CONTENTS

Preface

This Instructor's Solutions Manual contains the solutions to all the problems and exercises in *University Physics*, Fifteenth Edition, by Hugh Young and Roger Freedman.

In preparing this manual, we assumed that its primary users would be college professors; thus the solutions are condensed, and some steps are not shown. Some calculations were carried out to more significant figures than demanded by the input data in order to allow for differences in calculator rounding. In many cases answers were then rounded off. Therefore, you may obtain slightly different results, especially when powers or trig functions are involved.

This edition was constructed from the previous editions authored by Craig Watkins and Mark Hollabaugh, and much of what is here is due to them.

UNITS, PHYSICAL QUANTITIES, AND VECTORS

VP1.7.1. **IDENTIFY:** We know that the sum of three known vectors and a fourth unknown vector is zero. We want to find the magnitude and direction of the unknown vector.

SET UP: The sum of their x-components and the sum of their y-components must both be zero.

$A_x + B_x + C_x + D_x = 0$

$A_y + B_y + C_y + D_y = 0$

The magnitude of a vector is w $A = \sqrt{A_x^2 + A_y^2}$ and the angle θ it makes with the $+x$-axis is

$\theta = \arctan\dfrac{A_y}{A_x}$.

EXECUTE: We use the results of Ex. 1.7. See Fig. 1.23 in the text.

$A_x = 38.37$ m, $B_x = -46.36$ m, $C_x = 0.00$ m, $A_y = 61.40$ m, $B_y = -33.68$ m, $C_y = -17.80$ m

Adding the x-components gives

38.37 m + (–46.36 m) + 0.00 m + $D_x = 0$ $\quad\rightarrow\quad$ $D_x = 7.99$ m

Adding the y-components gives

61.40 m + (–33.68 m) + (–17.80 m) + $D_y = 0$ $\quad\rightarrow\quad$ $D_y = -9.92$ m

$D = \sqrt{D_x^2 + D_y^2} = \sqrt{(7.99\text{ m})^2 + (-9.92\text{ m})^2} = 12.7$ m

glo $\quad \theta = \arctan\dfrac{D_y}{D_x} = \arctan[(-9.92\text{ m})/(7.99\text{ m})] = -51°$

Since $\vec{D}$ has a positive x-component and a negative y-component, it points into the fourth quadrant making an angle of 51° below the $+x$-axis and an angle of 360° – 51° = 309° counterclockwise with the $+x$-axis.

EVALUATE: The vector $\vec{D}$ has the same magnitude as the resultant in Ex. 1.7 but points in the opposite direction. This is reasonable because $\vec{D}$ must be opposite to the resultant of the three vectors in Ex. 1.7 to make the resultant of all four vectors equal to zero.

VP1.7.2. **IDENTIFY:** We know three vectors $\vec{A}$, $\vec{B}$, and $\vec{C}$ and we want to find the sum $\vec{S}$ where $\vec{S} = \vec{A} - \vec{B} + \vec{C}$. The components of $-\vec{B}$ are the negatives of the components of $\vec{B}$.

SET UP: The components of $\vec{S}$ are

$S_x = A_x - B_x + C_x$

$S_y = A_y - B_y + C_y$

The magnitude A of a vector $\vec{A}$ is $A = \sqrt{A_x^2 + A_y^2}$ and the angle θ it makes with the $+x$-axis is

$\theta = \arctan\dfrac{A_y}{A_x}$.

EXECUTE: Using the components from Ex. 1.7 we have

S_x = 38.37 m – (–46.36 m) + 0.00 m = 84.73 m

S_y = 61.40 m – (–33.68 m) + (–17.80 m) = 77.28 m

$$S = \sqrt{S_x^2 + S_y^2} = \sqrt{(84.73\text{ m})^2 + (77.28\text{ m})^2} = 115\text{ m}$$

$$\theta = \arctan\frac{S_y}{S_x} = \arctan[(77.28\text{ m})/(84.73\text{ m})] = 42°$$

Since both components of $\vec{S}$ are positive, $\vec{S}$ points into the first quadrant. Therefore it makes an angle of 42° with the +x-axis.

EVALUATE:

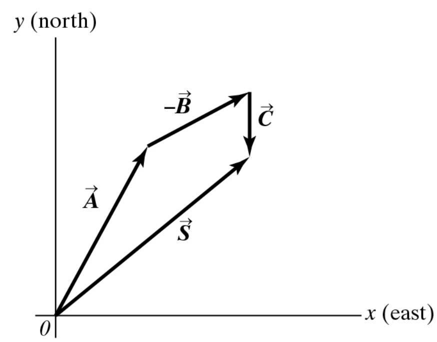

Figure VP1.7.2

The graphical solution shown in Fig. VP1.7.2 shows that our results are reasonable.

VP1.7.3. **IDENTIFY:** We know three vectors $\vec{A}$, $\vec{B}$, and $\vec{C}$ and we want to find the sum $\vec{T}$ where $\vec{T} = \vec{A} + \vec{B} + 2\vec{C}$.

SET UP: Find the components of vectors $\vec{A}$, $\vec{B}$, and $\vec{C}$ and use them to find the magnitude and direction of $\vec{T}$. The components of $2\vec{C}$ are twice those of $\vec{C}$.

EXECUTE: $S_x = A_x + B_x + 2C_x$ and $S_y = A_y + B_y + 2C_y$

(a) Using the components from Ex. 1.7 gives

T_x = 38.37 m + (–46.36 m) + 2(0.00 m) = –7.99 m

T_y = 61.40 m + (–33.68 m) + 2(–17.80 m) = –7.88 m

(b) $T = \sqrt{T_x^2 + T_y^2} = \sqrt{(-7.99\text{ m})^2 + (-7.88\text{ m})^2} = 11.2\text{ m}$

$$\theta = \arctan\frac{T_y}{T_x} = \arctan[(-7.88\text{ m})/(-7.99\text{ m})] = 45°$$

Both components of $\vec{T}$ are negative, so it points into the third quadrant, making an angle of 45° below the –x-axis or 45° + 180° = 225° counterclockwise with the +x-axis, in the third quadrant.

EVALUATE:

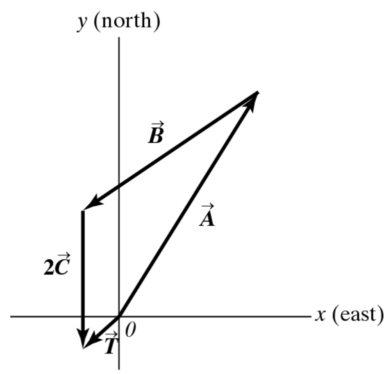

Figure VP1.7.3

The graphical solution shown in Fig. VP1.7.3 shows that this result is reasonable.

VP1.7.4. **IDENTIFY:** The hiker makes two displacements. We know the first one and their resultant, and we want to find the second displacement.

SET UP: Calling $\vec{A}$ the known displacement, $\vec{R}$ the known resultant, and $\vec{D}$ the unknown vector, we know that $\vec{A} + \vec{D} = \vec{R}$. We also know that $R = 38.0$ m and $\vec{R}$ makes an angle $\theta_R = 37.0° + 90° = 127°$ with the $+x$-axis. Fig. VP1.7.4 shows a sketch of these vectors.

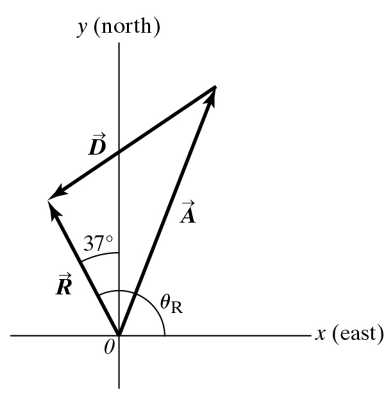

Figure VP1.7.4

EXECUTE: From Ex. 1.7 we have $A_x = 38.37$ m and $A_y = 61.40$ m. The components of $\vec{R}$ are
$R_x = R \cos 127.0° = (38.0 \text{ m}) \cos 127.0° = –22.87$ m
$R_y = R \sin 38.0° = (38.0 \text{ m}) \sin 127.0° = 30.35$ m
$R_x = A_x + D_x$ and $R_y = A_y + D_y$

Using these components, we find the components of $\vec{D}$.
$38.37 \text{ m} + D_x = –22.87 \text{ m} \quad \rightarrow \quad D_x = –22.87 \text{ m}$
$61.40 \text{ m} + D_y = –31.05 \text{ m} \quad \rightarrow \quad D_y = –31.05 \text{ m}$

$$D = \sqrt{D_x^2 + D_y^2} = \sqrt{(–61.24 \text{ m})^2 + (–31.05 \text{ m})^2} = 68.7 \text{ m}$$

$$\theta = \arctan\frac{D_y}{D} = \arctan[(–31.05 \text{ m})/(–61.24 \text{ m})] = 27°$$

Both components of $\vec{D}$ are negative, so it points into the third quadrant, making an angle of 27° + 180° = 207° with the +x-axis.

EVALUATE: A graphical solution will confirm these results.

VP1.10.1. **IDENTIFY:** We know the magnitude and direction of two vectors. We want to use these to find their components and their scalar product.

SET UP: $A_x = A\cos\theta_A$, $A_y = A\sin\theta_A$, $B_x = B\cos\theta_B$, $B_y = B\sin\theta_B$. We can find the scalar product using the vector components or using their magnitudes and the angle between them. $\vec{A}\cdot\vec{B} = A_xB_x + A_yB_y$ and $\vec{A}\cdot\vec{B} = AB\cos\phi$. Which form you use depends on the information you have.

EXECUTE: (a) $A_x = A\cos\theta_A = (5.00)\cos(360° - 36.9°) = 4.00$

$A_y = A\sin\theta_A = (5.00)\sin(360° - 36.9°) = -3.00$

$B_x = (6.40)\cos(90° + 20.0°) = -2.19$

$B_y = (6.40)\sin(90° + 20.0°) = 6.01$

(b) Using components gives

$\vec{A}\cdot\vec{B} = A_xB_x + A_yB_y = (4.00)(-2.19) + (-3.00)(6.01) = -26.8$

EVALUATE: We check by using $\vec{A}\cdot\vec{B} = AB\cos\phi$.

$\vec{A}\cdot\vec{B} = AB\cos\phi = (5.00)(6.40)\cos(20.0° + 90° + 36.9°) = -26.8$

This agrees with our result in part (b).

VP1.10.2. **IDENTIFY:** We know the magnitude and direction of one vector and the components of another vector. We want to use these to find their scalar product and the angle between them.

SET UP: The scalar product can be expressed as $\vec{A}\cdot\vec{B} = A_xB_x + A_yB_y$ and $\vec{A}\cdot\vec{B} = AB\cos\phi$. Which form you use depends on the information you have.

EXECUTE: (a) $C_x = C\cos\theta_C = (6.50)\cos 55.0° = 3.728$

$C_y = C\sin\theta_C = (6.50)\sin 55.0° = 5.324$

$D_x = 4.80$ and $D_y = -8.40$

Using components gives $\vec{C}\cdot\vec{D} = C_xD_x + C_yD_y = (3.728)(4.80) + (5.324)(-8.40) = -26.8$

(b) $D = \sqrt{D_x^2 + D_y^2} = \sqrt{(4.80)^2 + (-8.40)^2} = 9.675$

$\vec{C}\cdot\vec{D} = CD\cos\phi$, so $\cos\phi = \vec{C}\cdot\vec{D}/CD = (-26.8)/[(6.50)(9.67)] = -0.426$. $\phi = 115°$.

EVALUATE: Find the angle that $\vec{D}$ makes with the +x-axis.

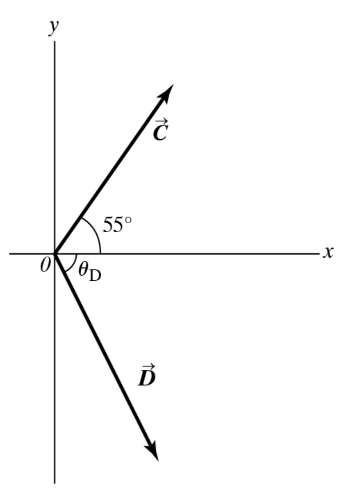

Figure VP1.10.2

$\theta_D = \arctan\dfrac{D_y}{D_x}$ = arctan[8.40/(–4.80] = –60.3°, which is 60.3° below the +x-axis. From Fig. VP1.10.2, we can easily seed that the angle between $\vec{C}$ and $\vec{D}$ is ϕ = 60.3° + 55.0° = 115°, as we found in (b).

VP1.10.3. **IDENTIFY:** We know the components of two vectors and want to find the angle between them.
SET UP: The scalar product $\vec{A}\cdot\vec{B} = AB\cos\phi$ involves the angle between two vectors. We can find this product using components from $\vec{A}\cdot\vec{B} = A_xB_x + A_yB_y$. From this result we can find the angle ϕ.
EXECUTE: First find the magnitudes of the two vectors.
$A = \sqrt{A_x^2 + A_y^2 + A_z^2} = \sqrt{(-5.00)^2 + (3.00)^2 + 0^2} = 5.83$
$B = \sqrt{B_x^2 + B_y^2 + B_z^2} = \sqrt{(2.50)^2 + (4.00)^2 + (-1.50)^2} = 4.95$
Now use $\vec{A}\cdot\vec{B} = AB\cos\phi = A_xB_x + A_yB_y$ and solve for ϕ.
$(5.83)(4.95)\cos\phi = (-5.00)(2.50) + (3.00)(4.00) + (0)(-1.50) \quad\rightarrow\quad \phi = 91°$.
EVALUATE: The scalar product is positive, so ϕ must be between 90° and 180°, which agrees with our result.

VP1.10.4. **IDENTIFY:** We know the scalar product of two vectors. We also know both components of one of them and the x-component of the other one. We want to find the y-component of the other one and the angle between the two vectors. The scalar product involves the angle between two vectors.
SET UP: We use $\vec{A}\cdot\vec{B} = A_xB_x + A_yB_y$ and $\vec{A}\cdot\vec{B} = AB\cos\phi$.
EXECUTE: (a) Use $\vec{F}\cdot\vec{s} = F_xs_x + F_ys_y$ to find F_y.
$26.0\ \text{N}\cdot\text{m} = (-12.0\ \text{N})(4.00\ \text{m}) + F_y(5.00\ \text{m}) \quad\rightarrow\quad F_y = 14.8\ \text{N}$.
(b) Use $\vec{F}\cdot\vec{s} = Fs\cos\phi$ and $A = \sqrt{A_x^2 + A_y^2}$ to find the magnitudes of the two vectors.
$\sqrt{(-12.0\ \text{N})^2 + (14.8\ \text{N})^2}\ \sqrt{(4.00\ \text{m})^2 + (5.00\ \text{m})^2}\ \cos\phi = 26.0\ \text{N}\cdot\text{m} \quad\rightarrow\quad \phi = 77.7°$.
EVALUATE: The work is positive, so the angle between $\vec{F}$ and $\vec{s}$ must be between 0° and 90°, which agrees with our result in part (b).

1.1. **IDENTIFY:** Convert units from mi to km and from km to ft.
SET UP: 1 in. = 2.54 cm, 1 km = 1000 m, 12 in. = 1 ft, 1 mi = 5280 ft.
EXECUTE: **(a)** $1.00\ \text{mi} = (1.00\ \text{mi})\left(\dfrac{5280\ \text{ft}}{1\ \text{mi}}\right)\left(\dfrac{12\ \text{in.}}{1\ \text{ft}}\right)\left(\dfrac{2.54\ \text{cm}}{1\ \text{in.}}\right)\left(\dfrac{1\ \text{m}}{10^2\ \text{cm}}\right)\left(\dfrac{1\ \text{km}}{10^3\ \text{m}}\right) = 1.61\ \text{km}$
(b) $1.00\ \text{km} = (1.00\ \text{km})\left(\dfrac{10^3\ \text{m}}{1\ \text{km}}\right)\left(\dfrac{10^2\ \text{cm}}{1\ \text{m}}\right)\left(\dfrac{1\ \text{in.}}{2.54\ \text{cm}}\right)\left(\dfrac{1\ \text{ft}}{12\ \text{in.}}\right) = 3.28\times10^3\ \text{ft}$
EVALUATE: A mile is a greater distance than a kilometer. There are 5280 ft in a mile but only 3280 ft in a km.

1.2. **IDENTIFY:** Convert volume units from L to in.^{3}.
SET UP: $1\ \text{L} = 1000\ \text{cm}^3$. 1 in. = 2.54 cm
EXECUTE: $0.473\ \text{L}\times\left(\dfrac{1000\ \text{cm}^3}{1\ \text{L}}\right)\times\left(\dfrac{1\ \text{in.}}{2.54\ \text{cm}}\right)^3 = 28.9\ \text{in.}^3$.
EVALUATE: 1 in.^{3} is greater than 1 cm^3, so the volume in in.^{3} is a smaller number than the volume in cm^3, which is 473 cm^3.

1.3. **IDENTIFY:** We know the speed of light in m/s. $t = d/v$. Convert 1.00 ft to m and t from s to ns.
SET UP: The speed of light is $v = 3.00\times10^8$ m/s. 1 ft = 0.3048 m. 1 s = 10^9 ns.

EXECUTE: $t = \dfrac{0.3048\text{ m}}{3.00\times10^8\text{ m/s}} = 1.02\times10^{-9}\text{ s} = 1.02\text{ ns}$

EVALUATE: In 1.00 s light travels $3.00\times10^8\text{ m} = 3.00\times10^5\text{ km} = 1.86\times10^5\text{ mi}$.

1.4. IDENTIFY: Convert the units from g to kg and from cm^3 to m^3.
SET UP: $1\text{ kg} = 1000\text{ g}$. $1\text{ m} = 100\text{ cm}$.

EXECUTE: $19.3\dfrac{\text{g}}{\text{cm}^3}\times\left(\dfrac{1\text{ kg}}{1000\text{ g}}\right)\times\left(\dfrac{100\text{ cm}}{1\text{ m}}\right)^3 = 1.93\times10^4\dfrac{\text{kg}}{\text{m}^3}$

EVALUATE: The ratio that converts cm to m is cubed, because we need to convert cm^3 to m^3.

1.5. IDENTIFY: Convert seconds to years. 1 gigasecond is a billion seconds.
SET UP: $1\text{ gigasecond} = 1\times10^9\text{ s}$. $1\text{ day} = 24\text{ h}$. $1\text{ h} = 3600\text{ s}$.

EXECUTE: $1.00\text{ gigasecond} = (1.00\times10^9\text{ s})\left(\dfrac{1\text{ h}}{3600\text{ s}}\right)\left(\dfrac{1\text{ day}}{24\text{ h}}\right)\left(\dfrac{1\text{ y}}{365\text{ days}}\right) = 31.7\text{ y}.$

EVALUATE: The conversion $1\text{ y} = 3.156\times10^7\text{ s}$ assumes $1\text{ y} = 365.24\text{ d}$, which is the average for one extra day every four years, in leap years. The problem says instead to assume a 365-day year.

1.6. IDENTIFY: Convert units.
SET UP: Use the unit conversions given in the problem. Also, $100\text{ cm} = 1\text{ m}$ and $1000\text{ g} = 1\text{ kg}$.

EXECUTE: **(a)** $\left(60\dfrac{\text{mi}}{\text{h}}\right)\left(\dfrac{1\text{ h}}{3600\text{ s}}\right)\left(\dfrac{5280\text{ ft}}{1\text{ mi}}\right) = 88\dfrac{\text{ft}}{\text{s}}$

(b) $\left(32\dfrac{\text{ft}}{\text{s}^2}\right)\left(\dfrac{30.48\text{ cm}}{1\text{ ft}}\right)\left(\dfrac{1\text{ m}}{100\text{ cm}}\right) = 9.8\dfrac{\text{m}}{\text{s}^2}$

(c) $\left(1.0\dfrac{\text{g}}{\text{cm}^3}\right)\left(\dfrac{100\text{ cm}}{1\text{ m}}\right)^3\left(\dfrac{1\text{ kg}}{1000\text{ g}}\right) = 10^3\dfrac{\text{kg}}{\text{m}^3}$

EVALUATE: The relations $60\text{ mi/h} = 88\text{ ft/s}$ and $1\text{ g/cm}^3 = 10^3\text{ kg/m}^3$ are exact. The relation $32\text{ ft/s}^2 = 9.8\text{ m/s}^2$ is accurate to only two significant figures.

1.7. IDENTIFY: Convert miles/gallon to km/L.
SET UP: $1\text{ mi} = 1.609\text{ km}$. $1\text{ gallon} = 3.788\text{ L}$.

EXECUTE: **(a)** $55.0\text{ miles/gallon} = (55.0\text{ miles/gallon})\left(\dfrac{1.609\text{ km}}{1\text{ mi}}\right)\left(\dfrac{1\text{ gallon}}{3.788\text{ L}}\right) = 23.4\text{ km/L}.$

(b) The volume of gas required is $\dfrac{1500\text{ km}}{23.4\text{ km/L}} = 64.1\text{ L}$. $\dfrac{64.1\text{ L}}{45\text{ L/tank}} = 1.4\text{ tanks}.$

EVALUATE: $1\text{ mi/gal} = 0.425\text{ km/L}$. A km is very roughly half a mile and there are roughly 4 liters in a gallon, so $1\text{ mi/gal} \sim \frac{2}{4}\text{ km/L}$, which is roughly our result.

1.8. IDENTIFY: Convert units.
SET UP: We know the equalities $1\text{ mg} = 10^{-3}\text{ g}$, $1\ \mu\text{g}\ 10^{-6}\text{ g}$, and $1\text{ kg} = 10^3\text{ g}$.

EXECUTE: **(a)** $(410\text{ mg/day})\left(\dfrac{10^{-3}\text{ g}}{1\text{ mg}}\right)\left(\dfrac{1\ \mu\text{g}}{10^{-6}\text{ g}}\right) = 4.10\times10^5\ \mu\text{g/day}.$

(b) $(12\text{ mg/kg})(75\text{ kg}) = (900\text{ mg})\left(\dfrac{10^{-3}\text{ g}}{1\text{ mg}}\right) = 0.900\text{ g}.$

(c) The mass of each tablet is $(2.0\text{ mg})\left(\dfrac{10^{-3}\text{ g}}{1\text{ mg}}\right) = 2.0\times10^{-3}\text{ g}$. The number of tablets required each day is the number of grams recommended per day divided by the number of grams per tablet:
$\dfrac{0.0030\text{ g/day}}{2.0\times10^{-3}\text{ g/tablet}} = 1.5$ tablet/day. Take 2 tablets each day.

(d) $(0.000070\text{ g/day})\left(\dfrac{1\text{ mg}}{10^{-3}\text{ g}}\right) = 0.070\text{ mg/day}$.

EVALUATE: Quantities in medicine and nutrition are frequently expressed in a wide variety of units.

1.9. **IDENTIFY:** We know the density and mass; thus we can find the volume using the relation density = mass/volume = m/V. The radius is then found from the volume equation for a sphere and the result for the volume.

SET UP: Density $= 19.5\text{ g/cm}^3$ and $m_{\text{critical}} = 60.0\text{ kg}$. For a sphere $V = \frac{4}{3}\pi r^3$.

EXECUTE: $V = m_{\text{critical}}/\text{density} = \left(\dfrac{60.0\text{ kg}}{19.5\text{ g/cm}^3}\right)\left(\dfrac{1000\text{ g}}{1.0\text{ kg}}\right) = 3080\text{ cm}^3$.

$r = \sqrt[3]{\dfrac{3V}{4\pi}} = \sqrt[3]{\dfrac{3}{4\pi}(3080\text{ cm}^3)} = 9.0\text{ cm}$.

EVALUATE: The density is very large, so the 130-pound sphere is small in size.

1.10. **IDENTIFY:** Model the bacteria as spheres. Use the diameter to find the radius, then find the volume and surface area using the radius.

SET UP: From Appendix B, the volume V of a sphere in terms of its radius is $V = \frac{4}{3}\pi r^3$ while its surface area A is $A = 4\pi r^2$. The radius is one-half the diameter or $r = d/2 = 1.0\ \mu\text{m}$. Finally, the necessary equalities for this problem are: $1\ \mu\text{m} = 10^{-6}\text{ m}$; $1\text{ cm} = 10^{-2}\text{ m}$; and $1\text{ mm} = 10^{-3}\text{ m}$.

EXECUTE: $V = \frac{4}{3}\pi r^3 = \frac{4}{3}\pi(1.0\ \mu\text{m})^3\left(\dfrac{10^{-6}\text{ m}}{1\ \mu\text{m}}\right)^3\left(\dfrac{1\text{ cm}}{10^{-2}\text{ m}}\right)^3 = 4.2\times10^{-12}\text{ cm}^3$ and

$A = 4\pi r^2 = 4\pi(1.0\ \mu\text{m})^2\left(\dfrac{10^{-6}\text{ m}}{1\ \mu\text{m}}\right)^2\left(\dfrac{1\text{ mm}}{10^{-3}\text{ m}}\right)^2 = 1.3\times10^{-5}\text{ mm}^2$

EVALUATE: On a human scale, the results are extremely small. This is reasonable because bacteria are not visible without a microscope.

1.11. **IDENTIFY:** When numbers are multiplied or divided, the number of significant figures in the result can be no greater than in the factor with the fewest significant figures. When we add or subtract numbers it is the location of the decimal that matters.

SET UP: 12 mm has two significant figures and 5.98 mm has three significant figures.

EXECUTE: **(a)** $(12\text{ mm})\times(5.98\text{ mm}) = 72\text{ mm}^2$ (two significant figures)

(b) s $\dfrac{5.98\text{ mm}}{12\text{ mm}} = 0.50$ (also two significant figures)

(c) 36 mm (to the nearest millimeter)

(d) 6 mm

(e) 2.0 (two significant figures)

EVALUATE: The length of the rectangle is known only to the nearest mm, so the answers in parts **(c)** and (d) are known only to the nearest mm.

1.12. **IDENTIFY:** This is a problem in conversion of units.
SET UP: 10 mm = 1 cm, $V = \pi r^2 h$.
EXECUTE: $V = \pi(0.036\text{ cm})^2(12.1\text{ cm}) = 0.049\text{ cm}^3$. Now convert to mm^3.

$$0.049\text{ cm}^3\left(\frac{10\text{ mm}}{1\text{ cm}}\right)^3 = 49\text{ mm}^3.$$

EVALUATE: The answer has only 2 significant figures. Even though π and h have more than that, r has only 2 which limits the answer.

1.13. **IDENTIFY:** Use your calculator to display $\pi \times 10^7$. Compare that number to the number of seconds in a year.
SET UP: $1\text{ yr} = 365.24\text{ days}$, $1\text{ day} = 24\text{ h}$, and $1\text{ h} = 3600\text{ s}$.
EXECUTE: $(365.24\text{ days/1 yr})\left(\frac{24\text{ h}}{1\text{ day}}\right)\left(\frac{3600\text{ s}}{1\text{ h}}\right) = 3.15567\ldots\times 10^7\text{ s}$; $\pi\times 10^7\text{ s} = 3.14159\ldots\times 10^7\text{ s}$

The approximate expression is accurate to two significant figures. The percent error is 0.45%.
EVALUATE: The close agreement is a numerical accident.

1.14. **IDENTIFY:** To asses the accuracy of the approximations, we must convert them to decimals.
SET UP: Use a calculator to calculate the decimal equivalent of each fraction and then round the numeral to the specified number of significant figures. Compare to π rounded to the same number of significant figures.
EXECUTE: **(a)** 22/7 = 3.14286 **(b)** 355/113 = 3.14159 **(c)** The exact value of π rounded to six significant figures is 3.14159.
EVALUATE: We see that 355/113 is a much better approximation to π than is 22/7.

1.15. **IDENTIFY:** Express 200 kg in pounds. Express each of 200 m, 200 cm and 200 mm in inches. Express 200 months in years.
SET UP: A mass of 1 kg is equivalent to a weight of about 2.2 lbs. $1\text{ in.} = 2.54\text{ cm}$. $1\text{ y} = 12\text{ months}$.
EXECUTE: **(a)** 200 kg is a weight of 440 lb. This is much larger than the typical weight of a man.
(b) $200\text{ m} = (2.00\times 10^4\text{ cm})\left(\frac{1\text{ in.}}{2.54\text{ cm}}\right) = 7.9\times 10^3$ inches. This is much greater than the height of a person.
(c) $200\text{ cm} = 2.00\text{ m} = 79\text{ inches} = 6.6\text{ ft}$. Some people are this tall, but not an ordinary man.
(d) $200\text{ mm} = 0.200\text{ m} = 7.9\text{ inches}$. This is much too short.
(e) $200\text{ months} = (200\text{ mon})\left(\frac{1\text{ y}}{12\text{ mon}}\right) = 17\text{ y}$. This is the age of a teenager; a middle-aged man is much older than this.
EVALUATE: None are plausible. When specifying the value of a measured quantity it is essential to give the units in which it is being expressed.

1.16. **IDENTIFY:** Estimate the number of people and then use the estimates given in the problem to calculate the number of gallons.
SET UP: Estimate 3×10^8 people, so 2×10^8 cars.
EXECUTE: (Number of cars × miles/car day)/(mi/gal) = gallons/day

$$(2\times 10^8\text{ cars}\times 10000\text{ mi/yr/car}\times 1\text{ yr/365 days})/(20\text{ mi/gal}) = 3\times 10^8\text{ gal/day}$$

EVALUATE: The number of gallons of gas used each day approximately equals the population of the U.S.

1.17. IDENTIFY: Estimation problem.

SET UP: Estimate that the pile is $18\text{ in.}\times 18\text{ in.}\times 5\text{ ft }8\text{ in.}$. Use the density of gold to calculate the mass of gold in the pile and from this calculate the dollar value.

EXECUTE: The volume of gold in the pile is $V = 18\text{ in.}\times 18\text{ in.}\times 68\text{ in.} = 22{,}000\text{ in.}^3$. First convert to cm^3:

$$V = 22{,}000\text{ in.}^3(1000\text{ cm}^3/61.02\text{ in.}^3) = 3.6\times 10^5\text{ cm}^3.$$

The density of gold is 19.3 g/cm^3, so the mass of this volume of gold is

$$m = (19.3\text{ g/cm}^3)(3.6\times 10^5\text{ cm}^3) = 6.95\times 10^6\text{ g}.$$

The monetary value of one gram is \$40, so the gold has a value of

$$(\$40\text{ /gram})\ (6.95\times 10^6\text{ grams}) = \$2.8\times 10^8$$

or about $\$300\times 10^6$ (three hundred million dollars).

EVALUATE: This is quite a large pile of gold, so such a large monetary value is reasonable.

1.18. IDENTIFY: Approximate the number of breaths per minute. Convert minutes to years and cm^3 to m^3 to find the volume in m^3 breathed in a year.

SET UP: Assume 10 breaths/min. $1\text{ y} = (365\text{ d})\left(\dfrac{24\text{ h}}{1\text{ d}}\right)\left(\dfrac{60\text{ min}}{1\text{ h}}\right) = 5.3\times 10^5\text{ min}$. $10^2\text{ cm} = 1\text{ m}$ so $10^6\text{ cm}^3 = 1\text{ m}^3$. The volume of a sphere is $V = \frac{4}{3}\pi r^3 = \frac{1}{6}\pi d^3$, where r is the radius and d is the diameter. Don't forget to account for four astronauts.

EXECUTE: **(a)** The volume is $(4)(10\text{ breaths/min})(500\times 10^{-6}\text{ m}^3)\left(\dfrac{5.3\times 10^5\text{ min}}{1\text{ y}}\right) = 1\times 10^4\text{ m}^3\text{/yr}$.

(b) $d = \left(\dfrac{6V}{\pi}\right)^{1/3} = \left(\dfrac{6[1\times 10^4\text{ m}^3]}{\pi}\right)^{1/3} = 27\text{ m}$

EVALUATE: Our estimate assumes that each cm^3 of air is breathed in only once, where in reality not all the oxygen is absorbed from the air in each breath. Therefore, a somewhat smaller volume would actually be required.

1.19. IDENTIFY: Estimate the diameter of a drop and from that calculate the volume of a drop, in m^3. Convert m^3 to L.

SET UP: Estimate the diameter of a drop to be $d = 2\text{ mm}$. The volume of a spherical drop is $V = \frac{4}{3}\pi r^3 = \frac{1}{6}\pi d^3$. $10^3\text{ cm}^3 = 1\text{ L}$.

EXECUTE: $V = \frac{1}{6}\pi(0.2\text{ cm})^3 = 4\times 10^{-3}\text{ cm}^3$. The number of drops in 1.0 L is $\dfrac{1000\text{ cm}^3}{4\times 10^{-3}\text{ cm}^3} = 2\times 10^5$

EVALUATE: Since $V \sim d^3$, if our estimate of the diameter of a drop is off by a factor of 2 then our estimate of the number of drops is off by a factor of 8.

1.20. IDENTIFY: Estimate the number of beats per minute and the duration of a lifetime. The volume of blood pumped during this interval is then the volume per beat multiplied by the total beats.

SET UP: An average middle-aged (40 year-old) adult at rest has a heart rate of roughly 75 beats per minute. To calculate the number of beats in a lifetime, use the current average lifespan of 80 years.

EXECUTE: $N_{\text{beats}} = (75\text{ beats/min})\left(\dfrac{60\text{ min}}{1\text{ h}}\right)\left(\dfrac{24\text{ h}}{1\text{ day}}\right)\left(\dfrac{365\text{ days}}{\text{yr}}\right)\left(\dfrac{80\text{ yr}}{\text{lifespan}}\right) = 3\times 10^9\text{ beats/lifespan}$

$$V_{\text{blood}} = (50\text{ cm}^3\text{/beat})\left(\frac{1\text{ L}}{1000\text{ cm}^3}\right)\left(\frac{1\text{ gal}}{3.788\text{ L}}\right)\left(\frac{3\times 10^9\text{ beats}}{\text{lifespan}}\right) = 4\times 10^7\text{ gal/lifespan}$$

EVALUATE: This is a very large volume.

1.21. **IDENTIFY:** Draw each subsequent displacement tail to head with the previous displacement. The resultant displacement is the single vector that points from the starting point to the stopping point.
SET UP: Call the three displacements $\vec{A}$, $\vec{B}$, and $\vec{C}$. The resultant displacement $\vec{R}$ is given by $\vec{R} = \vec{A} + \vec{B} + \vec{C}$.
EXECUTE: The vector addition diagram is given in Figure 1.21. Careful measurement gives that $\vec{R}$ is 7.8 km, 38° north of east.
EVALUATE: The magnitude of the resultant displacement, 7.8 km, is less than the sum of the magnitudes of the individual displacements, $2.6\text{ km} + 4.0\text{ km} + 3.1\text{ km}$.

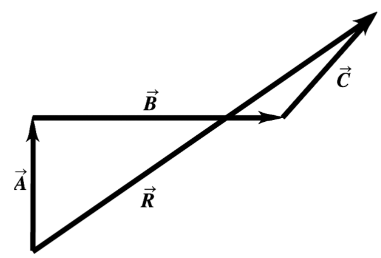

Figure 1.21

1.22. **IDENTIFY:** Draw the vector addition diagram to scale.
SET UP: The two vectors $\vec{A}$ and $\vec{B}$ are specified in the figure that accompanies the problem.
EXECUTE: **(a)** The diagram for $\vec{R} = \vec{A} + \vec{B}$ is given in Figure 1.22a. Measuring the length and angle of $\vec{R}$ gives $R = 9.0$ m and an angle of $\theta = 34°$.
(b) The diagram for $\vec{E} = \vec{A} - \vec{B}$ is given in Figure 1.22b. Measuring the length and angle of $\vec{E}$ gives $D = 22$ m and an angle of $\theta = 250°$.
(c) $-\vec{A} - \vec{B} = -(A + B)$, so $-\vec{A} - \vec{B}$ has a magnitude of 9.0 m (the same as $\vec{A} + \vec{B}$) and an angle with the $+x$ axis of $214°$ (opposite to the direction of $\vec{A} + \vec{B}$).
(d) $\vec{B} - \vec{A} = -(\vec{A} - \vec{B})$, so $\vec{B} - \vec{A}$ has a magnitude of 22 m and an angle with the $+x$ axis of $70°$ (opposite to the direction of $\vec{A} - \vec{B}$).
EVALUATE: The vector $-\vec{A}$ is equal in magnitude and opposite in direction to the vector $\vec{A}$.

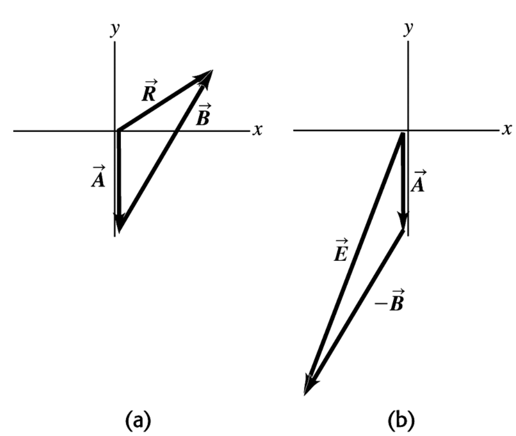

Figure 1.22

1.23. **IDENTIFY:** Since she returns to the starting point, the vector sum of the four displacements must be zero.

SET UP: Call the three given displacements $\vec{A}$, $\vec{B}$, and $\vec{C}$, and call the fourth displacement $\vec{D}$. $\vec{A}+\vec{B}+\vec{C}+\vec{D}=0.$

EXECUTE: The vector addition diagram is sketched in Figure 1.23. Careful measurement gives that $\vec{D}$ is 144 m, 41° south of west.

EVALUATE: $\vec{D}$ is equal in magnitude and opposite in direction to the sum $\vec{A}+\vec{B}+\vec{C}$.

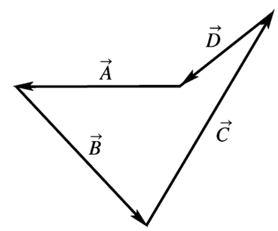

Figure 1.23

1.24. **IDENTIFY:** $\tan\theta = \dfrac{A_y}{A_x}$, for θ measured counterclockwise from the $+x$-axis.

SET UP: A sketch of A_x, A_y and $\vec{A}$ tells us the quadrant in which $\vec{A}$ lies.

EXECUTE:

(a) $\tan\,\theta = \dfrac{A_y}{A_x} = \dfrac{-1.00 \text{ m}}{2.00 \text{ m}} = -0.500.\ \theta = \tan^{-1}(-0.500) = 360° - 26.6° = 333°.$

(b) $\tan\,\theta = \dfrac{A_y}{A_x} = \dfrac{1.00 \text{ m}}{2.00 \text{ m}} = 0.500.\ \theta = \tan^{-1}(0.500) = 26.6°.$

(c) $\tan\,\theta = \dfrac{A_y}{A_x} = \dfrac{1.00 \text{ m}}{-2.00 \text{ m}} = -0.500.\ \theta = \tan^{-1}(-0.500) = 180° - 26.6° = 153°.$

(d) $\tan\,\theta = \dfrac{A_y}{A_x} = \dfrac{-1.00 \text{ m}}{-2.00 \text{ m}} = 0.500.\ \theta = \tan^{-1}(0.500) = 180° + 26.6° = 207°$

EVALUATE: The angles 26.6° and 207° have the same tangent. Our sketch tells us which is the correct value of θ.

1.25. **IDENTIFY:** For each vector $\vec{V}$, use that $V_x = V\cos\theta$ and $V_y = V\sin\theta$, when θ is the angle $\vec{V}$ makes with the $+x$ axis, measured counterclockwise from the axis.

SET UP: For $\vec{A}$, $\theta = 270.0°$. For $\vec{B}$, $\theta = 60.0°$. For $\vec{C}$, $\theta = 205.0°$. For $\vec{D}$, $\theta = 143.0°$.

EXECUTE: $A_x = 0$, $A_y = -8.00$ m. $B_x = 7.50$ m, $B_y = 13.0$ m. $C_x = -10.9$ m, $C_y = -5.07$ m. $D_x = -7.99$ m, $D_y = 6.02$ m.

EVALUATE: The signs of the components correspond to the quadrant in which the vector lies.

1.26. **IDENTIFY:** Given the direction and one component of a vector, find the other component and the magnitude.

SET UP: Use the tangent of the given angle and the definition of vector magnitude.

EXECUTE: **(a)** $\tan 34.0° = \dfrac{|A_x|}{|A_y|}$

$$|A_y| = \frac{|A_x|}{\tan 34.0°} = \frac{16.0 \text{ m}}{\tan 34.0°} = 23.72 \text{ m}$$

$A_y = -23.7$ m.

(b) $A = \sqrt{A_x^2 + A_y^2} = 28.6$ m.

EVALUATE: The magnitude is greater than either of the components.

1.27. **IDENTIFY:** Given the direction and one component of a vector, find the other component and the magnitude.

SET UP: Use the tangent of the given angle and the definition of vector magnitude.

EXECUTE: **(a)** $\tan 32.0° = \dfrac{|A_x|}{|A_y|}$

$|A_x| = (9.60 \text{ m})\tan 32.0° = 6.00$ m. $A_x = -6.00$ m.

(b) $A = \sqrt{A_x^2 + A_y^2} = 11.3$ m.

EVALUATE: The magnitude is greater than either of the components.

1.28. **IDENTIFY:** Find the vector sum of the three given displacements.

SET UP: Use coordinates for which $+x$ is east and $+y$ is north. The driver's vector displacements are:

$\vec{A} = 2.6$ km, 0° of north; $\vec{B} = 4.0$ km, 0° of east; $\vec{C} = 3.1$ km, 45° north of east.

EXECUTE: $R_x = A_x + B_x + C_x = 0 + 4.0 \text{ km} + (3.1 \text{ km})\cos(45°) = 6.2$ km; $R_y = A_y + B_y + C_y =$

$2.6 \text{ km} + 0 + (3.1 \text{ km})(\sin 45°) = 4.8$ km; $R = \sqrt{R_x^2 + R_y^2} = 7.8$ km; $\theta = \tan^{-1}[(4.8 \text{ km})/(6.2 \text{ km})] = 38°$;

$\vec{R} = 7.8$ km, 38° north of east. This result is confirmed by the sketch in Figure 1.28.

EVALUATE: Both R_x and R_y are positive and $\vec{R}$ is in the first quadrant.

