: The movement of 0.34 m turned points of constructive interference into points of destructive interference, so that distance must be one-half of a wavelength. We use $v = f\lambda$ to find the frequency.
EXECUTE: $\lambda/2 = 0.34$ m, so $\lambda = 0.68$ m. $v = f\lambda$ gives $f = v/\lambda$ = (340 m/s)/(0.68 m) = 500 Hz, which is choice (c).
EVALUATE: If the professor moves the speaker an additional 0.34 m, the students will hear what they originally heard since that distance is a full wavelength.

35.60. **IDENTIFY and SET UP:** Since $v = f\lambda$, reducing the frequency half increases the wavelength by a factor of 2. For constructive interference, the path difference is $m\lambda$, where m = 0, 1, 2, 3, …, and for destructive interference the path difference is $(m+\frac{1}{2})\lambda$, where m = 0, 1, 2, 3, ….
EXECUTE: The new wavelength λ is twice as long as the original wavelength λ_0. Students who heard a loud tone before were at locations for which the path difference was λ, 2λ, 3λ, 4λ, 5λ, …. But since the new wavelength is $\lambda = 2\lambda_0$, students who were at a path difference of λ_0 are now at a point where the path difference is $\lambda/2$, and those where it was $3\lambda_0$ are now where it is $3\lambda/2$, etc. So all those students for whom the path difference was λ_0, $3\lambda_0$, $5\lambda_0$, $7\lambda_0$, … will hear nothing. For the students who are at points where the path difference was $2\lambda_0$, $4\lambda_0$, $6\lambda_0$, …, the path difference is now λ, 2λ, 3λ, …, so they will still hear a loud tone. Therefore choice (c) is correct.
EVALUATE: Students at various points in between those discussed here hear sound, but not of maximum loudness.

36

DIFFRACTION

VP36.3.1. **IDENTIFY:** This problem is about single-slit diffraction.

SET UP: For small angles, dark spots occur at $y_m = R\dfrac{m\lambda}{a}$. The small-angle approximation is valid.

EXECUTE: **(a)** We want R. Solve $y_m = R\dfrac{m\lambda}{a}$. $R = \dfrac{a\lambda}{my} = \dfrac{(0.250\text{ mm})(14.0\text{ mm})}{2(645\text{ mn})} = 2.71\text{ m}$.

(b) We want the distance 2y. Use $y_m = R\dfrac{m\lambda}{a}$ and divide. $\dfrac{y_{525}}{y_{645}} = \dfrac{\dfrac{Rm(525\text{ nm})}{a}}{\dfrac{Rm(645\text{ nm})}{a}} = 0.81395$. The distance is $2y_{645}$ = (0.81395)(28.0 mm) = 22.8 m.

EVALUATE: Since $y \propto \lambda$, shorter-wavelength dark fringes should be close together, as we have just seen.

VP36.3.2. **IDENTIFY:** We are dealing with single-slit diffraction.

SET UP: For small angles, dark spots occur at $y_m = R\dfrac{m\lambda}{a}$. The small-angle approximation is valid.

EXECUTE: **(a)** We want λ. Solve $y_m = R\dfrac{m\lambda}{a}$. $\lambda = \dfrac{ay_m}{mR} = \dfrac{(0.221\text{ mm})(45.7\text{ mm})}{3(5.00\text{ m})} = 673\text{ nm}$.

(b) We want θ to the second dark fringe. $a\sin\theta_2 = 2\lambda$ gives $\theta_2 = 0.349°$.

EVALUATE: With such a small angle of 0.349°, it is clear that the small-angle approximation is valid.

VP36.3.3. **IDENTIFY:** This problem involves the intensity of a single-slit diffraction pattern.

SET UP: $I = I_0\left(\dfrac{\sin\beta/2}{\beta/2}\right)^2$, $\beta = \dfrac{2\pi a\sin\theta}{\lambda}$, 17.5 rad = 1002.7°.

EXECUTE: **(a)** We want θ. Using $\beta = \dfrac{2\pi a\sin\theta}{\lambda}$ gives

$\theta = \arcsin\left(\dfrac{\lambda\beta}{2\pi a}\right) = \arcsin\left(\dfrac{(545\text{ nm})(35.0\text{ rad})}{2\pi(0.250\text{ mm})}\right) = 0.696°$.

(b) We want I. $I = I_0\left(\dfrac{\sin\beta/2}{\beta/2}\right)^2 = I_0\left(\dfrac{\sin 17.5\text{ rad}}{17.5\text{ rad}}\right)^2 = I_0\left(\dfrac{\sin 1002.7°}{17.5\text{ rad}}\right)^2 = 0.00311 I_0$.

EVALUATE: It is important to realize that in the intensity equation, the $\beta/2$ in the numerator can be expressed as degrees or radians, but in the numerator it must be in radians.

VP36.3.4. **IDENTIFY:** We are dealing with the intensity in single-slit diffraction.

SET UP: $I = I_0\left(\dfrac{\sin\beta/2}{\beta/2}\right)^2$, $\beta = \dfrac{2\pi a\sin\theta}{\lambda}$.

EXECUTE: **(a)** We want θ to the first dark fringe. $a\sin\theta_1 = \lambda$.

$\theta_1 = \arcsin(\lambda/a) = \arcsin\left(\dfrac{576 \text{ nm}}{0.185 \text{ mm}}\right) = 0.178°.$

(b) We want the intensity. $\dfrac{\beta}{2} = \dfrac{2\pi a\sin\theta}{\lambda}$. $\theta = \dfrac{0.178°}{2} = 0.0892°$. First get $\beta/2$.

$\dfrac{\beta}{2} = \dfrac{\pi(0.185 \text{ mm})\sin(0.0892°)}{576 \text{ nm}} = 1.5708 \text{ rad} = 90.0°$. Now use $I = I_0\left(\dfrac{\sin\beta/2}{\beta/2}\right)^2$.

$I = I_0\left(\dfrac{\sin 90.0°}{1.5708 \text{ rad}}\right)^2 = 0.405 I_0.$

EVALUATE: The intensity is close to $I_0/2$, but not equal to it.

VP36.5.1. **IDENTIFY:** We have a diffraction grating.

SET UP: Bright fringes occur at $d\sin\theta_m = m\lambda$, $d = 1/(825 \text{ slits/mm})$.

EXECUTE: **(a)** We want λ. Solve $d\sin\theta_m = m\lambda$ for λ, giving

$\lambda = \dfrac{[1/(825 \text{ slits/mm})]\sin 41.0°}{2} = 398 \text{ nm}.$

(b) We want θ_1 and θ_3. $\theta_1 = \arcsin(\lambda/d) = \arcsin\left(\dfrac{398 \text{ nm}}{825 \text{ mm}}\right) = 19.1°.$

$\theta_3 = \arcsin(3\lambda/d) = \arcsin\left(\dfrac{3(398 \text{ nm})}{825 \text{ mm}}\right) = 79.8°.$

EVALUATE: Notice that the bright fringes are *not* evenly spaced.

VP36.5.2. **IDENTIFY:** We have a diffraction grating.

SET UP: Bright fringes occur at $d\sin\theta_m = m\lambda$.

EXECUTE: **(a)** We want the slit density. Solve $d\sin\theta_m = m\lambda$ for d, giving

$d = \dfrac{\lambda}{\sin\theta_1} = \dfrac{625 \text{ nm}}{\sin 24.0°} = 1537 \text{ nm}$. The slit spacing is $1/d$, so the slit spacing is 651 slits/mm.

(b) We want θ_2 and θ_3. $\theta_2 = \arcsin(2\lambda/d) = \arcsin\left(\dfrac{2(625 \text{ nm})}{1537 \text{ nm}}\right) = 54.4°.$

$\theta_3 = \arcsin(3\lambda/d) = \arcsin\left(\dfrac{3(625 \text{ nm})}{1537 \text{ nm}}\right) = \arcsin(1.22)$, so there is no θ_3.

EVALUATE: Once $\sin\theta > 1$ there are no more fringes.

VP36.5.3. **IDENTIFY:** We are dealing with x-ray diffraction by a crystal.

SET UP: The plane spacing is $d = 0.124$ nm. Strong interference maxima occur when $2d\sin\theta_m = m\lambda$.

EXECUTE: **(a)** We want θ for the first strong maximum. Solve $2d\sin\theta_m = m\lambda$.

$\theta_1 = \arcsin(\lambda/2d) = \arcsin\left(\dfrac{0.124 \text{ nm}}{2(0.165 \text{ nm})}\right) = 22.1°.$

(b) Are there other angles? $\theta_2 = \arcsin(2\lambda/2d) = \arcsin\left(\dfrac{0.124 \text{ nm}}{0.165 \text{ nm}}\right) = 48.7°$. There are no other angles because $\sin\theta_3 > 1$.

EVALUATE: If $\lambda << d$, there could be many more maxima.