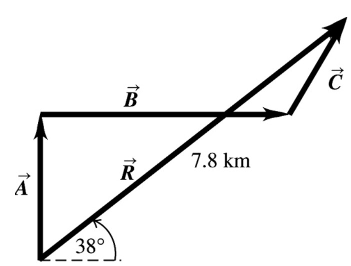

Figure 1.28

1.29. **IDENTIFY:** If $\vec{C} = \vec{A} + \vec{B}$, then $C_x = A_x + B_x$ and $C_y = A_y + B_y$. Use C_x and C_y to find the magnitude and direction of $\vec{C}$.

SET UP: From Figure E1.30 in the textbook, $A_x = 0$, $A_y = -8.00$ m and $B_x = +B\sin 30.0° = 7.50$ m, $B_y = +B\cos 30.0° = 13.0$ m.

EXECUTE: **(a)** $\vec{C} = \vec{A} + \vec{B}$ so $C_x = A_x + B_x = 7.50$ m and $C_y = A_y + B_y = +5.00$ m. $C = 9.01$ m.

$\tan\theta = \dfrac{C_y}{C_x} = \dfrac{5.00 \text{ m}}{7.50 \text{ m}}$ and $\theta = 33.7°$.

(b) $\vec{B} + \vec{A} = \vec{A} + \vec{B}$, so $\vec{B} + \vec{A}$ has magnitude 9.01 m and direction specified by 33.7°.

(c) $\vec{\boldsymbol{D}} = \vec{\boldsymbol{A}} - \vec{\boldsymbol{B}}$ so $D_x = A_x - B_x = -7.50 \text{ m}$ and $D_y = A_y - B_y = -21.0 \text{ m}$. $D = 22.3 \text{ m}$.

$\tan\phi = \dfrac{D_y}{D_x} = \dfrac{-21.0 \text{ m}}{-7.50 \text{ m}}$ and $\phi = 70.3°$. $\vec{\boldsymbol{D}}$ is in the 3rd quadrant and the angle θ counterclockwise from the $+x$ axis is $180° + 70.3° = 250.3°$.

(d) $\vec{\boldsymbol{B}} - \vec{\boldsymbol{A}} = -(\vec{\boldsymbol{A}} - \vec{\boldsymbol{B}})$, so $\vec{\boldsymbol{B}} - \vec{\boldsymbol{A}}$ has magnitude 22.3 m and direction specified by $\theta = 70.3°$.

EVALUATE: These results agree with those calculated from a scale drawing in Problem 1.22.

1.30. **IDENTIFY:** Use $A = \sqrt{A_x^2 + A_y^2}$ and $\tan\theta = \dfrac{A_y}{A_x}$ to calculate the magnitude and direction of each of the given vectors.

SET UP: A sketch of A_x, A_y and $\vec{\boldsymbol{A}}$ tells us the quadrant in which $\vec{\boldsymbol{A}}$ lies.

EXECUTE: **(a)** $\sqrt{(-8.60 \text{ cm})^2 + (5.20 \text{ cm})^2} = 10.0 \text{ cm}$, $\arctan\left(\dfrac{5.20}{-8.60}\right) = 148.8°$ (which is $180° - 31.2°$).

(b) $\sqrt{(-9.7 \text{ m})^2 + (-2.45 \text{ m})^2} = 10.0 \text{ m}$, $\arctan\left(\dfrac{-2.45}{-9.7}\right) = 14° + 180° = 194°$.

(c) $\sqrt{(7.75 \text{ km})^2 + (-2.70 \text{ km})^2} = 8.21 \text{ km}$, $\arctan\left(\dfrac{-2.7}{7.75}\right) = 340.8°$ (which is $360° - 19.2°$).

EVALUATE: In each case the angle is measured counterclockwise from the $+x$ axis. Our results for θ agree with our sketches.

1.31. **IDENTIFY:** Vector addition problem. We are given the magnitude and direction of three vectors and are asked to find their sum.

SET UP:

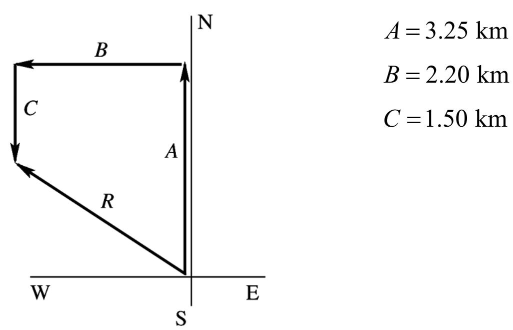

Figure 1.31a

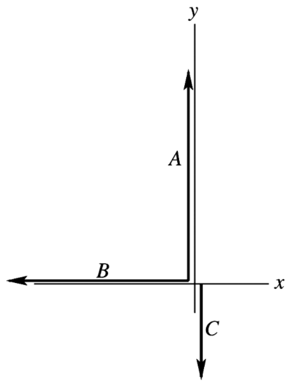
Select a coordinate system where $+x$ is east and $+y$ is north. Let $\vec{\boldsymbol{A}}$, $\vec{\boldsymbol{B}}$, and $\vec{\boldsymbol{C}}$ be the three displacements of the professor. Then the resultant displacement $\vec{\boldsymbol{R}}$ is given by $\vec{\boldsymbol{R}} = \vec{\boldsymbol{A}} + \vec{\boldsymbol{B}} + \vec{\boldsymbol{C}}$. By the method of components, $R_x = A_x + B_x + C_x$ and $R_y = A_y + B_y + C_y$. Find the x and y components of each vector; add them to find the components of the resultant. Then the magnitude and direction of the resultant can be found from its x and y components that we have calculated. As always it is essential to draw a sketch.

EXECUTE:



$A_x = 0,\ A_y = +3.25\ \text{km}$

$B_x = -2.20\ \text{km},\ B_y = 0$

$C_x = 0,\ C_y = -1.50\ \text{km}$

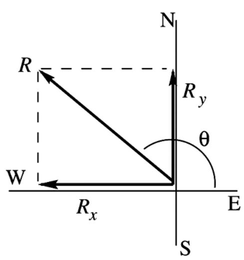
$R_x = A_x + B_x + C_x$

$R_x = 0 - 2.20\ \text{km} + 0 = -2.20\ \text{km}$

$R_y = A_y + B_y + C_y$

$R_y = 3.25\ \text{km} + 0 - 1.50\ \text{km} = 1.75\ \text{km}$

Figure 1.31b



$R = \sqrt{R_x^2 + R_y^2} = \sqrt{(-2.20\ \text{km})^2 + (1.75\ \text{km})^2}$

$R = 2.81\ \text{km}$

$\tan\theta = \dfrac{R_y}{R_x} = \dfrac{1.75\ \text{km}}{-2.20\ \text{km}} = -0.800$

$\theta = 141.5°$

Figure 1.31c

The angle θ measured counterclockwise from the $+x$-axis. In terms of compass directions, the resultant displacement is $38.5°$ N of W.

Evaluate: $R_x < 0$ and $R_y > 0$, so $\vec{R}$ is in the 2nd quadrant. This agrees with the vector addition diagram.

1.32. **Identify:** This problem involves vector addition. We know one vector and the resultant of that vector with a second vector, and we want to find the magnitude and direction of the second vector.

Set Up: $\vec{A} + \vec{B} = \vec{R}$. We know $\vec{A}$ and $\vec{R}$ and want to find $\vec{B}$. Use $A_x + B_x = R_x$ and $A_y + B_y = R_y$ to find the components of $\vec{B}$, then use $B = \sqrt{B_x^2 + B_y^2}$ to find B and $\theta = \arctan\dfrac{B_y}{B_x}$ to find its direction. First do a graphical sum, as shown in Fig. 1.32.

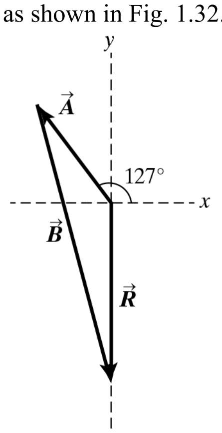


Figure 1.32

EXECUTE: First find the components. $A_x = A\cos 127° = (8.00 \text{ m})\cos 127° = -4.185$ m, $R_x = 0$, $A_y = A \sin 127° = (8.00 \text{ m})\sin 127° = 6.389$ m, $R_y = -12.0$ m. Now use $A_x + B_x = R_x$ and $A_y + B_y = R_y$ to find the components of $\vec{B}$.

$-4.185 \text{ m} + B_x = 0 \quad \rightarrow \quad B_x = 4.185$ m. $6.389 \text{ m} + B_y = -12.0 \text{ m} \quad \rightarrow \quad B_y = -18.39$ m.

$$B = \sqrt{B_x^2 + B_y^2} = \sqrt{(4.185 \text{ m})^2 + (-18.39 \text{ m})^2} = 19.0 \text{ m}.$$

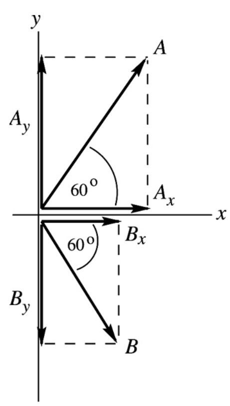
$\theta = \arctan\dfrac{B_y}{B_x} = \arctan\left(\dfrac{-18.39 \text{ m}}{4.185 \text{ m}}\right) = -75.3°$. From Fig. 1.32 we can see that $\vec{B}$ must point below the x-axis. This tells us that $\vec{B}$ makes an angle of 75.3° clockwise below the $+x$-axis, which we can also express as $360° - 75.3° = 284.7°$ counterclockwise with the $+x$-axis.

EVALUATE: Our vector sum in Fig. 1.32 agrees with our calculations.

1.33. **IDENTIFY:** Vector addition problem. $\vec{A} - \vec{B} = \vec{A} + (-\vec{B})$.

SET UP: Find the x- and y-components of $\vec{A}$ and $\vec{B}$. Then the x- and y-components of the vector sum are calculated from the x- and y-components of $\vec{A}$ and $\vec{B}$.

EXECUTE:



$$A_x = A\cos(60.0°)$$
$$A_x = (2.80 \text{ cm})\cos(60.0°) = +1.40 \text{ cm}$$
$$A_y = A\sin(60.0°)$$
$$A_y = (2.80 \text{ cm})\sin(60.0°) = +2.425 \text{ cm}$$
$$B_x = B\cos(-60.0°)$$
$$B_x = (1.90 \text{ cm})\cos(-60.0°) = +0.95 \text{ cm}$$
$$B_y = B\sin(-60.0°)$$
$$B_y = (1.90 \text{ cm})\sin(-60.0°) = -1.645 \text{ cm}$$

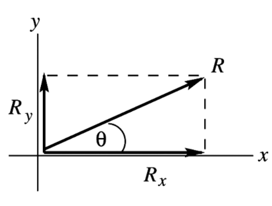
Note that the signs of the components correspond to the directions of the component vectors.

Figure 1.33a

(a) Now let $\vec{R} = \vec{A} + \vec{B}$.

$R_x = A_x + B_x = +1.40 \text{ cm} + 0.95 \text{ cm} = +2.35 \text{ cm}.$

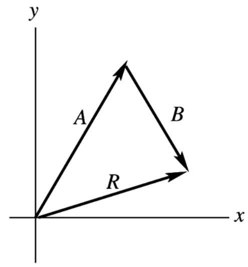
$R_y = A_y + B_y = +2.425 \text{ cm} - 1.645 \text{ cm} = +0.78 \text{ cm}.$



$$R = \sqrt{R_x^2 + R_y^2} = \sqrt{(2.35 \text{ cm})^2 + (0.78 \text{ cm})^2}$$
$$R = 2.48 \text{ cm}$$
$$\tan\theta = \frac{R_y}{R_x} = \frac{+0.78 \text{ cm}}{+2.35 \text{ cm}} = +0.3319$$
$$\theta = 18.4°$$

Figure 1.33b

EVALUATE: The vector addition diagram for $\vec{R} = \vec{A} + \vec{B}$ is



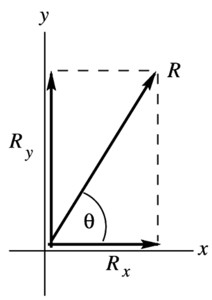
$\vec{R}$ is in the 1st quadrant, with $|R_y| < |R_x|$, in agreement with our calculation.

Figure 1.33c

(b) EXECUTE: Now let $\vec{R} = \vec{A} - \vec{B}$.

$R_x = A_x - B_x = +1.40 \text{ cm} - 0.95 \text{ cm} = +0.45 \text{ cm}.$

$R_y = A_y - B_y = +2.425 \text{ cm} + 1.645 \text{ cm} = +4.070 \text{ cm}.$



$$R = \sqrt{R_x^2 + R_y^2} = \sqrt{(0.45 \text{ cm})^2 + (4.070 \text{ cm})^2}$$

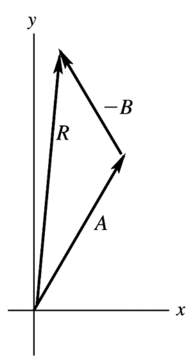
$$R = 4.09 \text{ cm}$$

$$\tan\theta = \frac{R_y}{R_x} = \frac{4.070 \text{ cm}}{0.45 \text{ cm}} = +9.044$$

$$\theta = 83.7°$$

Figure 1.33d

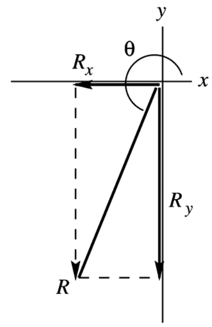
EVALUATE: The vector addition diagram for $\vec{R} = \vec{A} + (-\vec{B})$ is



$\vec{R}$ is in the 1st quadrant, with $|R_x| < |R_y|$, in agreement with our calculation.

Figure 1.33e

(c) EXECUTE:



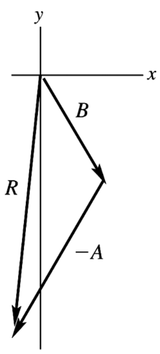
$\vec{B} - \vec{A} = -(\vec{A} - \vec{B})$

$\vec{B} - \vec{A}$ and $\vec{A} - \vec{B}$ are equal in magnitude and opposite in direction.

$R = 4.09$ cm and $\theta = 83.7° + 180° = 264°$

Figure 1.33f

EVALUATE: The vector addition diagram for $\vec{R} = \vec{B} + (-\vec{A})$ is



$\vec{R}$ is in the 3rd quadrant, with $|R_x| < |R_y|$, in agreement with our calculation.

Figure 1.33g

1.34. **IDENTIFY:** The general expression for a vector written in terms of components and unit vectors is $\vec{A} = A_x\hat{i} + A_y\hat{j}$.

SET UP: $5.0\vec{B} = 5.0(4\hat{i} - 6\hat{j}) = 20\vec{i} - 30\vec{j}$

EXECUTE: **(a)** $A_x = 5.0,\ A_y = -6.3$ **(b)** $A_x = 11.2,\ A_y = -9.91$ **(c)** $A_x = -15.0,\ A_y = 22.4$

(d) $A_x = 20,\ A_y = -30$

EVALUATE: The components are signed scalars.

1.35. **IDENTIFY:** Find the components of each vector and then use the general equation $\vec{A} = A_x\hat{i} + A_y\hat{j}$ for a vector in terms of its components and unit vectors.

SET UP: $A_x = 0,\ A_y = -8.00$ m. $B_x = 7.50$ m, $B_y = 13.0$ m. $C_x = -10.9$ m, $C_y = -5.07$ m. $D_x = -7.99$ m, $D_y = 6.02$ m.

EXECUTE: $\vec{A} = (-8.00\text{ m})\hat{j}$; $\vec{B} = (7.50\text{ m})\hat{i} + (13.0\text{ m})\hat{j}$; $\vec{C} = (-10.9\text{ m})\hat{i} + (-5.07\text{ m})\hat{j}$; $\vec{D} = (-7.99\text{ m})\hat{i} + (6.02\text{ m})\hat{j}$.

EVALUATE: All these vectors lie in the *xy*-plane and have no *z*-component.

1.36. **IDENTIFY:** Find A and B. Find the vector difference using components.

SET UP: Identify the *x*- and *y*-components and use $A = \sqrt{A_x^2 + A_y^2}$.

EXECUTE: **(a)** $\vec{A} = 4.00\hat{i} + 7.00\hat{j}$; $A_x = +4.00$; $A_y = +7.00$.

$A = \sqrt{A_x^2 + A_y^2} = \sqrt{(4.00)^2 + (7.00)^2} = 8.06$. $\vec{B} = 5.00\hat{i} - 2.00\hat{j}$; $B_x = +5.00$; $B_y = -2.00$;

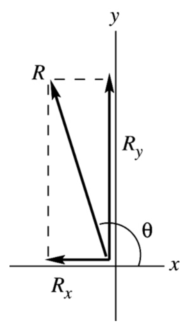
$B = \sqrt{B_x^2 + B_y^2} = \sqrt{(5.00)^2 + (-2.00)^2} = 5.39$.

EVALUATE: Note that the magnitudes of $\vec{A}$ and $\vec{B}$ are each larger than either of their components.

EXECUTE: **(b)** $\vec{A} - \vec{B} = 4.00\hat{i} + 7.00\hat{j} - (5.00\hat{i} - 2.00\hat{j}) = (4.00 - 5.00)\hat{i} + (7.00 + 2.00)\hat{j}$.

$\vec{A} - \vec{B} = -1.00\hat{i} + 9.00\hat{j}$

(c) Let $\vec{R} = \vec{A} - \vec{B} = -1.00\hat{i} + 9.00\hat{j}$. Then $R_x = -1.00$, $R_y = 9.00$.



$R = \sqrt{R_x^2 + R_y^2}$

$R = \sqrt{(-1.00)^2 + (9.00)^2} = 9.06$.

$\tan\theta = \frac{R_y}{R_x} = \frac{9.00}{-1.00} = -9.00$

$\theta = -83.6° + 180° = 96.3°$.

Figure 1.36

EVALUATE: $R_x < 0$ and $R_y > 0$, so $\vec{R}$ is in the 2nd quadrant.

1.37. **IDENTIFY:** Use trigonometry to find the components of each vector. Use $R_x = A_x + B_x + \cdots$ and $R_y = A_y + B_y + \cdots$ to find the components of the vector sum. The equation $\vec{A} = A_x\hat{i} + A_y\hat{j}$ expresses a vector in terms of its components.

SET UP: Use the coordinates in the figure that accompanies the problem.

EXECUTE: **(a)** $\vec{A} = (3.60\text{ m})\cos 70.0°\hat{i} + (3.60\text{ m})\sin 70.0°\hat{j} = (1.23\text{ m})\hat{i} + (3.38\text{ m})\hat{j}$

$\vec{B} = -(2.40\text{ m})\cos 30.0°\hat{i} - (2.40\text{ m})\sin 30.0°\hat{j} = (-2.08\text{ m})\hat{i} + (-1.20\text{ m})\hat{j}$

(b) $\vec{C} = (3.00)\vec{A} - (4.00)\vec{B} = (3.00)(1.23\text{ m})\hat{i} + (3.00)(3.38\text{ m})\hat{j} - (4.00)(-2.08\text{ m})\hat{i} - (4.00)(-1.20\text{ m})\hat{j}$

$\vec{C} = (12.01\text{ m})\hat{i} + (14.94\text{ m})\hat{j}$

(c) From $A = \sqrt{A_x^2 + A_y^2}$ and $\tan\theta = \frac{A_y}{A_x}$,

$C = \sqrt{(12.01\text{ m})^2 + (14.94\text{ m})^2} = 19.17\text{ m}$, $\arctan\left(\frac{14.94\text{ m}}{12.01\text{ m}}\right) = 51.2°$

EVALUATE: C_x and C_y are both positive, so θ is in the first quadrant.

1.38. **IDENTIFY:** We use the vector components and trigonometry to find the angles.

SET UP: Use the fact that $\tan\theta = A_y / A_x$.

EXECUTE: **(a)** $\tan\theta = A_y / A_x = \frac{6.00}{-3.00}$. $\theta = 117°$ with the $+x$-axis.

(b) $\tan\theta = B_y / B_x = \frac{2.00}{7.00}$. $\theta = 15.9°$.

(c) First find the components of $\vec{C}$. $C_x = A_x + B_x = -3.00 + 7.00 = 4.00,$

$C_y = A_y + B_y = 6.00 + 2.00 = 8.00$

$\tan\theta = C_y / C_x = \dfrac{8.00}{4.00} = 2.00$. $\theta = 63.4°$

EVALUATE: Sketching each of the three vectors to scale will show that the answers are reasonable.

1.39. **IDENTIFY:** $\vec{A}$ and $\vec{B}$ are given in unit vector form. Find A, B and the vector difference $\vec{A}-\vec{B}$.

SET UP: $\vec{A} = -2.00\hat{i} + 3.00\hat{j} + 4.00\hat{k}$, $\vec{B} = 3.00\hat{i} + 1.00\hat{j} - 3.00\hat{k}$

Use $A = \sqrt{A_x^2 + A_y^2 + A_z^2}$ to find the magnitudes of the vectors.

EXECUTE: **(a)** $A = \sqrt{A_x^2 + A_y^2 + A_z^2} = \sqrt{(-2.00)^2 + (3.00)^2 + (4.00)^2} = 5.38$

$B = \sqrt{B_x^2 + B_y^2 + B_z^2} = \sqrt{(3.00)^2 + (1.00)^2 + (-3.00)^2} = 4.36$

(b) $\vec{A}-\vec{B} = (-2.00\hat{i} + 3.00\hat{j} + 4.00\hat{k}) - (3.00\hat{i} + 1.00\hat{j} - 3.00\hat{k})$

$\vec{A}-\vec{B} = (-2.00-3.00)\hat{i} + (3.00-1.00)\hat{j} + (4.00-(-3.00))\hat{k} = -5.00\hat{i} + 2.00\hat{j} + 7.00\hat{k}.$

(c) Let $\vec{C} = \vec{A}-\vec{B}$, so $C_x = -5.00,\ C_y = +2.00,\ C_z = +7.00$

$$C = \sqrt{C_x^2 + C_y^2 + C_z^2} = \sqrt{(-5.00)^2 + (2.00)^2 + (7.00)^2} = 8.83$$

$\vec{B}-\vec{A} = -(\vec{A}-\vec{B})$, so $\vec{A}-\vec{B}$ and $\vec{B}-\vec{A}$ have the same magnitude but opposite directions.

EVALUATE: A, B, and C are each larger than any of their components.

1.40. **IDENTIFY:** Target variables are $\vec{A}\cdot\vec{B}$ and the angle ϕ between the two vectors.

SET UP: We are given $\vec{A}$ and $\vec{B}$ in unit vector form and can take the scalar product using $\vec{A}\cdot\vec{B} = A_xB_x + A_yB_y + A_zB_z$. The angle ϕ can then be found from $\vec{A}\cdot\vec{B} = AB\cos\phi$.

EXECUTE: **(a)** $\vec{A} = 4.00\hat{i} + 7.00\hat{j}$, $\vec{B} = 5.00\hat{i} - 2.00\hat{j}$; $A = 8.06$, $B = 5.39$.

$\vec{A}\cdot\vec{B} = (4.00\hat{i} + 7.00\hat{j})\cdot(5.00\hat{i} - 2.00\hat{j}) = (4.00)(5.00) + (7.00)(-2.00) = 20.0 - 14.0 = +6.00.$

(b) $\cos\phi = \dfrac{\vec{A}\cdot\vec{B}}{AB} = \dfrac{6.00}{(8.06)(5.39)} = 0.1382;\ \phi = 82.1°.$

EVALUATE: The component of $\vec{B}$ along $\vec{A}$ is in the same direction as $\vec{A}$, so the scalar product is positive and the angle ϕ is less than $90°$.

1.41. **IDENTIFY:** $\vec{A}\cdot\vec{B} = AB\cos\phi$

SET UP: For $\vec{A}$ and $\vec{B}$, $\phi = 150.0°$. For $\vec{B}$ and $\vec{C}$, $\phi = 145.0°$. For $\vec{A}$ and $\vec{C}$, $\phi = 65.0°$.

EXECUTE: **(a)** $\vec{A}\cdot\vec{B} = (8.00\text{ m})(15.0\text{ m})\cos 150.0° = -104\text{ m}^2$

(b) $\vec{B}\cdot\vec{C} = (15.0\text{ m})(12.0\text{ m})\cos 145.0° = -148\text{ m}^2$

(c) $\vec{A}\cdot\vec{C} = (8.00\text{ m})(12.0\text{ m})\cos 65.0° = 40.6\text{ m}^2$

EVALUATE: When $\phi < 90°$ the scalar product is positive and when $\phi > 90°$ the scalar product is negative.

1.42. **IDENTIFY:** Target variable is the vector $\vec{A}\times\vec{B}$ expressed in terms of unit vectors.

SET UP: We are given $\vec{A}$ and $\vec{B}$ in unit vector form and can take the vector product using $\hat{i}\times\hat{i} = \hat{j}\times\hat{j} = 0$, $\hat{i}\times\hat{j} = \hat{k}$, and $\hat{j}\times\hat{i} = -\hat{k}$.

EXECUTE: $\vec{A} = 4.00\hat{i} + 7.00\hat{j}$, $\vec{B} = 5.00\hat{i} - 2.00\hat{j}$.

$\vec{A}\times\vec{B} = (4.00\hat{i} + 7.00\hat{j})\times(5.00\hat{i} - 2.00\hat{j}) = 20.0\hat{i}\times\hat{i} - 8.00\hat{i}\times\hat{j} + 35.0\hat{j}\times\hat{i} - 14.0\hat{j}\times\hat{j}$. But $\hat{i}\times\hat{i} = \hat{j}\times\hat{j} = 0$ and $\hat{i}\times\hat{j} = \hat{k}$, $\hat{j}\times\hat{i} = -\hat{k}$, so $\vec{A}\times\vec{B} = -8.00\hat{k} + 35.0(-\hat{k}) = -43.0\hat{k}$. The magnitude of $\vec{A}\times\vec{B}$ is 43.0.

EVALUATE: Sketch the vectors $\vec{A}$ and $\vec{B}$ in a coordinate system where the *xy*-plane is in the plane of the paper and the *z*-axis is directed out toward you. By the right-hand rule $\vec{A}\times\vec{B}$ is directed into the plane of the paper, in the $-z$-direction. This agrees with the above calculation that used unit vectors.

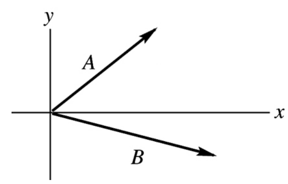


Figure 1.42

1.43. **IDENTIFY:** For all of these pairs of vectors, the angle is found from combining $\vec{A}\cdot\vec{B} = AB\cos\phi$ and $\vec{A}\cdot\vec{B} = A_xB_x + A_yB_y + A_zB_z$, to give the angle ϕ as $\phi = \arccos\left(\dfrac{\vec{A}\cdot\vec{B}}{AB}\right) = \arccos\left(\dfrac{A_xB_x + A_yB_y}{AB}\right)$.

SET UP: $\vec{A}\cdot\vec{B} = A_xB_x + A_yB_y + A_zB_z$ shows how to obtain the components for a vector written in terms of unit vectors.

EXECUTE: **(a)** $\vec{A}\cdot\vec{B} = -22$, $A = \sqrt{40}$, $B = \sqrt{13}$, and so $\phi = \arccos\left(\dfrac{-22}{\sqrt{40}\sqrt{13}}\right) = 165°$.

(b) $\vec{A}\cdot\vec{B} = 60$, $A = \sqrt{34}$, $B = \sqrt{136}$, $\phi = \arccos\left(\dfrac{60}{\sqrt{34}\sqrt{136}}\right) = 28°$.

(c) $\vec{A}\cdot\vec{B} = 0$ and $\phi = 90°$.

EVALUATE: If $\vec{A}\cdot\vec{B} > 0$, $0 \le \phi < 90°$. If $\vec{A}\cdot\vec{B} < 0$, $90° < \phi \le 180°$. If $\vec{A}\cdot\vec{B} = 0$, $\phi = 90°$ and the two vectors are perpendicular.

1.44. **IDENTIFY:** The right-hand rule gives the direction and $|\vec{A}\times\vec{B}| = AB\sin\phi$ gives the magnitude.

SET UP: $\phi = 120.0°$.

EXECUTE: **(a)** The direction of $\vec{A}\times\vec{B}$ is into the page (the $-z$-direction). The magnitude of the vector product is $AB\sin\phi = (2.80\text{ cm})(1.90\text{ cm})\sin 120° = 4.61\text{ cm}^2$.

(b) Rather than repeat the calculations, $\vec{B}\times\vec{A} = -\vec{A}\times\vec{B}$ may be used to see that $\vec{B}\times\vec{A}$ has magnitude 4.61 cm^2 and is in the $+z$-direction (out of the page).

EVALUATE: For part (a) we could use the components of the cross product and note that the only non-vanishing component is $C_z = A_xB_y - A_yB_x = (2.80\text{ cm})\cos 60.0°(-1.90\text{ cm})\sin 60°$

$$-(2.80\text{ cm})\sin 60.0°(1.90\text{ cm})\cos 60.0° = -4.61\text{ cm}^2.$$

This gives the same result.

1.45. **IDENTIFY:** $\vec{A}\times\vec{D}$ has magnitude $AD\sin\phi$. Its direction is given by the right-hand rule.

SET UP: $\phi = 180° - 53° = 127°$

EXECUTE: **(a)** $|\vec{A}\times\vec{D}| = (8.00\text{ m})(10.0\text{ m})\sin 127° = 63.9\text{ m}^2$. The right-hand rule says $\vec{A}\times\vec{D}$ is in the $-z$-direction (into the page).

(b) $\vec{D}\times\vec{A}$ has the same magnitude as $\vec{A}\times\vec{D}$ and is in the opposite direction.

EVALUATE: The component of $\vec{D}$ perpendicular to $\vec{A}$ is $D_{\perp} = D\sin 53.0° = 7.99$ m.
$|\vec{A}\times\vec{D}| = AD_{\perp} = 63.9\text{ m}^2$, which agrees with our previous result.

1.46. **IDENTIFY:** Apply Eqs. (1.16) and (1.20).
SET UP: The angle between the vectors is $20° + 90° + 30° = 140°$.
EXECUTE: **(a)** $\vec{A}\cdot\vec{B} = AB\cos\phi$ gives $\vec{A}\cdot\vec{B} = (3.60\text{ m})(2.40\text{ m})\cos 140° = -6.62\text{ m}^2$.
(b) From $|\vec{A}\times\vec{B}| = AB\sin\phi$, the magnitude of the cross product is $(3.60\text{ m})(2.40\text{ m})\sin 140° = 5.55\text{ m}^2$ and the direction, from the right-hand rule, is out of the page (the $+z$-direction).
EVALUATE: We could also use $\vec{A}\cdot\vec{B} = A_xB_x + A_yB_y + A_zB_z$ and the cross product, with the components of $\vec{A}$ and $\vec{B}$.

1.47. **IDENTIFY:** This problem involves the vector product of two vectors.
SET UP: The magnitude is $\left|\vec{A}\times\vec{B}\right| = AB\sin\phi$ and the right-hand rule gives the direction. Since $\vec{A}\times\vec{B}$ is in the $+z$ direction, both $\vec{A}$ and $\vec{B}$ must lie in the xy-plane.
EXECUTE: $\vec{A}$ has no y-component and $\vec{B}$ has no x-component, so they must be perpendicular to each other. Since $\vec{A}\times\vec{B}$ is in the $+z$ direction, the right-hand rule tells us that $\vec{B}$ must point in the $-y$ direction. $\left|\vec{A}\times\vec{B}\right| = AB\sin\phi = (8.0\text{ m})B\sin 90° = 16.0\text{ m}^2$, so $B = 2.0$ m.
EVALUATE: In unit vector notation, $\vec{B} = -2.0\text{ m }\hat{j}$.

1.48. **IDENTIFY:** This problem involves the vector product and the scalar of two vectors.
SET UP: The scalar product is $\vec{A}\cdot\vec{B} = AB\cos\phi$ and the magnitude of the vector product is $\left|\vec{A}\times\vec{B}\right| = AB\sin\phi$.
EXECUTE: **(a)** Calculate both products. $\left|\vec{A}\times\vec{B}\right| = AB\sin\phi = AB\sin 30.0° = 0.500\,AB$ and $\vec{A}\cdot\vec{B} = AB\cos\phi = AB\cos 30.0° = 0.866\,AB$. Therefore the scalar product has the greater magnitude.
(b) Equate the magnitudes. $AB\sin\phi = AB\cos\phi \rightarrow \tan\phi = 1 \rightarrow \phi = 45°$ or $135°$. At 45° both products are positive, but at 135° the scalar product is negative. However in both cases the *magnitudes* are the same.
EVALUATE: Note that the problem says that the *magnitudes* of the products are equal. We *cannot* say that the products are equal because $\vec{A}\cdot\vec{B}$ is a scalar but $\vec{A}\times\vec{B}$ is a vector.

1.49. **IDENTIFY:** We model the earth, white dwarf, and neutron star as spheres. Density is mass divided by volume.
SET UP: We know that density = mass/volume = m/V where $V = \frac{4}{3}\pi r^3$ for a sphere. From Appendix B, the earth has mass of $m = 5.97\times10^{24}$ kg and a radius of $r = 6.37\times10^6$ m whereas for the sun at the end of its lifetime, $m = 1.99\times10^{30}$ kg and $r = 7500\text{ km} = 7.5\times10^6$ m. The star possesses a radius of $r = 10\text{ km} = 1.0\times10^4$ m and a mass of $m = 1.99\times10^{30}$ kg.
EXECUTE: **(a)** The earth has volume $V = \frac{4}{3}\pi r^3 = \frac{4}{3}\pi(6.37\times10^6\text{ m})^3 = 1.0827\times10^{21}\text{ m}^3$. Its density is

$$\text{density} = \frac{m}{V} = \frac{5.97\times10^{24}\text{ kg}}{1.0827\times10^{21}\text{ m}^3} = (5.51\times10^3\text{ kg/m}^3)\left(\frac{10^3\text{ g}}{1\text{ kg}}\right)\left(\frac{1\text{ m}}{10^2\text{ cm}}\right)^3 = 5.51\text{ g/cm}^3$$

(b) $V = \frac{4}{3}\pi r^3 = \frac{4}{3}\pi(7.5\times10^6\text{ m})^3 = 1.77\times10^{21}\text{ m}^3$

$$\text{density} = \frac{m}{V} = \frac{1.99\times10^{30}\text{ kg}}{1.77\times10^{21}\text{ m}^3} = (1.1\times10^9\text{ kg/m}^3)\left(\frac{1\text{ g/cm}^3}{1000\text{ kg/m}^3}\right) = 1.1\times10^6\text{ g/cm}^3$$

(c) $V = \frac{4}{3}\pi r^3 = \frac{4}{3}\pi(1.0\times10^4 \text{ m})^3 = 4.19\times10^{12} \text{ m}^3$

$$\text{density} = \frac{m}{V} = \frac{1.99\times10^{30} \text{ kg}}{4.19\times10^{12} \text{ m}^3} = (4.7\times10^{17} \text{ kg/m}^3)\left(\frac{1 \text{ g/cm}^3}{1000 \text{ kg/m}^3}\right) = 4.7\times10^{14} \text{ g/cm}^3$$

EVALUATE: For a fixed mass, the density scales as $1/r^3$. Thus, the answer to (c) can also be obtained from (b) as

$$(1.1\times10^6 \text{ g/cm}^3)\left(\frac{7.50\times10^6 \text{ m}}{1.0\times10^4 \text{ m}}\right)^3 = 4.7\times10^{14} \text{ g/cm}^3.$$

1.50. **IDENTIFY** and **SET UP:** Unit conversion.

EXECUTE: **(a)** $f = 1.420\times10^9$ cycles/s, so $\dfrac{1}{1.420\times10^9}$ s $= 7.04\times10^{-10}$ s for one cycle.

(b) $\dfrac{3600 \text{ s/h}}{7.04\times10^{-10} \text{ s/cycle}} = 5.11\times10^{12}$ cycles/h

(c) Calculate the number of seconds in 4600 million years $= 4.6\times10^9$ y and divide by the time for 1 cycle:

$$\frac{(4.6\times10^9 \text{ y})(3.156\times10^7 \text{ s/y})}{7.04\times10^{-10} \text{ s/cycle}} = 2.1\times10^{26} \text{ cycles}$$

(d) The clock is off by 1 s in $100{,}000 \text{ y} = 1\times10^5$ y, so in 4.60×10^9 y it is off by

$(1 \text{ s})\left(\dfrac{4.60\times10^9}{1\times10^5}\right) = 4.6\times10^4$ s (about 13 h).

EVALUATE: In each case the units in the calculation combine algebraically to give the correct units for the answer.

1.51. **IDENTIFY:** The density relates mass and volume. Use the given mass and density to find the volume and from this the radius.

SET UP: The earth has mass $m_E = 5.97\times10^{24}$ kg and radius $r_E = 6.37\times10^6$ m. The volume of a sphere is $V = \frac{4}{3}\pi r^3$. $\rho = 1.76 \text{ g/cm}^3 = 1760 \text{ km/m}^3$.

EXECUTE: **(a)** The planet has mass $m = 5.5m_E = 3.28\times10^{25}$ kg.

$V = \dfrac{m}{\rho} = \dfrac{3.28\times10^{25} \text{ kg}}{1760 \text{ kg/m}^3} = 1.86\times10^{22} \text{ m}^3.$

$$r = \left(\frac{3V}{4\pi}\right)^{1/3} = \left(\frac{3[1.86\times10^{22} \text{ m}^3]}{4\pi}\right)^{1/3} = 1.64\times10^7 \text{ m} = 1.64\times10^4 \text{ km}$$

(b) $r = 2.57r_E$

EVALUATE: Volume V is proportional to mass and radius r is proportional to $V^{1/3}$, so r is proportional to $m^{1/3}$. If the planet and earth had the same density its radius would be $(5.5)^{1/3}r_E = 1.8r_E$. The radius of the planet is greater than this, so its density must be less than that of the earth.

1.52. **IDENTIFY:** Use the extreme values in the piece's length and width to find the uncertainty in the area.

SET UP: The length could be as large as 7.61 cm and the width could be as large as 1.91 cm.

EXECUTE: **(a)** The area is $14.44 \pm 0.095 \text{ cm}^2$.

(b) The fractional uncertainty in the area is $\dfrac{0.095\ \text{cm}^2}{14.44\ \text{cm}^2} = 0.66\%,$ and the fractional uncertainties in the length and width are $\dfrac{0.01\ \text{cm}}{7.61\ \text{cm}} = 0.13\%$ and $\dfrac{0.01\ \text{cm}}{1.9\ \text{cm}} = 0.53\%.$ The sum of these fractional uncertainties is $0.13\% + 0.53\% = 0.66\%,$ in agreement with the fractional uncertainty in the area.

EVALUATE: The fractional uncertainty in a product of numbers is greater than the fractional uncertainty in any of the individual numbers.

1.53. **IDENTIFY:** The number of atoms is your mass divided by the mass of one atom.
SET UP: Assume a 70-kg person and that the human body is mostly water. Use Appendix D to find the mass of one H_2O molecule: $18.015\ \text{u} \times 1.661 \times 10^{-27}\ \text{kg/u} = 2.992 \times 10^{-26}\ \text{kg/molecule}.$

EXECUTE: $(70\ \text{kg})/(2.992 \times 10^{-26}\ \text{kg/molecule}) = 2.34 \times 10^{27}$ molecules. Each H_2O molecule has 3 atoms, so there are about 6×10^{27} atoms.

EVALUATE: Assuming carbon to be the most common atom gives 3×10^{27} molecules, which is a result of the same order of magnitude.

1.54. **IDENTIFY:** Estimate the volume of each object. The mass m is the density times the volume.
SET UP: The volume of a sphere of radius r is $V = \frac{4}{3}\pi r^3.$ The volume of a cylinder of radius r and length l is $V = \pi r^2 l.$ The density of water is $1000\ \text{kg/m}^3.$

EXECUTE: **(a)** Estimate the volume as that of a sphere of diameter 10 cm: $V = 5.2 \times 10^{-4}\ \text{m}^3.$
$m = (0.98)(1000\ \text{kg / m}^3)(5.2 \times 10^{-4}\ \text{m}^3) = 0.5\ \text{kg}.$

(b) Approximate as a sphere of radius $r = 0.25\,\mu\text{m}$ (probably an overestimate): $V = 6.5 \times 10^{-20}\ \text{m}^3.$
$m = (0.98)(1000\ \text{kg / m}^3)(6.5 \times 10^{-20}\ \text{m}^3) = 6 \times 10^{-17}\ \text{kg} = 6 \times 10^{-14}\ \text{g}.$

(c) Estimate the volume as that of a cylinder of length 1 cm and radius 3 mm: $V = \pi r^2 l = 2.8 \times 10^{-7}\ \text{m}^3.$
$m = (0.98)(1000\ \text{kg/m}^3)(2.8 \times 10^{-7}\ \text{m}^3) = 3 \times 10^{-4}\ \text{kg} = 0.3\ \text{g}.$

EVALUATE: The mass is directly proportional to the volume.

1.55. **IDENTIFY:** We are dealing with unit vectors, which must have magnitude 1. We will need to use the scalar product and to express vectors using the unit vectors.
SET UP: $A = \sqrt{A_x^2 + A_y^2 + A_z^2}$, $\vec{A} \cdot \vec{B} = A_x B_x + A_y B_y + A_z B_z$. If two vectors are perpendicular, their scalar product is zero.
EXECUTE: **(a)** If we divide a vector by its magnitude, the result will have magnitude 1 but still point in the same direction as the original vector, so it will be a unit vector. First find the magnitude of the given vector. $A = \sqrt{A_x^2 + A_z^2} = \sqrt{(3.0)^2 + (-4.0)^2} = 5.0$. Therefore $\dfrac{3.0\hat{\boldsymbol{i}} - 4.0\hat{\boldsymbol{k}}}{5} = 0.60\,\hat{\boldsymbol{i}} - 0.80\,\hat{\boldsymbol{k}}$ is a unit vector that is parallel to $\vec{A}$.
(b) Reversing the direction of the unit vector in (a) will make it antiparallel to $\vec{A}$, so the unit vector is $-0.60\,\hat{\boldsymbol{i}} + 0.80\,\hat{\boldsymbol{k}}$.
(c) Call $\vec{B}$ the unknown unit vector. Since it has no y-component, we can express it as $\vec{B} = B_x\hat{\boldsymbol{i}} + B_z\hat{\boldsymbol{k}}$. Since $\vec{A}$ and $\vec{B}$ are perpendicular, $\vec{A} \cdot \vec{B} = 0$, so $A_x B_x + A_y B_y + A_z B_z = 0$. This gives $(3.0)B_x - (4.0)B_z = 0 \ \rightarrow\ B_z = 0.75\,B_x$. Since $\vec{B}$ is a unit vector, we have $B_x^2 + B_z^2 = B_x^2 + \left(0.75 B_x\right)^2 = 1$. Solving gives $B_x = \pm 0.80$. Therefore $B_z = \pm(0.75\,B_x) = \pm(0.75)(0.80) = \pm 0.60$. Therefore $\vec{B} = \pm(0.80\,\hat{\boldsymbol{i}} + 0.60\,\hat{\boldsymbol{k}}$), so the two unit vectors are

$\vec{B}_+ = 0.80\,\hat{i} + 0.60\,\hat{k}$ and $\vec{B}_- = -0.80\,\hat{i} - 0.60\,\hat{k}$.

EVALUATE: $\vec{A}\Box\vec{B}_+ = (3.0)(0.80) + (-4.0)(6.0) = 0$ and $\vec{A}\cdot\vec{B}_- = (3.0)(-0.80) + (-4.0)(-6.0) = 0$, so the two vectors are perpendicular to $\vec{A}$. Their magnitudes are $\sqrt{(\pm 0.80)^2 + (\pm 0.60)^2} = 1$, so they are unit vectors.

1.56. **IDENTIFY:** Let $\vec{D}$ be the fourth force. Find $\vec{D}$ such that $\vec{A}+\vec{B}+\vec{C}+\vec{D}=0$, so $\vec{D}=-(\vec{A}+\vec{B}+\vec{C})$.

SET UP: Use components and solve for the components D_x and D_y of $\vec{D}$.

EXECUTE: $A_x = +A\cos 30.0° = +86.6\text{ N}$, $A_y = +A\sin 30.0° = +50.00\text{ N}$.

$B_x = -B\sin 30.0° = -40.00\text{ N}$, $B_y = +B\cos 30.0° = +69.28\text{ N}$.

$C_x = -C\cos 53.0° = -24.07\text{ N}$, $C_y = -C\sin 53.0° = -31.90\text{ N}$.

Then $D_x = -22.53$ N, $D_y = -87.34$ N and $D = \sqrt{D_x^2 + D_y^2} = 90.2$ N. $\tan\alpha = |D_y/D_x| = 87.34/22.53$.

$\alpha = 75.54°$. $\phi = 180° + \alpha = 256°$, counterclockwise from the $+x$-axis.

EVALUATE: As shown in Figure 1.56, since D_x and D_y are both negative, $\vec{D}$ must lie in the third quadrant.

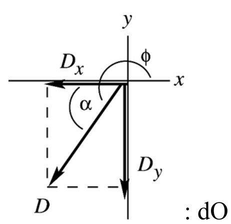

Figure 1.56

1.57. **IDENTIFY:** Vector addition. Target variable is the 4th displacement.

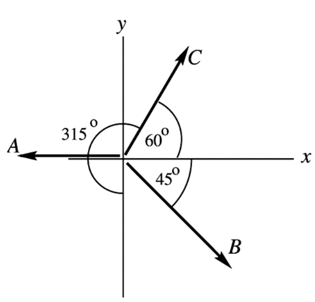
SET UP: Use a coordinate system where east is in the $+x$-direction and north is in the $+y$-direction.

Let $\vec{A}$, $\vec{B}$, and $\vec{C}$ be the three displacements that are given and let $\vec{D}$ be the fourth unmeasured displacement. Then the resultant displacement is $\vec{R} = \vec{A}+\vec{B}+\vec{C}+\vec{D}$. And since she ends up back where she started, $\vec{R} = 0$.

$0 = \vec{A}+\vec{B}+\vec{C}+\vec{D}$, so $\vec{D} = -(\vec{A}+\vec{B}+\vec{C})$

$D_x = -(A_x + B_x + C_x)$ and $D_y = -(A_y + B_y + C_y)$

EXECUTE:



$A_x = -180$ m, $A_y = 0$

$B_x = B\cos 315° = (210\text{ m})\cos 315° = +148.5$ m

$B_y = B\sin 315° = (210\text{ m})\sin 315° = -148.5$ m

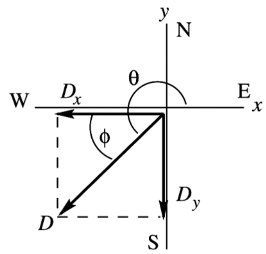
$C_x = C\cos 60° = (280\text{ m})\cos 60° = +140$ m

$C_y = C\sin 60° = (280\text{ m})\sin 60° = +242.5$ m

Figure 1.57a

$D_x = -(A_x + B_x + C_x) = -(-180\text{ m} + 148.5\text{ m} + 140\text{ m}) = -108.5$ m

$D_y = -(A_y + B_y + C_y) = -(0 - 148.5\text{ m} + 242.5\text{ m}) = -94.0$ m



$$D = \sqrt{D_x^2 + D_y^2}$$

$$D = \sqrt{(-108.5\text{ m})^2 + (-94.0\text{ m})^2} = 144\text{ m}$$

$$\tan\theta = \frac{D_y}{D_x} = \frac{-94.0\text{ m}}{-108.5\text{ m}} = 0.8664$$

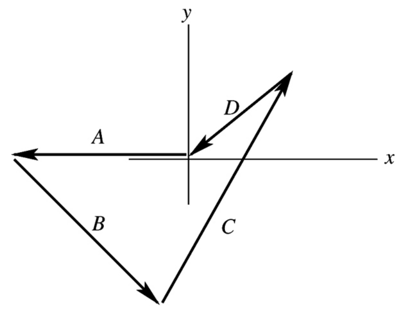
$$\theta = 180° + 40.9° = 220.9°$$

($\vec{D}$ is in the third quadrant since both D_x and D_y are negative.)

Figure 1.57b

The direction of $\vec{D}$ can also be specified in terms of $\phi = \theta - 180° = 40.9°$; $\vec{D}$ is $41°$ south of west.

EVALUATE: The vector addition diagram, approximately to scale, is



Vector $\vec{D}$ in this diagram agrees qualitatively with our calculation using components.

Figure 1.57c

1.58. **IDENTIFY:** Find the vector sum of the two displacements.

SET UP: Call the two displacements $\vec{A}$ and $\vec{B}$, where $A = 170$ km and $B = 230$ km. $\vec{A} + \vec{B} = \vec{R}$. $\vec{A}$ and $\vec{B}$ are as shown in Figure 1.58.

EXECUTE: $R_x = A_x + B_x = (170\text{ km})\sin 68° + (230\text{ km})\cos 36° = 343.7$ km.

$R_y = A_y + B_y = (170\text{ km})\cos 68° - (230\text{ km})\sin 36° = -71.5$ km.

a $R = \sqrt{R_x^2 + R_y^2} = \sqrt{(343.7\text{ km})^2 + (-71.5\text{ km})^2} = 351$ km. $\tan\theta_R = \left|\frac{R_y}{R_x}\right| = \frac{71.5\text{ km}}{343.7\text{ km}} = 0.208$.

$\theta_R = 11.8°$ south of east.

EVALUATE: Our calculation using components agrees with $\vec{R}$ shown in the vector addition diagram, Figure 1.58.

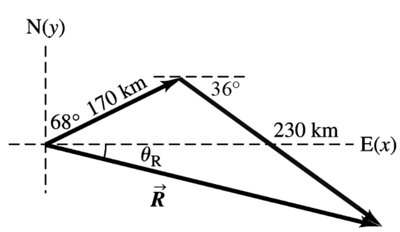


Figure 1.58

1.59. **IDENTIFY:** This problem requires vector addition. We can find the components of the given vectors and then use them to find the magnitude and direction of the resultant vector.

SET UP: $A_x = A\cos\theta$, $A_y = A\sin\theta$, $\theta = \arctan\dfrac{A_y}{A_x}$, $A = \sqrt{A_x^2 + A_y^2 + A_z^2}$, $R_x = A_x + B_x$, and $R_y = A_y + B_y$. Sketch the given vectors to help find the components (see Fig. 1.59).

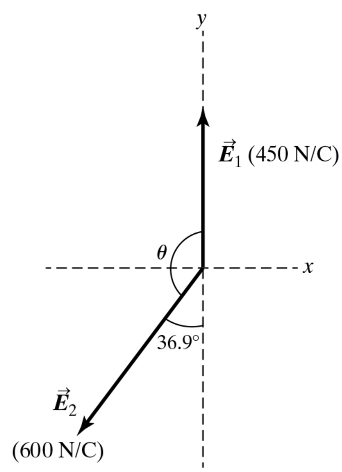

Figure 1.59

EXECUTE: From Fig. 1.59 we can see that the component s are

$E_{1x} = 0$ and $E_{1y} = 450$ N/C

$E_{2x} = E_2\cos\theta = (600\text{ N/C})\cos 233.1° = -360.25$ N/C

$E_{2y} = E_2\sin\theta = (600\text{ N/C})\sin 233.1° = -479.81$ N/C.

Now find the components of the resultant field:

$E_x = E_{1x} + E_{2x} = 0 + (-360.25\text{ N/C}) = -360.25$ N/C

$E_y = E_{1y} + E_{2y} = 450\text{ N/C} + (-479.81\text{ N/C}) = -29.81$ N/C

Now find the magnitude and direction of $\vec{E}$:

$E = \sqrt{E_x^2 + E_y^2} = \sqrt{(-360.25\text{ N/C})^2 + (-29.81\text{ N/C})^2} = 361$ N/C.

$\theta = \arctan\dfrac{A_y}{A_x} = \theta = \arctan\left(\dfrac{-29.81\text{ N/C}}{-360.25\text{ N/C}}\right) = 4.73°$. Both components of $\vec{E}$ are negative, so it must point into the third quadrant. Therefore the angle below the $-x$-axis is 4.73°. The angle with the $+x$-axis is 180° + 4.73° = 184.73°.

EVALUATE: Make a careful graphical sum to check your answer.

1.60. **IDENTIFY:** Solve for one of the vectors in the vector sum. Use components.

SET UP: Use coordinates for which $+x$ is east and $+y$ is north. The vector displacements are:

$\vec{A} = 2.00$ km, 0°of east; $\vec{B} = 3.50$ m, 45° south of east; and $\vec{R} = 5.80$ m, 0° east

EXECUTE: $C_x = R_x - A_x - B_x = 5.80\text{ km} - (2.00\text{ km}) - (3.50\text{ km})(\cos 45°) = 1.33$ km;

$C_y = R_y - A_y - B_y$

$= 0\text{ km} - 0\text{ km} - (-3.50\text{ km})(\sin 45°) = 2.47$ km; $C = \sqrt{(1.33\text{ km})^2 + (2.47\text{ km})^2} = 2.81$ km;

$\theta = \tan^{-1}[(2.47\text{ km})/(1.33\text{ km})] = 61.7°$ north of east. The vector addition diagram in Figure 1.60 shows good qualitative agreement with these values.

EVALUATE: The third leg lies in the first quadrant since its x and y components are both positive.

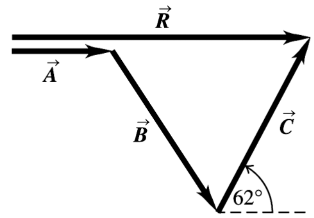

Figure 1.60

1.61. **IDENTIFY:** We know the resultant of two forces of known equal magnitudes and want to find that magnitude (the target variable).

SET UP: Use coordinates having a horizontal $+x$ axis and an upward $+y$ axis. Then $A_x + B_x = R_x$ and $R_x = 12.8\text{ N}$.

SOLVE: $A_x + B_x = R_x$ and $A\cos 32° + B\sin 32° = R_x$. Since $A = B$,

$2A\cos 32° = R_x$, so $A = \dfrac{R_x}{(2)(\cos 32°)} = 7.55\text{ N}$.

EVALUATE: The magnitude of the x component of each pull is 6.40 N, so the magnitude of each pull (7.55 N) is greater than its x component, as it should be.

1.62. **IDENTIFY:** The four displacements return her to her starting point, so $\vec{D} = -(\vec{A} + \vec{B} + \vec{C})$, where $\vec{A}$, $\vec{B}$, and $\vec{C}$ are in the three given displacements and $\vec{D}$ is the displacement for her return.

SET UP: Let $+x$ be east and $+y$ be north.

EXECUTE: **(a)** $D_x = -[(147\text{ km})\sin 85° + (106\text{ km})\sin 167° + (166\text{ km})\sin 235°] = -34.3\text{ km}$.

$D_y = -[(147\text{ km})\cos 85° + (106\text{ km})\cos 167° + (166\text{ km})\cos 235°] = +185.7\text{ km}$.

$D = \sqrt{(-34.3\text{ km})^2 + (185.7\text{ km})^2} = 189\text{ km}$.

(b) The direction relative to north is $\phi = \arctan\left(\dfrac{34.3\text{ km}}{185.7\text{ km}}\right) = 10.5°$. Since $D_x < 0$ and $D_y > 0$, the direction of $\vec{D}$ is $10.5°$ west of north.

EVALUATE: The four displacements add to zero.

1.63. **IDENTIFY:** We have two known vectors and a third unknown vector, and we know the resultant of these three vectors.

SET UP: Use coordinates for which $+x$ is east and $+y$ is north. The vector displacements are:

$\vec{A} = 23.0\text{ km}$ at 34.0° south of east; $\vec{B} = 46.0\text{ km}$ due north; $\vec{R} = 32.0\text{ km}$ due west ; $\vec{C}$ is unknown.

EXECUTE: $C_x = R_x - A_x - B_x = -32.0\text{ km} - (23.0\text{ km})\cos 34.0° - 0 = -51.07\text{ km}$;

$C_y = R_y - A_y - B_y = 0 - (-23.0\text{ km})\sin 34.0° - 46.0\text{ km} = -33.14\text{ km}$;

$C = \sqrt{C_x^2 + C_y^2} = 60.9\text{ km}$

Calling θ the angle that $\vec{C}$ makes with the $-x$-axis (the westward direction), we have

$\tan\theta = C_y / C_x = \dfrac{33.14}{51.07}$; $\theta = 33.0°$ south of west.

EVALUATE: A graphical vector sum will confirm this result.

1.64. **IDENTIFY:** Let the three given displacements be $\vec{A}$, $\vec{B}$ and $\vec{C}$, where $A = 40$ steps, $B = 80$ steps and $C = 50$ steps. $\vec{R} = \vec{A} + \vec{B} + \vec{C}$. The displacement $\vec{C}$ that will return him to his hut is $-\vec{R}$.

SET UP: Let the east direction be the $+x$-direction and the north direction be the $+y$-direction.

EXECUTE: **(a)** The three displacements and their resultant are sketched in Figure 1.64.

(b) $R_x = (40)\cos 45° - (80)\cos 60° = -11.7$ and $R_y = (40)\sin 45° + (80)\sin 60° - 50 = 47.6$.

The magnitude and direction of the resultant are $\sqrt{(-11.7)^2 + (47.6)^2} = 49$, acrtan$\left(\frac{47.6}{11.7}\right) = 76°$, north of west. We know that $\vec{R}$ is in the second quadrant because $R_x < 0$, $R_y > 0$. To return to the hut, the explorer must take 49 steps in a direction $76°$ south of east, which is $14°$ east of south.

EVALUATE: It is useful to show R_x, R_y, and $\vec{R}$ on a sketch, so we can specify what angle we are computing.

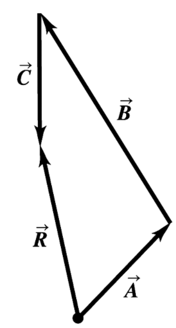

Figure 1.64

1.65. **IDENTIFY:** We want to find the resultant of three known displacement vectors: $\vec{R} = \vec{A} + \vec{B} + \vec{C}$.

SET UP: Let $+x$ be east and $+y$ be north and find the components of the vectors.

EXECUTE: The magnitudes are A = 20.8 m, B = 38.0 m, C = 18.0 m. The components are
$A_x = 0$, A_y = 28.0 m, B_x = 38.0 m, $B_y = 0$,
C_x = –(18.0 m)(sin33.0°) = –9.804 m, C_y = –(18.0 m)(cos33.0°) = –15.10 m
$R_x = A_x + B_x + C_x$ = 0 + 38.0 m + (–9.80 m) = 28.2 m
$R_y = A_y + B_y + C_y$ = 20.8 m + 0 + (–15.10 m) = 5.70 m
$R = \sqrt{R_x^2 + R_y^2}$ = 28.8 m is the distance you must run. Calling θ_R the angle the resultant makes with the $+x$-axis (the easterly direction), we have
tan $\theta_R = R_y/R_x$ = (5.70 km)/(28.2 km); θ_R = 11.4° north of east.

EVALUATE: A graphical sketch will confirm this result.

1.66. **IDENTIFY:** This is a problem in vector addition. We want the magnitude of the resultant of four known displacement vectors in three dimensions. We can use components to do this.

SET UP: $R_x = A_x + B_x + C_x + D_x$, and likewise for the other components. The magnitude is $R = \sqrt{R_x^2 + R_y^2 + R_z^2}$. Call the $+x$-axis toward the east, the $+y$-axis toward the north, and the $+z$-axis vertically upward. First find the components of the four displacements, then use them to find the magnitude of the resultant displacement.

EXECUTE: Finding the components in the order in which the displacements are listed in the problem, the components of the four displacement vectors are A_x = –14.0 m, B_z = +22.0 m, C_y = +12.0 m, and D_x = 6.0 m. All the other components are zero. Now find the components of $\vec{R}$.

$R_x = -14.0\text{ m} + 6.0\text{ m} = -8.0\text{ m}$, $R_y = 12.0\text{ m}$, $R_z = 22.0\text{ m}$. Now find the resultant displacement using $R = \sqrt{R_x^2 + R_y^2 + R_z^2}$. $R = \sqrt{(-8.0\text{ m})^2 + (12.0\text{ m})^2 + (22.0\text{ m})^2} = 26\text{ m}$.

EVALUATE: This is one case where a graphical solution would not be useful as a check since three-dimensional drawings are very difficult to visualize. Note that the answer has only 2 significant figures even though all the given numbers have 3 significant figures. The reason for this is that in the subtraction to find R_x we lost one significant figure because $-14.0 + 6.0 = 8.0$, which has only 2 significant figures.

1.67. **IDENTIFY:** We know the resultant of two vectors and one of the vectors, and we want to find the second vector.

SET UP: Let the westerly direction be the $+x$-direction and the northerly direction be the $+y$-direction. We also know that $\vec{R} = \vec{A} + \vec{B}$ where $\vec{R}$ is the vector from you to the truck. Your GPS tells you that you are 122.0 m from the truck in a direction of 58.0° east of south, so a vector from the truck to you is 122.0 m at 58.0° east of south. Therefore the vector from you to the truck is 122.0 m at 58.0° west of north. Thus $\vec{R}$ = 122.0 m at 58.0° west of north and $\vec{A}$ is 72.0 m due west. We want to find the magnitude and direction of vector $\vec{B}$.

EXECUTE: $B_x = R_x - A_x = (122.0\text{ m})(\sin 58.0°) - 72.0\text{ m} = 31.462\text{ m}$

$B_y = R_y - A_y = (122.0\text{ m})(\cos 58.0°) - 0 = 64.450\text{ m}$; $B = \sqrt{B_x^2 + B_y^2} = 71.9\text{ m}$.

$\tan\theta_B = B_y / B_x = \dfrac{64.650\text{ m}}{31.462\text{ m}} = 2.05486$; $\theta_B = 64.1°$ north of west.

EVALUATE: A graphical sum will show that the results are reasonable.

1.68. **IDENTIFY:** We are dealing with vector addition. We know the resultant vector is the same for both trips, but we take different displacements on two different days. It is best to use components.

SET UP: First make a clear sketch showing the displacement vectors on the two different days (see Fig. 1.68). Use $R_x = A_x + B_x$ and $R_y = A_y + B_y$ and $A = \sqrt{A_x^2 + A_y^2}$ for the magnitude of a vector. Let the x-axis be eastward the y-axis be toward the north.

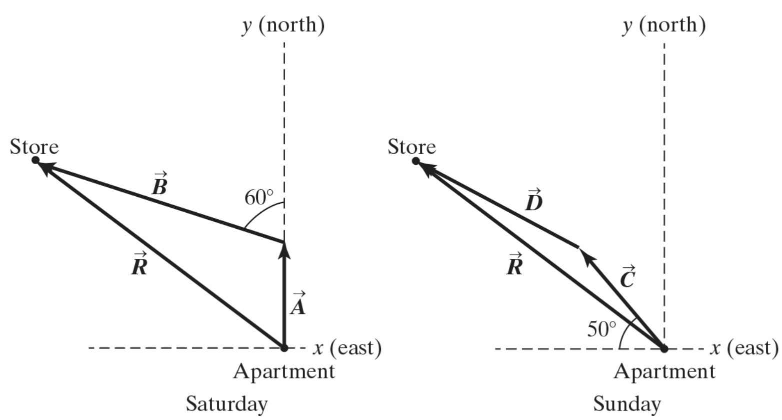

Figure 1.68

EXECUTE: **(a)** The magnitude R of the resultant is the distance to the store from your apartment. Using the Saturday trip, let $\vec{A}$ be the first drive and $\vec{B}$ be the second drive, so $\vec{A} + \vec{B} = \vec{R}$. First find the components of $\vec{R}$.

$R_x = A_x + B_x = 0 + (1.40 \text{ km}) \cos 150.0° = -1.212$ km

$R_y = A_y + B_y = 0.600 \text{ km} + (1.40 \text{ km}) \sin 150.0° = 1.30$ km.

Now find R: $R = \sqrt{R_x^2 + R_y^2} = \sqrt{(-1.212 \text{ km})^2 + (1.30 \text{ km})^2} = 1.78$ km.

(b) The distance traveled each day is *not* the magnitude of the resultant. Rather, it is the sum of the magnitudes of both displacement vectors for each trip. We know all of them except the second drive on the Sunday trip. Call $\vec{C}$ the first drive on Sunday and $\vec{D}$ the second Sunday drive. The resultant of these is the same as for the Saturday trip, so we can find the components of $\vec{D}$.

$C_x + D_x = R_x$: $(0.80 \text{ km}) \cos 130° + D_x = -1.212$ km $\rightarrow$ $D_x = -0.6978$ km

$C_y + D_y = R_y$: $(0.80 \text{ km}) \sin 130° + D_y = 1.30$ km $\rightarrow$ $D_y = 0.6872$ km.

Now find the magnitude of $\vec{D}$: $D = \sqrt{D_x^2 + D_y^2} = \sqrt{(-0.6978 \text{ km})^2 + (0.6872 \text{ km})^2} = 0.9793$ km.

The distances driven on the two days are

Saturday: 0.60 km + 1.40 km = 2.00 km

Sunday: 0.80 km + 0.9793 km = 1.7793 km

The difference in distance is 2.00 km – 1.7793 km = 0.22 km. On Saturday you drove 0.22 km farther than on Sunday.

EVALUATE: Even though the resultant displacement was the same on both days, you drove different distances on the two days because you took different paths.

1.69. **IDENTIFY:** The sum of the four displacements must be zero. Use components.

SET UP: Call the displacements $\vec{A}$, $\vec{B}$, $\vec{C}$, and $\vec{D}$, where $\vec{D}$ is the final unknown displacement for the return from the treasure to the oak tree. Vectors $\vec{A}$, $\vec{B}$, and $\vec{C}$ are sketched in Figure 1.69a. $\vec{A} + \vec{B} + \vec{C} + \vec{D} = 0$ says $A_x + B_x + C_x + D_x = 0$ and $A_y + B_y + C_y + D_y = 0$. $A = 825$ m, $B = 1250$ m, and $C = 1000$ m. Let $+x$ be eastward and $+y$ be north.

EXECUTE: (a) $A_x + B_x + C_x + D_x = 0$ gives $D_x = -(A_x + B_x + C_x) = -[0 - (1250 \text{ m})\sin 30.0° + (1000 \text{ m})\cos 32.0°] = -223.0$ m. $A_y + B_y + C_y + D_y = 0$ gives $D_y = -(A_y + B_y + C_y) = -[-825 \text{ m} + (1250 \text{ m})\cos 30.0° + (1000 \text{ m})\sin 32.0°] = -787.4$ m. The fourth displacement $\vec{D}$ and its components are sketched in Figure 1.69b. $D = \sqrt{D_x^2 + D_y^2} = 818.4$ m.

$\tan\phi = \dfrac{|D_x|}{|D_y|} = \dfrac{223.0 \text{ m}}{787.4 \text{ m}}$ and $\phi = 15.8°$. You should head 15.8° west of south and must walk 818 m.

(b) The vector diagram is sketched in Figure 1.69c. The final displacement $\vec{D}$ from this diagram agrees with the vector $\vec{D}$ calculated in part **(a)** using components.

EVALUATE: Note that $\vec{D}$ is the negative of the sum of $\vec{A}$, $\vec{B}$, and $\vec{C}$, as it should be.

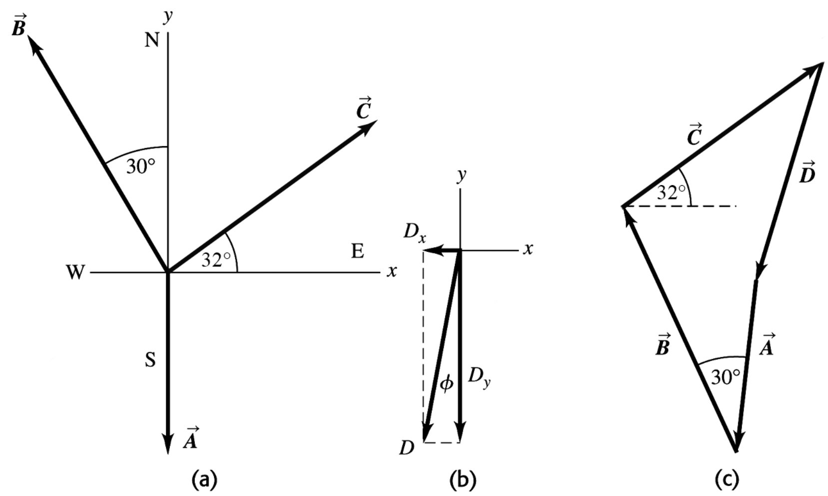

Figure 1.69

1.70. **IDENTIFY:** The displacements are vectors in which we want to find the magnitude of the resultant and know the other vectors.

SET UP: Calling $\vec{A}$ the vector from you to the first post, $\vec{B}$ the vector from you to the second post, and $\vec{C}$ the vector from the first post to the second post, we have $\vec{A}+\vec{C}=\vec{B}$. We want to find the magnitude of vector $\vec{B}$. We use components and the magnitude of $\vec{C}$. Let $+x$ be toward the east and $+y$ be toward the north.

EXECUTE: $B_x = 0$ and B_y is unknown. $C_x = -A_x = -(52.0\text{ m})(\cos 37.0°) = -41.529\text{ m}$ $A_x = 41.53\text{ m}$ $C = 68.0\text{ m}$, so $C_y = \pm\sqrt{C^2 - C_x^2} = -53.8455\text{ m}$. We use the minus sign because the second post is south of the first post.

$B_y = A_y + C_y = (52.0\text{ m})(\sin 37°) + (-53.8455\text{ m}) = -22.551\text{ m}$.

Therefore you are 22.6 m from the second post.

EVALUATE: B_y is negative since post is south of you (in the negative y direction), but the distance to you is positive.

1.71. **IDENTIFY:** We are given the resultant of three vectors, two of which we know, and want to find the magnitude and direction of the third vector.

SET UP: Calling $\vec{C}$ the unknown vector and $\vec{A}$ and $\vec{B}$ the known vectors, we have $\vec{A}+\vec{B}+\vec{C}=\vec{R}$. The components are $A_x + B_x + C_x = R_x$ and $A_y + B_y + C_y = R_y$.

EXECUTE: The components of the known vectors are $A_x = 12.0\text{ m}$, $A_y = 0$, $B_x = -B\sin 50.0° = -21.45\text{ m}$, $B_y = B\cos 50.0° = +18.00\text{ m}$, $R_x = 0$, and $R_y = -10.0\text{ m}$. Therefore the components of $\vec{C}$ are $C_x = R_x - A_x - B_x = 0 - 12.0\text{ m} - (-21.45\text{ m}) = 9.45\text{ m}$ and $C_y = R_y - A_y - B_y = -10.0\text{ m} - 0 - 18.0\text{ m} = -28.0\text{ m}$.

Using these components to find the magnitude and direction of $\vec{C}$ gives $C = 29.6\text{ m}$ and $\tan\theta = \dfrac{9.45}{28.0}$ and $\theta = 18.6°$ east of south.

EVALUATE: A graphical sketch shows that this answer is reasonable.

1.72. **IDENTIFY:** The displacements are vectors in which we know the magnitude of the resultant and want to find the magnitude of one of the other vectors.

SET UP: Calling $\vec{A}$ the vector of Ricardo's displacement from the tree, $\vec{B}$ the vector of Jane's displacement from the tree, and $\vec{C}$ the vector from Ricardo to Jane, we have $\vec{A}+\vec{C}=\vec{B}$. Let the $+x$-axis be to the east and the $+y$-axis be to the north. Solving using components we have $A_x + C_x = B_x$ and $A_y + C_y = B_y$.

EXECUTE: **(a)** The components of $\vec{A}$ and $\vec{B}$ are $A_x = -(26.0\text{ m})\sin 60.0° = -22.52\text{ m}$,
$A_y = (26.0\text{ m})\cos 60.0° = +13.0\text{ m}$, $B_x = -(16.0\text{ m})\cos 30.0° = -13.86\text{ m}$,
$B_y = -(16.0\text{ m})\sin 30.0° = -8.00\text{ m}$, $C_x = B_x - A_x = -13.86\text{ m} - (-22.52\text{ m}) = +8.66\text{ m}$,
$C_y = B_y - A_y = -8.00\text{ m} - (13.0\text{ m}) = -21.0\text{ m}$

Finding the magnitude from the components gives $C = 22.7\text{ m}$.

(b) Finding the direction from the components gives $\tan\theta = \dfrac{8.66}{21.0}$ and $\theta = 22.4°$, east of south.

EVALUATE: A graphical sketch confirms that this answer is reasonable.

1.73. **IDENTIFY:** If the vector from your tent to Joe's is $\vec{A}$ and from your tent to Karl's is $\vec{B}$, then the vector from Karl's tent to Joe's tent is $\vec{A}-\vec{B}$.

SET UP: Take your tent's position as the origin. Let $+x$ be east and $+y$ be north.

EXECUTE: The position vector for Joe's tent is
$[(21.0\text{ m})\cos 23°]\hat{i} - [(21.0\text{ m})\sin 23°]\hat{j} = (19.33\text{ m})\hat{i} - (8.205\text{ m})\hat{j}$.

The position vector for Karl's tent is $[(32.0\text{ m})\cos 37°]\hat{i} + [(32.0\text{ m})\sin 37°]\hat{j} = (25.56\text{ m})\hat{i} + (19.26\text{ m})\hat{j}$.

The difference between the two positions is
$(19.33\text{ m} - 25.56\text{ m})\hat{i} + (-8.205\text{ m} - 19.25\text{ m})\hat{j} = -(6.23\text{ m})\hat{i} - (27.46\text{ m})\hat{j}$. The magnitude of this vector is the distance between the two tents: $D = \sqrt{(-6.23\text{ m})^2 + (-27.46\text{ m})^2} = 28.2\text{ m}$.

EVALUATE: If both tents were due east of yours, the distance between them would be $32.0\text{ m} - 21.0\text{ m} = 11.0\text{ m}$. If Joe's was due north of yours and Karl's was due south of yours, then the distance between them would be $32.0\text{ m} + 21.0\text{ m} = 53.0\text{ m}$. The actual distance between them lies between these limiting values.

1.74. **IDENTIFY:** Calculate the scalar product and use Eq. (1.16) to determine ϕ.

SET UP: The unit vectors are perpendicular to each other.

EXECUTE: The direction vectors each have magnitude $\sqrt{3}$, and their scalar product is $(1)(1)+(1)(-1)+(1)(-1) = -1$, so from Eq. (1.16) the angle between the bonds is
$\arccos\left(\dfrac{-1}{\sqrt{3}\sqrt{3}}\right) = \arccos\left(-\dfrac{1}{3}\right) = 109°$.

EVALUATE: The angle between the two vectors in the bond directions is greater than $90°$.

1.75. **IDENTIFY:** This problem involves the scalar product of two vectors.

SET UP: $W = \vec{F}\cdot\vec{s} = Fs\cos\phi = F_x s_x + F_y s_y$.

EXECUTE: Since $\vec{F}$ is at 60° above the $-x$-axis and $\vec{s}$ is along the $+x$-axis, the angle between them is 120°. The work is $W = Fs\cos\phi = (5.00\text{ N})(0.800\text{ m})\cos 120° = -2.00\text{ J}$.

EVALUATE: Use $W = F_x s_x + F_y s_y$ to check.

$W = (5.00\text{ N}\cos 120°)(0.800\text{ m}) + (5.00\text{ N}\sin 120°)(0) = -2.00\text{ J}$, which agrees with our result.

1.76. **IDENTIFY:** This problem involves the vector product of two vectors.

SET UP: The magnetic force is $\vec{F} = q\vec{v}\times\vec{B}$, $F = qvB\sin\phi$.

EXECUTE: $F = qvB \sin\phi$ gives the *magnitude* of a vector, so it must be positive. Therefore we only need to use the sign of q, so $F = (8.00\times 10^{-6}\ \text{C})(3.00\times 10^{4}\ \text{m/s})(5.00\ \text{T}) \sin 90° = 1.20\ \text{N}$.
Since $\vec{v}$ is in the $+x$ direction and $\vec{B}$ is in the $-y$ direction, $\vec{v}\times\vec{B}$ is in the $-z$ direction. But $q\vec{v}\times\vec{B}$ is in the $+z$ direction because q is negative, so the force is in the $-z$ direction.
EVALUATE: Careful! The quantity $qvB\sin\phi$ cannot be negative since it is the magnitude of a vector. Both v and B are vector magnitudes, so they are always positive, and $\sin\phi$ is positive because $0 \le \phi \le 120°$. Only q could be negative, but when using $qvB\sin\phi$, we must use only the *magnitude* of q. When using $\vec{F} = q\vec{v}\times\vec{B}$, we *do* use the minus sign for q because it affects the direction of the force.

1.77. **IDENTIFY:** We know the scalar product and the magnitude of the vector product of two vectors and want to know the angle between them.
SET UP: The scalar product is $\vec{A}\cdot\vec{B} = AB\cos\theta$ and the vector product is $|\vec{A}\times\vec{B}| = AB\sin\theta$.
EXECUTE: $\vec{A}\cdot\vec{B} = AB\cos\theta = -6.00$ and $|\vec{A}\times\vec{B}| = AB\sin\theta = +9.00$. Taking the ratio gives

$\tan\theta = \dfrac{9.00}{-6.00}$, so $\theta = 124°$.

EVALUATE: Since the scalar product is negative, the angle must be between 90° and 180°.

1.78. **IDENTIFY:** This problem involves the vector product of two vectors.
SET UP: The torque is $\vec{r}\times\vec{F}$, so its magnitude is $rF\sin\phi$.
EXECUTE: We know that $\vec{r}$ makes a 36° angle counterclockwise from the $+y$-axis and $\vec{F}$ points in the $-y$ direction. Therefore the angle between these two vectors is 180° – 36° = 144°. So the magnitude of the torque is $|\vec{r}\times\vec{F}| = rF\sin\phi = (4.0\ \text{m})(22.0\ \text{N})\sin 144° = 52\ \text{N}\cdot\text{m}$. The direction of the torque is in the direction of $\vec{r}\times\vec{F}$. By the right-hand rule, this is in the $+z$ direction.
EVALUATE: The torque vector could point along a negative axis (such as –z), but it would still always have a positive *magnitude*.

1.79. **IDENTIFY:** This problem involves the vector product and the scalar product of two vectors. It is best to use components.
SET UP: $\vec{A}\cdot\vec{B} = A_xB_x + A_yB_y + A_zB_z$, the components of $\vec{A}\times\vec{B}$ are shown in Eq. 1.25 in the text.
EXECUTE: **(a)** $\vec{A}\cdot\vec{B} = A_xB_x + A_yB_y + A_zB_z = a(0) + (0)(-c) + (-b)(d) = -bd$.

Realizing that $A_y = 0$ and $B_x = 0$, Eq. 1.25 gives the components of $\vec{A}\times\vec{B}$.
$(\vec{A}\times\vec{B})_x = -A_zB_y = -(-b)(-c) = -bc$
$(\vec{A}\times\vec{B})_y = -A_xB_z = -(a)(d) = -ad$
$(\vec{A}\times\vec{B})_z = A_xB_y = (a)(-c) = -ac$
$\vec{A}\times\vec{B} = -bc\,\hat{i} - ad\,\hat{j} - ac\,\hat{k}$.

(b) If $c = 0$, $\vec{A}\cdot\vec{B} = -bd$ and $\vec{A}\times\vec{B} = -ad\,\hat{j}$. The magnitude of $\vec{A}\times\vec{B}$ is ad and its direction is $-\hat{j}$ (which is in the $-y$ direction). Figure 1.79 shows a sketch of $\vec{A}$ and $\vec{B}$ in the xy plane. In this figure, the $+y$ axis would point into the paper. By the right-hand rule, $\vec{A}\times\vec{B}$ points out of the paper, which is in the $-y$ direction (or the $-\hat{j}$ direction), which agrees with our results.

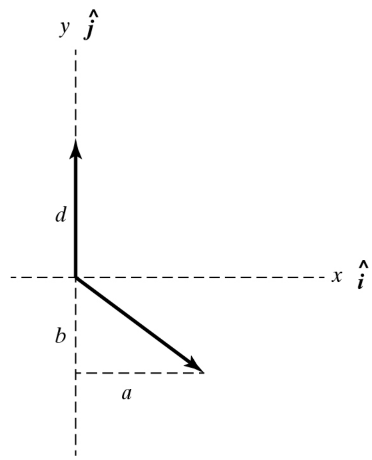

Figure 1.79

From Fig. 1.79 we see that the component of $\vec{A}$ that is parallel to $\vec{B}$ is $-b$. So the product of B with the component of $\vec{A}$ that is parallel to $\vec{B}$ is $d(-b) = -bd$, which agrees with our result. From the same figure we see that the component of $\vec{A}$ that is perpendicular to $\vec{B}$ is a. So the product of B and the component of $\vec{A}$ that is perpendicular to $\vec{B}$ is da, which is the magnitude of the vector product we found above.

EVALUATE: The geometric interpretations of $\vec{A}\cdot\vec{B}$ and $\vec{A}\times\vec{B}$ can be reversed in the sense that $\vec{A}\cdot\vec{B}$ equals A times the component of $\vec{B}$ that is parallel to $\vec{A}$ and $|\vec{A}\times\vec{B}|$ equals A times the component of $\vec{B}$ that is perpendicular to $\vec{A}$.

1.80. IDENTIFY: We are dealing with the scalar product and the vector product of two vectors.

SET UP: $\vec{A}\cdot\vec{B} = AB\cos\phi$ and $|\vec{A}\times\vec{B}| = AB\sin\phi$.

EXECUTE: **(a)** For the notation in the problem, $AB\cos\theta$ has its maximum value when $\theta = 0°$. In that case $|\vec{A}\times\vec{B}| = 0$ because $\sin 0° = 0$.

(b) $|\vec{A}\times\vec{B}| = AB\sin\theta$, so its value occurs when $\theta = 90°$. The scalar product is zero at that angle because $\cos 90° = 0$.

(c) $\vec{A}\cdot\vec{B} = 2|\vec{A}\times\vec{B}|$, so $AB\cos\theta = 2AB\sin\theta \rightarrow \tan\theta = ½ \rightarrow \theta = 26.6°$.

EVALUATE: It might appear that a second solution is $\theta = 180° - 26.6° = 153.4°$, but that is not true because in that case $\vec{A}\cdot\vec{B} = -2|\vec{A}\times\vec{B}|$.

1.81. IDENTIFY: We know the magnitude of two vectors and their scalar product and want to find the magnitude of their vector product.

SET UP: The scalar product is $\vec{A}\cdot\vec{B} = AB\cos\phi$ and the vector product is $|\vec{A}\times\vec{B}| = AB\sin\phi$.

EXECUTE: $\vec{A}\cdot\vec{B} = AB\cos\phi = 90.0\ \text{m}^2$, which gives $\cos\phi = \dfrac{112.0\ \text{m}^2}{AB} = \dfrac{112.0\ \text{m}^2}{(12.0\ \text{m})(16.0\ \text{m})} = 0.5833$, so $\phi = 54.31°$. Therefore $|\vec{A}\times\vec{B}| = AB\sin\phi = (12.0\ \text{m})(16.0\ \text{m})(\sin 54.31°) = 156\ \text{m}^2$.

EVALUATE: The magnitude of the vector product is greater than the scalar product because the angle between the vectors is greater than 45º.

1.82. IDENTIFY: We are dealing with the scalar product and the vector product of two vectors.

SET UP: $\vec{A}\cdot\vec{B} = AB\cos\phi$ and $|\vec{A}\times\vec{B}| = AB\sin\phi$.

EXECUTE: **(a)** In order to have the maximum positive z-component, $\vec{A}\times\vec{B}$ should have its maximum magnitude (which is AB) and it should all point in the $+z$ direction. Thus $\vec{B}$ should be perpendicular to $\vec{A}$ and have a direction so that $\vec{A}\times\vec{B}$ points in the $+z$ direction, as shown in Fig. 1.82. As you can see in this figure, the direction of $\vec{B}$ is at an angle of 53.0° + 90° = 143.0° with the $+x$-axis.