VP36.5.4. **IDENTIFY:** This problem is about x-ray diffraction by a crystal.

SET UP: The plane spacing is d = 0.158 nm. Strong interference maxima occur when $2d\sin\theta_m = m\lambda$. We want λ.

EXECUTE: **(a)** $2d\sin\theta_m = m\lambda = \lambda$, so λ = 2(0.158 nm) sin 36.0° = 0.186 nm.

(b) $2d\sin\theta_3 = 3\lambda$. λ = 2(0.158 nm)(sin 88.0°)/3 = 0.105 nm.

EVALUATE: Since $\sin\theta_m = m\lambda/2d$, to have a large m, λ/d must be small, so $\lambda << d$.

VP36.6.1. **IDENTIFY:** This problem is about the resolving power of a telescope.

SET UP: Rayleigh criterion: $\theta \approx 1.22\dfrac{\lambda}{D}$.

EXECUTE: **(a)** We want D. Solve for D: $D = (1.22)\,(1.70\text{ cm})/(9.00\times10^{-5}\text{rad}) = 230$ m.

(b) We want θ if λ = 21.1 cm. $\theta \approx 1.22\dfrac{\lambda}{D}$ = (1.22)(21.1 cm)/(230 m) = 0.114 mrad = 0.0640°.

EVALUATE: To increase resolution, either increase D or decrease λ, or both.

VP36.6.2. **IDENTIFY:** We are looking at resolving power.

SET UP: For small angles $\theta \approx 1.22\dfrac{\lambda}{D}$, $\dfrac{1}{f} = \dfrac{1}{s} + \dfrac{1}{s'}$, $m = -s'/s$, f = 0.250 m = 250 mm.

EXECUTE: **(a)** We want the maximum distance. At f/4 the diameter of the lens is $D = f/4$, so D = (250 mm)/4 = 62.5 mm. This gives $\theta \approx 1.22\dfrac{\lambda}{D}$ = (1.22)(550 nm)/(62.5 mm) = 1.074×10^{-5}rad. For the two points, $\sin\theta = \dfrac{5.00\text{ mm}}{x}$, so $x = (5.00\text{ mm})/(1.074\times10^{-5}\text{rad.}) = 466$ m.

(b) We want the distance between the two points on the lens's image. Use $\dfrac{1}{f} = \dfrac{1}{s} + \dfrac{1}{s'}$. $\dfrac{1}{s'} = \dfrac{1}{f} - \dfrac{1}{s}$ = 1/(0.250 m) – 1/(466 m), so s' = 0.2501 m. $h' = h_0|m| = h_0\dfrac{s'}{s}$. This gives

$$h' = (5.00\text{ mm})\left(\frac{0.2501\text{ m}}{466\text{ m}}\right) = 0.00268\text{ mm}.$$

EVALUATE: 466 m is around 1500 ft. Most people could not even *see* the two points to focus at that distance.

VP36.6.3. **IDENTIFY:** This problem involves an Airy disk and a camera lens.

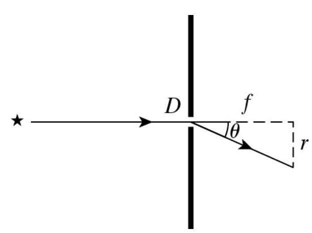

Figure VP36.6.3

SET UP and **EXECUTE:** **(a)** We want D. Refer to Fig. VP36.63. $\sin\theta = 1.22\dfrac{\lambda}{D}$ The image of a very distant object is formed at the focal point of the lens, so it is 135 mm from the lens. $r << f$, so $\theta \approx r/f$. Thus $\dfrac{r}{f} = 1.22\dfrac{\lambda}{D}$, giving $D = \dfrac{1.22\lambda f}{r}$ = (1.22)(575 nm)(135 mm)/(0.0112 mm) = 8.46 mm.

(b) We want the *f*-number. If the *f*-number is *f/x*, it means that $D = f/x$. Therefore $x = \dfrac{f}{D} = \dfrac{135\text{ mm}}{8.46\text{ mm}} = 16.0$, so the *f*-number is *f*/16.0.

EVALUATE: An *f*-number of *f*/16 is considered a fairly small lens aperture.

VP36.6.4. **IDENTIFY:** This problem is about the resolving power of a telescope.

SET UP: Rayleigh criterion: $\theta \approx 1.22\dfrac{\lambda}{D}$. We want the distance to the planet and its star.