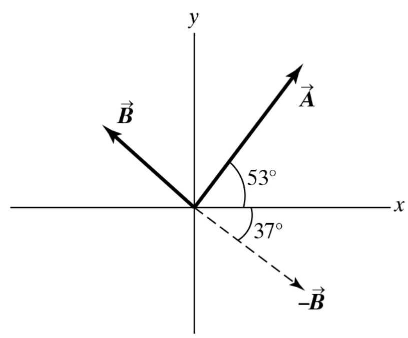

Figure 1.82

(b) In this case, $\vec{A}\times\vec{B}$ must point in the $-z$ direction, so $\vec{B}$ must be the reverse of what we found in part (a). Therefore its angle with the $+x$-axis is 90° – 53.0° = 37.0° clockwise as shown in Fig. 1.82. This angle is 323° counterclockwise with the $+x$-axis.

(c) $\vec{A}\times\vec{B} = 0$ when the angle ϕ between $\vec{A}$ and $\vec{B}$ is 0° or 180°. When ϕ = 0°, the vectors point in the same direction, so they are parallel. When ϕ = 180°, they point in opposite directions, so they are antiparallel. When $\vec{B}$ is parallel to $\vec{A}$, $\vec{B}$ makes an angle of 53.0° counterclockwise from the $+x$-axis. When $\vec{B}$ is antiparallel to $\vec{A}$, $\vec{B}$ makes an angle of 53° + 180° = 233° with the $+x$-axis.

EVALUATE: When calculating the work done by a force, we frequently encounter parallel and antiparallel vectors.

1.83. **IDENTIFY:** We know the scalar product of two vectors, both their directions, and the magnitude of one of them, and we want to find the magnitude of the other vector.

SET UP: $\vec{A}\cdot\vec{B} = AB\cos\phi$. Since we know the direction of each vector, we can find the angle between them.

EXECUTE: The angle between the vectors is $\theta = 79.0°$. Since $\vec{A}\cdot\vec{B} = AB\cos\phi$, we have

$$B = \frac{\vec{A}\cdot\vec{B}}{A\cos\phi} = \frac{48.0\ \text{m}^2}{(9.00\ \text{m})\cos 79.0°} = 28.0\ \text{m}.$$

EVALUATE: Vector $\vec{B}$ has the same units as vector $\vec{A}$.

1.84. **IDENTIFY:** The cross product $\vec{A}\times\vec{B}$ is perpendicular to both $\vec{A}$ and $\vec{B}$.

SET UP: Use Eq. (1.23) to calculate the components of $\vec{A}\times\vec{B}$.

EXECUTE: The cross product is

$(-13.00)\hat{\boldsymbol{i}} + (6.00)\hat{\boldsymbol{j}} + (-11.00)\hat{\boldsymbol{k}} = 13\left[-(1.00)\hat{\boldsymbol{i}} + \left(\frac{6.00}{13.00}\right)\hat{\boldsymbol{j}} - \frac{11.00}{13.00}\hat{\boldsymbol{k}}\right]$. The magnitude of the vector in square brackets is $\sqrt{1.93}$, and so a unit vector in this direction is

$$\left[\frac{-(1.00)\hat{\boldsymbol{i}} + (6.00/13.00)\hat{\boldsymbol{j}} - (11.00/13.00)\hat{\boldsymbol{k}}}{\sqrt{1.93}}\right].$$

The negative of this vector,

$$\left[\frac{(1.00)\hat{\boldsymbol{i}}-(6.00/13.00)\hat{\boldsymbol{j}}+(11.00/13.00)\hat{\boldsymbol{k}}}{\sqrt{1.93}}\right],$$

is also a unit vector perpendicular to $\vec{A}$ and $\vec{B}$.

EVALUATE: Any two vectors that are not parallel or antiparallel form a plane and a vector perpendicular to both vectors is perpendicular to this plane.

1.85. **IDENTIFY** and **SET UP:** The target variables are the components of $\vec{C}$. We are given $\vec{A}$ and $\vec{B}$. We also know $\vec{A}\cdot\vec{C}$ and $\vec{B}\cdot\vec{C}$, and this gives us two equations in the two unknowns C_x and C_y.

EXECUTE: $\vec{A}$ and $\vec{C}$ are perpendicular, so $\vec{A}\cdot\vec{C}=0$. $A_xC_x+A_yC_y=0$, which gives $5.0C_x-6.5C_y=0$.

$\vec{B}\cdot\vec{C}=15.0$, so $3.5C_x-7.0C_y=15.0$

We have two equations in two unknowns C_x and C_y. Solving gives $C_x=-8.0$ and $C_y=-6.1$.

EVALUATE: We can check that our result does give us a vector $\vec{C}$ that satisfies the two equations $\vec{A}\cdot\vec{C}=0$ and $\vec{B}\cdot\vec{C}=15.0$.

1.86. **IDENTIFY:** Calculate the magnitude of the vector product and then use $|\vec{A}\times\vec{B}|=AB\sin\theta$.

SET UP: The magnitude of a vector is related to its components by $A=\sqrt{A_x^2+A_y^2}$.

EXECUTE: $|\vec{A}\times\vec{B}|=AB\sin\theta$. $\sin\theta=\dfrac{|\vec{A}\times\vec{B}|}{AB}=\dfrac{\sqrt{(-5.00)^2+(2.00)^2}}{(3.00)(3.00)}=0.5984$ and

$\theta=\sin^{-1}(0.5984)=36.8°$.

EVALUATE: We haven't found $\vec{A}$ and $\vec{B}$, just the angle between them.

1.87. **IDENTIFY:** Express all the densities in the same units to make a comparison.

SET UP: Density ρ is mass divided by volume. Use the numbers given in the table in the problem and convert all the densities to kg/m³.

EXECUTE: Sample A: $\rho_A=\dfrac{8.00\text{ g}\left(\dfrac{1\text{ kg}}{1000\text{ g}}\right)}{1.67\times10^{-6}\text{ m}^3}=4790\text{ kg/m}^3$

Sample B: $\rho_B=\dfrac{6.00\times10^{-6}\text{ g}\left(\dfrac{1\text{ kg}}{1000\text{ g}}\right)}{9.38\times10^{6}\ \mu\text{m}^3\left(\dfrac{10^{-6}\text{ m}}{1\ \mu\text{m}}\right)^3}=640\text{ kg/m}^3$

Sample C: $\rho_C=\dfrac{8.00\times10^{-3}\text{ g}\left(\dfrac{1\text{ kg}}{1000\text{ g}}\right)}{2.50\times10^{-3}\text{ cm}^3\left(\dfrac{1\text{ m}}{100\text{ cm}}\right)^3}=3200\text{ kg/m}^3$

Sample D: $\rho_D=\dfrac{9.00\times10^{-4}\text{ kg}}{2.81\times10^{3}\text{ mm}^3\left(\dfrac{1\text{ m}}{1000\text{ mm}}\right)^3}=320\text{ kg/m}^3$

Sample E: $\rho_E=\dfrac{9.00\times10^{4}\text{ ng}\left(\dfrac{1\text{ g}}{10^9\text{ ng}}\right)\left(\dfrac{1\text{ kg}}{1000\text{ g}}\right)}{1.41\times10^{-2}\text{ mm}^3\left(\dfrac{1\text{ m}}{1000\text{ mm}}\right)^3}=6380\text{ kg/m}^3$

Sample F: $\rho_F = \dfrac{6.00\times 10^{-5}\ \text{g}\left(\dfrac{1\ \text{kg}}{1000\ \text{g}}\right)}{1.25\ \times\ 10^{8}\ \mu\text{m}^3\left(\dfrac{1\ \text{m}}{10^6\ \mu\text{m}}\right)^3} = 480\ \text{kg/m}^3$

EVALUATE: In order of increasing density, the samples are D, F, B, C, A, E.

1.88. **IDENTIFY:** We know the magnitude of the resultant of two vectors at four known angles between them, and we want to find out the magnitude of each of these two vectors.

SET UP: Use the information in the table in the problem for $\theta = 0.0°$ and 90.0°. Call A and B the magnitudes of the vectors.

EXECUTE: **(a)** At 0°: The vectors point in the same direction, so $A + B = 8.00$ N.

At 90.0°: The vectors are perpendicular to each other, so $A^2 + B^2 = R^2 = (5.83\ \text{N})^2 = 33.99\ \text{N}^2$.

Solving these two equations simultaneously gives

$B = 8.00\ \text{N} - A$

$A^2 + (8.00\ \text{N} - A)^2 = 33.99\ \text{N}^2$

$A^2 + 64.00\ \text{N}^2 - 16.00\ \text{N}\ A + A^2 = 33.99\ \text{N}^2$

The quadratic formula gives two solutions: $A = 5.00$ N and $B = 3.00$ N or $A = 3.00$ N and $B = 5.00$ N. In either case, the larger force has magnitude 5.00 N.

(b) Let $A = 5.00$ N and $B = 3.00$ N, with the larger vector along the x-axis and the smaller one making an angle of +30.0° with the +x-axis in the first quadrant. The components of the resultant are

$R_x = A_x + B_x = 5.00\ \text{N} + (3.00\ \text{N})(\cos 30.0°) = 7.598\ \text{N}$

$R_y = A_y + B_y = 0 + (3.00\ \text{N})(\sin 30.0°) = 1.500\ \text{N}$

$R = \sqrt{R_x^2 + R_y^2} = 7.74\ \text{N}$

EVALUATE: To check our answer, we could use the other resultants and angles given in the table with the problem.

1.89. **IDENTIFY:** Use the x and y coordinates for each object to find the vector from one object to the other; the distance between two objects is the magnitude of this vector. Use the scalar product to find the angle between two vectors.

SET UP: If object A has coordinates (x_A, y_A) and object B has coordinates (x_B, y_B), the vector $\vec{r}_{AB}$ from A to B has x-component $x_B - x_A$ and y-component $y_B - y_A$.

EXECUTE: **(a)** The diagram is sketched in Figure 1.89.

(b) (i) In AU, $\sqrt{(0.3182)^2 + (0.9329)^2} = 0.9857$.

(ii) In AU, $\sqrt{(1.3087)^2 + (-0.4423)^2 + (-0.0414)^2} = 1.3820$.

(iii) In AU, $\sqrt{(0.3182 - 1.3087)^2 + (0.9329 - (-0.4423))^2 + (0.0414)^2} = 1.695$.

(c) The angle between the directions from the Earth to the Sun and to Mars is obtained from the dot product. Combining Eqs. (1.16) and (1.19),

$$\phi = \arccos\left(\frac{(-0.3182)(1.3087 - 0.3182) + (-0.9329)(-0.4423 - 0.9329) + (0)}{(0.9857)(1.695)}\right) = 54.6°.$$

(d) Mars could not have been visible at midnight, because the Sun-Mars angle is less than 90°.

EVALUATE: Our calculations correctly give that Mars is farther from the Sun than the earth is. Note that on this date Mars was farther from the earth than it is from the Sun.

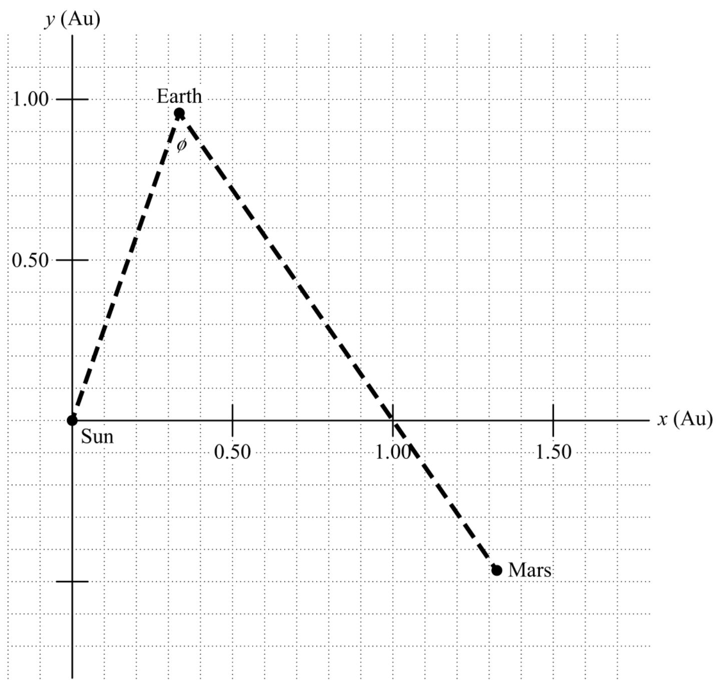

Figure 1.89

1.90. **IDENTIFY:** Add the vector displacements of the receiver and then find the vector from the quarterback to the receiver.

SET UP: Add the x-components and the y-components.

EXECUTE: The receiver's position is

$[(+1.0+9.0-6.0+12.0)\text{yd}]\hat{\boldsymbol{i}}+[(-5.0+11.0+4.0+18.0)\,\text{yd}]\,\hat{\boldsymbol{j}}=(16.0\text{ yd})\hat{\boldsymbol{i}}+(28.0\text{ yd})\hat{\boldsymbol{j}}.$

The vector from the quarterback to the receiver is the receiver's position minus the quarterback's position, or $(16.0\text{ yd})\hat{\boldsymbol{i}}+(35.0\text{ yd})\hat{\boldsymbol{j}},$ a vector with magnitude $\sqrt{(16.0\text{ yd})^2+(35.0\text{ yd})^2}=38.5\text{ yd}.$ The angle is $\arctan\left(\dfrac{16.0}{35.0}\right)=24.6°$ to the right of downfield.

EVALUATE: The vector from the quarterback to receiver has positive x-component and positive y-component.

1.91. **IDENTIFY:** Draw the vector addition diagram for the position vectors.

SET UP: Use coordinates in which the Sun to Merak line lies along the x-axis. Let $\vec{\boldsymbol{A}}$ be the position vector of Alkaid relative to the Sun, $\vec{\boldsymbol{M}}$ is the position vector of Merak relative to the Sun, and $\vec{\boldsymbol{R}}$ is the position vector for Alkaid relative to Merak. $A=138$ ly and $M=77$ ly.

EXECUTE: The relative positions are shown in Figure 1.91. $\vec{\boldsymbol{M}}+\vec{\boldsymbol{R}}=\vec{\boldsymbol{A}}.$ $A_x=M_x+R_x$ so

$R_x=A_x-M_x=(138\text{ ly})\cos 25.6°-77\text{ ly}=47.5\text{ ly}.$ $R_y=A_y-M_y=(138\text{ ly})\sin 25.6°-0=59.6\text{ ly}.$

$R=76.2$ ly is the distance between Alkaid and Merak.

(b) The angle is angle ϕ in Figure 1.91. $\cos\theta=\dfrac{R_x}{R}=\dfrac{47.5\text{ ly}}{76.2\text{ ly}}$ and $\theta=51.4°.$ Then $\phi=180°-\theta=129°.$

EVALUATE: The concepts of vector addition and components make these calculations very simple.

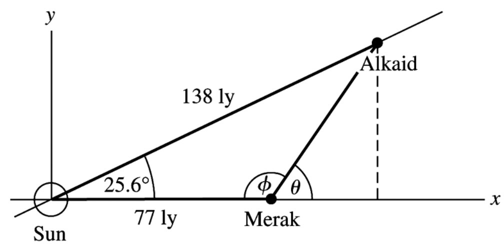

Figure 1.91

1.92. **IDENTIFY:** The total volume of the gas-exchanging region of the lungs must be at least as great as the total volume of all the alveoli, which is the product of the volume per alveoli times the number of alveoli.

SET UP: $V = NV_{alv}$, and we use the numbers given in the introduction to the problem.

EXECUTE: $V = NV_{alv} = (480 \times 10^6)(4.2 \times 10^6\ \mu\text{m}^3) = 2.02 \times 10^{15}\ \mu\text{m}^3$. Converting to liters gives

$V = 2.02\times10^{15}\ \text{m}^3\left(\dfrac{1\ \text{m}}{10^6\ \mu\text{m}}\right)^3 = 2.02\ \text{L} \approx 2.0\ \text{L}$. Therefore choice (c) is correct.

EVALUATE: A volume of 2 L is reasonable for the lungs.

1.93. **IDENTIFY:** We know the volume and want to find the diameter of a typical alveolus, assuming it to be a sphere.

SET UP: The volume of a sphere of radius r is $V = 4/3\ \pi r^3$ and its diameter is $D = 2r$.

EXECUTE: Solving for the radius in terms of the volume gives $r = (3V/4\pi)^{1/3}$, so the diameter is

$D = 2r = 2(3V/4\pi)^{1/3} = 2\left[\dfrac{3\left(4.2\times10^6\ \mu\text{m}^3\right)}{4\pi}\right]^{1/3} = 200\ \mu\text{m}$. Converting to mm gives

$D = (200\ \mu\text{m})[(1\ \text{mm})/(1000\ \mu\text{m})] = 0.20\ \text{mm}$, so choice (a) is correct.

EVALUATE: A sphere that is 0.20 mm in diameter should be visible to the naked eye for someone with good eyesight.

1.94. **IDENTIFY:** Draw conclusions from a given graph.

SET UP: The dots lie more-or-less along a horizontal line, which means that the average alveolar volume does not vary significantly as the lung volume increases.

EXECUTE: The volume of individual alveoli does not vary (as stated in the introduction). The graph shows that the volume occupied by alveoli stays constant for higher and higher lung volumes, so there must be more of them, which makes choice (c) the correct one.

EVALUATE: It is reasonable that a large lung would need more alveoli than a small lung because a large lung probably belongs to a larger person than a small lung.

2

MOTION ALONG A STRAIGHT LINE

VP2.5.1. **IDENTIFY:** The bus and the car leave the same point at the same time. The bus has constant velocity, but the car starts from rest with constant acceleration. So the constant-acceleration formulas apply. We want to know how long it takes for the car to catch up to the bus and how far they both travel during that time.

SET UP: When they meet, x is the same for both of them and they have traveled for the same time. The formulas $x = x_0 + v_{0x}t + \frac{1}{2}a_x t^2$ and $v_x = v_{0x} + a_x t$ both apply.

EXECUTE: (a) When the car and bus meet, they have traveled the same distance in the same time. We apply the formula $x = x_0 + v_{0x}t + \frac{1}{2}a_x t^2$ to each of them, with the origin at their starting point, which makes $x_0 = 0$ for both of them. The bus has no acceleration and the car has no initial velocity. The equation reduces to $\frac{1}{2}a_{\text{car}}t^2 = v_{\text{bus}}t \quad \rightarrow \quad t = 2v_{\text{bus}}/a_{\text{car}}$.

$t = 2(18\text{ m/s})/(8.0\text{ m/s}^2) = 4.5\text{ s}$.

(b) The bus has zero acceleration, so $v_x = v_{0x} + a_x t$ reduces to $x_{\text{bus}} = v_{\text{bus}}t$

$x_{\text{bus}} = (18\text{ m/s})(4.5\text{ s}) = 81\text{ m}$.

EVALUATE: To check, use the car's motion to find the distance.

$x_{\text{car}} = \frac{1}{2}a_{\text{car}}t^2 = \frac{1}{2}(8.0\text{ m/s}^2)(4.5\text{ s})^2 = 81\text{ m}$, which agrees with our result in part (b).

VP2.5.2. **IDENTIFY:** This is very similar to VP2.5.1 and VP2.5.2. The motorcycle and the SUV leave the same point at the same time. The motorcycle has a constant velocity, but the SUV has an initial velocity and a constant acceleration. So the constant-acceleration formulas apply.

SET UP: When they meet, x is the same for both of them and they have traveled for the same time. The formulas $x = x_0 + v_{0x}t + \frac{1}{2}a_x t^2$ and $v_x = v_{0x} + a_x t$ both apply.

EXECUTE: (a) When the SUV and motorcycle meet, they have traveled the same distance in the same time. We apply the formula $x = x_0 + v_{0x}t + \frac{1}{2}a_x t^2$ to each of them, with the origin at their starting point, which makes $x_0 = 0$ for both of them. The motorcycle has no acceleration and the SUV has an initial velocity and an acceleration. The acceleration is *opposite* to the velocity of the SUV. If we take the x-axis to be in the direction of motion, a_{SUV} is negative. The equation reduces to

$v_{\text{motorcycle}}t = v_{\text{SUV}}t + \frac{1}{2}a_{\text{SUV}}t^2$. We want the time. Putting in the numbers gives

$(20.0\text{ m/s})t = (30.0\text{ m/s})t + \frac{1}{2}(-1.80\text{ m/s}^2)t^2$

$t = 0$ s and $t = 11.1$ s. The $t = 0$ s solution is when they both of them leave the same point, and the $t =$ 11.1 s is the time when the motorcycle passes the SUV.

(b) Both have traveled the same distance when they meet. For the motorcycle this gives $x_{\text{motorcycle}} = v_{\text{motorcycle}}t = (20.0\text{ m/s})(11.1\text{ s}) = 222$ m.

(c) The equation $v_x = v_{0x} + a_x t$ gives the speed of the SUV when they meet in 11.1 s.

$v_x = 30.0\text{ m/s} + (-1.80\text{ m/s}^2)(11.1\text{ s}) = 10.0$ s.

EVALUATE: Use $x = v_{\text{av}}t$ to find the distance the SUV has traveled in 11.1 s. For constant acceleration, the average velocity is $v_{\text{av}} = (v_1 + v_2)/2$, which gives us

$x = [(30.0\text{ m/s} + 10.0\text{ m/s})/2](11.1\text{ s}) = 222$ m, which agrees with our previous result.

VP2.5.4. **IDENTIFY:** The truck and car have constant (but different) accelerations and the car has an initial velocity but the truck starts from rest. They leave from the same place at the same time and the truck eventually passes the car. The constant-acceleration equation $x = x_0 + v_{0x}t + \frac{1}{2}a_x t^2$ applies.

SET UP: (a) The truck and car have traveled the same distance in the same time when the truck reaches the car to pass. They start at the same place so x_0 is the same for both and the truck has no initial velocity.

EXECUTE: Use the equation $x = x_0 + v_{0x}t + \frac{1}{2}a_x t^2$ for each of them, which gives

$$\frac{1}{2}a_{\text{T}}t^2 = v_{\text{C}}t - \frac{1}{2}a_{\text{C}}t^2 \qquad \rightarrow \qquad t = \frac{2v_{\text{C}}}{a_{\text{T}} + a_{\text{C}}}.$$

(b) Looking at the truck gives $x_{\text{T}} = \frac{1}{2}a_{\text{T}}t^2 = \frac{1}{2}a_{\text{T}}\left(\frac{2v_{\text{C}}}{a_{\text{T}} + a_{\text{C}}}\right)^2 = \frac{2a_{\text{T}}v_{\text{C}}^2}{(a_{\text{T}} + a_{\text{C}})^2}$.

EVALUATE: We can calculate the distance the car travels using $x_{\text{C}} = v_{\text{C}}t - \frac{1}{2}a_{\text{C}}t^2$ and the value of t we found in part (a). Doing this and simplifying the result gives the same answer as in part (b).

VP2.7.1. **IDENTIFY:** The ball is in freefall so its acceleration is g downward and the constant-acceleration equations apply.

SET UP: Calling the y-axis vertical, the formulas $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ and $v_y = v_{0y} + a_y t$ apply to the motion of the ball. We know that $a_y = 9.80\text{ m/s}^2$ downward and $v_{0y} = 12.0$ m/s upward.

EXECUTE: (a) At time $t = 0.300$ s, the vertical coordinate of the ball is given by $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$, where $y_0 = 0$ at the location of the hand.

$y = 0 + (12.0\text{ m/s})(0.300\text{ s}) + \frac{1}{2}(-9.80\text{ m/s}^2)(0.300\text{ s})^2 = 3.16$ m. Since y is positive, the ball is above the hand. The vertical velocity is given by $v_y = v_{0y} + a_y t$.

$v_y = 12.0\text{ m/s} + (-9.80\text{ m/s}^2)(0.300\text{ s}) = 9.06$ m/s. Since v_y is positive, the ball is moving upward.

(b) At $t = 2.60$ s, $y = (12.0\text{ m/s})(2.60\text{ s}) + \frac{1}{2}(-9.80\text{ m/s}^2)(2.60\text{ s})^2 = -1.92$ m. Since y is negative, the ball is now below the hand. The ball must be moving downward since it is now below the hand.

EVALUATE: Check with v_y: $v_y = v_{0y} + a_y t = 12.0\text{ m/s} + (-9.80\text{ m/s}^2)(2.60\text{ s}) = -13.5$ m/s. Since v_y is negative, the ball is moving downward, as we saw above.

VP2.7.2. **IDENTIFY:** The stone is in freefall so its acceleration is g downward and the constant-acceleration equations apply.

SET UP: Calling the y-axis vertical, the formulas $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$, $v_y = v_{0y} + a_y t$, and $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ apply to the motion of the stone. We know that a_y = 9.80 m/s^2 downward, v_{0y} = 8.00 m/s downward, and y_0 = 0.

EXECUTE: (a) The equation $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ gives

y = 0 + (–8.00 m/s)(1.50 s) + $\frac{1}{2}$(–9.80 m/s^2)(1.50 s)^2 = –23.0 m. The minus sign means that the stone is below your hand. The velocity of the stone is given by

$v_y = v_{0y} + a_y t$ = –8.00 m/s + (–9.80 m/s^2)(1.50 s) = –22.7 m/s. The minus sign tells us it is moving downward.

(b) We know the stone's position and acceleration and want its velocity. The equation

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

v_y^2 = (–8.00 m/s)^2 + 2(–9.80 m/s^2)(–8.00 m)

v_y = ±14.9 m/s. The stone must be moving downward, so v_y = –14.9 m/s.

EVALUATE: When the stone returned to the level of your hand, its speed was the same as its initial speed of 8.00 m/s. But as the stone has continued to accelerate downward since then, its speed must be greater than its initial speed, which is what we found.

VP2.7.3. **IDENTIFY:** The football is in freefall so its acceleration is g downward and the constant-acceleration equations apply.

SET UP: Calling the y-axis vertical, the formulas $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$, $v_y = v_{0y} + a_y t$, and $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ apply. We know that a_y = 9.80 m/s^2 downward, v_y = 0.500 m/s upward when y = 4.00 m, and y_0 = 0.

EXECUTE: (a) We know the speed, acceleration, and position of the ball and want its initial speed, so we use the equation $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ to find its initial speed v_{0y}.

(0.500 m/s)^2 = v_{0y}^2 + 2(–9.80 m/s^2)(4.00 m) → v_{0y} = 8.87 m/s.

(b) Use the result from (a) in the equation $v_y = v_{0y} + a_y t$ to find the time.

0.500 m/s = 8.87 m/s + (–9.80 m/s^2)t → t = 0.854 s.

EVALUATE: Calculate y using the time from (b) and compare it with the given value of 4.00 m.

$y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ = 0 + (8.87 m/s)(0.854 s) + $\frac{1}{2}$(–9.80 m/s^2)(0.854 s)^2 = 4.00 m, which agrees with the given value.

VP2.7.4. **IDENTIFY:** The tennis ball is in freefall so its acceleration is g downward and the constant-acceleration equations apply.

SET UP: When the ball is at its highest point, its vertical velocity is zero. The equation $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ applies.

EXECUTE: (a) At the highest point, v_y = 0. Use $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ to find v_{0y}.

0 = v_{0y}^2 + 2(–g)(H) → $v_{0y} = \sqrt{2gH}$

(b) We now know H, v_{0y} and want v_y. The same equation gives

$v_y^2 = v_{0y}^2 + 2(-g)(H/2)$ = $2gH - 2gH/2 = 2gH/2$

$$v_y = \sqrt{\frac{2gH}{2}} = \frac{\sqrt{2gH}}{\sqrt{2}} = \frac{v_0}{\sqrt{2}}.$$

(c) We want $y - y_0$, we know v_0, a, and v. The same equation gives

$$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$$

$$\left(\frac{v_0}{2}\right)^2 = v_0^2 + 2(-g)(y - y_0)$$

$$y - y_0 = \frac{3v_0^2}{8g} = \frac{3(2gH)}{8g} = \frac{3H}{4}.$$

EVALUATE: When the ball is half way to the top, $v \neq v_0/2$ because the motion equations involve the *squares* of quanties such as v^2 and t^2.

VP2.8.1. **IDENTIFY:** The rock is in freefall so its acceleration is g downward and the constant-acceleration equations apply.

SET UP: The equation $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ applies.

EXECUTE: (a) With the origin at the hand and the y-axis positive upward, $y = 4.00$ m and $y_0 = 0$. We want the time at which this occurs. The equation $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ gives

4.00 m = (12.0 m/s)t + $\frac{1}{2}$(–9.80 m/s^2)t^2. Solving this quadratic equation for t gives two answers: t = 0.398 s and t = 2.05 s.

(b) Use the same procedure as in (a) except that y = –4.00 m. This gives

–4.00 m = (12.0 m/s)t + $\frac{1}{2}$(–9.80 m/s^2)t^2. This quadratic equation has two solutions, t = 2.75 s and t = –0.297 s. The negative answer is not physical, so t = 2.75 s.

EVALUATE: The ball is at 4.00 m above your hand twice, when it is going up and when it is going down, so we get two answers. It is at 4.00 m below the hand only once, when it is going down, so we have just one answer.

VP2.8.2. **IDENTIFY:** The ball is in freefall so its acceleration is g downward and the constant-acceleration equations apply.

SET UP: Calling the y-axis vertical with the origin at the hand, the formulas $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$, $v_y = v_{0y} + a_y t$, and $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ apply. We know that a_y = 9.80 m/s^2 downward and v_y is initially 9.00 m/s downward. Since all the quantities are downward, it is convenient to call the +y-axis downward.

EXECUTE: First find v_y when y = 5.00 m. Then use this result to find the time for the ball to reach this height.

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ = (9.00 m/s)^2 + 2(9.80 m/s^2)(5.00 m)

v_y = 13.38 m/s

Now use $v_y = v_{0y} + a_y t$ to find the time t.

13.38 m/s = 9.00 m/s + (9.80 m/s^2)t → t = 0.447 s.

EVALUATE: Check using the equation $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ when t = 0.447 s.

y = (9.00 m/s)(0.447 s) + $\frac{1}{2}$(9.80 m/s^2)(0.447 s)^2 = 5.00 m, which agrees with the given value.

VP2.8.3. **IDENTIFY:** The apple is in freefall so its acceleration is g downward and the constant-acceleration equations apply.

SET UP: Calling the y-axis vertically upward with the origin at the hand, the formulas $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$, $v_y = v_{0y} + a_y t$, and $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ apply. We know that $a_y = 9.80\ \text{m/s}^2$ downward and v_y is initially 5.50 m/s upward.

EXECUTE: (a) Using $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ gives

$1.30\ \text{m} = (5.50\ \text{m/s})t + \frac{1}{2}(-9.80\ \text{m/s}^2)(0.447\ \text{s})^2$

Solving using the quadratic formula gives $t = 0.338$ s and $t = 0.784$ s. The apple passes through this point twice: going up at 0.338 s and going down at 0784 s.

(b) Use the same approach as in (a).

$1.80\ \text{m} = (5.50\ \text{m/s})t + \frac{1}{2}(-9.80\ \text{m/s}^2)t^2$

This equation has no real solutions, so the apple *never* reaches a height of 1.80 m.

EVALUATE: The highest point the apple reaches is when $v_y = 0$. Use $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ to find the maximum height.

$0 = (5.50\ \text{m/s})^2 + 2(-9.80\ \text{m/s}^2)(y - y_0)$

$y - y_0 = 1.54$ m, which is *less than* 1.80 m. This is why we had no solutions to the quadratic equation in part (b).

VP2.8.4. **IDENTIFY:** The orange is in freefall so its acceleration is g downward and the constant-acceleration equations apply.

SET UP: Calling the y-axis vertically upward with the origin at the hand, the formula $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ applies. We know that $a_y = g$ downward and v_y is initially v_0 upward.

EXECUTE: We want the time when $y = \frac{v_0^2}{2g}$, so we use $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$.

$\frac{v_0^2}{2g} = v_0 t - \frac{1}{2}gt^2$. Solving this quadratic equation gives $t = v_0/g$. There is only one solution, so the orange reaches this height only once.

(b) Use the same approach as in part (a). $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ gives

$\frac{3v_0^2}{8g} = v_0 t - \frac{1}{2}gt^2$. The quadratic formula gives two solutions: $t = v_0/2g$ and $t = 3v_0/2g$.

The orange is going up at the smaller solution and going down at the larger solution.

EVALUATE: We got only one solution for part (a) because $y = \frac{v_0^2}{2g}$ is the highest point the orange reaches, and that occurs only once because the orange stops there. In (b) the height $\frac{3v_0^2}{8g}$ is less than the maximum height, so the orange reaches this height twice, once going up and once going down.

2.1. **IDENTIFY:** $\Delta x = v_{\text{av-}x}\Delta t$

SET UP: We know the average velocity is 6.25 m/s.

EXECUTE: $\Delta x = v_{\text{av-}x}\Delta t = 25.0$ m

EVALUATE: In round numbers, 6 m/s × 4 s = 24 m ≈ 25 m, so the answer is reasonable.

2.2. **IDENTIFY:** $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t}$

SET UP: $13.5 \text{ days} = 1.166\times10^6 \text{ s}$. At the release point, $x = +5.150\times10^6 \text{ m}$.

EXECUTE: **(a)** $v_{\text{av-}x} = \dfrac{x_2 - x_1}{\Delta t} = \dfrac{-5.150\times10^6 \text{ m}}{1.166\times10^6 \text{ s}} = -4.42 \text{ m/s}$.

(b) For the round trip, $x_2 = x_1$ and $\Delta x = 0$. The average velocity is zero.

EVALUATE: The average velocity for the trip from the nest to the release point is positive.

2.3. **IDENTIFY:** Target variable is the time Δt it takes to make the trip in heavy traffic. Use Eq. (2.2) that relates the average velocity to the displacement and average time.

SET UP: $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t}$ so $\Delta x = v_{\text{av-}x}\Delta t$ and $\Delta t = \dfrac{\Delta x}{v_{\text{av-}x}}$.

EXECUTE: Use the information given for normal driving conditions to calculate the distance between the two cities, where the time is 1 h and 50 min, which is 110 min:

$$\Delta x = v_{\text{av-}x}\Delta t = (105 \text{ km/h})(1 \text{ h}/60 \text{ min})(110 \text{ min}) = 192.5 \text{ km}.$$

Now use $v_{\text{av-}x}$ for heavy traffic to calculate Δt; Δx is the same as before:

$$\Delta t = \frac{\Delta x}{v_{\text{av-}x}} = \frac{192.5 \text{ km}}{70 \text{ km/h}} = 2.75 \text{ h} = 2 \text{ h and } 45 \text{ min}.$$

The additional time is (2 h and 45 min) – (1 h and 50 min) = (1 h and 105 min) – (1 h and 50 min) = 55 min.

EVALUATE: At the normal speed of 105 km/s the trip takes 110 min, but at the reduced speed of 70 km/h it takes 165 min. So decreasing your average speed by about 30% adds 55 min to the time, which is 50% of 110 min. Thus a 30% reduction in speed leads to a 50% increase in travel time. This result (perhaps surprising) occurs because the time interval is inversely proportional to the average speed, not directly proportional to it.

2.4. **IDENTIFY:** The average velocity is $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t}$. Use the average speed for each segment to find the time traveled in that segment. The average speed is the distance traveled divided by the time.

SET UP: The post is 80 m west of the pillar. The total distance traveled is $200 \text{ m} + 280 \text{ m} = 480 \text{ m}$.

EXECUTE: **(a)** The eastward run takes time $\dfrac{200 \text{ m}}{5.0 \text{ m/s}} = 40.0 \text{ s}$ and the westward run takes $\dfrac{280 \text{ m}}{4.0 \text{ m/s}} = 70.0 \text{ s}$. The average speed for the entire trip is $\dfrac{480 \text{ m}}{110.0 \text{ s}} = 4.4 \text{ m/s}$.

(b) $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t} = \dfrac{-80 \text{ m}}{110.0 \text{ s}} = -0.73 \text{ m/s}$. The average velocity is directed westward.

EVALUATE: The displacement is much less than the distance traveled, and the magnitude of the average velocity is much less than the average speed. The average speed for the entire trip has a value that lies between the average speed for the two segments.

2.5. **IDENTIFY:** Given two displacements, we want the average velocity and the average speed.

SET UP: The average velocity is $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t}$ and the average speed is just the total distance walked divided by the total time to walk this distance.

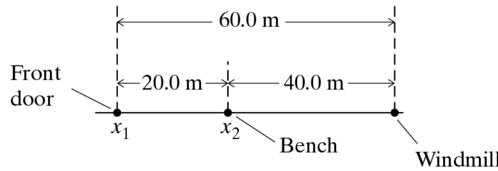

Figure 2.5

EXECUTE: **(a)** Let $+x$ be eastward with the origin at the front door. The trip begins at the front door and ends at the bench as shown in Fig. 2.5. Therefore $x_1 = 0.00$ m and $x_2 = 20.0$ m.
$\Delta x = x_2 - x_1 = 20.0\text{ m} - 0.00\text{ m} = 20.0\text{ m}$. The total time is $\Delta t = 28.0\text{ s} + 36.0\text{ s} = 64.0\text{ s}$. So
$v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t} = \dfrac{20.0\text{ m}}{64.0\text{ s}} = 0.313\text{ m/s}.$

(b) Average speed $= \dfrac{60.0\text{ m} + 40.0\text{ m}}{64.0\text{ s}} = 1.56\text{ m/s}$.

EVALUATE: The average speed is much greater than the average velocity because the total distance walked is much greater than the magnitude of the displacement vector.

2.6. **IDENTIFY:** The average velocity is $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t}$. Use $x(t)$ to find x for each t.

SET UP: $x(0) = 0$, $x(2.00\text{ s}) = 5.60\text{ m}$, and $x(4.00\text{ s}) = 20.8\text{ m}$

EXECUTE: **(a)** $v_{\text{av-}x} = \dfrac{5.60\text{ m} - 0}{2.00\text{ s}} = +2.80\text{ m/s}$

(b) $v_{\text{av-}x} = \dfrac{20.8\text{ m} - 0}{4.00\text{ s}} = +5.20\text{ m/s}$

(c) $v_{\text{av-}x} = \dfrac{20.8\text{ m} - 5.60\text{ m}}{2.00\text{ s}} = +7.60\text{ m/s}$

EVALUATE: The average velocity depends on the time interval being considered.

2.7. **(a) IDENTIFY:** Calculate the average velocity using $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t}$.

SET UP: $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t}$ so use $x(t)$ to find the displacement Δx for this time interval.

EXECUTE: $t = 0$: $x = 0$

$t = 10.0\text{ s}$: $x = (2.40\text{ m/s}^2)(10.0\text{ s})^2 - (0.120\text{ m/s}^3)(10.0\text{ s})^3 = 240\text{ m} - 120\text{ m} = 120\text{ m}.$

Then $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t} = \dfrac{120\text{ m}}{10.0\text{ s}} = 12.0\text{ m/s}.$

(b) IDENTIFY: Use $v_x = \dfrac{dx}{dt}$ to calculate $v_x(t)$ and evaluate this expression at each specified t.

SET UP: $v_x = \dfrac{dx}{dt} = 2bt - 3ct^2.$

EXECUTE: (i) $t = 0$: $v_x = 0$

(ii) $t = 5.0\text{ s}$: $v_x = 2(2.40\text{ m/s}^2)(5.0\text{ s}) - 3(0.120\text{ m/s}^3)(5.0\text{ s})^2 = 24.0\text{ m/s} - 9.0\text{ m/s} = 15.0\text{ m/s}.$

(iii) $t = 10.0\text{ s}$: $v_x = 2(2.40\text{ m/s}^2)(10.0\text{ s}) - 3(0.120\text{ m/s}^3)(10.0\text{ s})^2 = 48.0\text{ m/s} - 36.0\text{ m/s} = 12.0\text{ m/s}.$

(c) IDENTIFY: Find the value of t when $v_x(t)$ from part (b) is zero.

SET UP: $v_x = 2bt - 3ct^2$

$v_x = 0$ at $t = 0$.

$v_x = 0$ next when $2bt - 3ct^2 = 0$

EXECUTE: $2b = 3ct$ so $t = \dfrac{2b}{3c} = \dfrac{2(2.40\text{ m/s}^2)}{3(0.120\text{ m/s}^3)} = 13.3\text{ s}$

EVALUATE: $v_x(t)$ for this motion says the car starts from rest, speeds up, and then slows down again.

2.8. **IDENTIFY:** We know the position $x(t)$ of the bird as a function of time and want to find its instantaneous velocity at a particular time.

SET UP: The instantaneous velocity is $v_x(t) = \dfrac{dx}{dt} = \dfrac{d\left[28.0\text{ m} + (12.4\text{ m/s})t - (0.0450\text{ m/s}^3)t^3\right]}{dt}$.

EXECUTE: $v_x(t) = \dfrac{dx}{dt} = 12.4\text{ m/s} - (0.135\text{ m/s}^3)t^2$. Evaluating this at $t = 8.0\text{ s}$ gives $v_x = 3.76\text{ m/s}$.

EVALUATE: The acceleration is not constant in this case.

2.9. **IDENTIFY:** The average velocity is given by $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t}$. We can find the displacement Δt for each constant velocity time interval. The average speed is the distance traveled divided by the time.

SET UP: For $t = 0$ to $t = 2.0\text{ s}$, $v_x = 2.0\text{ m/s}$. For $t = 2.0\text{ s}$ to $t = 3.0\text{ s}$, $v_x = 3.0\text{ m/s}$. In part (b), $v_x = -3.0\text{ m/s}$ for $t = 2.0\text{ s}$ to $t = 3.0\text{ s}$. When the velocity is constant, $\Delta x = v_x \Delta t$.

EXECUTE: **(a)** For $t = 0$ to $t = 2.0\text{ s}$, $\Delta x = (2.0\text{ m/s})(2.0\text{ s}) = 4.0\text{ m}$. For $t = 2.0\text{ s}$ to $t = 3.0\text{ s}$, $\Delta x = (3.0\text{ m/s})(1.0\text{ s}) = 3.0\text{ m}$. For the first 3.0 s, $\Delta x = 4.0\text{ m} + 3.0\text{ m} = 7.0\text{ m}$. The distance traveled is also 7.0 m. The average velocity is $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t} = \dfrac{7.0\text{ m}}{3.0\text{ s}} = 2.33\text{ m/s}$. The average speed is also 2.33 m/s.

(b) For $t = 2.0\text{ s to }3.0\text{ s}$, $\Delta x = (-3.0\text{ m/s})(1.0\text{ s}) = -3.0\text{ m}$. For the first 3.0 s, $\Delta x = 4.0\text{ m} + (-3.0\text{ m}) = +1.0\text{ m}$. The ball travels 4.0 m in the $+x$-direction and then 3.0 m in the $-x$-direction, so the distance traveled is still 7.0 m. $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t} = \dfrac{1.0\text{ m}}{3.0\text{ s}} = 0.33\text{ m/s}$. The average speed is $\dfrac{7.00\text{ m}}{3.00\text{ s}} = 2.33\text{ m/s}$.

EVALUATE: When the motion is always in the same direction, the displacement and the distance traveled are equal and the average velocity has the same magnitude as the average speed. When the motion changes direction during the time interval, those quantities are different.

2.10. **IDENTIFY** and **SET UP:** The instantaneous velocity is the slope of the tangent to the x versus t graph.

EXECUTE: **(a)** The velocity is zero where the graph is horizontal; point IV.

(b) The velocity is constant and positive where the graph is a straight line with positive slope; point I.

(c) The velocity is constant and negative where the graph is a straight line with negative slope; point V.

(d) The slope is positive and increasing at point II.

(e) The slope is positive and decreasing at point III.

EVALUATE: The sign of the velocity indicates its direction.

2.11. **IDENTIFY:** Find the instantaneous velocity of a car using a graph of its position as a function of time.

SET UP: The instantaneous velocity at any point is the slope of the x versus t graph at that point. Estimate the slope from the graph.

EXECUTE: A: $v_x = 6.7\text{ m/s}$; B: $v_x = 6.7\text{ m/s}$; C: $v_x = 0$; D: $v_x = -40.0\text{ m/s}$; E: $v_x = -40.0\text{ m/s}$; F: $v_x = -40.0\text{ m/s}$; G: $v_x = 0$.

EVALUATE: The sign of v_x shows the direction the car is moving. v_x is constant when x versus t is a straight line.

2.12. **IDENTIFY:** $a_{\text{av-}x} = \dfrac{\Delta v_x}{\Delta t}$. $a_x(t)$ is the slope of the v_x versus t graph.

SET UP: $60\text{ km/h} = 16.7\text{ m/s}$

EXECUTE: **(a)** (i) $a_{\text{av-}x} = \dfrac{16.7\text{ m/s} - 0}{10\text{ s}} = 1.7\text{ m/s}^2$. (ii) $a_{\text{av-}x} = \dfrac{0 - 16.7\text{ m/s}}{10\text{ s}} = -1.7\text{ m/s}^2$.

(iii) $\Delta v_x = 0$ and $a_{\text{av-}x} = 0$. (iv) $\Delta v_x = 0$ and $a_{\text{av-}x} = 0$.

(b) At $t = 20$ s, v_x is constant and $a_x = 0$. At $t = 35$ s, the graph of v_x versus t is a straight line and $a_x = a_{\text{av-}x} = -1.7\text{ m/s}^2$.

EVALUATE: When $a_{\text{av-}x}$ and v_x have the same sign the speed is increasing. When they have opposite signs, the speed is decreasing.

2.13. **IDENTIFY** and **SET UP:** Use $v_x = \dfrac{dx}{dt}$ and $a_x = \dfrac{dv_x}{dt}$ to calculate $v_x(t)$ and $a_x(t)$.

EXECUTE: $v_x = \dfrac{dx}{dt} = 2.00\text{ cm/s} - (0.125\text{ cm/s}^2)t$

$a_x = \dfrac{dv_x}{dt} = -0.125\text{ cm/s}^2$

(a) At $t = 0$, $x = 50.0$ cm, $v_x = 2.00$ cm/s, $a_x = -0.125\text{ cm/s}^2$.

(b) Set $v_x = 0$ and solve for t: $t = 16.0$ s.

(c) Set $x = 50.0$ cm and solve for t. This gives $t = 0$ and $t = 32.0$ s. The turtle returns to the starting point after 32.0 s.

(d) The turtle is 10.0 cm from starting point when $x = 60.0$ cm or $x = 40.0$ cm.
Set $x = 60.0$ cm and solve for t: $t = 6.20$ s and $t = 25.8$ s.
At $t = 6.20$ s, $v_x = +1.23$ cm/s.
At $t = 25.8$ s, $v_x = -1.23$ cm/s.
Set $x = 40.0$ cm and solve for t: $t = 36.4$ s (other root to the quadratic equation is negative and hence nonphysical).
At $t = 36.4$ s, $v_x = -2.55$ cm/s.

(e) The graphs are sketched in Figure 2.13.

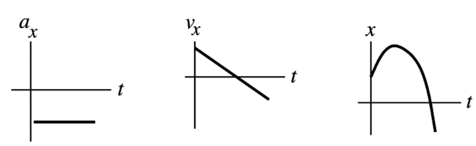

Figure 2.13

EVALUATE: The acceleration is constant and negative. v_x is linear in time. It is initially positive, decreases to zero, and then becomes negative with increasing magnitude. The turtle initially moves farther away from the origin but then stops and moves in the $-x$-direction.

2.14. **IDENTIFY:** We know the velocity $v(t)$ of the car as a function of time and want to find its acceleration at the instant that its velocity is 12.0 m/s.

SET UP: We know that $v_x(t) = (0.860\text{ m/s}^3)t^2$ and that $a_x(t) = \dfrac{dv_x}{dt} = \dfrac{d\left[(0.860\text{ m/s}^3)t^2\right]}{dt}$.

EXECUTE: $a_x(t) = \dfrac{dv_x}{dt} = (1.72\text{ m/s}^3)t$. When $v_x = 12.0$ m/s, $(0.860\text{ m/s}^3)t^2 = 12.0$ m/s, which gives $t = 3.735$ s. At this time, $a_x = 6.42\text{ m/s}^2$.

EVALUATE: The acceleration of this car is not constant.

2.15. **IDENTIFY:** The average acceleration is $a_{\text{av-}x} = \dfrac{\Delta v_x}{\Delta t}$. Use $v_x(t)$ to find v_x at each t. The instantaneous acceleration is $a_x = \dfrac{dv_x}{dt}$.

SET UP: $v_x(0) = 3.00 \text{ m/s}$ and $v_x(5.00 \text{ s}) = 5.50 \text{ m/s}$.

EXECUTE: **(a)** $a_{\text{av-}x} = \dfrac{\Delta v_x}{\Delta t} = \dfrac{5.50 \text{ m/s} - 3.00 \text{ m/s}}{5.00 \text{ s}} = 0.500 \text{ m/s}^2$

(b) $a_x = \dfrac{dv_x}{dt} = (0.100 \text{ m/s}^3)(2t) = (0.200 \text{ m/s}^3)t$. At $t = 0$, $a_x = 0$. At $t = 5.00 \text{ s}$, $a_x = 1.00 \text{ m/s}^2$.

(c) Graphs of $v_x(t)$ and $a_x(t)$ are given in Figure 2.15.

EVALUATE: $a_x(t)$ is the slope of $v_x(t)$ and increases as t increases. The average acceleration for $t = 0$ to $t = 5.00 \text{ s}$ equals the instantaneous acceleration at the midpoint of the time interval, $t = 2.50 \text{ s}$, since $a_x(t)$ is a linear function of t.

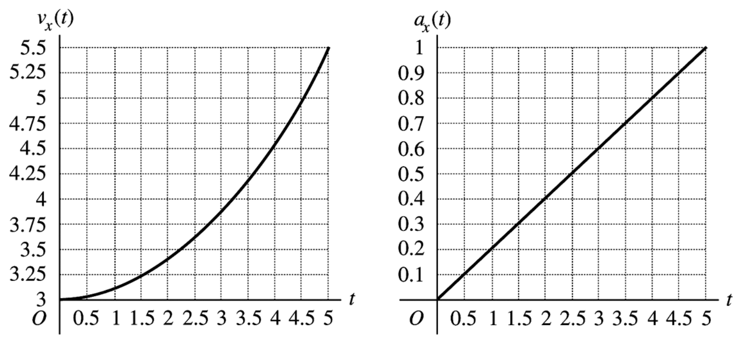

Figure 2.15

2.16. **IDENTIFY:** Use $a_{\text{av-}x} = \dfrac{\Delta v_x}{\Delta t}$, with $\Delta t = 10 \text{ s}$ in all cases.

SET UP: v_x is negative if the motion is to the left.

EXECUTE: **(a)** $[(5.0 \text{ m/s}) - (15.0 \text{ m/s})]/(10 \text{ s}) = -1.0 \text{ m/s}^2$

(b) $[(-15.0 \text{ m/s}) - (-5.0 \text{ m/s})]/(10 \text{ s}) = -1.0 \text{ m/s}^2$

(c) $[(-15.0 \text{ m/s}) - (+15.0 \text{ m/s})]/(10 \text{ s}) = -3.0 \text{ m/s}^2$

EVALUATE: In all cases, the negative acceleration indicates an acceleration to the left.

2.17. **IDENTIFY:** $v_x(t) = \dfrac{dx}{dt}$ and $a_x(t) = \dfrac{dv_x}{dt}$

SET UP: $\dfrac{d}{dt}(t^n) = nt^{n-1}$ for $n \geq 1$.

EXECUTE: **(a)** $v_x(t) = (9.60 \text{ m/s}^2)t - (0.600 \text{ m/s}^6)t^5$ and $a_x(t) = 9.60 \text{ m/s}^2 - (3.00 \text{ m/s}^6)t^4$. Setting $v_x = 0$ gives $t = 0$ and $t = 2.00 \text{ s}$. At $t = 0$, $x = 2.17 \text{ m}$ and $a_x = 9.60 \text{ m/s}^2$. At $t = 2.00 \text{ s}$, $x = 15.0 \text{ m}$ and $a_x = -38.4 \text{ m/s}^2$.

(b) The graphs are given in Figure 2.17.

EVALUATE: For the entire time interval from $t = 0$ to $t = 2.00 \text{ s}$, the velocity v_x is positive and x increases. While a_x is also positive the speed increases and while a_x is negative the speed decreases.

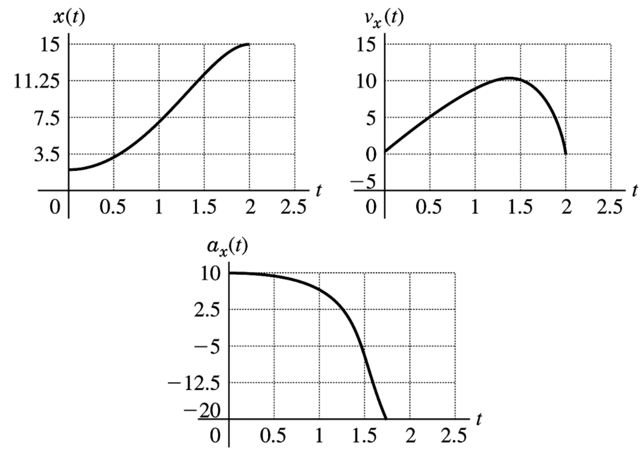

Figure 2.17

2.18. **IDENTIFY:** We have motion with constant acceleration, so the constant-acceleration equations apply. We want to determine the acceleration of a car on the entrance ramp of a highway.

SET UP: Estimate: 300 ft on the entrance ramp. We know the initial and final velocities and the distance traveled, and we want to find the acceleration. So $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ applies.

EXECUTE: Convert units: $30\text{ mph}\left(\dfrac{1.466\text{ ft/s}}{1\text{ mph}}\right) = 44\text{ ft/s}$; $70\text{ mph}\left(\dfrac{1.466\text{ ft/s}}{1\text{ mph}}\right) = 103\text{ ft/s}.$

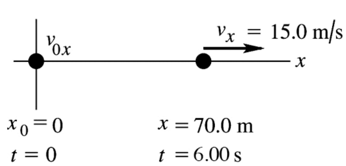
Now use $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$: $(103\text{ ft/s})^2 = (44\text{ ft/s})^2 + 2a_x(300\text{ ft})$ $\rightarrow$ $a_x = 14\text{ ft/s}^2$.

In SI units, $a_x = 14\text{ ft/s}^2\left(\dfrac{0.3048\text{ m/s}^2}{1\text{ ft/s}^2}\right) = 4.4\text{ m/s}^2$.

EVALUATE: Compare with acceleration due to gravity: $a/g = (14\text{ ft/s}^2)/(32\text{ ft/s}^2) = 0.45$, so this acceleration is around 45% of g. This seems rather large for an ordinary car. Calculate the time to reach the 70 mph speed, using $v_x = v_{0x} + a_x t$: $103\text{ ft/s} = 44\text{ ft/s} + (14\text{ ft/s}^2)t$ $\rightarrow$ $t = 4.2$ s. This is too small to be reasonable for most cars. My estimate of the length of the on-ramp must be too small.

2.19. **IDENTIFY:** Use the constant acceleration equations to find v_{0x} and a_x.

(a) SET UP: The situation is sketched in Figure 2.19.



$x - x_0 = 70.0$ m
$t = 6.00$ s
$v_x = 15.0$ m/s
$v_{0x} = ?$

Figure 2.19

EXECUTE: Use $x - x_0 = \left(\dfrac{v_{0x} + v_x}{2}\right)t$, so $v_{0x} = \dfrac{2(x - x_0)}{t} - v_x = \dfrac{2(70.0\text{ m})}{6.00\text{ s}} - 15.0\text{ m/s} = 8.33\text{ m/s}.$

(b) Use $v_x = v_{0x} + a_x t$, so $a_x = \dfrac{v_x - v_{0x}}{t} = \dfrac{15.0\text{ m/s} - 5.0\text{ m/s}}{6.00\text{ s}} = 1.11\text{ m/s}^2$.

EVALUATE: The average velocity is $(70.0\text{ m})/(6.00\text{ s}) = 11.7$ m/s. The final velocity is larger than this, so the antelope must be speeding up during the time interval; $v_{0x} < v_x$ and $a_x > 0$.

2.20. **IDENTIFY:** For constant acceleration, the standard kinematics equations apply.

SET UP: Assume the ball moves in the $+x$ direction.

EXECUTE: **(a)** $v_x = 73.14\text{ m/s}$, $v_{0x} = 0$ and $t = 30.0\text{ ms}$. $v_x = v_{0x} + a_x t$ gives

$$a_x = \frac{v_x - v_{0x}}{t} = \frac{73.14\text{ m/s} - 0}{30.0\times10^{-3}\text{ s}} = 2440\text{ m/s}^2.$$

(b) $x - x_0 = \left(\frac{v_{0x} + v_x}{2}\right)t = \left(\frac{0 + 73.14\text{ m/s}}{2}\right)(30.0\times10^{-3}\text{ s}) = 1.10\text{ m}$.

EVALUATE: We could also use $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ to calculate $x - x_0$:

$x - x_0 = \frac{1}{2}(2440\text{ m/s}^2)(30.0\times10^{-3}\text{ s})^2 = 1.10\text{ m}$, which agrees with our previous result. The acceleration of the ball is very large.

2.21. **IDENTIFY:** For constant acceleration, the standard kinematics equations apply.

SET UP: Assume the ball starts from rest and moves in the $+x$-direction.

EXECUTE: **(a)** $x - x_0 = 1.50\text{ m}$, $v_x = 45.0\text{ m/s}$ and $v_{0x} = 0$. $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives

$$a_x = \frac{v_x^2 - v_{0x}^2}{2(x - x_0)} = \frac{(45.0\text{ m/s})^2}{2(1.50\text{ m})} = 675\text{ m/s}^2.$$

(b) $x - x_0 = \left(\frac{v_{0x} + v_x}{2}\right)t$ gives $t = \frac{2(x - x_0)}{v_{0x} + v_x} = \frac{2(1.50\text{ m})}{45.0\text{ m/s}} = 0.0667\text{ s}$

EVALUATE: We could also use $v_x = v_{0x} + a_x t$ to find $t = \frac{v_x}{a_x} = \frac{45.0\text{ m/s}}{675\text{ m/s}^2} = 0.0667\text{ s}$ which agrees with our previous result. The acceleration of the ball is very large.

2.22. **IDENTIFY:** A car is slowing down with uniform acceleration, so the constant-acceleration equations apply. We want to determine the acceleration of the car as it slows down.

SET UP: Estimate: It takes 5.0 s to reduce the speed from 70 mph to 30 mph. $v_x = v_{0x} + a_x t$,

$v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$, and $a_{x\text{-av}} = \frac{\Delta v_x}{\Delta t}$ apply. Call the $+x$-axis the direction in which the car is moving.

EXECUTE: **(a)** Δv_x = 30 mph – 70 mph = –40 mph = –59 ft/s, so $a_{x\text{-av}} = \frac{-59\text{ ft/s}}{5.0\text{ s}} = -12\text{ ft/s}^2$. The magnitude is 12 ft/s^2 and its direction is opposite to the velocity of the car.

(b) The initial velocity is 70 mph = 103 ft/s and $v_x = 0$ when the car stops, so $v_x = v_{0x} + a_x t$ gives $0 = 103\text{ ft/s} + (-12\text{ ft/s}^2)t \rightarrow t = 8.6\text{ s}$. This is the time from first hitting the brakes. The time to stop from 30 mph is 8.6 s – 5.0 s = 3.6 s.

(c) Use $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ since we know everything in it except the distance traveled.

$0 = (103\text{ ft/s})^2 + 2(-12\text{ ft/s}^2)(x - x_0) \quad \rightarrow \quad x - x_0 = 440\text{ ft}$.

EVALUATE: As a check, use $x = x_0 + v_{0x}t + \frac{1}{2}a_x t^2$ to calculate the distance in (c). This gives

$x = 0 + (103\text{ ft/s})(8.6\text{ s}) + \frac{1}{2}(-12\text{ ft/s}^2)(8.6\text{ s})^2 = 440\text{ ft}$, which agrees with our answer. Compare the acceleration to g: $a_x g = (12\text{ ft/s}^2)/(32\text{ ft/s}^2) = 0.38$, so a_x is about 38% of g. This is fairly large, but if you really slam on your brakes, it might be reasonable.

2.23. **IDENTIFY:** Assume that the acceleration is constant and apply the constant acceleration kinematic equations. Set $|a_x|$ equal to its maximum allowed value.

SET UP: Let $+x$ be the direction of the initial velocity of the car. $a_x = -250\text{ m/s}^2$.

$105\text{ km/h} = 29.17\text{ m/s}$.

EXECUTE: $v_{0x} = 29.17$ m/s. $v_x = 0$. $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives

$$x - x_0 = \frac{v_x^2 - v_{0x}^2}{2a_x} = \frac{0 - (29.17 \text{ m/s})^2}{2(-250 \text{ m/s}^2)} = 1.70 \text{ m.}$$

EVALUATE: The car frame stops over a shorter distance and has a larger magnitude of acceleration. Part of your 1.70 m stopping distance is the stopping distance of the car and part is how far you move relative to the car while stopping.

2.24. **IDENTIFY:** Apply constant acceleration equations to the motion of the car.
SET UP: Let $+x$ be the direction the car is moving.

EXECUTE: **(a)** From $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$, with $v_{0x} = 0$, $a_x = \dfrac{v_x^2}{2(x - x_0)} = \dfrac{(20 \text{ m/s})^2}{2(120 \text{ m})} = 1.67 \text{ m/s}^2$.

(b) Using $x - x_0 = \frac{1}{2}(v_{0x} + v_x)t$, we have $t = 2(x - x_0)/v_x = 2(120 \text{ m})/(20 \text{ m/s}) = 12$ s.

(c) $(12 \text{ s})(20 \text{ m/s}) = 240$ m.

EVALUATE: The average velocity of the car is half the constant speed of the traffic, so the traffic travels twice as far.

2.25. **IDENTIFY:** If a person comes to a stop in 36 ms while slowing down with an acceleration of 60*g*, how far does he travel during this time?
SET UP: Let $+x$ be the direction the person travels. $v_x = 0$ (he stops), a_x is negative since it is opposite to the direction of the motion, and $t = 36 \text{ ms} = 3.6 \times 10^{-2}$ s. The equations $v_x = v_{0x} + a_x t$ and $x = x_0 + v_{0x}t + \frac{1}{2}a_x t^2$ both apply since the acceleration is constant.

EXECUTE: Solving $v_x = v_{0x} + a_x t$ for v_{0x} gives $v_{0x} = -a_x t$. Then $x = x_0 + v_{0x}t + \frac{1}{2}a_x t^2$ gives $x = -\frac{1}{2}a_x t^2 = -\frac{1}{2}(-588 \text{ m/s}^2)(3.6 \times 10^{-2} \text{ s})^2 = 38$ cm.

EVALUATE: Notice that we were not given the initial speed, but we could find it:

$$v_{0x} = -a_x t = -(-588 \text{ m/s}^2)(36 \times 10^{-3} \text{ s}) = 21 \text{ m/s} = 47 \text{ mph.}$$

2.26. **IDENTIFY:** The acceleration a_x is the slope of the graph of v_x versus *t*.

SET UP: The signs of v_x and of a_x indicate their directions.

EXECUTE: **(a)** Reading from the graph, at $t = 4.0$ s, $v_x = 2.7$ cm/s, to the right and at $t = 7.0$ s, $v_x = 1.3$ cm/s, to the left.

(b) v_x versus *t* is a straight line with slope $-\dfrac{8.0 \text{ cm/s}}{6.0 \text{ s}} = -1.3 \text{ cm/s}^2$. The acceleration is constant and equal to 1.3 cm/s^2, to the left. It has this value at all times.

(c) Since the acceleration is constant, $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$. Call $x_0 = 0$ the cat's position when $t = 0$.

<u>During the first 4.5 s</u>: $x = (8.0 \text{ cm/s})(4.5 \text{ s}) + \frac{1}{2}(-1.3 \text{ cm/s}^2)(4.5 \text{ s})^2 = 22.8$ cm which rounds to 23 cm.

This is the change in the cat's position, but it is also the distance the cat walks.
<u>During the first 7.5 s</u>: After 6.0 s, v_x becomes negative so the cat is walking backward. However the *distance* it is moving does *not* become negative. The position of the car at $t = 6.0$ s is $x = (8.0 \text{ cm/s})(6.0 \text{ s}) + \frac{1}{2}(-1.3 \text{ cm/s}^2)(6.0 \text{ s})^2 = 24.6$ cm. At the end of 7.5 s, the position is

$x = (8.0 \text{ cm/s})(7.5 \text{ s}) + \frac{1}{2}(-1.3 \text{ cm/s}^2)(7.5 \text{ s})^2 = 23.4$ cm. Therefore from $t = 6.0$ s to $t = 7.5$ s, the cat has walked back a *distance* of 24.6 cm – 23.4 cm = 1.2 cm. During the first 7.5 s, the cat has walked a total distance of 24.6 cm + 1.2 cm = 25.8 cm which rounds to 26 cm.
(d) The graphs of a_x and *x* versus *t* are given in Figure 2.26.

EVALUATE: In part (c) we could have instead used $x - x_0 = \left(\frac{v_{0x} + v_x}{2}\right)t.$

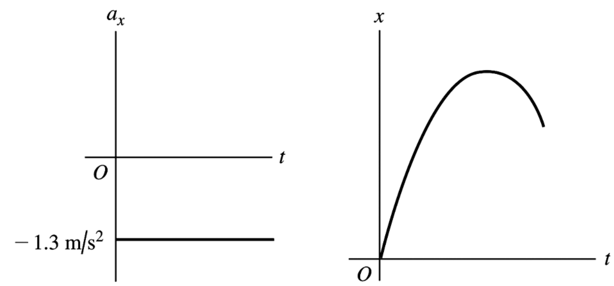


Figure 2.26

2.27. **IDENTIFY:** We know the initial and final velocities of the object, and the distance over which the velocity change occurs. From this we want to find the magnitude and duration of the acceleration of the object.

SET UP: The constant-acceleration kinematics formulas apply. $v_x^2 = v_{0x}^2 + 2a_x(x - x_0),$ where $v_{0x} = 0,$ $v_x = 5.0\times10^3$ m/s, and $x - x_0 = 4.0$ m.

EXECUTE: **(a)** $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives

$$a_x = \frac{v_x^2 - v_{0x}^2}{2(x - x_0)} = \frac{(5.0\times10^3\ \text{m/s})^2}{2(4.0\ \text{m})} = 3.1\times10^6\ \text{m/s}^2 = 3.2\times10^5\ g.$$

(b) $v_x = v_{0x} + a_x t$ gives $t = \frac{v_x - v_{0x}}{a_x} = \frac{5.0\times10^3\ \text{m/s}}{3.1\times10^6\ \text{m/s}^2} = 1.6\ \text{ms}.$

EVALUATE: **(c)** The calculated a is less than 450,000 g so the acceleration required doesn't rule out this hypothesis.

2.28. **IDENTIFY:** $v_x(t)$ is the slope of the x versus t graph. Car B moves with constant speed and zero acceleration. Car A moves with positive acceleration; assume the acceleration is constant.

SET UP: For car B, v_x is positive and $a_x = 0.$ For car A, a_x is positive and v_x increases with t.

EXECUTE: **(a)** The motion diagrams for the cars are given in Figure 2.28a.

(b) The two cars have the same position at times when their x-t graphs cross. The figure in the problem shows this occurs at approximately $t = 1$ s and $t = 3$ s.

(c) The graphs of v_x versus t for each car are sketched in Figure 2.28b.

(d) The cars have the same velocity when their x-t graphs have the same slope. This occurs at approximately $t = 2$ s.

(e) Car A passes car B when x_A moves above x_B in the x-t graph. This happens at $t = 3$ s.

(f) Car B passes car A when x_B moves above x_A in the x-t graph. This happens at $t = 1$ s.

EVALUATE: When $a_x = 0,$ the graph of v_x versus t is a horizontal line. When a_x is positive, the graph of v_x versus t is a straight line with positive slope.

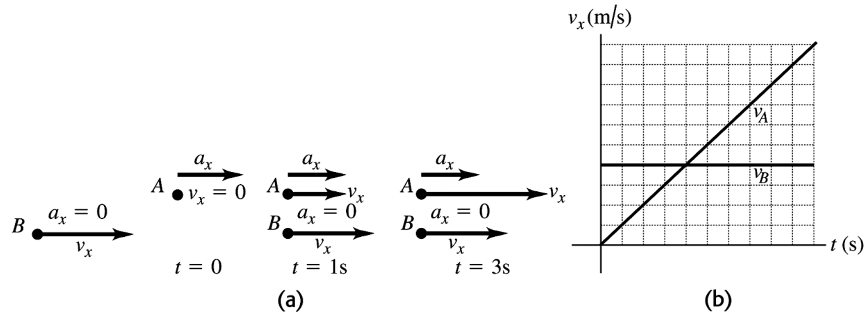

Figure 2.28

2.29. **(a) IDENTIFY** and **SET UP:** The acceleration a_x at time t is the slope of the tangent to the v_x versus t curve at time t.

EXECUTE: At $t = 3$ s, the v_x versus t curve is a horizontal straight line, with zero slope. Thus $a_x = 0$.

At $t = 7$ s, the v_x versus t curve is a straight-line segment with slope $\dfrac{45\text{ m/s} - 20\text{ m/s}}{9\text{ s} - 5\text{ s}} = 6.3\text{ m/s}^2$.

Thus $a_x = 6.3\text{ m/s}^2$.

At $t = 11$ s the curve is again a straight-line segment, now with slope $\dfrac{-0 - 45\text{ m/s}}{13\text{ s} - 9\text{ s}} = -11.2\text{ m/s}^2$.

Thus $a_x = -11.2\text{ m/s}^2$.

EVALUATE: $a_x = 0$ when v_x is constant, $a_x > 0$ when v_x is positive and the speed is increasing, and $a_x < 0$ when v_x is positive and the speed is decreasing.

(b) IDENTIFY: Calculate the displacement during the specified time interval.

SET UP: We can use the constant acceleration equations only for time intervals during which the acceleration is constant. If necessary, break the motion up into constant acceleration segments and apply the constant acceleration equations for each segment. For the time interval $t = 0$ to $t = 5$ s the acceleration is constant and equal to zero. For the time interval $t = 5$ s to $t = 9$ s the acceleration is constant and equal to 6.25 m/s^2. For the interval $t = 9$ s to $t = 13$ s the acceleration is constant and equal to -11.2 m/s^2.

EXECUTE: During the first 5 seconds the acceleration is constant, so the constant acceleration kinematic formulas can be used.

$v_{0x} = 20\text{ m/s}$ $\quad a_x = 0$ $\quad t = 5\text{ s}$ $\quad x - x_0 = ?$

$x - x_0 = v_{0x}t$ ($a_x = 0$ so no $\frac{1}{2}a_x t^2$ term)

$x - x_0 = (20\text{ m/s})(5\text{ s}) = 100\text{ m}$; this is the distance the officer travels in the first 5 seconds.

During the interval $t = 5$ s to 9 s the acceleration is again constant. The constant acceleration formulas can be applied to this 4-second interval. It is convenient to restart our clock so the interval starts at time $t = 0$ and ends at time $t = 4$ s. (Note that the acceleration is *not* constant over the entire $t = 0$ to $t = 9$ s interval.)

$v_{0x} = 20\text{ m/s}$ $\quad a_x = 6.25\text{ m/s}^2$ $\quad t = 4\text{ s}$ $\quad x_0 = 100\text{ m}$ $\quad x - x_0 = ?$

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$

$x - x_0 = (20\text{ m/s})(4\text{ s}) + \frac{1}{2}(6.25\text{ m/s}^2)(4\text{ s})^2 = 80\text{ m} + 50\text{ m} = 130\text{ m}.$

Thus $x - x_0 + 130\text{ m} = 100\text{ m} + 130\text{ m} = 230\text{ m}$.

At $t = 9$ s the officer is at $x = 230$ m, so she has traveled 230 m in the first 9 seconds.

During the interval $t = 9\text{ s}$ to $t = 13\text{ s}$ the acceleration is again constant. The constant acceleration formulas can be applied for this 4-second interval but *not* for the whole $t = 0$ to $t = 13\text{ s}$ interval. To use the equations restart our clock so this interval begins at time $t = 0$ and ends at time $t = 4\text{ s}$.

$v_{0x} = 45\text{ m/s}$ (at the start of this time interval)

$a_x = -11.2\text{ m/s}^2$ $t = 4\text{ s}$ $x_0 = 230\text{ m}$ $x - x_0 = ?$

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$

$x - x_0 = (45\text{ m/s})(4\text{ s}) + \frac{1}{2}(-11.2\text{ m/s}^2)(4\text{ s})^2 = 180\text{ m} - 89.6\text{ m} = 90.4\text{ m}.$

Thus $x = x_0 + 90.4\text{ m} = 230\text{ m} + 90.4\text{ m} = 320\text{ m}.$

At $t = 13\text{ s}$ the officer is at $x = 320\text{ m},$ so she has traveled 320 m in the first 13 seconds.

EVALUATE: The velocity v_x is always positive so the displacement is always positive and displacement and distance traveled are the same. The average velocity for time interval Δt is $v_{\text{av-}x} = \Delta x/\Delta t.$ For $t = 0$ to 5 s, $v_{\text{av-}x} = 20\text{ m/s}.$ For $t = 0$ to 9 s, $v_{\text{av-}x} = 26\text{ m/s}.$ For $t = 0$ to 13 s, $v_{\text{av-}x} = 25\text{ m/s}.$ These results are consistent with the figure in the textbook.

2.30. **IDENTIFY:** For constant acceleration, the kinematics formulas apply. We can use the total displacement and final velocity to calculate the acceleration and then use the acceleration and shorter distance to find the speed.

SET UP: Take $+x$ to be down the incline, so the motion is in the $+x$ direction. The formula $v_x^2 = v_{0x}^2 + 2a(x - x_0)$ applies.

EXECUTE: First look at the motion over 6.80 m. We use the following numbers: $v_{0x} = 0$, $x - x_0 = 6.80$ m, and $v_x = 3.80$ /s. Solving the above equation for a_x gives $a_x = 1.062\text{ m/s}^2$. Now look at the motion over the 3.40 m using $v_{0x} = 0$, $a_x = 1.062\text{ m/s}^2$ and $x - x_0 = 3.40$ m. Solving the same equation, but this time for v_x, gives $v_x = 2.69$ m/s.

EVALUATE: Even though the block has traveled half way down the incline, its speed is not half of its speed at the bottom.

2.31. **IDENTIFY:** Apply the constant acceleration equations to the motion of the flea. After the flea leaves the ground, $a_y = g,$ downward. Take the origin at the ground and the positive direction to be upward.

(a) SET UP: At the maximum height $v_y = 0.$

$v_y = 0$ $y - y_0 = 0.440\text{ m}$ $a_y = -9.80\text{ m/s}^2$ $v_{0y} = ?$

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$

EXECUTE: $v_{0y} = \sqrt{-2a_y(y - y_0)} = \sqrt{-2(-9.80\text{ m/s}^2)(0.440\text{ m})} = 2.94\text{ m/s}$

(b) SET UP: When the flea has returned to the ground $y - y_0 = 0.$

$y - y_0 = 0$ $v_{0y} = +2.94\text{ m/s}$ $a_y = -9.80\text{ m/s}^2$ $t = ?$

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$

EXECUTE: With $y - y_0 = 0$ this gives $t = -\dfrac{2v_{0y}}{a_y} = -\dfrac{2(2.94\text{ m/s})}{-9.80\text{ m/s}^2} = 0.600\text{ s}.$

EVALUATE: We can use $v_y = v_{0y} + a_y t$ to show that with $v_{0y} = 2.94\text{ m/s},$ $v_y = 0$ after 0.300 s.

2.32. **IDENTIFY:** The rock has a constant downward acceleration of 9.80 m/s^2. We know its initial velocity and position and its final position.

SET UP: We can use the kinematics formulas for constant acceleration.

EXECUTE: **(a)** $y - y_0 = -30\text{ m}$, $v_{0y} = 22.0\text{ m/s}$, $a_y = -9.80\text{ m/s}^2$. The kinematics formulas give $v_y = -\sqrt{v_{0y}^2 + 2a_y(y - y_0)} = -\sqrt{(22.0\text{ m/s})^2 + 2(-9.80\text{ m/s}^2)(-30\text{ m})} = -32.74\text{ m/s}$, so the speed is 32.7 m/s.

(b) $v_y = v_{0y} + a_y t$ and $t = \dfrac{v_y - v_{0y}}{a_y} = \dfrac{-32.74\text{ m/s} - 22.0\text{ m/s}}{-9.80\text{ m/s}^2} = 5.59\text{ s}$.

EVALUATE: The vertical velocity in part (a) is negative because the rock is moving downward, but the speed is always positive. The 5.59 s is the total time in the air.

2.33. **IDENTIFY:** The pin has a constant downward acceleration of 9.80 m/s^2 and returns to its initial position.
SET UP: We can use the kinematics formulas for constant acceleration.

EXECUTE: The kinematics formulas give $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$. We know that $y - y_0 = 0$, so

$t = -\dfrac{2v_{0y}}{a_y} = -\dfrac{2(8.20\text{ m/s})}{-9.80\text{ m/s}^2} = +1.67\text{ s}$.

EVALUATE: It takes the pin half this time to reach its highest point and the remainder of the time to return.

2.34. **IDENTIFY:** The putty has a constant downward acceleration of 9.80 m/s^2. We know the initial velocity of the putty and the distance it travels.
SET UP: We can use the kinematics formulas for constant acceleration.
EXECUTE: **(a)** $v_{0y} = 9.50$ m/s and $y - y_0 = 3.60$ m, which gives
$v_y = \sqrt{v_{0y}^2 + 2a_y(y - y_0)} = \sqrt{(9.50\text{ m/s})^2 + 2(-9.80\text{ m/s}^2)(3.60\text{ m})} = 4.44\text{ m/s}$

(b) $t = \dfrac{v_y - v_{0y}}{a_y} = \dfrac{4.44\text{ m/s} - 9.50\text{ m/s}}{-9.8\text{ m/s}^2} = 0.517\text{ s}$

EVALUATE: The putty is stopped by the ceiling, not by gravity.

2.35. **IDENTIFY:** A ball on Mars that is hit directly upward returns to the same level in 8.5 s with a constant downward acceleration of $0.379g$. How high did it go and how fast was it initially traveling upward?
SET UP: Take $+y$ upward. $v_y = 0$ at the maximum height. $a_y = -0.379g = -3.71\text{ m/s}^2$. The constant-acceleration formulas $v_y = v_{0y} + a_y t$ and $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ both apply.

EXECUTE: Consider the motion from the maximum height back to the initial level. For this motion $v_{0y} = 0$ and $t = 4.25$ s. $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2 = \frac{1}{2}(-3.71\text{ m/s}^2)(4.25\text{ s})^2 = -33.5\text{ m}$. The ball went 33.5 m above its original position.
(b) Consider the motion from just after it was hit to the maximum height. For this motion $v_y = 0$ and $t = 4.25$ s. $v_y = v_{0y} + a_y t$ gives $v_{0y} = -a_y t = -(-3.71\text{ m/s}^2)(4.25\text{ s}) = 15.8\text{ m/s}$.
(c) The graphs are sketched in Figure 2.35.

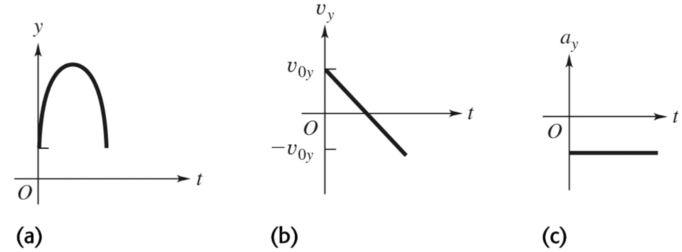

Figure 2.35

EVALUATE: The answers can be checked several ways. For example, $v_y = 0,\ v_{0y} = 15.8\ \text{m/s},$ and

$a_y = -3.71\ \text{m/s}^2$ in $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $y - y_0 = \dfrac{v_y^2 - v_{0y}^2}{2a_y} = \dfrac{0 - (15.8\ \text{m/s})^2}{2(-3.71\ \text{m/s}^2)} = 33.6\ \text{m},$

which agrees with the height calculated in (a).

2.36. **IDENTIFY:** A baseball is thrown upward, so its acceleration is downward and uniform. Therefore the constant-acceleration equations apply.

SET UP: Estimate: It is not easy to throw a ball straight up, so estimate 25 ft for the maximum height. Its acceleration is g = 32.2 ft/s^2 downward, and the formulas $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ and $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ apply. Call the +y-axis upward, with the origin at the point where the ball leaves the hand; this makes $y_0 = 0$ and $a_y = -32.2$ ft/s^2. At its maximum height, the ball stops moving, so $v_y = 0$.

EXECUTE: **(a)** First find the initial speed of the ball using $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ and $v_y = 0$ at the maximum height. $0 = v_{0y}^2 + 2(-32.2\ \text{ft/s}^2)(25\ \text{ft}) \quad \to \quad v_{0y} = 40.1\ \text{ft/s}$. Now use

$y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ to get the time t to reach the maximum height.'

$0 = 0 + (40.1\ \text{ft/s})t + \frac{1}{2}(-32.2\ \text{ft/s}^2)t^2 \quad \to \quad t = 2.5\ \text{s}.$

(b) Estimate: The ball moves about 2.5 ft while it is being thrown. We want the average accelerating during this time. The ball starts from rest and reaches a velocity of 40.1 ft/s while traveling 2.5 ft upward. So we use $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$.

$(40.1\ \text{ft/s})^2 = 0 + 2a_y(2.5\ \text{ft}) \quad \to \quad a_y = 320\ \text{ft/s}^2 \approx 10g.$

EVALUATE: The result in (b) seems rather large, so maybe the 2.5-ft estimate was too short, or maybe the maximum height of 25 ft was too large.

2.37. **IDENTIFY:** A rock is thrown upward, so its acceleration is downward and uniform. Therefore the constant-acceleration equations apply. We want to know the rock's velocity at times 1.0 s and 3.0 s after it is thrown.

SET UP: The formula $v_y = v_{0y} + a_y t$ applies. Call the +y-axis upward, with the origin at the point where the rock leaves the hand; this makes $y_0 = 0$, $v_{0y} = 24.0$ m/s, and $a_y = -9.80$ m/s^2.

EXECUTE: **(a)** At 1.0 s: $v_y = v_{0y} + a_y t = 24.0\ \text{m/s} + (-9.80\ \text{m/s}^2)(1.0\ \text{s}) = +14.2\ \text{m/s}$. The acceleration is downward. The velocity is upward but the speed is decreasing because the acceleration is downward.

(b) At 3.0 s: $v_y = v_{0y} + a_y t = 24.0\ \text{m/s} + (-9.80\ \text{m/s}^2)(3.0\ \text{s}) = -5.40\ \text{m/s}$. The acceleration is downward. The velocity is downward and the speed is increasing because the acceleration is also downward. The rock has passed its highest point and is now coming down.

EVALUATE: If only gravity acts on an object, its acceleration is always downward with a magnitude of 9.80 m/s^2.

2.38. **IDENTIFY:** Apply constant acceleration equations to the vertical motion of the brick.

SET UP: Let $+y$ be downward. $a_y = 9.80\ \text{m/s}^2$

EXECUTE: **(a)**

$v_{0y} = 0,\ t = 1.90\ \text{s},\ a_y = 9.80\ \text{m/s}^2.\ y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = \frac{1}{2}(9.80\ \text{m/s}^2)(1.90\ \text{s})^2 = 17.7\ \text{m}.$

The building is 17.7 m tall.

(b) $v_y = v_{0y} + a_y t = 0 + (9.80\ \text{m/s}^2)(1.90\ \text{s}) = 18.6\ \text{m/s}$

(c) The graphs of a_y, v_y and y versus t are given in Figure 2.38. Take $y = 0$ at the ground.

EVALUATE: We could use either $y - y_0 = \left(\frac{v_{0y} + v_y}{2}\right)t$ or $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ to check our results.