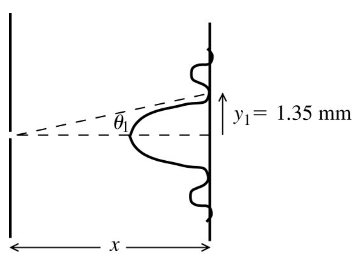
EXECUTE: **(a)** λ = 690 nm. $\theta \approx 1.22\dfrac{\lambda}{D}$ = (1.22)(690 nm)/(8.0 m) = 1.052×10^{-7} rad. For planet and star: $\theta = R/x \rightarrow x = R/\theta = 1.5\times10^{11}\text{ m}/1.052\times10^{-7}\text{ rad} = 1.6\times10^{19}$ m. Using the fact that 1 ly $= 9.46\times10^{15}$ m, we get x = 150 ly.

(b) λ = 1400 nm. λ increases by a factor 1400/690, so θ increases by the same factor since $\theta \propto \lambda$. $x \propto 1/\theta$, so x decreases by a factor 690/1400. Therefore x = (690/1400)(150 ly) = 74 ly.

EVALUATE: Clearly it's better to use the shortest possible wavelength.

36.1. **IDENTIFY:** Use $y = x\tan\theta$ to calculate the angular position θ of the first minimum. The minima are located by $\sin\theta = \dfrac{m\lambda}{a}$, $m = \pm1, \pm2, \ldots$. First minimum means $m = 1$ and $\sin\theta_1 = \lambda/a$ and $\lambda = a\sin\theta_1$. Use this equation to calculate λ.

SET UP: The central maximum is sketched in Figure 36.1.



EXECUTE: $y_1 = x\tan\theta_1$.

$\tan\theta_1 = \dfrac{y_1}{x} =$

$\dfrac{1.35\times10^{-3}\text{ m}}{2.00\text{ m}} = 0.675\times10^{-3}$.

$\theta_1 = 0.675\times10^{-3}$ rad.

Figure 36.1

$\lambda = a\sin\theta_1 = (0.750\times10^{-3}\text{ m})\sin(0.675\times10^{-3}\text{ rad}) = 506\text{ nm}.$

EVALUATE: θ_1 is small so the approximation used to obtain $y_m = x\dfrac{m\lambda}{a}$ is valid and this equation could have been used.

36.2. **IDENTIFY:** This problem is about single-slit diffraction.

SET UP: Dark spots occur when $a\sin\theta_m = m\lambda$, $y = R\tan\theta$, for small angles $y_m = R\dfrac{m\lambda}{a}$. We want the width of the central maximum on the screen when λ = 0.125 mm.

EXECUTE: When λ = 500 nm, we can use the small-angle approximation to find the width a of the slit. The width of the central maximum is 8.00 mm, so 8.00 mm = $2y_1 = 2R\dfrac{\lambda}{a} = 2(2.00\text{ m})\dfrac{500\text{ nm}}{a}$, which gives a = 0.250 mm. Now find θ when λ = 0.125 mm. We don't know that we can use the small-angle approximation, so use $a\sin\theta_m = m\lambda$. At the first dark fringe we have $\sin\theta = \dfrac{\lambda}{a} = \dfrac{0.125\text{ mm}}{0.250\text{ mm}} = 0.500$, so θ = 30.0°. (As we see, the small-angle approximation would not be justified.) $y = R\tan\theta$, and the width of the central maximum is $2y$, so we have $2y = 2R\tan\theta = 2(2.00\text{ m})\tan 30.0° = 2.31\text{ m}.$

EVALUATE: The central maximum is much wider with the greater wavelength light. In that case, the small-angle approximation certainly cannot be used.

36.3. IDENTIFY: The dark fringes are located at angles θ that satisfy $\sin\theta = \dfrac{m\lambda}{a}$, $m = \pm 1, \pm 2, \ldots$.

SET UP: The largest value of $|\sin\theta|$ is 1.00.

EXECUTE: **(a)** Solve for *m* that corresponds to $\sin\theta = 1$: $m = \dfrac{a}{\lambda} = \dfrac{0.0666\times10^{-3}\text{ m}}{585\times10^{-9}\text{ m}} = 113.8.$ The largest value *m* can have is 113. $m = \pm 1, \pm 2, \ldots, \pm 113$ gives 226 dark fringes.

(b) For $m = \pm 113$, $\sin\theta = \pm 113\left(\dfrac{585\times10^{-9}\text{ m}}{0.0666\times10^{-3}\text{ m}}\right) = \pm 0.9926$ and $\theta = \pm 83.0°$.