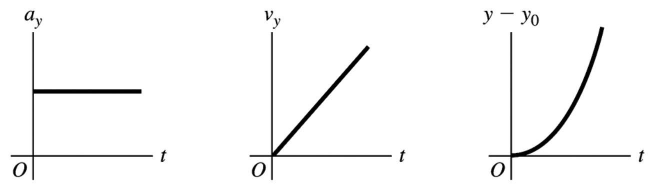

Figure 2.38

2.39. **IDENTIFY:** Apply constant acceleration equations to the motion of the meterstick. The time the meterstick falls is your reaction time.

SET UP: Let $+y$ be downward. The meter stick has $v_{0y} = 0$ and $a_y = 9.80\ \text{m/s}^2$. Let d be the distance the meterstick falls.

EXECUTE: **(a)** $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $d = (4.90\ \text{m/s}^2)t^2$ and $t = \sqrt{\frac{d}{4.90\ \text{m/s}^2}}$.

(b) $t = \sqrt{\frac{0.176\ \text{m}}{4.90\ \text{m/s}^2}} = 0.190\ \text{s}$

EVALUATE: The reaction time is proportional to the square of the distance the stick falls.

2.40. **IDENTIFY:** Apply constant acceleration equations to the motion of the lander.

SET UP: Let $+y$ be downward. Since the lander is in free-fall, $a_y = +1.6\ \text{m/s}^2$.

EXECUTE: $v_{0y} = 0.8\ \text{m/s}$, $y - y_0 = 5.0\ \text{m}$, $a_y = +1.6\ \text{m/s}^2$ in $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$v_y = \sqrt{v_{0y}^2 + 2a_y(y - y_0)} = \sqrt{(0.8\ \text{m/s})^2 + 2(1.6\ \text{m/s}^2)(5.0\ \text{m})} = 4.1\ \text{m/s}.$

EVALUATE: The same descent on earth would result in a final speed of 9.9 m/s, since the acceleration due to gravity on earth is much larger than on the moon.

2.41. **IDENTIFY:** When the only force is gravity the acceleration is $9.80\ \text{m/s}^2$, downward. There are two intervals of constant acceleration and the constant acceleration equations apply during each of these intervals.

SET UP: Let $+y$ be upward. Let $y = 0$ at the launch pad. The final velocity for the first phase of the motion is the initial velocity for the free-fall phase.

EXECUTE: **(a)** Find the velocity when the engines cut off. $y - y_0 = 525\ \text{m}$, $a_y = 2.25\ \text{m/s}^2$, $v_{0y} = 0$.

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $v_y = \sqrt{2(2.25\ \text{m/s}^2)(525\ \text{m})} = 48.6\ \text{m/s}$.

Now consider the motion from engine cut-off to maximum height: $y_0 = 525\ \text{m}$, $v_{0y} = +48.6\ \text{m/s}$, $v_y = 0$ (at the maximum height), $a_y = -9.80\ \text{m/s}^2$. $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$y - y_0 = \frac{v_y^2 - v_{0y}^2}{2a_y} = \frac{0 - (48.6\ \text{m/s})^2}{2(-9.80\ \text{m/s}^2)} = 121\ \text{m}$ and $y = 121\ \text{m} + 525\ \text{m} = 646\ \text{m}$.

(b) Consider the motion from engine failure until just before the rocket strikes the ground: $y - y_0 = -525\ \text{m}$, $a_y = -9.80\ \text{m/s}^2$, $v_{0y} = +48.6\ \text{m/s}$. $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$v_y = -\sqrt{(48.6\ \text{m/s})^2 + 2(-9.80\ \text{m/s}^2)(-525\ \text{m})} = -112\ \text{m/s}$. Then $v_y = v_{0y} + a_y t$ gives

$t = \frac{v_y - v_{0y}}{a_y} = \frac{-112\ \text{m/s} - 48.6\ \text{m/s}}{-9.80\ \text{m/s}^2} = 16.4\ \text{s}.$

(c) Find the time from blast-off until engine failure: $y-y_0=525\text{ m}$, $v_{0y}=0$, $a_y=+2.25\text{ m/s}^2$.

$y-y_0=v_{0y}t+\frac{1}{2}a_yt^2$ gives $t=\sqrt{\dfrac{2(y-y_0)}{a_y}}=\sqrt{\dfrac{2(525\text{ m})}{2.25\text{ m/s}^2}}=21.6\text{ s}$. The rocket strikes the launch pad $21.6\text{ s}+16.4\text{ s}=38.0\text{ s}$ after blast-off. The acceleration a_y is $+2.25\text{ m/s}^2$ from $t=0$ to $t=21.6\text{ s}$. It is -9.80 m/s^2 from $t=21.6\text{ s}$ to 38.0 s. $v_y=v_{0y}+a_yt$ applies during each constant acceleration segment, so the graph of v_y versus t is a straight line with positive slope of 2.25 m/s^2 during the blast-off phase and with negative slope of -9.80 m/s^2 after engine failure. During each phase $y-y_0=v_{0y}t+\frac{1}{2}a_yt^2$. The sign of a_y determines the curvature of $y(t)$. At $t=38.0\text{ s}$ the rocket has returned to $y=0$. The graphs are sketched in Figure 2.41.

EVALUATE: In part (b) we could have found the time from $y-y_0=v_{0y}t+\frac{1}{2}a_yt^2$, finding v_y first allows us to avoid solving for t from a quadratic equation.

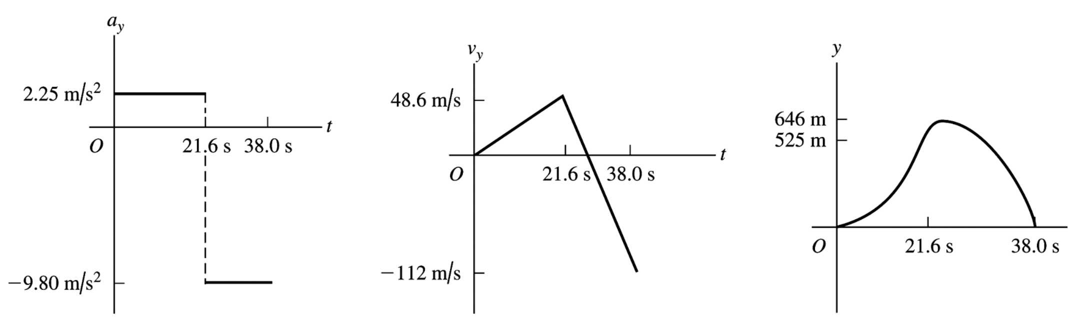

Figure 2.41

2.42. IDENTIFY: Apply constant acceleration equations to the vertical motion of the sandbag.

SET UP: Take $+y$ upward. $a_y=-9.80\text{ m/s}^2$. The initial velocity of the sandbag equals the velocity of the balloon, so $v_{0y}=+5.00\text{ m/s}$. When the balloon reaches the ground, $y-y_0=-40.0\text{ m}$. At its maximum height the sandbag has $v_y=0$.

EXECUTE: (a)

$t=0.250\text{ s}$: $y-y_0=v_{0y}t+\frac{1}{2}a_yt^2=(5.00\text{ m/s})(0.250\text{ s})+\frac{1}{2}(-9.80\text{ m/s}^2)(0.250\text{ s})^2=0.94\text{ m}$. The sandbag is 40.9 m above the ground. $v_y=v_{0y}+a_yt=+5.00\text{ m/s}+(-9.80\text{ m/s}^2)(0.250\text{ s})=2.55\text{ m/s}$.

$t=1.00\text{ s}$: $y-y_0=(5.00\text{ m/s})(1.00\text{ s})+\frac{1}{2}(-9.80\text{ m/s}^2)(1.00\text{ s})^2=0.10\text{ m}$. The sandbag is 40.1 m above the ground. $v_y=v_{0y}+a_yt=+5.00\text{ m/s}+(-9.80\text{ m/s}^2)(1.00\text{ s})=-4.80\text{ m/s}$.

(b) $y-y_0=-40.0\text{ m}$, $v_{0y}=5.00\text{ m/s}$, $a_y=-9.80\text{ m/s}^2$. $y-y_0=v_{0y}t+\frac{1}{2}a_yt^2$ gives $-40.0\text{ m}=(5.00\text{ m/s})t-(4.90\text{ m/s}^2)t^2$. $(4.90\text{ m/s}^2)t^2-(5.00\text{ m/s})t-40.0\text{ m}=0$ and

$t=\dfrac{1}{9.80}\left(5.00\pm\sqrt{(-5.00)^2-4(4.90)(-40.0)}\right)\text{ s}=(0.51\pm 2.90)\text{ s}$. t must be positive, so $t=3.41\text{ s}$.

(c) $v_y=v_{0y}+a_yt=+5.00\text{ m/s}+(-9.80\text{ m/s}^2)(3.41\text{ s})=-28.4\text{ m/s}$

(d) $v_{0y}=5.00\text{ m/s}$, $a_y=-9.80\text{ m/s}^2$, $v_y=0$. $v_y^2=v_{0y}^2+2a_y(y-y_0)$ gives

$y-y_0=\dfrac{v_y^2-v_{0y}^2}{2a_y}=\dfrac{0-(5.00\text{ m/s})^2}{2(-9.80\text{ m/s}^2)}=1.28\text{ m}$. The maximum height is 41.3 m above the ground.

(e) The graphs of a_y, v_y, and y versus t are given in Figure 2.42. Take $y = 0$ at the ground.

EVALUATE: The sandbag initially travels upward with decreasing velocity and then moves downward with increasing speed.

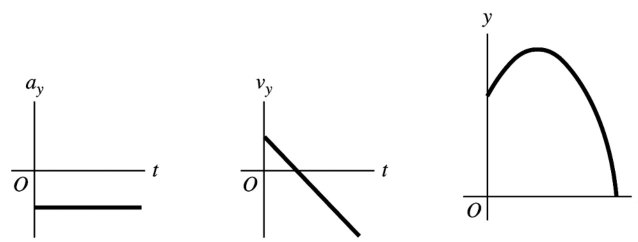

Figure 2.42

2.43. **IDENTIFY:** You throw a rock thrown upward, so its acceleration is downward and uniform. Therefore the constant-acceleration equations apply.

SET UP: We want to know how high the rock went if it returned to your hand 3.60 s after you threw it upward. With constant downward acceleration, the time it takes the rock to reach its highest point is the same as the time to fall back to your hand. Therefore it took 1.80 s to reach that highest point, and the rock's velocity was zero at the point. We can use $v_y = v_{0y} + a_y t$ to find the initial speed and then use $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ to find how high it went.

EXECUTE: First find v_{0y} using $v_y = v_{0y} + a_y t$ with $v_y = 0$ at the highest point.

$0 = v_{0y} - gt$, so $v_{0y} = (9.80\text{ m/s}^2)(1.80\text{ s}) = 17.64\text{ m/s}$. Now use $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ to find the maximum height the rock reached. $0 = (17.64\text{ m/s})^2 + 2(-9.80\text{ m/s}^2)(y - y_0) \rightarrow y - y_0 = 15.9\text{ m}$.

EVALUATE: Check by using $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ to calculate y at the maximum height.

$y = 0 + (17.64\text{ m/s})(1.80\text{ s}) + \frac{1}{2}(-9.80\text{ m/s}^2)(1.80\text{ s})^2 = 15.9\text{ m}$, which agrees with our result.

2.44. **IDENTIFY:** Since air resistance is ignored, the egg is in free-fall and has a constant downward acceleration of magnitude 9.80 m/s^2. Apply the constant acceleration equations to the motion of the egg.

SET UP: Take $+y$ to be upward. At the maximum height, $v_y = 0$.

EXECUTE: **(a)** $y - y_0 = -30.0\text{ m}$, $t = 5.00\text{ s}$, $a_y = -9.80\text{ m/s}^2$. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives

$$v_{0y} = \frac{y - y_0}{t} - \tfrac{1}{2}a_y t = \frac{-30.0\text{ m}}{5.00\text{ s}} - \tfrac{1}{2}(-9.80\text{ m/s}^2)(5.00\text{ s}) = +18.5\text{ m/s}.$$

(b) $v_{0y} = +18.5\text{ m/s}$, $v_y = 0$ (at the maximum height), $a_y = -9.80\text{ m/s}^2$. $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$$y - y_0 = \frac{v_y^2 - v_{0y}^2}{2a_y} = \frac{0 - (18.5\text{ m/s})^2}{2(-9.80\text{ m/s}^2)} = 17.5\text{ m}.$$

(c) At the maximum height $v_y = 0$.

(d) The acceleration is constant and equal to 9.80 m/s^2, downward, at all points in the motion, including at the maximum height.

(e) The graphs are sketched in Figure 2.44.

EVALUATE: The time for the egg to reach its maximum height is $t = \dfrac{v_y - v_{0y}}{a_y} = \dfrac{-18.5\text{ m/s}}{-9.8\text{ m/s}^2} = 1.89\text{ s}.$

The egg has returned to the level of the cornice after 3.78 s and after 5.00 s it has traveled downward from the cornice for 1.22 s.

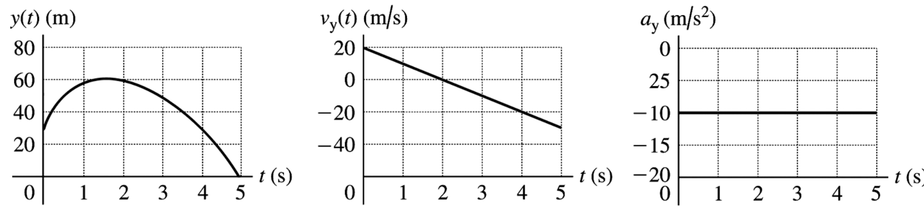

Figure 2.44

2.45. **IDENTIFY:** We can avoid solving for the common height by considering the relation between height, time of fall, and acceleration due to gravity, and setting up a ratio involving time of fall and acceleration due to gravity.

SET UP: Let g_{En} be the acceleration due to gravity on Enceladus and let g be this quantity on earth. Let h be the common height from which the object is dropped. Let $+y$ be downward, so $y - y_0 = h.\ v_{0y} = 0$

EXECUTE: $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $h = \frac{1}{2}g t_{\text{E}}^2$ and $h = \frac{1}{2}g_{\text{En}} t_{\text{En}}^2$. Combining these two equations gives $g t_{\text{E}}^2 = g_{\text{En}} t_{\text{En}}^2$ and $g_{\text{En}} = g\left(\dfrac{t_{\text{E}}}{t_{\text{En}}}\right)^2 = (9.80\text{ m/s}^2)\left(\dfrac{1.75\text{ s}}{18.6\text{ s}}\right)^2 = 0.0868\text{ m/s}^2.$

EVALUATE: The acceleration due to gravity is inversely proportional to the square of the time of fall.

2.46. **IDENTIFY:** Since air resistance is ignored, the boulder is in free-fall and has a constant downward acceleration of magnitude 9.80 m/s^2. Apply the constant acceleration equations to the motion of the boulder.

SET UP: Take $+y$ to be upward.

EXECUTE: **(a)** $v_{0y} = +40.0\text{ m/s},\ v_y = +20.0\text{ m/s},\ a_y = -9.80\text{ m/s}^2.\ v_y = v_{0y} + a_y t$ gives

$$t = \frac{v_y - v_{0y}}{a_y} = \frac{20.0\text{ m/s} - 40.0\text{ m/s}}{-9.80\text{ m/s}^2} = +2.04\text{ s}.$$

(b) $v_y = -20.0\text{ m/s}.\ t = \dfrac{v_y - v_{0y}}{a_y} = \dfrac{-20.0\text{ m/s} - 40.0\text{ m/s}}{-9.80\text{ m/s}^2} = +6.12\text{ s}.$

(c) $y - y_0 = 0,\ v_{0y} = +40.0\text{ m/s},\ a_y = -9.80\text{ m/s}^2.\ y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = 0$ and

$$t = -\frac{2v_{0y}}{a_y} = -\frac{2(40.0\text{ m/s})}{-9.80\text{ m/s}^2} = +8.16\text{ s}.$$

(d) $v_y = 0,\ v_{0y} = +40.0\text{ m/s},\ a_y = -9.80\text{ m/s}^2.\ v_y = v_{0y} + a_y t$ gives $t = \dfrac{v_y - v_{0y}}{a_y} = \dfrac{0 - 40.0\text{ m/s}}{-9.80\text{ m/s}^2} = 4.08\text{ s}.$

(e) The acceleration is 9.80 m/s^2, downward, at all points in the motion.

(f) The graphs are sketched in Figure 2.46.

EVALUATE: $v_y = 0$ at the maximum height. The time to reach the maximum height is half the total time in the air, so the answer in part (d) is half the answer in part (c). Also note that $2.04\text{ s} < 4.08\text{ s} < 6.12\text{ s}$. The boulder is going upward until it reaches its maximum height and after the maximum height it is traveling downward.

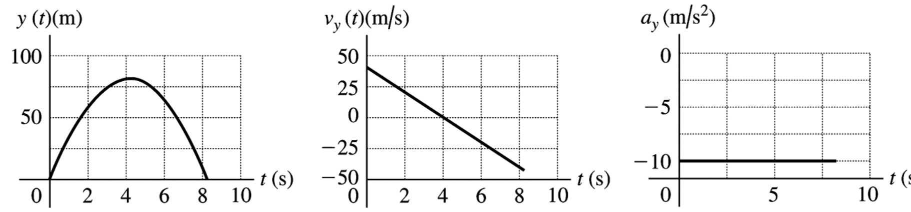

Figure 2.46

2.47. **IDENTIFY:** The rock has a constant downward acceleration of 9.80 m/s^2. The constant-acceleration kinematics formulas apply.

SET UP: The formulas $y = y_0 + v_{0y}t + \frac{1}{2}a_yt^2$ and $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ both apply. Call $+y$ upward. First find the initial velocity and then the final speed.

EXECUTE: **(a)** 6.00 s after it is thrown, the rock is back at its original height, so $y = y_0$ at that instant. Using $a_y = -9.80\text{ m/s}^2$ and $t = 6.00$ s, the equation $y = y_0 + v_{0y}t + \frac{1}{2}a_yt^2$ gives $v_{0y} = 29.4$ m/s. When the rock reaches the water, $y - y_0 = -28.0$ m. The equation $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $v_y = -37.6$ m/s, so its speed is 37.6 m/s.

EVALUATE: The final speed is greater than the initial speed because the rock accelerated on its way down below the bridge.

2.48. **IDENTIFY:** We want to interpret a graph of v_x versus t.

SET UP: The area under a graph of v_x versus t is equal to the change in position $x_2 - x_1$. The average velocity is $v_{x\text{-av}} = \dfrac{\Delta x}{\Delta t}$.

EXECUTE: **(a)** The area of a triangle is $\frac{1}{2}bh$, which gives $A = \frac{1}{2}(6.0\text{ s})(8.0\text{ m/s}) = 24$ m.

(b) The area under a graph of v_x versus t is equal to the change in position $x_2 - x_1$, which in this case is the distance traveled, which is 24 m in 6.0 s. Thus $v_{x\text{-av}} = \dfrac{\Delta x}{\Delta t} = \dfrac{24\text{ m}}{6.0\text{ s}} = 4.0$ m/s.

(c) $\Delta x = v_{x\text{-av}}\,\Delta t = (4.0\text{ m/s})(6.0\text{ s}) = 24$ m, which is the same as the area in (a).

EVALUATE: For constant acceleration $v_{x\text{-av}} = \dfrac{v_{x\text{-}0} + v_x}{2} = \dfrac{8.0\text{ m/s} + 0}{2} = 4.0$ m/s, which agrees with our answer in (b).

2.49. **IDENTIFY:** The acceleration is not constant, but we know how it varies with time. We can use the definitions of instantaneous velocity and position to find the rocket's position and speed.

SET UP: The basic definitions of velocity and position are $v_y(t) = v_{0y} + \int_0^t a_y dt$ and $y - y_0 = \int_0^t v_y dt$.

EXECUTE: **(a)** $v_y(t) = \int_0^t a_y dt = \int_0^t (2.80\text{ m/s}^3)t\,dt = (1.40\text{ m/s}^3)t^2$

$y - y_0 = \int_0^t v_y dt = \int_0^t (1.40\text{ m/s}^3)t^2 dt = (0.4667\text{ m/s}^3)t^3$. For $t = 10.0$ s, $y - y_0 = 467$ m.

(b) $y - y_0 = 325$ m so $(0.4667\text{ m/s}^3)t^3 = 325$ m and $t = 8.864$ s. At this time $v_y = (1.40\text{ m/s}^3)(8.864\text{ s})^2 = 110$ m/s.

EVALUATE: The time in part (b) is less than 10.0 s, so the given formulas are valid.

2.50. **IDENTIFY:** The acceleration is not constant, so we must use calculus instead of the standard kinematics formulas.

SET UP: The general calculus formulas are $v_x = v_{0x} + \int_0^t a_x dt$ and $x = x_0 + \int_0^t v_x dt.$ First integrate a_x to find $v(t)$, and then integrate that to find $x(t)$.

EXECUTE: Find $v(t)$: $v_x(t) = v_{0x} + \int_0^t a_x dt = v_{0x} + \int_0^t -(0.0320 \text{ m/s}^3)(15.0 \text{ s} - t)dt.$ Carrying out the integral and putting in the numbers gives $v_x(t) = 8.00 \text{ m/s} - (0.0320 \text{ m/s}^3)[(15.0 \text{ s})t - t^2/2]$. Now use this result to find $x(t)$.

$x = x_0 + \int_0^t v_x dt = x_0 + \int_0^t \left[8.00 \text{ m/s} - (0.0320 \text{ m/s}^3)\left((15.0 \text{ s})t - \frac{t^2}{2}\right)\right]dt,$ which gives $x = x_0 + (8.00 \text{ m/s})t - (0.0320 \text{ m/s}^3)[(7.50 \text{ s})t^2 - t^3/6)]$. Using $x_0 = -14.0$ m and $t = 10.0$ s, we get $x = 47.3$ m.

EVALUATE: The standard kinematics formulas apply only when the acceleration is constant.

2.51. **(a) IDENTIFY:** Integrate $a_x(t)$ to find $v_x(t)$ and then integrate $v_x(t)$ to find $x(t)$.

SET UP: $v_x = v_{0x} + \int_0^t a_x \, dt$, $a_x = At - Bt^2$ with $A = 1.50 \text{ m/s}^3$ and $B = 0.120 \text{ m/s}^4$.

EXECUTE: $v_x = v_{0x} + \int_0^t (At - Bt^2)\, dt = v_{0x} + \frac{1}{2}At^2 - \frac{1}{3}Bt^3$

At rest at $t = 0$ says that $v_{0x} = 0,$ so

$v_x = \frac{1}{2}At^2 - \frac{1}{3}Bt^3 = \frac{1}{2}(1.50 \text{ m/s}^3)t^2 - \frac{1}{3}(0.120 \text{ m/s}^4)t^3$

$v_x = (0.75 \text{ m/s}^3)t^2 - (0.040 \text{ m/s}^4)t^3$

SET UP: $x - x_0 + \int_0^t v_x \, dt$

EXECUTE: $x = x_0 + \int_0^t (\frac{1}{2}At^2 - \frac{1}{3}Bt^3)\, dt = x_0 + \frac{1}{6}At^3 - \frac{1}{12}Bt^4$

At the origin at $t = 0$ says that $x_0 = 0,$ so

$x = \frac{1}{6}At^3 - \frac{1}{12}Bt^4 = \frac{1}{6}(1.50 \text{ m/s}^3)t^3 - \frac{1}{12}(0.120 \text{ m/s}^4)t^4$

$x = (0.25 \text{ m/s}^3)t^3 - (0.010 \text{ m/s}^4)t^4$

EVALUATE: We can check our results by using them to verify that $v_x(t) = \frac{dx}{dt}$ and $a_x(t) = \frac{dv_x}{dt}.$

(b) IDENTIFY and SET UP: At time t, when v_x is a maximum, $\frac{dv_x}{dt} = 0.$ (Since $a_x = \frac{dv_x}{dt},$ the maximum velocity is when $a_x = 0.$ For earlier times a_x is positive so v_x is still increasing. For later times a_x is negative and v_x is decreasing.)

EXECUTE: $a_x = \frac{dv_x}{dt} = 0$ so $At - Bt^2 = 0$

One root is $t = 0,$ but at this time $v_x = 0$ and not a maximum.

The other root is $t = \frac{A}{B} = \frac{1.50 \text{ m/s}^3}{0.120 \text{ m/s}^4} = 12.5 \text{ s}$

At this time $v_x = (0.75 \text{ m/s}^3)t^2 - (0.040 \text{ m/s}^4)t^3$ gives

$v_x = (0.75 \text{ m/s}^3)(12.5 \text{ s})^2 - (0.040 \text{ m/s}^4)(12.5 \text{ s})^3 = 117.2 \text{ m/s} - 78.1 \text{ m/s} = 39.1 \text{ m/s}.$

EVALUATE: For $t < 12.5$ s, $a_x > 0$ and v_x is increasing. For $t > 12.5$ s, $a_x < 0$ and v_x is decreasing.

2.52. **IDENTIFY:** The acceleration is not constant so the constant acceleration equations cannot be used. Instead, use $v_x = v_{0x} + \int_0^t a_x dt$ and $x = x_0 + \int_0^t v_x dt$. Use the values of v_x and of x at $t = 1.0$ s to evaluate v_{0x} and x_0.

SET UP: $\int t^n dt = \frac{1}{n+1} t^{n+1}$, for $n \geq 0$.

EXECUTE: **(a)** $v_x = v_{0x} + \int_0^t \alpha t dt = v_{0x} + \frac{1}{2}\alpha t^2 = v_{0x} + (0.60 \text{ m/s}^3)t^2$. $v_x = 5.0$ m/s when $t = 1.0$ s gives $v_{0x} = 4.4$ m/s. Then, at $t = 2.0$ s, $v_x = 4.4 \text{ m/s} + (0.60 \text{ m/s}^3)(2.0 \text{ s})^2 = 6.8$ m/s.

(b) $x = x_0 + \int_0^t (v_{0x} + \frac{1}{2}\alpha t^2)dt = x_0 + v_{0x}t + \frac{1}{6}\alpha t^3$. $x = 6.0$ m at $t = 1.0$ s gives $x_0 = 1.4$ m. Then, at $t = 2.0$ s, $x = 1.4 \text{ m} + (4.4 \text{ m/s})(2.0 \text{ s}) + \frac{1}{6}(1.2 \text{ m/s}^3)(2.0 \text{ s})^3 = 11.8$ m.

(c) $x(t) = 1.4 \text{ m} + (4.4 \text{ m/s})t + (0.20 \text{ m/s}^3)t^3$. $v_x(t) = 4.4 \text{ m/s} + (0.60 \text{ m/s}^3)t^2$. $a_x(t) = (1.20 \text{ m/s}^3)t$. The graphs are sketched in Figure 2.52.

EVALUATE: We can verify that $a_x = \frac{dv_x}{dt}$ and $v_x = \frac{dx}{dt}$.

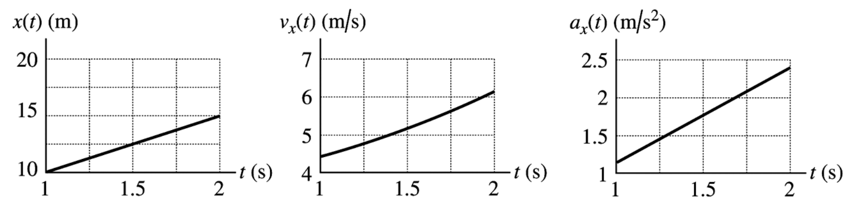

Figure 2.52

2.53. **IDENTIFY:** The sprinter's acceleration is constant for the first 2.0 s but zero after that, so it is not constant over the entire race. We need to break up the race into segments.

SET UP: When the acceleration is constant, the formula $x - x_0 = \left(\frac{v_{0x} + v_x}{2}\right)t$ applies. The average velocity is $v_{\text{av-}x} = \frac{\Delta x}{\Delta t}$.

EXECUTE: **(a)** $x - x_0 = \left(\frac{v_{0x} + v_x}{2}\right)t = \left(\frac{0 + 10.0 \text{ m/s}}{2}\right)(2.0 \text{ s}) = 10.0$ m.

(b) (i) 40.0 m at 10.0 m/s so time at constant speed is 4.0 s. The total time is 6.0 s, so $v_{\text{av-}x} = \frac{\Delta x}{\Delta t} = \frac{50.0 \text{ m}}{6.0 \text{ s}} = 8.33$ m/s.

(ii) He runs 90.0 m at 10.0 m/s so the time at constant speed is 9.0 s. The total time is 11.0 s, so $v_{\text{av-}x} = \frac{100 \text{ m}}{11.0 \text{ s}} = 9.09$ m/s.

(iii) He runs 190 m at 10.0 m/s so time at constant speed is 19.0 s. His total time is 21.0 s, so $v_{\text{av-}x} = \frac{200 \text{ m}}{21.0 \text{ s}} = 9.52$ m/s.

EVALUATE: His average velocity keeps increasing because he is running more and more of the race at his top speed.

2.54. IDENTIFY: We know the vertical position of the lander as a function of time and want to use this to find its velocity initially and just before it hits the lunar surface.

SET UP: By definition, $v_y(t) = \dfrac{dy}{dt}$, so we can find v_y as a function of time and then evaluate it for the desired cases.

EXECUTE: **(a)** $v_y(t) = \dfrac{dy}{dt} = -c + 2dt$. At $t = 0$, $v_y(t) = -c = -60.0$ m/s. The initial velocity is 60.0 m/s downward.

(b) $y(t) = 0$ says $b - ct + dt^2 = 0$. The quadratic formula says $t = 28.57\text{ s} \pm 7.38\text{ s}$. It reaches the surface at $t = 21.19$ s. At this time, $v_y = -60.0\text{ m/s} + 2(1.05\text{ m/s}^2)(21.19\text{ s}) = -15.5\text{ m/s}$.

EVALUATE: The given formula for $y(t)$ is of the form $y = y_0 + v_{0y}t + \frac{1}{2}at^2$. For part (a), $v_{0y} = -c = -60$ m/s.

2.55. IDENTIFY: In time t_S the S-waves travel a distance $d = v_S t_S$ and in time t_P the P-waves travel a distance $d = v_P t_P$.

SET UP: $t_S = t_P + 33\text{ s}$

EXECUTE: $\dfrac{d}{v_S} = \dfrac{d}{v_P} + 33\text{ s}$. $d\left(\dfrac{1}{3.5\text{ km/s}} - \dfrac{1}{6.5\text{ km/s}}\right) = 33\text{ s}$ and $d = 250$ km.

EVALUATE: The times of travel for each wave are $t_S = 71\text{ s}$ and $t_P = 38\text{ s}$.

2.56. IDENTIFY: A rock is thrown upward from the edge of a roof and eventually lands on the ground a distance H below the edge. Its acceleration is g downward, so the constant-acceleration equations apply.

SET UP: The time to reach the maximum height is T_{max} and the time after throwing to reach the ground is $3T_{max}$. The equations $v_y = v_{0y} + a_y t$ and $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ apply. Call the y-axis upward with $y = 0$ at the edge of the roof. At the highest point, $v_y = 0$ and at the ground $y = -H$. We want the initial speed V_0 in terms of H. Making a sketch helps to organize the information, as in Fig. 2.56.

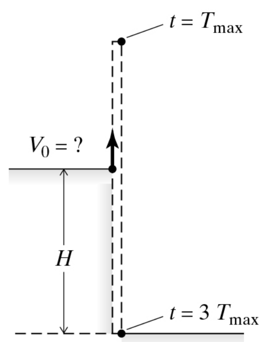

Figure 2.56

EXECUTE: At the highest point: $v_y = v_{0y} + a_y t$ gives $0 = V_0 - gT_{max}$, so $V_0 = gT_{max}$.

At the ground: After the rock was thrown, it took time T_{max} to reach the highest point and time $3T_{max}$ to reach the ground. Therefore the time to fall from the highest point to the ground was $2T_{max}$. Apply $v_y = v_{0y} + a_y t$ to the interval from the highest point to the ground to find the speed v_y when the rock reaches the ground. $v_y = 0 + (-g)(2T_{max}) = -2gT_{max}$. Now look at the entire motion from the instant the rock is thrown up until the instant it reaches the ground a distance H below the edge of the roof. We have already found that $V_0 = gT_{max}$ and $v_y = -2gT_{max}$ at ground level. Therefore $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$

gives $(-2gT_{max})^2 = V_0^2 + 2(-g)(-H)$. Using $T_{max} = V_0/g$ gives $\left[-2g\left(\frac{V_0}{g}\right)\right]^2 = V_0^2 + 2gH \quad \rightarrow$

$$V_0 = \sqrt{\frac{2gH}{3}}.$$

EVALUATE: It might seem like a good idea to check the special case if $H = 0$ (the edge of the roof is at ground level). Our result seems to give $V_0 = 0$ in that case. But if the roof were at ground level, the time for the entire up-and-down trip would take $2T_{max}$, not $3T_{max}$, so our result would not apply. Checking units in the final answer would be a good idea.

2.57. **IDENTIFY:** The average velocity is $v_{av\text{-}x} = \frac{\Delta x}{\Delta t}$.

SET UP: Let $+x$ be upward.

EXECUTE: **(a)** $v_{av\text{-}x} = \frac{1000\text{ m} - 63\text{ m}}{4.75\text{ s}} = 197\text{ m/s}$

(b) $v_{av\text{-}x} = \frac{1000\text{ m} - 0}{5.90\text{ s}} = 169\text{ m/s}$

EVALUATE: For the first 1.15 s of the flight, $v_{av\text{-}x} = \frac{63\text{ m} - 0}{1.15\text{ s}} = 54.8\text{ m/s}$. When the velocity isn't constant the average velocity depends on the time interval chosen. In this motion the velocity is increasing.

2.58. **IDENTIFY:** The block has a constant westward acceleration, so we can use the constant-acceleration equations.

SET UP: The equations $x = x_0 + v_{0x}t + \frac{1}{2}a_xt^2$, $v_x = v_{0x} + a_xt$, $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$, and $v_{av\text{-}x} = \frac{\Delta x}{\Delta t}$ apply.

EXECUTE: **(a)** The target variable is the time for the block to return to $x = 0$. Using $x = x_0 + v_{0x}t + \frac{1}{2}a_xt^2$ gives $0 = (12.0\text{ m/s})t + \frac{1}{2}(-2.00\text{ m/s}^2)t^2$. So $t = 12.0$ s.

(b) The block instantaneously stops when it reaches it maximum distance east, so $v_x = v_{0x} + a_xt$ gives 0 = 12.0 m/s + (–2.00 m/s)t, which gives $t = 6.00$ s. Using $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ we have $0 = (12.0\text{ m/s})^2 + 2(-2.00\text{ m/s}^2)\Delta x$, which gives $\Delta x = 36.0$ m.

EVALUATE: To check, we can use $v_{av\text{-}x} = \frac{\Delta x}{\Delta t}$ to find Δx. This gives $\Delta x = v_{av}\Delta t = \left(\frac{0 + 12.0\text{ m/s}}{2}\right)(6.00\text{ s})$ = 36.0 m, which agrees with our result in (b).

2.59. **IDENTIFY:** A block is moving with constant acceleration on an incline, so the constant-acceleration equations apply.

SET UP: All quantities are *down* the surface of the incline, so choose the x-axis along this surface and pointing downward. We first find the acceleration of the block and then use that to find its speed after sliding 16.0 m starting from rest and how long it takes to slide that distance.

EXECUTE: **(a)** First use $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ to find a_x. $(3.00\text{ m/s})^2 = 0 + 2a_x(8.00\text{ m})$. $a_x = 0.5625\text{ m/s}^2$. Now use the same equation to find the speed when the block has moved 16.0 m.

$v_x^2 = 0 + 2(0.5625\text{ m/s}^2)(16.0\text{ m}) \rightarrow v_x = 4.24$ m/s.

(b) Use $x = x_0 + v_{0x}t + \frac{1}{2}a_xt^2$ to find the time to travel 16.0 m.

$16.0\text{ m} = 0 + 0 + \frac{1}{2}(0.5625\text{ m/s}^2)t^2 \quad \rightarrow \quad t = 7.54$ s.

EVALUATE: From $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$, with $v_{0x} = 0$, we see that $v_x^2 \propto (x - x_0)$, so $v_x \propto \sqrt{x - x_0}$. So if $(x - x_0)$ increases by a factor of 2, v_x should increase by a factor of $\sqrt{2}$. At the end of 8.00 m, the block was moving at 3.00 m/s, so at the end of 16.0 m, it should be moving at (3.00 m/s) $\sqrt{2}$ = 4.24 m/s, which agrees with our result in (a).

2.60. **IDENTIFY:** Use constant acceleration equations to find $x - x_0$ for each segment of the motion.

SET UP: Let $+x$ be the direction the train is traveling.

EXECUTE: $t = 0$ to 14.0 s: $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = \frac{1}{2}(1.60\text{ m/s}^2)(14.0\text{ s})^2 = 157\text{ m}$.

At $t = 14.0\text{ s}$, the speed is $v_x = v_{0x} + a_x t = (1.60\text{ m/s}^2)(14.0\text{ s}) = 22.4\text{ m/s}$. In the next 70.0 s, $a_x = 0$ and $x - x_0 = v_{0x}t = (22.4\text{ m/s})(70.0\text{ s}) = 1568\text{ m}$.

For the interval during which the train is slowing down, $v_{0x} = 22.4\text{ m/s}$, $a_x = -3.50\text{ m/s}^2$ and $v_x = 0$.

$v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives $x - x_0 = \dfrac{v_x^2 - v_{0x}^2}{2a_x} = \dfrac{0 - (22.4\text{ m/s})^2}{2(-3.50\text{ m/s}^2)} = 72\text{ m}$.

The total distance traveled is $157\text{ m} + 1568\text{ m} + 72\text{ m} = 1800\text{ m}$.

EVALUATE: The acceleration is not constant for the entire motion, but it does consist of constant acceleration segments, and we can use constant acceleration equations for each segment.

2.61. **IDENTIFY:** When the graph of v_x versus t is a straight line the acceleration is constant, so this motion consists of two constant acceleration segments and the constant acceleration equations can be used for each segment. Since v_x is always positive the motion is always in the $+x$ direction and the total distance moved equals the magnitude of the displacement. The acceleration a_x is the slope of the v_x versus t graph.

SET UP: For the $t = 0$ to $t = 10.0\text{ s}$ segment, $v_{0x} = 4.00\text{ m/s}$ and $v_x = 12.0\text{ m/s}$. For the $t = 10.0\text{ s}$ to 12.0 s segment, $v_{0x} = 12.0\text{ m/s}$ and $v_x = 0$.

EXECUTE: **(a)** For $t = 0$ to $t = 10.0\text{ s}$, $x - x_0 = \left(\dfrac{v_{0x} + v_x}{2}\right)t = \left(\dfrac{4.00\text{ m/s} + 12.0\text{ m/s}}{2}\right)(10.0\text{ s}) = 80.0\text{ m}$.

For $t = 10.0\text{ s}$ to $t = 12.0\text{ s}$, $x - x_0 = \left(\dfrac{12.0\text{ m/s} + 0}{2}\right)(2.00\text{ s}) = 12.0\text{ m}$. The total distance traveled is 92.0 m.

(b) $x - x_0 = 80.0\text{ m} + 12.0\text{ m} = 92.0\text{ m}$

(c) For $t = 0$ to 10.0 s, $a_x = \dfrac{12.0\text{ m/s} - 4.00\text{ m/s}}{10.0\text{ s}} = 0.800\text{ m/s}^2$. For $t = 10.0\text{ s}$ to 12.0 s,

$a_x = \dfrac{0 - 12.0\text{ m/s}}{2.00\text{ s}} = -6.00\text{ m/s}^2$. The graph of a_x versus t is given in Figure 2.61.

EVALUATE: When v_x and a_x are both positive, the speed increases. When v_x is positive and a_x is negative, the speed decreases.

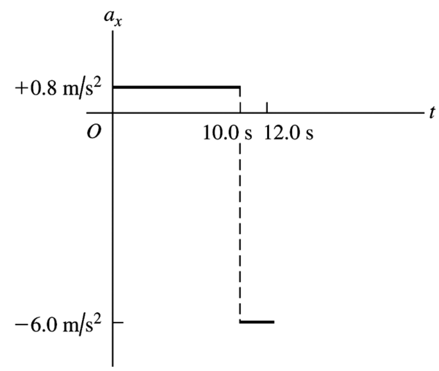

Figure 2.61

2.62. **IDENTIFY:** Apply $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ to the motion of each train. A collision means the front of the passenger train is at the same location as the caboose of the freight train at some common time.

SET UP: Let P be the passenger train and F be the freight train. For the front of the passenger train $x_0 = 0$ and for the caboose of the freight train $x_0 = 200$ m. For the freight train $v_F = 15.0$ m/s and $a_F = 0$. For the passenger train $v_P = 25.0$ m/s and $a_P = -0.100\ \text{m/s}^2$.

EXECUTE: **(a)** $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ for each object gives $x_P = v_P t + \frac{1}{2}a_P t^2$ and $x_F = 200\ \text{m} + v_F t$. Setting $x_P = x_F$ gives $v_P t + \frac{1}{2}a_P t^2 = 200\ \text{m} + v_F t$. $(0.0500\ \text{m/s}^2)t^2 - (10.0\ \text{m/s})t + 200\ \text{m} = 0$. The quadratic formula gives $t = \dfrac{1}{0.100}\left(+10.0 \pm \sqrt{(10.0)^2 - 4(0.0500)(200)}\right)\ \text{s} = (100 \pm 77.5)\ \text{s}$. The collision occurs at $t = 100\ \text{s} - 77.5\ \text{s} = 22.5\ \text{s}$. The equations that specify a collision have a physical solution (real, positive t), so a collision does occur.

(b) $x_P = (25.0\ \text{m/s})(22.5\ \text{s}) + \frac{1}{2}(-0.100\ \text{m/s}^2)(22.5\ \text{s})^2 = 537\ \text{m}$. The passenger train moves 537 m before the collision. The freight train moves $(15.0\ \text{m/s})(22.5\ \text{s}) = 337\ \text{m}$.

(c) The graphs of x_F and x_P versus t are sketched in Figure 2.62.

EVALUATE: The second root for the equation for t, $t = 177.5$ s is the time the trains would meet again if they were on parallel tracks and continued their motion after the first meeting.

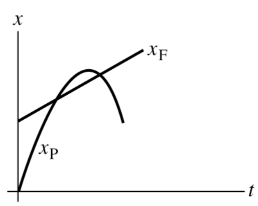

Figure 2.62

2.63. **IDENTIFY** and **SET UP:** Apply constant acceleration kinematics equations.
Find the velocity at the start of the second 5.0 s; this is the velocity at the end of the first 5.0 s. Then find $x - x_0$ for the first 5.0 s.

EXECUTE: For the first 5.0 s of the motion, $v_{0x} = 0$, $t = 5.0$ s.

$v_x = v_{0x} + a_x t$ gives $v_x = a_x(5.0\ \text{s})$.

This is the initial speed for the second 5.0 s of the motion. For the second 5.0 s:

$v_{0x} = a_x(5.0\text{ s}),\ t = 5.0\text{ s},\ x - x_0 = 200\text{ m}.$

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $200\text{ m} = (25\text{ s}^2)a_x + (12.5\text{ s}^2)a_x$ so $a_x = 5.333\text{ m/s}^2$.

Use this a_x and consider the first 5.0 s of the motion:

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = 0 + \frac{1}{2}(5.333\text{ m/s}^2)(5.0\text{ s})^2 = 67\text{ m}.$

EVALUATE: The ball is speeding up so it travels farther in the second 5.0 s interval than in the first.

2.64. IDENTIFY: The rock has a constant acceleration, so we can apply the constant-acceleration equations.

SET UP: We use $x = x_0 + v_{0x}t + \frac{1}{2}a_x t^2$ and $v_x = v_{0x} + a_x t$. The force is applied starting at $t = 0$ and maintains a constant acceleration of 4.00 m/s^2 in the $-x$ direction. Our target variables are the three times when the rock is 24.0 m from where it was when the force began to be applied. We also want its velocity at those instants.

EXECUTE: When the rock is 24.0 m on the $+x$ side of the origin, $x = x_0 + v_{0x}t + \frac{1}{2}a_x t^2$ gives

$24.0\text{ m} = (16.0\text{ m/s})t + \frac{1}{2}(-4.00\text{ m/s}^2)t^2$. Using the quadratic formula we get $t = 2.00$ s and $t = 6.00$ s.

At these times $v_x = v_{0x} + a_x t$ gives $v_x = 16.0\text{ m/s} + (-4.00\text{ m/s}^2)(2.00\text{ s}) = 8.00\text{ m/s}$ and $v_x = 16.0\text{ m/s} + (-4.00\text{ m/s}^2)(6.00\text{ s}) = -8.00\text{ m/s}$. But the rock is also 24.0 m from the origin when it is 24.0 m on the $-x$ side. In this case we get $-24.0\text{ m} = (16.0\text{ m/s})t + \frac{1}{2}(-4.00\text{ m/s}^2)t^2$. This quadratic equation has two roots, one of which is negative. We discard that root, leaving only $t = 9.29$ s. At this time, the velocity is $v_x = 16.0\text{ m/s} + (-4.00\text{ m/s}^2)(9.29\text{ s}) = -21.2\text{ m/s}$.

EVALUATE: To find the third time when the rock was 24.0 m from the origin, we had to think about the rock's behavior. It was not sufficient just to plug into an equation and get all three answers.

2.65. IDENTIFY: Apply constant acceleration equations to each object.
Take the origin of coordinates to be at the initial position of the truck, as shown in Figure 2.65a.
Let d be the distance that the car initially is behind the truck, so $x_0(\text{car}) = -d$ and $x_0(\text{truck}) = 0$. Let T be the time it takes the car to catch the truck. Thus at time T the truck has undergone a displacement $x - x_0 = 60.0\text{ m}$, so is at $x = x_0 + 60.0\text{ m} = 60.0\text{ m}$. The car has caught the truck so at time T is also at $x = 60.0\text{ m}$.

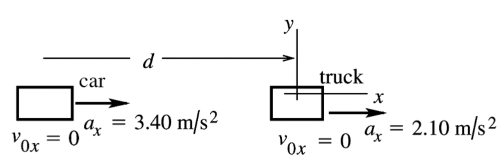

Figure 2.65a

(a) SET UP: Use the motion of the truck to calculate T:

$x - x_0 = 60.0\text{ m},\ v_{0x} = 0$ (starts from rest), $a_x = 2.10\text{ m/s}^2,\ t = T$

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$

Since $v_{0x} = 0$, this gives $t = \sqrt{\dfrac{2(x - x_0)}{a_x}}$

EXECUTE: $T = \sqrt{\dfrac{2(60.0\text{ m})}{2.10\text{ m/s}^2}} = 7.56\text{ s}$

(b) **SET UP:** Use the motion of the car to calculate d:

$x - x_0 = 60.0\ \text{m} + d,\ v_{0x} = 0,\ a_x = 3.40\ \text{m/s}^2,\ t = 7.56\ \text{s}$

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$

EXECUTE: $d + 60.0\ \text{m} = \frac{1}{2}(3.40\ \text{m/s}^2)(7.56\ \text{s})^2$

$d = 97.16\ \text{m} - 60.0\ \text{m} = 37.2\ \text{m}$.

(c) car: $v_x = v_{0x} + a_x t = 0 + (3.40\ \text{m/s}^2)(7.56\ \text{s}) = 25.7\ \text{m/s}$

truck: $v_x = v_{0x} + a_x t = 0 + (2.10\ \text{m/s}^2)(7.56\ \text{s}) = 15.9\ \text{m/s}$

(d) The graph is sketched in Figure 2.65b.

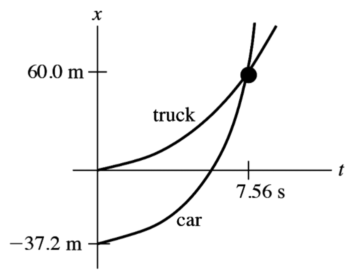

Figure 2.65b

EVALUATE: In part (c) we found that the auto was traveling faster than the truck when they came abreast. The graph in part (d) agrees with this: at the intersection of the two curves the slope of the *x-t* curve for the auto is greater than that of the truck. The auto must have an average velocity greater than that of the truck since it must travel farther in the same time interval.

2.66. **IDENTIFY:** The bus has a constant velocity but you have a constant acceleration, starting from rest.
SET UP: When you catch the bus, you and the bus have been traveling for the same time, but you have traveled an extra 12.0 m during that time interval. The constant-acceleration kinematics formula $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ applies.

EXECUTE: Call d the distance the bus travels after you start running and t the time until you catch the bus. For the bus we have $d = (5.00\ \text{m/s})t$, and for you we have $d + 12.0\ \text{m} = (1/2)(0.960\ \text{m/s}^2)t^2$. Solving these two equations simultaneously, and using the positive root, gives $t = 12.43$ s and $d = 62.14$ m. The distance you must run is 12.0 m + 62.14 m = 74.1 m. Your final speed just as you reach the bus is $v_x = (0.960\ \text{m/s}^2)(12.43\text{s}) = 11.9$ m/s. This might be possible for a college runner for a brief time, but it would be highly demanding!
EVALUATE: Note that when you catch the bus, you are moving much faster than it is.

2.67. **IDENTIFY:** The runner has constant acceleration in each segment of the dash, but it is not the same acceleration in the two segments. Therefore we must solve this problem in two segments.
SET UP: In the first segment, her acceleration is a constant a_x for 3.0 s, and in the next 9.0 s her speed remains constant. The total distance she runs is 100 m. A sketch as in Fig. 2.67 helps to organize the information. The constant-acceleration equations apply to each segment. We want a_x.

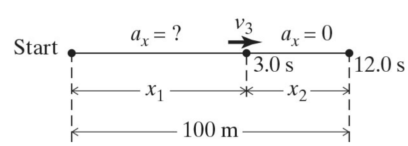

Figure 2.67

EXECUTE: Calling v_3 the velocity at the end of the first 3.0 s and using the notation shown in the figure, we look at one segment at a time. We realize that $v_0 = 0$ and v_3 is the constant speed during the second segment because she is not accelerating during that segment.

First segment: $v_x = v_{0x} + a_x t$ gives $v_3 = (3.0\text{ s})a_x$

$x = x_0 + v_{0x}t + \frac{1}{2}a_x t^2$ gives $x_1 = \frac{1}{2}a_x(3.0\text{ s})^2 = (4.5\text{ s}^2)\,a_x$.

Second segment: She has no acceleration, so $x_2 = v_3 t_2 = [(3.0\text{ s})a_x](9.0\text{ s}) = (27\text{ s}^2)a_x$.

The dash is 100 m long, so $x_1 + x_2 = 100$ m, so $(4.5\text{ s}^2)a_x + (27\text{ s}^2)a_x = 100\text{ m} \rightarrow a_x = 3.2\text{ m/s}^2$.

EVALUATE: We cannot solve this problem in a single step by averaging the accelerations because the accelerations (a_x during the first 3.0 s and zero during the last 9.0 s) do not last for the same time.

2.68. IDENTIFY: The acceleration is not constant so the constant acceleration equations cannot be used. Instead, use $a_x(t) = \dfrac{dv_x}{dt}$ and $x = x_0 + \int_0^t v_x(t)dt$.

SET UP: $\int t^n dt = \dfrac{1}{n+1}t^{n+1}$ for $n \ge 0$.

EXECUTE: **(a)** $x(t) = x_0 + \int_0^t [\alpha - \beta t^2]dt = x_0 + \alpha t - \frac{1}{3}\beta t^3$. $x = 0$ at $t = 0$ gives $x_0 = 0$ and

$x(t) = \alpha t - \frac{1}{3}\beta t^3 = (4.00\text{ m/s})t - (0.667\text{ m/s}^3)t^3$. $a_x(t) = \dfrac{dv_x}{dt} = -2\beta t = -(4.00\text{ m/s}^3)t$.

(b) The maximum positive x is when $v_x = 0$ and $a_x < 0$. $v_x = 0$ gives $\alpha - \beta t^2 = 0$ and

$t = \sqrt{\dfrac{\alpha}{\beta}} = \sqrt{\dfrac{4.00\text{ m/s}}{2.00\text{ m/s}^3}} = 1.41\text{ s}$. At this t, a_x is negative. For $t = 1.41$ s,

$x = (4.00\text{ m/s})(1.41\text{ s}) - (0.667\text{ m/s}^3)(1.41\text{ s})^3 = 3.77\text{ m}$.

EVALUATE: After $t = 1.41$ s the object starts to move in the $-x$ direction and goes to $x = -\infty$ as $t \to \infty$.

2.69. IDENTIFY: In this problem the acceleration is not constant, so the constant-acceleration equations do not apply. We need to go to the basic definitions of velocity and acceleration and use calculus.

SET UP: We know the object starts at $x = 0$ and its velocity is given by $v_x = \alpha t - \beta t^3$. We want to find out when it returns to the origin and what are its velocity and acceleration at that instant. We need to use the definitions $v_x = dx/dt$ and $a_x = dv_x/dt$.

EXECUTE: **(a)** To find when the object returns to the origin we need to find $x(t)$ and use it to find t when $x = 0$. Using $v_x = dx/dt$ gives $dx = v_x dt$. Using $v_x = \alpha t - \beta t^3$, we integrate to find $x(t)$.

$x - x_0 = \int v_x dt = \int\left(\alpha t - \beta t^3\right)dt = \dfrac{\alpha t^2}{2} - \dfrac{\beta t^4}{4}$. The object starts from the origin, so $x_0 = 0$ and when $t = 0$, $x = 0$. This gives $\dfrac{\alpha t^2}{2} - \dfrac{\beta t^4}{4} = 0$. Solving for t gives $t = \sqrt{\dfrac{2\alpha}{\beta}} = \sqrt{\dfrac{2(8.0\text{ m/s}^2)}{4.0\text{ m/s}^4}} = 2.0$ s.

(b) When $t = 2.0$ s, $v_x = \alpha t - \beta t^3 = (8.0\text{ m/s}^2)(2.0\text{ s}) - (4.0\text{ m/s}^4)(2.0\text{ s})^3 = -16$ m/s. The minus sign tells us the object is moving in the $-x$ direction. To find the acceleration, we $a_x = dv_x/dt$.

$a_x = \dfrac{d\left(\alpha t - \beta t^3\right)}{dt} = \alpha - 3\beta t^2 = 8.0\text{ m/s}^2 - 3(4.0\text{ m/s}^4)(2.0\text{ s})^2 = -40\text{ m/s}^2$, in the $-x$ direction.

EVALUATE: The standard constant-acceleration formulas do not apply when the acceleration is a function of time.

2.70. **IDENTIFY:** Find the distance the professor walks during the time t it takes the egg to fall to the height of his head.

SET UP: Let $+y$ be downward. The egg has $v_{0y}=0$ and $a_y=9.80\text{ m/s}^2$. At the height of the professor's head, the egg has $y-y_0=44.2\text{ m}$.

EXECUTE: $y-y_0=v_{0y}t+\frac{1}{2}a_yt^2$ gives $t=\sqrt{\dfrac{2(y-y_0)}{a_y}}=\sqrt{\dfrac{2(44.2\text{ m})}{9.80\text{ m/s}^2}}=3.00\text{ s}$. The professor walks a distance $x-x_0=v_{0x}t=(1.20\text{ m/s})(3.00\text{ s})=3.60\text{ m}$. Release the egg when your professor is 3.60 m from the point directly below you.

EVALUATE: Just before the egg lands its speed is $(9.80\text{ m/s}^2)(3.00\text{ s})=29.4\text{ m/s}$. It is traveling much faster than the professor.

2.71. **(a) IDENTIFY** and **SET UP:** Integrate $a_x(t)$ to find $v_x(t)$ and then integrate $v_x(t)$ to find $x(t)$. We know $a_x(t)=\alpha+\beta t$, with $\alpha=-2.00\text{ m/s}^2$ and $\beta=3.00\text{ m/s}^3$.

EXECUTE: $v_x=v_{0x}+\int_0^t a_x\,dt=v_{0x}+\int_0^t(\alpha+\beta t)\,dt=v_{0x}+\alpha t+\frac{1}{2}\beta t^2$

$x=x_0+\int_0^t v_x\,dt=x_0+\int_0^t(v_{0x}+\alpha t+\frac{1}{2}\beta t^2)\,dt=x_0+v_{0x}t+\frac{1}{2}\alpha t^2+\frac{1}{6}\beta t^3$

At $t=0$, $x=x_0$.

To have $x=x_0$ at $t_1=4.00\text{ s}$ requires that $v_{0x}t_1+\frac{1}{2}\alpha t_1^2+\frac{1}{6}\beta t_1^3=0$.

Thus $v_{0x}=-\frac{1}{6}\beta t_1^2-\frac{1}{2}\alpha t_1=-\frac{1}{6}(3.00\text{ m/s}^3)(4.00\text{ s})^2-\frac{1}{2}(-2.00\text{ m/s}^2)(4.00\text{ s})=-4.00\text{ m/s}$.

(b) With v_{0x} as calculated in part (a) and $t=4.00\text{ s}$,

$v_x=v_{0x}+\alpha t+\frac{1}{2}\beta t^2=-4.00\text{ m/s}+(-2.00\text{ m/s}^2)(4.00\text{ s})+\frac{1}{2}(3.00\text{ m/s}^3)(4.00\text{ s})^2=+12.0\text{ m/s}$.

EVALUATE: $a_x=0$ at $t=0.67\text{ s}$. For $t>0.67\text{ s}$, $a_x>0$. At $t=0$, the particle is moving in the $-x$-direction and is speeding up. After $t=0.67\text{ s}$, when the acceleration is positive, the object slows down and then starts to move in the $+x$-direction with increasing speed.

2.72. **IDENTIFY:** After it is thrown upward, the rock has a constant downward acceleration g, so the constant-acceleration equations apply. It lands on the ground, a distance H below the point where it started.

SET UP: For constant acceleration, $v_{\text{av-}y}=\dfrac{v_1+v_2}{2}$. We know $v_1=v_0$ and can use $v_y^2=v_{0y}^2+2a_y(y-y_0)$ to find v_2.

EXECUTE: **(a)** Use $v_{\text{av-}y}=\dfrac{\Delta y}{\Delta t}$. The rock starts at $y=0$ and ends up at $y=-H$, so $\Delta y=y_2-y_1=-H-0=-H$. We need the total time from the instant the rock is thrown up until it hits the ground. Break the motion into two parts: the upward motion to the highest point and the fall from the highest point to the ground.

<u>Upward motion</u>: Using $v_y=v_{0y}+a_yt$ gives $t_{\text{up}}=v_0/g$. Using $v_y^2=v_{0y}^2+2a_y(y-y_0)$ gives the maximum height: $0=v_0^2-2gy_{\text{top}}\ \rightarrow\ y_{\text{top}}=v_0^2/2g$.

<u>Downward motion</u>: The downward motion starts from rest, and the rock falls a distance $y_{\text{top}}+H$, so $y=y_0+v_{0y}t+\dfrac{1}{2}a_yt^2$ gives $\dfrac{v_0^2}{2g}+H=\dfrac{1}{2}gt_{\text{fall}}^2\ \rightarrow\ t_{\text{fall}}=\sqrt{\dfrac{v_0^2}{g^2}+\dfrac{2H}{g}}$.

The total time for the entire motion is $t_{\text{tot}}=t_{\text{up}}+t_{\text{fall}}=\dfrac{v_0}{g}+\sqrt{\dfrac{v_0^2}{g^2}+\dfrac{2H}{g}}$. Now use $v_{\text{av-}y}=\dfrac{\Delta y}{\Delta t}$.

$v_{\text{av-}y} = \dfrac{\Delta y}{\Delta t} = \dfrac{-H}{\dfrac{v_0}{g}+\sqrt{\dfrac{v_0^2}{g^2}+\dfrac{2H}{g}}} = \dfrac{-H}{v_0+\sqrt{v_0^2+2gH}}$. Rationalizing the denominator and simplifying gives

$v_{\text{av-}y} = \dfrac{v_0-\sqrt{v_0^2+2gH}}{2}$.

(b) When $H = 0$, $v_{\text{av-}y} = \dfrac{v_0-\sqrt{v_0^2+2gH}}{2} = \dfrac{v_0-\sqrt{v_0^2}}{2} = 0$. This result is reasonable because in this case $v_2 = -v_0$, so $v_{\text{av-}y} = \dfrac{v_1+v_2}{2} = \dfrac{v_0-v_0}{2} = 0$.

EVALUATE: (c) Using $v_2^2 = v_0^2 - 2g(-H)$ gives $v_2 = -\sqrt{v_0^2+2gH}$. We used the negative root because the rock is moving downward. Now use $v_{\text{av-}y} = \dfrac{v_1+v_2}{2}$, which gives $v_{\text{av-}y} = \dfrac{v_0-\sqrt{v_0^2+2gH}}{2}$. We get the same result as in part (a). If $H = 0$, $y_1 = y_2$, so $\Delta y = 0$, so $v_{\text{av-}y} = \dfrac{\Delta y}{\Delta t} = 0$.

2.73. IDENTIFY: The watermelon is in freefall so it has a constant downward acceleration of g. The constant-acceleration equations apply to its motion.

SET UP: The melon starts from rest at the top of a building. You observe that 1.50 s after it is 30.0 m above the ground, it hits the ground, and you want to find the height of the building. It is very helpful to make a sketch to organize the information, as in Fig. 2.73. In the figure, we see that the height h of the building is $h = y_1 + 30.0$ m, and it takes 1.50 s to travel those last 30.0 m of the fall. We know that $v_{\text{av-}y} = \dfrac{\Delta y}{\Delta t}$, and for constant acceleration it is also true that $v_{\text{av-}y} = \dfrac{v_1+v_2}{2}$. All quantities are downward, so choose the +y-axis downward.

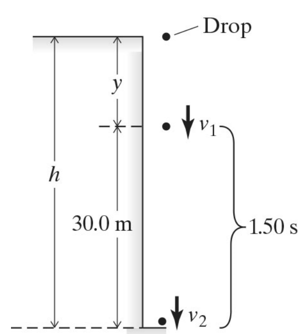

Figure 2.73

EXECUTE: We need to find y_1, but first we need to get v_1. Using $v_{\text{av-}y} = \dfrac{\Delta y}{\Delta t}$ during the last 1.50 s of the fall, we have $v_{\text{av-}y} = \dfrac{30.0\text{ m}}{1.50\text{ s}} = 20.0$ m/s. It is also true that $v_{\text{av-}y} = \dfrac{v_1+v_2}{2}$, so $\dfrac{v_1+v_2}{2} = 20.0$ m/s, which gives $v_2 = 40.0\text{ m/s} - v_1$. We can also use $v_y = v_{0y} + a_y t$ to get v_2 in terms of v_1.

$v_2 = v_1 + gt = v_1 + (9.80\text{ m/s}^2)(1.50\text{ s}) = v_1 + 14.7$ m/s. Equating our two expressions for v_2 gives $v_1 + 14.7\text{ m/s} = 40.0\text{ m/s} - v_1$. Solving for v_1 gives $v_1 = 12.65$ m/s. Now use $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ to find y_1. $(12.65\text{ m/s})^2 = 0 + 2(9.80\text{ m/s}^2)y_1 \quad\rightarrow\quad y_1 = 8.16$ m. The total height h of the building is $h = y_1 + 30.0\text{ m} = 8.16\text{ m} + 30.0\text{ m} = 38.2$ m.

EVALUATE: Use our results to find the time to fall the last 30.0 m; it should be 1.50 s if our answer is correct.

Time to fall 8.16 m from rest: $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$: 8.16 m = 0 + $\frac{1}{2}$(9.80 m/s²)t^2 $\rightarrow$ $t = 1.29$ s.

Time to fall 38.2 m from rest: 38.2 m = $\frac{1}{2}$(9.80 m/s²)t^2 $\rightarrow$ $t = 2.79$ s.

Time to fall the last 30.0 m: 2.79 s – 1.29 s = 1.50 s, which agrees with the observed time.

2.74. **IDENTIFY:** The flowerpot is in free-fall. Apply the constant acceleration equations. Use the motion past the window to find the speed of the flowerpot as it reaches the top of the window. Then consider the motion from the windowsill to the top of the window.

SET UP: Let $+y$ be downward. Throughout the motion $a_y = +9.80\text{ m/s}^2$. The constant-acceleration kinematics formulas all apply.

EXECUTE: Motion past the window:

$y - y_0 = 1.90$ m, $t = 0.380$ s, $a_y = +9.80\text{ m/s}^2$. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives

$v_{0y} = \dfrac{y - y_0}{t} - \frac{1}{2}a_y t = \dfrac{1.90\text{ m}}{0.380\text{ s}} - \frac{1}{2}(9.80\text{ m/s}^2)(0.380\text{ s}) = 3.138\text{ m/s}$. This is the velocity of the flowerpot when it is at the top of the window.

Motion from the windowsill to the top of the window: $v_{0y} = 0$, $v_y = 2.466$ m/s, $a_y = +9.80\text{ m/s}^2$.

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $y - y_0 = \dfrac{v_y^2 - v_{0y}^2}{2a_y} = \dfrac{(3.138\text{ m/s})^2 - 0}{2(9.80\text{ m/s}^2)} = 0.502\text{ m}$. The top of the window is 0.502 m below the windowsill.

EVALUATE: It takes the flowerpot $t = \dfrac{v_y - v_{0y}}{a_y} = \dfrac{3.138\text{ m/s}}{9.80\text{ m/s}^2} = 0.320\text{ s}$ to fall from the sill to the top of the window. Our result says that from the windowsill the pot falls $0.502\text{ m} + 1.90\text{ m} = 2.4\text{ m}$ in $0.320\text{ s} + 0.380\text{ s} = 0.700\text{ s}$. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = \frac{1}{2}(9.80\text{ m/s}^2)(0.700\text{ s})^2 = 2.4\text{ m}$, which checks.

2.75. **(a) IDENTIFY:** Consider the motion from when he applies the acceleration to when the shot leaves his hand.

SET UP: Take positive y to be upward. $v_{0y} = 0$, $v_y = ?$, $a_y = 35.0\text{ m/s}^2$, $y - y_0 = 0.640$ m,

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$

EXECUTE: $v_y = \sqrt{2a_y(y - y_0)} = \sqrt{2(35.0\text{ m/s}^2)(0.640\text{ m})} = 6.69\text{ m/s}$

(b) IDENTIFY: Consider the motion of the shot from the point where he releases it to its maximum height, where $v = 0$. Take $y = 0$ at the ground.

SET UP: $y_0 = 2.20$ m, $y = ?$, $a_y = -9.80\text{ m/s}^2$ (free fall), $v_{0y} = 6.69$ m/s (from part (a), $v_y = 0$ at maximum height), $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$

EXECUTE: $y - y_0 = \dfrac{v_y^2 - v_{0y}^2}{2a_y} = \dfrac{0 - (6.69\text{ m/s})^2}{2(-9.80\text{ m/s}^2)} = 2.29\text{ m}$, $y = 2.20\text{ m} + 2.29\text{ m} = 4.49\text{ m}$.

(c) IDENTIFY: Consider the motion of the shot from the point where he releases it to when it returns to the height of his head. Take $y = 0$ at the ground.

SET UP: $y_0 = 2.20$ m, $y = 1.83$ m, $a_y = -9.80\text{ m/s}^2$, $v_{0y} = +6.69$ m/s, $t = ?$ $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$

EXECUTE: $1.83\text{ m} - 2.20\text{ m} = (6.69\text{ m/s})t + \frac{1}{2}(-9.80\text{ m/s}^2)t^2 = (6.69\text{ m/s})t - (4.90\text{ m/s}^2)t^2$,

$4.90t^2 - 6.69t - 0.37 = 0$, with t in seconds. Use the quadratic formula to solve for t:

$t = \dfrac{1}{9.80}\left(6.69 \pm \sqrt{(6.69)^2 - 4(4.90)(-0.37)}\right) = 0.6830 \pm 0.7362$. Since t must be positive, $t = 0.6830\ \text{s} + 0.7362\ \text{s} = 1.42\ \text{s}$.

EVALUATE: Calculate the time to the maximum height: $v_y = v_{0y} + a_y t$, so $t = (v_y - v_{0y})/a_y = -(6.69\ \text{m/s})/(-9.80\ \text{m/s}^2) = 0.68\ \text{s}$. It also takes 0.68 s to return to 2.2 m above the ground, for a total time of 1.36 s. His head is a little lower than 2.20 m, so it is reasonable for the shot to reach the level of his head a little later than 1.36 s after being thrown; the answer of 1.42 s in part (c) makes sense.

2.76. **IDENTIFY:** The motion of the rocket can be broken into 3 stages, each of which has constant acceleration, so in each stage we can use the standard kinematics formulas for constant acceleration. But the acceleration is not the same throughout all 3 stages.

SET UP: The formulas $y - y_0 = \left(\dfrac{v_{0y} + v_y}{2}\right)t$, $y - y_0 = v_{0y}t + \dfrac{1}{2}a_y t^2$, and $v_y = v_{0y} + a_y t$ apply.

EXECUTE: **(a)** Let $+y$ be upward. At $t = 25.0\ \text{s}$, $y - y_0 = 1094\ \text{m}$ and $v_y = 87.5\ \text{m/s}$. During the next 10.0 s the rocket travels upward an additional distance

$y - y_0 = \left(\dfrac{v_{0y} + v_y}{2}\right)t = \left(\dfrac{87.5\ \text{m/s} + 132.5\ \text{m/s}}{2}\right)(10.0\ \text{s}) = 1100\ \text{m}$. The height above the launch pad when the second stage quits therefore is $1094\ \text{m} + 1100\ \text{m} = 2194\ \text{m}$. For the free-fall motion after the second stage quits: $y - y_0 = \dfrac{v_y^2 - v_{0y}^2}{2a_y} = \dfrac{0 - (132.5\ \text{m/s})^2}{2(-9.8\ \text{m/s}^2)} = 896\ \text{m}$. The maximum height above the launch pad that the rocket reaches is $2194\ \text{m} + 896\ \text{m} = 3090\ \text{m}$.

(b) $y - y_0 = v_{0y}t + \dfrac{1}{2}a_y t^2$ gives $-2194\ \text{m} = (132.5\ \text{m/s})t - (4.9\ \text{m/s}^2)t^2$. From the quadratic formula the positive root is $t = 38.6\ \text{s}$.

(c) $v_y = v_{0y} + a_y t = 132.5\ \text{m/s} + (-9.8\ \text{m/s}^2)(38.6\ \text{s}) = -246\ \text{m/s}$. The rocket's speed will be 246 m/s just before it hits the ground.

EVALUATE: We cannot solve this problem in a single step because the acceleration, while constant in each stage, is not constant over the entire motion. The standard kinematics equations apply to each stage but not to the motion as a whole.

2.77. **IDENTIFY:** Two stones are thrown up with different speeds. (a) Knowing how soon the faster one returns to the ground, how long it will take the slow one to return? (b) Knowing how high the slower stone went, how high did the faster stone go?

SET UP: Use subscripts f and s to refer to the faster and slower stones, respectively. Take $+y$ to be upward and $y_0 = 0$ for both stones. $v_{0\text{f}} = 3v_{0\text{s}}$. When a stone reaches the ground, $y = 0$. The constant-acceleration formulas $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ and $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ both apply.

EXECUTE: **(a)** $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ gives $a_y = -\dfrac{2v_{0y}}{t}$. Since both stones have the same a_y, $\dfrac{v_{0\text{f}}}{t_\text{f}} = \dfrac{v_{0\text{s}}}{t_\text{s}}$ and $t_\text{s} = t_\text{f}\left(\dfrac{v_{0\text{s}}}{v_{0\text{f}}}\right) = \left(\frac{1}{3}\right)(10\ \text{s}) = 3.3\ \text{s}$.

(b) Since $v_y = 0$ at the maximum height, then $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $a_y = -\dfrac{v_{0y}^2}{2y}$. Since both have the same a_y, $\dfrac{v_{0\text{f}}^2}{y_\text{f}} = \dfrac{v_{0\text{s}}^2}{y_\text{s}}$ and $y_\text{f} = y_\text{s}\left(\dfrac{v_{0\text{f}}}{v_{0\text{s}}}\right)^2 = 9H$.

EVALUATE: The faster stone reaches a greater height so it travels a greater distance than the slower stone and takes more time to return to the ground.

2.78. **IDENTIFY:** The rocket accelerates uniformly upward at 16.0 m/s^2 with the engines on. After the engines are off, it moves upward but accelerates downward at 9.80 m/s^2.

SET UP: The formulas $y - y_0 = v_{0_y} t = \frac{1}{2} a_y t^2$ and $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ both apply to both parts of the motion since the accelerations are both constant, but the accelerations are different in both cases. Let $+y$ be upward.

EXECUTE: With the engines on, $v_{0y} = 0$, $a_y = 16.0$ m/s^2 upward, and $t = T$ at the instant the engines just shut off. Using these quantities, we get

$y - y_0 = v_{0_y} t + \frac{1}{2} a_y t^2$ = (8.00 m/s^2)T^2 and $v_y = v_{0y} + a_y t =$ (16.0 m/s^2)T.

With the engines off (free fall), the formula $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ for the highest point gives

$y - y_0$ = (13.06 m/s^2)T^2, using v_{0y} = (16.0 m/s^2)T, $v_y = 0$, and $a_y = -9.80$ m/s^2.

The total height reached is 960 m, so (distance in free-fall) + (distance with engines on) = 960 m.

Therefore (13.06 m/s^2) T^2 + (8.00 m/s^2) T^2 = 960 m, which gives T = 6.75 s.

EVALUATE: It we put in 6.75 s for T, we see that the rocket travels considerably farther during free fall than with the engines on.

2.79. **IDENTIFY:** The helicopter has two segments of motion with constant acceleration: upward acceleration for 10.0 s and then free-fall until it returns to the ground. Powers has three segments of motion with constant acceleration: upward acceleration for 10.0 s, free-fall for 7.0 s and then downward acceleration of 2.0 m/s^2.

SET UP: Let $+y$ be upward. Let $y = 0$ at the ground.

EXECUTE: **(a)** When the engine shuts off both objects have upward velocity $v_y = v_{0y} + a_y t =$ $(5.0 \text{ m/s}^2)(10.0 \text{ s}) = 50.0 \text{ m/s}$ and are at $y = v_{0y}t + \frac{1}{2}a_y t^2 = \frac{1}{2}(5.0 \text{ m/s}^2)(10.0 \text{ s})^2 = 250 \text{ m}$.

For the helicopter, $v_y = 0$ (at the maximum height), $v_{0y} = +50.0 \text{ m/s}$, $y_0 = 250 \text{ m}$, and $a_y = -9.80 \text{ m/s}^2$.

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $y = \dfrac{v_y^2 - v_{0y}^2}{2a_y} + y_0 = \dfrac{0 - (50.0 \text{ m/s})^2}{2(-9.80 \text{ m/s}^2)} + 250 \text{ m} = 378 \text{ m}$, which rounds to 380 m.

(b) The time for the helicopter to crash from the height of 250 m where the engines shut off can be found using $v_{0y} = +50.0 \text{ m/s}$, $a_y = -9.80 \text{ m/s}^2$, and $y - y_0 = -250 \text{ m}$. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $-250 \text{ m} = (50.0 \text{ m/s})t - (4.90 \text{ m/s}^2)t^2$. $(4.90 \text{ m/s}^2)t^2 - (50.0 \text{ m/s})t - 250 \text{ m} = 0$. The quadratic formula gives $t = \dfrac{1}{9.80}\left(50.0 \pm \sqrt{(50.0)^2 + 4(4.90)(250)}\right)$ s. Only the positive solution is physical, so $t = 13.9$ s.

Powers therefore has free-fall for 7.0 s and then downward acceleration of 2.0 m/s^2 for $13.9 \text{ s} - 7.0 \text{ s} = 6.9 \text{ s}$. After 7.0 s of free-fall he is at $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = 250 \text{ m} + (50.0 \text{ m/s})(7.0 \text{ s}) +$ $\frac{1}{2}(-9.80 \text{ m/s}^2)(7.0 \text{ s})^2 = 360 \text{ m}$ and has velocity $v_x = v_{0x} + a_x t = 50.0 \text{ m/s} + (-9.80 \text{ m/s}^2)(7.0 \text{ s}) =$ -18.6 m/s. After the next 6.9 s he is at $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = 360 \text{ m} + (-18.6 \text{ m/s})(6.9 \text{ s}) +$ $\frac{1}{2}(-2.00 \text{ m/s}^2)(6.9 \text{ s})^2 = 184 \text{ m}$. Powers is 184 m above the ground when the helicopter crashes.

EVALUATE: When Powers steps out of the helicopter he retains the initial velocity he had in the helicopter but his acceleration changes abruptly from 5.0 m/s^2 upward to 9.80 m/s^2 downward. Without the jet pack he would have crashed into the ground at the same time as the helicopter. The jet pack slows his descent so he is above the ground when the helicopter crashes.

2.80. **IDENTIFY:** Apply constant acceleration equations to the motion of the rock. Sound travels at constant speed.

SET UP: Let t_{f} be the time for the rock to fall to the ground and let t_{s} be the time it takes the sound to travel from the impact point back to you. $t_{\text{f}} + t_{\text{s}} = 8.00\text{ s}$. Both the rock and sound travel a distance h that is equal to the height of the cliff. Take $+y$ downward for the motion of the rock. The rock has $v_{0y} = 0$ and $a_y = g = 9.80\text{ m/s}^2$.

EXECUTE: **(a)** For the falling rock, $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $h = \frac{1}{2}gt_{\text{f}}^2$. For the sound, $h = v_s t_s$. Equating these two equations for h and using the fact that $t_{\text{f}} + t_{\text{s}} = 8.00\text{ s}$, we get $\frac{1}{2}gt_{\text{f}}^2 = v_s t_s = v_s(8.00\text{ s} - t_f)$. Using $v_s = 330$ m/s and $g = 9.80\text{ m/s}^2$, we get a quadratic equation. Solving it using the quadratic formula and using the positive square root, we get $t_f = 7.225$ s. Therefore $h = \frac{1}{2}gt_{\text{f}}^2 = (1/2)(9.80\text{ m/s}^2)(7.225\text{ s})^2 = 256$ m.

(b) Ignoring sound you would calculate $d = \frac{1}{2}(9.80\text{ m/s}^2)(8.00\text{ s})^2 = 314\text{ m}$, which is greater than the actual distance. So you would have overestimated the height of the cliff. It actually takes the rock less time than 8.00 s to fall to the ground.

EVALUATE: Once we know h we can calculate that $t_{\text{f}} = 7.225\text{ s}$ and $t_{\text{s}} = 0.775\text{ s}$. The time for the sound of impact to travel back to you is 6% of the total time and should not be neglected for best precision.

2.81. **(a) IDENTIFY:** We have nonconstant acceleration, so we must use calculus instead of the standard kinematics formulas.

SET UP: We know the acceleration as a function of time is $a_x(t) = -Ct$, so we can integrate to find the velocity and then the x-coordinate of the object. We know that $v_x(t) = v_{0x} + \int_0^t a_x dt$ and $x(t) = x_0 + \int_0^t v_x(t)dt$.

EXECUTE: **(a)** We have information about the velocity, so we need to find that by integrating the acceleration. $v_x(t) = v_{0x} + \int_0^t a_x dt = v_{0x} + \int_0^t -Ctdt = v_{0x} - \frac{1}{2}Ct^2$. Using the facts that the initial velocity is 20.0 m/s and $v_x = 0$ when $t = 8.00$ s, we have $0 = 20.0\text{ m/s} - C(8.00\text{ s})^2/2$, which gives $C = 0.625\text{ m/s}^3$.

(b) We need the change in position during the first 8.00 s. Using $x(t) = x_0 + \int_0^t v_x(t)dt$ gives

$$x - x_0 = \int_0^t \left(-\tfrac{1}{2}Ct^2 + (20.0\text{ m/s})\right)dt = -Ct^3/6 + (20.0\text{ m/s})t$$

Putting in $C = 0.625\text{ m/s}^3$ and $t = 8.00$ s gives an answer of 107 m.

EVALUATE: The standard kinematics formulas are of no use in this problem since the acceleration varies with time.

2.82. **IDENTIFY:** Both objects are in free-fall and move with constant acceleration 9.80 m/s^2, downward. The two balls collide when they are at the same height at the same time.

SET UP: Let $+y$ be upward, so $a_y = -9.80\text{ m/s}^2$ for each ball. Let $y = 0$ at the ground. Let ball A be the one thrown straight up and ball B be the one dropped from rest at height H. $y_{0A} = 0$, $y_{0B} = H$.

EXECUTE: **(a)** $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ applied to each ball gives $y_A = v_0 t - \frac{1}{2}gt^2$ and $y_B = H - \frac{1}{2}gt^2$. $y_A = y_B$ gives $v_0 t - \frac{1}{2}gt^2 = H - \frac{1}{2}gt^2$ and $t = \dfrac{H}{v_0}$.

(b) For ball A at its highest point, $v_{yA} = 0$ and $v_y = v_{0y} + a_y t$ gives $t = \frac{v_0}{g}$. Setting this equal to the time in part (a) gives $\frac{H}{v_0} = \frac{v_0}{g}$ and $H = \frac{v_0^2}{g}$.

EVALUATE: In part (a), using $t = \frac{H}{v_0}$ in the expressions for y_A and y_B gives $y_A = y_B = H\left(1 - \frac{gH}{2v_0^2}\right)$.

H must be less than $\frac{2v_0^2}{g}$ in order for the balls to collide before ball A returns to the ground. This is because it takes ball A time $t = \frac{2v_0}{g}$ to return to the ground and ball B falls a distance $\frac{1}{2}gt^2 = \frac{2v_0^2}{g}$ during this time. When $H = \frac{2v_0^2}{g}$ the two balls collide just as ball A reaches the ground and for H greater than this ball A reaches the ground before they collide.

2.83. **IDENTIFY** and **SET UP:** Use $v_x = dx/dt$ and $a_x = dv_x/dt$ to calculate $v_x(t)$ and $a_x(t)$ for each car. Use these equations to answer the questions about the motion.

EXECUTE: $x_A = \alpha t + \beta t^2$, $v_{Ax} = \frac{dx_A}{dt} = \alpha + 2\beta t$, $a_{Ax} = \frac{dv_{Ax}}{dt} = 2\beta$

$x_B = \gamma t^2 - \delta t^3$, $v_{Bx} = \frac{dx_B}{dt} = 2\gamma t - 3\delta t^2$, $a_{Bx} = \frac{dv_{Bx}}{dt} = 2\gamma - 6\delta t$

(a) IDENTIFY and **SET UP:** The car that initially moves ahead is the one that has the larger v_{0x}.

EXECUTE: At $t = 0$, $v_{Ax} = \alpha$ and $v_{Bx} = 0$. So initially car A moves ahead.

(b) IDENTIFY and **SET UP:** Cars at the same point implies $x_A = x_B$.

$\alpha t + \beta t^2 = \gamma t^2 - \delta t^3$

EXECUTE: One solution is $t = 0$, which says that they start from the same point. To find the other solutions, divide by t: $\alpha + \beta t = \gamma t - \delta t^2$

$\delta t^2 + (\beta - \gamma)t + \alpha = 0$

$t = \frac{1}{2\delta}\left(-(\beta - \gamma) \pm \sqrt{(\beta - \gamma)^2 - 4\delta\alpha}\right) = \frac{1}{0.40}\left(+1.60 \pm \sqrt{(1.60)^2 - 4(0.20)(2.60)}\right) = 4.00 \text{ s} \pm 1.73 \text{ s}$

So $x_A = x_B$ for $t = 0$, $t = 2.27$ s and $t = 5.73$ s.

EVALUATE: Car A has constant, positive a_x. Its v_x is positive and increasing. Car B has $v_{0x} = 0$ and a_x that is initially positive but then becomes negative. Car B initially moves in the $+x$-direction but then slows down and finally reverses direction. At $t = 2.27$ s car B has overtaken car A and then passes it. At $t = 5.73$ s, car B is moving in the $-x$-direction as it passes car A again.

(c) IDENTIFY: The distance from A to B is $x_B - x_A$. The rate of change of this distance is $\frac{d(x_B - x_A)}{dt}$.

If this distance is not changing, $\frac{d(x_B - x_A)}{dt} = 0$. But this says $v_{Bx} - v_{Ax} = 0$. (The distance between A and B is neither decreasing nor increasing at the instant when they have the same velocity.)

SET UP: $v_{Ax} = v_{Bx}$ requires $\alpha + 2\beta t = 2\gamma t - 3\delta t^2$

EXECUTE: $3\delta t^2 + 2(\beta - \gamma)t + \alpha = 0$

$t = \frac{1}{6\delta}\left(-2(\beta - \gamma) \pm \sqrt{4(\beta - \gamma)^2 - 12\delta\alpha}\right) = \frac{1}{1.20}\left(3.20 \pm \sqrt{4(-1.60)^2 - 12(0.20)(2.60)}\right)$

$t = 2.667 \text{ s} \pm 1.667\ s$, so $v_{Ax} = v_{Bx}$ for $t = 1.00$ s and $t = 4.33$ s.

EVALUATE: At $t = 1.00$ s, $v_{Ax} = v_{Bx} = 5.00$ m/s. At $t = 4.33$ s, $v_{Ax} = v_{Bx} = 13.0$ m/s. Now car *B* is slowing down while *A* continues to speed up, so their velocities aren't ever equal again.
(d) IDENTIFY and **SET UP:** $a_{Ax} = a_{Bx}$ requires $2\beta = 2\gamma - 6\delta t$

EXECUTE: $t = \dfrac{\gamma - \beta}{3\delta} = \dfrac{2.80 \text{ m/s}^2 - 1.20 \text{ m/s}^2}{3(0.20 \text{ m/s}^3)} = 2.67 \text{ s}.$

EVALUATE: At $t = 0$, $a_{Bx} > a_{Ax}$, but a_{Bx} is decreasing while a_{Ax} is constant. They are equal at $t = 2.67$ s but for all times after that $a_{Bx} < a_{Ax}$.

2.84. IDENTIFY: Interpret the data on a graph to draw conclusions about the motion of a glider having constant acceleration down a frictionless air track, starting from rest at the top.
SET UP: The constant-acceleration kinematics formulas apply. Take the +*x*-axis along the surface of the track pointing downward.

EXECUTE: **(a)** For constant acceleration starting from rest, we have $x = \dfrac{1}{2}a_x t^2$. Therefore a plot of *x* versus t^2 should be a straight line, and the slope of that line should be $a_x/2$.
(b) To construct the graph of *x* versus t^2, we can use readings from the graph given in the text to construct a table of values for *x* and t^2, or we could use graphing software if available. The result is a graph similar to the one shown in Figure 2.84, which was obtained using software. A graph done by hand could vary slightly from this one, depending on how one reads the values on the graph in the text. The graph shown is clearly a straight line having slope 3.77 m/s^2 and *x*-intercept 0.0092 m. Using the slope *y*-intercept form of the equation of a straight line, the equation of this line is $x = 3.77t^2 + 0.0092$, where *x* is in meters and *t* in seconds.

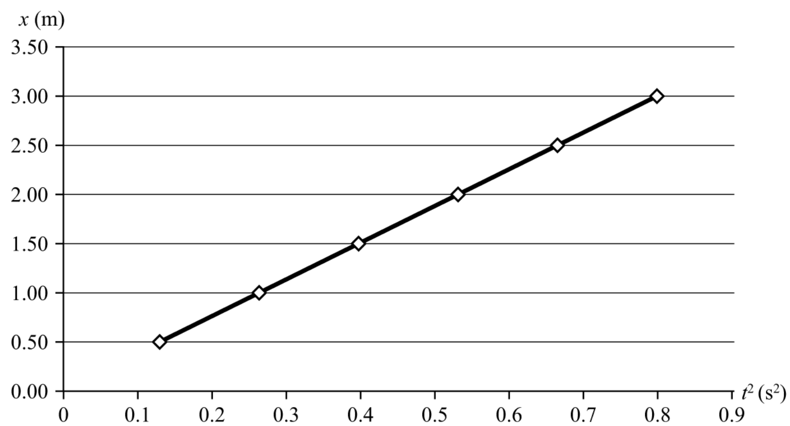

Figure 2.84

(c) The slope of the straight line in the graph is $a_x/2$, so $a_x = 2(3.77 \text{ m/s}^2) = 7.55 \text{ m/s}^2$.
(d) We know the distance traveled is 1.35 m, the acceleration is 7.55 m/s^2, and the initial velocity is zero, so we use the equation $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ and solve for v_x, giving $v_x = 4.51$ m/s.

EVALUATE: For constant acceleration in part (d), the average velocity is (4.51 m/s)/2 = 2.25 m/s. With this average velocity, the time for the glider to travel 1.35 m is x/v_{av} = (1.35 m)/(2.25 m) = 0.6 s, which is approximately the value of *t* read from the graph in the text for *x* = 1.35 m.

2.85. **IDENTIFY:** A ball is dropped from rest and falls from various heights with constant acceleration. Interpret a graph of the square of its velocity just as it reaches the floor as a function of its release height.

SET UP: Let $+y$ be downward since all motion is downward. The constant-acceleration kinematics formulas apply for the ball.

EXECUTE: **(a)** The equation $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ applies to the falling ball. Solving for $y - y_0$ and using $v_{0y} = 0$ and $a_y = g$, we get $y - y_0 = \dfrac{v_y^2}{2g}$. A graph of $y - y_0$ versus v_y^2 will be a straight line with slope $1/2g = 1/(19.6\ \text{m/s}^2) = 0.0510\ \text{s}^2/\text{m}$.

(b) With air resistance the acceleration is less than 9.80 m/s^2, so the final speed will be smaller.

(c) The graph will not be a straight line because the acceleration will vary with the speed of the ball. For a given release height, v_y with air resistance is less than without it. Alternatively, with air resistance the ball will have to fall a greater distance to achieve a given velocity than without air resistance. The graph is sketched in Figure 2.85.

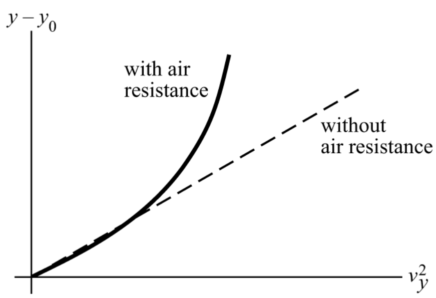

Figure 2.85

EVALUATE: Graphing $y - y_0$ versus v_y^2 for a set of data will tell us if the acceleration is constant. If the graph is a straight line, the acceleration is constant; if not, the acceleration is not constant.

2.86. **IDENTIFY:** Use data of acceleration and time for a model car to find information about its velocity and position.

SET UP: From the table of data in the text, we can see that the acceleration is not constant, so the constant-acceleration kinematics formlas do not apply. Therefore we must use calculus. The equations $v_x(t) = v_{0x} + \int_0^t a_x dt$ and $x(t) = x_0 + \int_0^t v_x dt$ apply.

EXECUTE: **(a)** Figure 2.86a shows the graph of a_x versus t. From the graph, we find that the slope of the line is –0.5131 m/s^3 and the a-intercept is 6.026 m/s^2. Using the slope y-intercept equation of a straight line, the equation is $a(t) = -0.513\ \text{m/s}^3\ t + 6.026\ \text{m/s}^2$, where t is in seconds and a is in m/s^2.

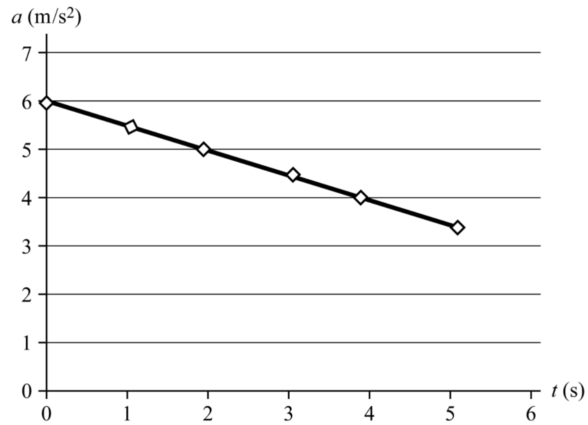

Figure 2.86a

(b) Integrate the acceleration to find the velocity, with the initial velocity equal to zero.

$v_x(t) = v_{0x} + \int_0^t a_x dt = v_{0x} + \int_0^t \left(6.026 \text{ m/s}^2 - 0.513 \text{ m/s}^3\ t\right) dt\ = 6.026 \text{ m/s}^2\ t - 0.2565 \text{ m/s}^3\ t^2.$

Figure 2.86b shows a sketch of the graph of v_x versus t.

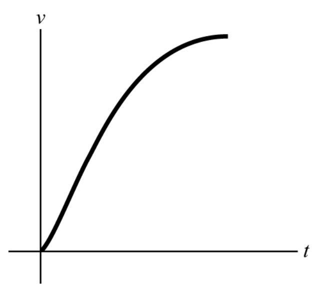

Figure 2.86b

(c) Putting $t = 5.00$ s into the equation we found in (b) gives $v_x = 23.7$ m/s.
(d) Integrate the velocity to find the change in position of the car.

$x - x_0 = \int_0^t v_x dt = \int_0^t \left[\left(6.026 \text{ m/s}^2\right)t - \left(0.2565 \text{ m/s}^3\right)t^2\right]dt\ = 3.013 \text{ m/s}^2\ t^2 - 0.0855 \text{ m/s}^3\ t^3$

At $t = 5.00$ s, this gives $x - x_0 = 64.6$ m.
EVALUATE: Since the acceleration is not constant, the standard kinematics formulas do not apply, so we must go back to basic definitions involving calculus.

2.87. **IDENTIFY:** Apply $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ to the motion from the maximum height, where $v_{0y} = 0$. The time spent above $y_{\text{max}}/2$ on the way down equals the time spent above $y_{\text{max}}/2$ on the way up.

SET UP: Let $+y$ be downward. $a_y = g$. $y - y_0 = y_{\text{max}}/2$ when he is a distance $y_{\text{max}}/2$ above the floor.

EXECUTE: The time from the maximum height to $y_{\text{max}}/2$ above the floor is given by $y_{\text{max}}/2 = \frac{1}{2}gt_1^2$. The time from the maximum height to the floor is given by $y_{\text{max}} = \frac{1}{2}gt_{\text{tot}}^2$ and the time from a height of $y_{\text{max}}/2$ to the floor is $t_2 = t_{\text{tot}} - t_1$.

$$\frac{2t_1}{t_2} = \frac{2\sqrt{y_{\text{max}}/2}}{\sqrt{y_{\text{max}}} - \sqrt{y_{\text{max}}/2}} = \frac{2}{\sqrt{2}-1} = 4.8.$$

EVALUATE: The person spends over twice as long above $y_{max}/2$ as below $y_{max}/2$. His average speed is less above $y_{max}/2$ than it is when he is below this height.

2.88. **IDENTIFY:** Apply constant acceleration equations to the motion of the two objects, the student and the bus.

SET UP: For convenience, let the student's (constant) speed be v_0 and the bus's initial position be x_0. Note that these quantities are for separate objects, the student and the bus. The initial position of the student is taken to be zero, and the initial velocity of the bus is taken to be zero. The positions of the student x_1 and the bus x_2 as functions of time are then $x_1 = v_0 t$ and $x_2 = x_0 + (1/2)at^2$.

EXECUTE: **(a)** Setting $x_1 = x_2$ and solving for the times *t* gives $t = \frac{1}{a}\left(v_0 \pm \sqrt{v_0^2 - 2ax_0}\right)$.

$$t = \frac{1}{0.170\ \text{m/s}^2}\left(5.0\ \text{m/s} \pm \sqrt{(5.0\ \text{m/s})^2 - 2(0.170\ \text{m/s}^2)(40.0\ \text{m})}\right) = 9.55\ \text{s and } 49.3\ \text{s}.$$

The student will be likely to hop on the bus the first time she passes it (see part (d) for a discussion of the later time). During this time, the student has run a distance $v_0 t = (5\ \text{m/s})(9.55\ \text{s}) = 47.8\ \text{m}$.

(b) The speed of the bus is $(0.170\ \text{m/s}^2)(9.55\ \text{s}) = 1.62\ \text{m/s}$.

(c) The results can be verified by noting that the *x* lines for the student and the bus intersect at two points, as shown in Figure 2.88a.

(d) At the later time, the student has passed the bus, maintaining her constant speed, but the accelerating bus then catches up to her. At this later time the bus's velocity is $(0.170\ \text{m/s}^2)(49.3\ \text{s}) = 8.38\ \text{m/s}$.

(e) No; $v_0^2 < 2ax_0$, and the roots of the quadratic are imaginary. When the student runs at $3.5\ \text{m/s}$, Figure 2.88b shows that the two lines do *not* intersect.

(f) For the student to catch the bus, $v_0^2 > 2ax_0$. And so the minimum speed is $\sqrt{2(0.170\ \text{m/s}^2)(40\ \text{m/s})} = 3.688\ \text{m/s}$. She would be running for a time $\frac{3.69\ \text{m/s}}{0.170\ \text{m/s}^2} = 21.7\ \text{s}$, and covers a distance $(3.688\ \text{m/s})(21.7\ \text{s}) = 80.0\ \text{m}$. However, when the student runs at $3.688\ \text{m/s}$, the lines intersect at *one* point, at $x = 80\ \text{m}$, as shown in Figure 2.88c.

EVALUATE: The graph in part (c) shows that the student is traveling faster than the bus the first time they meet but at the second time they meet the bus is traveling faster.

$t_2 = t_{tot} - t_1$

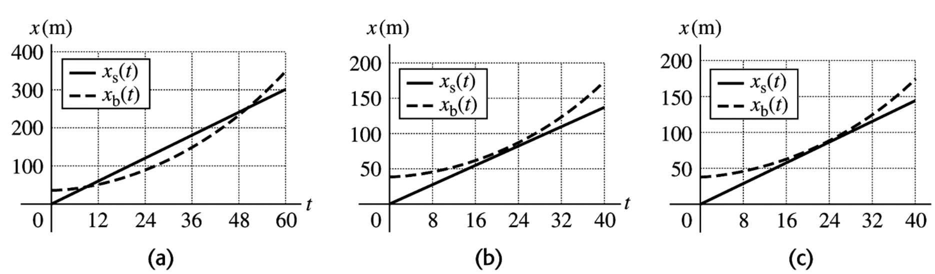

Figure 2.88

2.89. **IDENTIFY:** Apply constant acceleration equations to both objects.

SET UP: Let $+y$ be upward, so each ball has $a_y = -g$. For the purpose of doing all four parts with the least repetition of algebra, quantities will be denoted symbolically. That is, let $y_1 = h + v_0 t - \frac{1}{2}gt^2$, $y_2 = h - \frac{1}{2}g(t - t_0)^2$. In this case, $t_0 = 1.00$ s.

EXECUTE: **(a)** Setting $y_1 = y_2 = 0$, expanding the binomial $(t - t_0)^2$ and eliminating the common term $\frac{1}{2}gt^2$ yields $v_0 t = gt_0 t - \frac{1}{2}gt_0^2$. Solving for t: $t = \frac{\frac{1}{2}gt_0^2}{gt_0 - v_0} = \frac{t_0}{2}\left(\frac{1}{1 - v_0/(gt_0)}\right)$.

Substitution of this into the expression for y_1 and setting $y_1 = 0$ and solving for h as a function of v_0 yields, after some algebra, $h = \frac{1}{2}gt_0^2 \frac{\left(\frac{1}{2}gt_0 - v_0\right)^2}{(gt_0 - v_0)^2}$. Using the given value $t_0 = 1.00$ s and $g = 9.80\ \text{m/s}^2$,

$$h = 20.0\ \text{m} = (4.9\ \text{m})\left(\frac{4.9\ \text{m/s} - v_0}{9.8\ \text{m/s} - v_0}\right)^2.$$

This has two solutions, one of which is unphysical (the first ball is still going up when the second is released; see part (c)). The physical solution involves taking the negative square root before solving for v_0, and yields 8.2 m/s. The graph of y versus t for each ball is given in Figure 2.89.

(b) The above expression gives for (i) 0.411 m and for (ii) 1.15 km.

(c) As v_0 approaches 9.8 m/s, the height h becomes infinite, corresponding to a relative velocity at the time the second ball is thrown that approaches zero. If $v_0 > 9.8$ m/s, the first ball can never catch the second ball.

(d) As v_0 approaches 4.9 m/s, the height approaches zero. This corresponds to the first ball being closer and closer (on its way down) to the top of the roof when the second ball is released. If $v_0 < 4.9$ m/s, the first ball will already have passed the roof on the way down before the second ball is released, and the second ball can never catch up.

EVALUATE: Note that the values of v_0 in parts (a) and (b) are all greater than v_{min} and less than v_{max}.

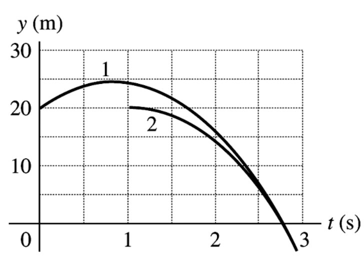

Figure 2.89

2.90. **IDENTIFY:** We know the change in velocity and the time for that change. We can use these quantities to find the average acceleration.

SET UP: The average acceleration is the change in velocity divided by the time for that change.

EXECUTE: $a_{\text{av}} = (v - v_0)/t = (0.80\ \text{m/s} - 0)/(250 \times 10^{-3}\ \text{s}) = 32\ \text{m/s}^2$, which is choice (c).

EVALUATE: This is about 1/3 the acceleration due to gravity, which is a reasonable acceleration for an organ.

2.91. **IDENTIFY:** The original area is divided into two equal areas. We want the diameter of these two areas, assuming the original and final areas are circular.
SET UP: The area A of a circle or radius r is $A = \pi r^2$ and the diameter d is $d = 2r$. $A_i = 2A_f$, and $r = d/2$, where A_f is the area of each of the two arteries.
EXECUTE: Call d the diameter of each artery. $A_i = \pi(d_a/2)^2 = 2[\pi(d/2)^2]$, which gives s $d = d_a/\sqrt{2}$, which is choice (b).
EVALUATE: The area of each artery is half the area of the aorta, but the diameters of the arteries are not half the diameter of the aorta.

2.92. **IDENTIFY:** We must interpret a graph of blood velocity during a heartbeat as a function of time.
SET UP: The instantaneous acceleration of a blood molecule is the slope of the velocity-versus-time graph.
EXECUTE: The magnitude of the acceleration is greatest when the slope of the v-t graph is steepest. That occurs at the upward sloping part of the graph, around $t = 0.10$ s, which makes choice (d) the correct one.
EVALUATE: The slope of the given graph is positive during the first 0.25 s and negative after that. Yet the velocity is positive throughout. Therefore the blood is always flowing forward, but it is increasing in speed during the first 0.25 s and slowing down after that.

3

MOTION IN TWO OR THREE DIMENSIONS

VP3.9.1. **IDENTIFY:** This is a projectile problem with only vertical acceleration.

SET UP: The formulas $y = (v_0 \sin\alpha_0)t - \frac{1}{2}gt^2$, $v_x = v_0 \cos\alpha_0$, $v_y = v_0 \sin\alpha_0 - gt$, and $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ apply.

EXECUTE: We know the launch speed and launch angle of the projectile, and want to know its maximum height, maximum range, and the time it is in the air.
(a) At the maximum height, $v_y = 0$. We use $v_y = v_0 \sin\alpha_0 - gt$ to find the time.

$0 = (25.0 \text{ m/s})(\sin 36.9°) - (9.80 \text{ m/s}^2)t \quad \rightarrow \quad t = 1.53$ s. Now use $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$.

$0 = [(25.0 \text{ m/s})(\sin 36.9°)]^2 - 2(9.80 \text{ m/s}^2)(y - y_0) \quad \rightarrow y - y_0 = 11.5$ m.

(b) When the projectile returns to ground level, $v_y = -v_0 \sin\alpha_0$. So

$v_y = v_0 \sin\alpha_0 - gt = -v_0 \sin\alpha_0$

$2v_0 \sin\alpha_0 = gt$

$2(25.0 \text{ m/s})(\sin 36.9°) = (9.80 \text{ m/s}^2)t \quad \rightarrow \quad t = 3.06$ s.

For the horizontal motion, we have

$x = (v_0 \cos\alpha_0)t = (25.0 \text{ m/s})(\cos 36.9°)(3.06 \text{ s}) = 61.2$ m.

EVALUATE: (a) Calculate y using $y = (v_0 \sin\alpha_0)t - \frac{1}{2}gt^2$.

$y = (25.0 \text{ m/s})(\sin 36.9°)(1.53 \text{ s}) - \frac{1}{2}(9.80 \text{ m/s}^2)(1.53 \text{ s})^2 = 11.5$ m, which agrees with our result. (b) The acceleration is constant, so the time for the upward motion is equal to the time for the downward motion. Thus $t_{\text{tot}} = 1.53 \text{ s} + 1.53 \text{ s} = 3.06$ s, which agrees with our result.

VP3.9.2. **IDENTIFY:** This is a projectile problem with only vertical acceleration.

SET UP: The formulas $v_x = v_0 \cos\alpha_0$, $v_y = v_0 \sin\alpha_0 - gt$, $y = (v_0 \sin\alpha_0)t - \frac{1}{2}gt^2$, and $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ apply. At the highest point in the baseball's trajectory, its vertical velocity is zero, but its horizontal velocity is the same as when it left the ground.

EXECUTE: (a) At the highest point, $v_y = 0$, so $v_y = v_0 \sin\alpha_0 - gt$ gives

$0 = v_0 \sin(30.0°) - (9.80 \text{ m/s}^2)(1.05 \text{ s})^2 \quad \rightarrow \quad v_0 = 20.6$ m/s.

(b) Using $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$0 = [(20.6 \text{ m/s})(\sin 30.0°)]^2 - 2(9.80 \text{ m/s}^2)(y - y_0) \quad \rightarrow \quad y - y_0 = 5.40$ m

EVALUATE: We can check by finding y when $t = 1.05$ s, using $y = (v_0 \sin\alpha_0)t - \frac{1}{2}gt^2$.

$y = (20.6 \text{ m/s})(\sin 30.0°)(1.05 \text{ s}) - \frac{1}{2}(9.80 \text{ m/s}^2)(1.05 \text{ s})^2 = 5.40$, which agrees with our result.

VP3.9.3. **IDENTIFY:** This is a projectile problem with only vertical acceleration.

SET UP: The formulas $v_x = v_0 \cos\alpha_0$, $v_y = v_0 \sin\alpha_0 - gt$, $x = (v_0 \cos\alpha_0)t$, and $y = (v_0 \sin\alpha_0)t - \frac{1}{2}gt^2$ apply. Call the origin the launch point with the $+y$-axis vertically upward.

EXECUTE: (a) When the walnut reaches the ground, $y = -20.0$ m. Use $y = (v_0 \sin\alpha_0)t - \frac{1}{2}gt^2$.

$-20.0 \text{ m} = (15.0 \text{ m/s})(\sin 50.0°)t - \frac{1}{2}(9.80 \text{ m/s}^2)t^2$. Using the quadratic formula gives two roots, only one of which is positive: $t = 3.51$ s.

(b) There is no horizontal acceleration, so we use $x = (v_0 \cos\alpha_0)t$ to find the distance x.

$x = (v_0 \cos\alpha_0)t = (15.0 \text{ m/s})(\cos 50.0°)(3.51 \text{ s}) = 33.8$ m.

(c) There is no horizontal acceleration, so $v_x = v_0 \cos\alpha_0 = (15.0 \text{ m/s})(\cos 50.0°) = 9.64$ m/s. The vertical velocity is

$v_y = v_0 \sin\alpha_0 - gt = (15.0 \text{ m/s}) \sin 50.0° - (9.80 \text{ m/s}^2)(3.51 \text{ s}) = -22.9$ m/s. The minus sign tells us the walnut is moving downward.

EVALUATE: We cannot use the projectile range formula because the landing point is not on the same level as the launch point.

VP3.9.4. **IDENTIFY:** This is a projectile problem with only vertical acceleration.

SET UP: The formulas $v_x = v_0 \cos\alpha_0$, $v_y = v_0 \sin\alpha_0 - gt$, $y = (v_0 \sin\alpha_0)t - \frac{1}{2}gt^2$, and $x = (v_0 \cos\alpha_0)t$ apply. Call the origin the launch point with the $+y$-axis vertically upward.

EXECUTE: (a) The horizontal and vertical distances are equal, so $y = -x$, so

$-(v_0 \cos\alpha_0)t = (v_0 \sin\alpha_0)t - \frac{1}{2}gt^2$. Since $\alpha_0 = 0$, we have $v_0t = \frac{1}{2}gt^2$, which gives $t = 2v_0/g$. At this time $x = v_0t = v_0(2v_0/g) = 2v_0^2/g$. Since $-x = y$, $y = -2v_0^2/g$.

(b) When the potato is moving at 45° below the horizontal, $v_y = -v_x$. $v_x = v_0$ and $v_y = -v_0 = -gt$. Therefore $t = v_0/g$. At this time, $x = v_0t = v_0(v_0/g) = v_0^2/g$, and $y = -\frac{1}{2}gt^2 = -\frac{1}{2}g(v_0/g)^2 = -v_0^2/2g$.

EVALUATE: As a check, solve for y using the time found in part (a).

$y = -\frac{1}{2}gt^2 = -\frac{1}{2}g(2v_0/g)^2 = -2v_0^2/g$, just as we found. Notice in part (b) that $x \neq y$ when the potato is traveling at 45° with the horizontal, but the magnitudes of the velocity are equal. We cannot use the projectile range formula because the landing point is not on the same level as the launch point.

VP3.12.1. **IDENTIFY:** This problem involves circular motion at constant speed. The acceleration of the cyclist is toward the center of the circle.

SET UP: The radial acceleration of the cyclist is $a_{\text{rad}} = \frac{v^2}{R}$ toward the center of the circular track. We know the speed and acceleration and want the radius of the circle.

EXECUTE: Solve $a_{\text{rad}} = \frac{v^2}{R}$ for R, giving $R = v^2/a_{\text{rad}} = (10.0 \text{ m/s})^2/(5.00 \text{ m/s}^2) = 20.0$ m.

EVALUATE: The speed of the cyclist is constant, but not the velocity since it is tangent to the circular path and is always changing direction.

VP3.12.2. **IDENTIFY:** This problem involves circular motion at constant speed. The acceleration of the car is toward the center of the circle.

SET UP: The radial acceleration of the car is $a_{\text{rad}} = \dfrac{v^2}{R}$ toward the center of the circular track. In terms of the period of motion, the acceleration is $a_{\text{rad}} = \dfrac{4\pi^2 R}{T^2}$. We know the speed of the car and the radius of the circle and want to find the period of the motion and centripetal acceleration of the car.

EXECUTE: (a) Equate the two expressions for a_{rad}, giving $\dfrac{4\pi^2 R}{T^2} = \dfrac{v^2}{R}$. Now solve for T.

$T = \sqrt{\dfrac{4\pi^2 R^2}{v^2}} = 2\pi R/v = 2\pi(265\text{ m})/(40.0\text{ m/s}) = 41.6\text{ s}$.

(b) $a_{\text{rad}} = \dfrac{v^2}{R} = (40.0\text{ m/s})^2/(265\text{ m}) = 6.04\text{ m/s}^2$.

EVALUATE: We can find the period by realizing that vT is the circumference of the track, which is $2\pi R$. Therefore $vT = 2\pi R$, so $T = 2\pi R/v = 2\pi(265\text{ m})/(40.0\text{ m/s}) = 41.6\text{ s}$, which is agrees with our answer in (a). The acceleration of the car (and the driver inside) is quite large, over 60% of g.

VP3.12.3. **IDENTIFY:** This problem involves circular motion at constant speed. The radial acceleration is toward the center of the circle.

SET UP: The equation $a_{\text{rad}} = \dfrac{4\pi^2 R}{T^2}$ applies and the speed is $v = 2\pi R/T$. The period is the same for all points on the wheel, but the speed (and hence acceleration) is not.

EXECUTE: (a) $v_{10} = 2\pi R/T = 2\pi(10.0\text{ cm})/(0.670\text{ s}) = 93.8\text{ cm/s} = 0.938\text{ m/s}$. Since R is twice as great at 20.0 cm, $v_{20} = 2v_{10} = 2(0.938\text{ m/s}) = 1.88\text{ m/s}$.

(b) $a_{10} = 4\pi^2 R/T^2 = 4\pi^2(0.100\text{ m})/(0.670\text{ s})^2 = 8.79\text{ m/s}^2$. As in (a), we see that $a_{20} = 2a_{10} = 2(8.79\text{ m/s}^2) = 17.6\text{ m/s}^2$.

(c) Both the speed and radial acceleration increase as R increases.

EVALUATE: As R increases, the points farther from the center must travel a greater distance than points closer to the center. So the speed and acceleration are greater for those distant points.

VP3.12.4. **IDENTIFY:** This problem involves circular motion at constant speed. The radial acceleration of a planet is toward the center of the circle, which is essentially the sun.

SET UP: The equation $a_{\text{rad}} = \dfrac{v^2}{R}$ applies and the speed of a planet is $v = 2\pi R/T$.

EXECUTE: (a) Apply $v = 2\pi R/T$ to each planet using the data given.

$v_V = 2\pi(1.08\times 10^{11}\text{ m})/[(225)(86{,}500)\text{s}] = 3.49\times 10^4\text{ m/s}$. Similar calculations for the earth and Mars gives $v_E = 2.99.\times.10^4\text{ m/s}$ and $v_M = 2.41\times 10^4\text{ m/s}$.

(b) Use $a_{\text{rad}} = \dfrac{v^2}{R}$ with the speeds found in part (a).

$a_V = (3.49\times 10^4\text{ m/s})^2/(1.08\times 10^{11}\text{ m}) = 1.13\times 10^{-2}\text{ m/s}^2$. Likewise we get $a_E = 5.95\times 10^{-3}\text{ m/s}^2$ and $a_M = 2.55\times 10^{-3}\text{ m/s}^2$.

(c) As the size of the orbit increases, both the orbital speed and the radial acceleration decrease.

EVALUATE: Since R increases and v decreases with distance from the sun, it must follow that the radial acceleration also decreases with distance. This is reasonable because the gravitational pull of the sun (to be studied in a later chapter) is weaker for distant planets than for closer ones.

VP3.12.5. **IDENTIFY:** This problem involves circular motion at constant speed.

SET UP: The equation $a_{\text{rad}} = \dfrac{v^2}{R}$ applies and the speed of an object moving in a circle is $v = 2\pi R/T$.

EXECUTE: (a) $v = 2\pi R/T$, so $T = 2\pi R/v$. Take the ratio of the two periods, giving $\dfrac{T_A}{T_B} = \dfrac{2\pi R_A / v_A}{2\pi R_B / v_B} = \dfrac{R_A}{R_B}\dfrac{v_B}{v_A}$. Putting in the given values for the speeds and radii gives $\dfrac{T_A}{T_B} = \dfrac{R(2v)}{(R/2)v} = 4.$

(b) Use $a_{\text{rad}} = \dfrac{v^2}{R}$, take the ratio of the accelerations, and use the given speeds and radii.

$$\frac{a_A}{a_B} = \frac{v_A^2 / R_A}{v_B^2 / R_B} = \left(\frac{v_A}{v_B}\right)^2 \frac{R_B}{R_A} = \left(\frac{v}{2v}\right)^2 \frac{R/2}{R} = \frac{1}{8}.$$

EVALUATE: Since $a_{\text{rad}} = \dfrac{v^2}{R}$, doubling the speed will increase a_{rad} by a factor of 4. Then halving the radius will increase a_{rad} by another factor of 2, giving a total factor of 8. This tells us that the inner object will have an acceleration 8 times that of the outer object, which is what we found in part (b).

VP3.15.1. **IDENTIFY:** This problem is about relative velocities.

SET UP: If object P is moving relative to object B and B is moving relative to A, then the velocity of P relative to A is given by $\vec{v}_{P/A} = \vec{v}_{P/B} + \vec{v}_{B/A}$. Let subscript P denote the police car, S the SUV, and E the earth.

EXECUTE: (a) We have one-dimensional motion, so the relative velocities in the x-direction are given by $v_{P/S} = v_{P/E} + v_{E/S}$. Using the given values gives

$v_{P/S} = 35.0\ \text{m/s} + 18.0\ \text{m/s} = 53.0\ \text{m/s}$.

(b) In this case, we want $v_{S/P}$, so

$v_{S/P} = v_{S/E} + v_{E/P} = -18.0\ \text{m/s} + (-35.0\ \text{m/s}) = -53.0\ \text{m/s}$.

EVALUATE: A rider in the SUV sees the police car going north at 53.0 m/s, but a rider in the police car sees the SUV going south at 53.0 m/s. Since they are going in opposite directions, their speeds relative to the earth add.

VP3.15.2. **IDENTIFY:** This problem is about relative velocities.

SET UP: If object P is moving relative to object B and B is moving relative to A, then the velocity of P relative to A is given by $\vec{v}_{P/A} = \vec{v}_{P/B} + \vec{v}_{B/A}$. Let subscript A denote the car A, B car B, and E the earth. The cars have only east-west velocities, so we look at velocity components along those directions.

EXECUTE: (a) We want the velocity of car A relative to car B.

$v_{A/B} = v_{A/E} + v_{E/B} = 45.0\ \text{m/s} + 45.0\ \text{m/sk} = 90.0\ \text{m/s}$, eastward.

(b) $v_{B/A} = v_{B/E} + v_{E/A} = -45.0\ \text{m/s} + (-45.0\ \text{m/s}) = -90.0\ \text{m/s}$, so the magnitude is 90.0 m/s and the direction is westward.

(c) At the points in this problem, the cars have only east-west velocities, so they have no relative velocity component along the line connecting them. Since both cars are traveling at the same speed in the same clockwise sense in a circle, they always remain the same distance apart. So they are neither approaching nor moving away from each other.

EVALUATE: In both cases the cars have east-west velocities in opposite directions, so their velocities relative to the earth add. When A sees B moving eastward at 90.0 m/s, B sees A moving westward at 90.0 m/s.

VP3.15.3. **IDENTIFY:** This problem is about relative velocities.

SET UP: If object P is moving relative to object B and B is moving relative to A, then the velocity of P relative to A is given by $\vec{\boldsymbol{v}}_{P/A} = \vec{\boldsymbol{v}}_{P/B} + \vec{\boldsymbol{v}}_{B/A}$. Let subscript T denote the truck, S the SUV, and E the earth.

EXECUTE: For this case, we have $\vec{\boldsymbol{v}}_{T/S} = \vec{\boldsymbol{v}}_{T/E} + \vec{\boldsymbol{v}}_{E/S}$. We want $\vec{\boldsymbol{v}}_{T/S}$. We know that $\vec{\boldsymbol{v}}_{T/E}$ = 16.0 m/s eastbound and $\vec{\boldsymbol{v}}_{S/E}$ = 20.0 m/s southbound. Therefore $\vec{\boldsymbol{v}}_{E/S}$ = 20.0 m/s northbound. Figure VP3.15.3 illustrates the velocity vectors.

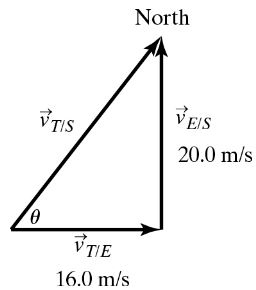

Figure VP3.15.3

Applying $A = \sqrt{A_x^2 + A_y^2}$ for the magnitude of a vector, we have

$v_{T/S} = \sqrt{(16.0 \text{ m/s})^2 + (20.0 \text{ m/s})^2}$ = 25.6 m/s. From the figure, we see that

θ = arctan[(20.0 m/s)/(16.0 m/s)] = 51.3° north of east.

(b) Using $\vec{\boldsymbol{v}}_{S/T} = -\vec{\boldsymbol{v}}_{T/S}$, the speed is 25.6 m/s, and the direction is 51.3° south of west.

EVALUATE: Check (b) by applying the relative velocity formula.

$\vec{\boldsymbol{v}}_{S/T} = \vec{\boldsymbol{v}}_{S/E} + \vec{\boldsymbol{v}}_{E/T} = -20.0 \text{ m/s } \hat{\boldsymbol{i}} + (-16.0 \text{ m/s}) \hat{\boldsymbol{j}} = -(16.0 \text{ m/s } \hat{\boldsymbol{i}} + 20.0 \text{ m/s } \hat{\boldsymbol{j}}) = -\vec{\boldsymbol{v}}_{T/S}$.

VP3.15.4. **IDENTIFY:** This problem is about relative velocities.

SET UP: If object P is moving relative to object B and B is moving relative to A, then the velocity of P relative to A is given by $\vec{\boldsymbol{v}}_{P/A} = \vec{\boldsymbol{v}}_{P/B} + \vec{\boldsymbol{v}}_{B/A}$. Let subscript J denote the jet, A the air, and E the earth.

EXECUTE: The jet's velocity relative to the earth is $\vec{\boldsymbol{v}}_{J/E} = \vec{\boldsymbol{v}}_{J/A} + \vec{\boldsymbol{v}}_{A/E}$. Figure VP3.15.4 illustrates these vectors. We want to find the magnitude of $\vec{\boldsymbol{v}}_{J/A}$ (the airspeed) and its direction (θ in the figure). Therefore we first find the components of $\vec{\boldsymbol{v}}_{J/A}$.

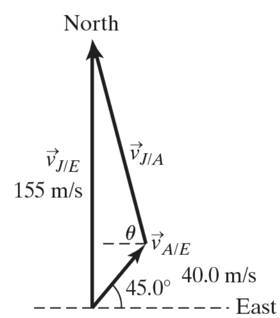

Figure VP3.15.4

Since $\vec{\boldsymbol{v}}_{J/E}$ is due north, it has no east-west component. From the figure, we can therefore see that the east-west components of $\vec{\boldsymbol{v}}_{A/E}$ and $\vec{\boldsymbol{v}}_{J/A}$ must have opposite sign and equal magnitudes.

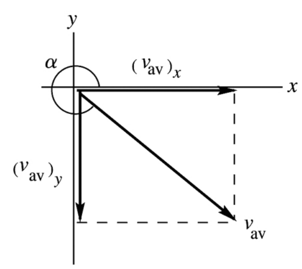
$\vec{v}_{J/A}$ (east component) = $-\vec{v}_{A/E}$ (west component) = –(40.0 m/s) cos 45.0° = –28.28 m/s. From the figure, we also see that
$\vec{v}_{J/A}$ (north component) + $\vec{v}_{A/E}$ (north component) = $\vec{v}_{J/E}$ (north component)
$\vec{v}_{J/A}$ (north component) + (40.0 m/s) cos 45.0° = 155 m/s
$\vec{v}_{J/A}$ (north component) = 126.7 m/s. Now find the magnitude of $\vec{v}_{J/A}$ using its components.
$v_{J/A} = \sqrt{(-28.28\text{ m/s})^2 + (126.7\text{ m/s})^2} = 130$ m/s. From the figure we see that
θ = arctan[(126.7 m/s)/(28.28 m/s)] = 77.4°. Therefore the airspeed of the jet is 130 m/s and the pilot must point it at 77.4° north of west.
EVALUATE: The pilot points the jet in a direction to offset the wind so the plane is flying directly north at 155 m/s as observed by someone standing on the ground.

3.1. **IDENTIFY** and **SET UP:** Use $\vec{v}_{\text{av}} = \dfrac{\vec{r}_2 - \vec{r}_1}{t_2 - t_1}$ in component form.

EXECUTE: **(a)** $v_{\text{av-}x} = \dfrac{\Delta x}{\Delta t} = \dfrac{x_2 - x_1}{t_2 - t_1} = \dfrac{5.3\text{ m} - 1.1\text{ m}}{3.0\text{ s} - 0} = 1.4\text{ m/s}$

$$v_{\text{av-}y} = \frac{\Delta y}{\Delta t} = \frac{y_2 - y_1}{t_2 - t_1} = \frac{-0.5\text{ m} - 3.4\text{ m}}{3.0\text{ s} - 0} = -1.3\text{ m/s}$$

(b)



$$\tan\alpha = \frac{(v_{\text{av}})_y}{(v_{\text{av}})_x} = \frac{-1.3\text{ m/s}}{1.4\text{ m/s}} = -0.9286$$

$$\alpha = 360° - 42.9° = 317°$$

$$v_{\text{av}} = \sqrt{(v_{\text{av}})_x^2 + (v_{\text{av}})_y^2}$$

$$v_{\text{av}} = \sqrt{(1.4\text{ m/s})^2 + (-1.3\text{ m/s})^2} = 1.9\text{ m/s}$$

Figure 3.1

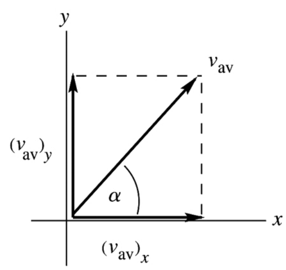
EVALUATE: Our calculation gives that $\vec{v}_{\text{av}}$ is in the 4th quadrant. This corresponds to increasing x and decreasing y.

3.2. **IDENTIFY:** Use $\vec{v}_{\text{av}} = \dfrac{\vec{r}_2 - \vec{r}_1}{t_2 - t_1}$ in component form. The distance from the origin is the magnitude of $\vec{r}$.
SET UP: At time t_1, $x_1 = y_1 = 0$.
EXECUTE: **(a)** $x = (v_{\text{av-}x})\Delta t = (-3.8\text{ m/s})(12.0\text{ s}) = -45.6\text{ m}$ and $y = (v_{\text{av-}y})\Delta t = (4.9\text{ m/s})(12.0\text{ s}) = 58.8\text{ m}$.
(b) $r = \sqrt{x^2 + y^2} = \sqrt{(-45.6\text{ m})^2 + (58.8\text{ m})^2} = 74.4\text{ m}$.
EVALUATE: $\Delta\vec{r}$ is in the direction of $\vec{v}_{\text{av}}$. Therefore, Δx is negative since $v_{\text{av-}x}$ is negative and Δy is positive since $v_{\text{av-}y}$ is positive.

3.3. **(a) IDENTIFY** and **SET UP:** From $\vec{r}$ we can calculate x and y for any t.
Then use $\vec{v}_{\text{av}} = \dfrac{\vec{r}_2 - \vec{r}_1}{t_2 - t_1}$ in component form.
EXECUTE: $\vec{r} = [4.0\text{ cm} + (2.5\text{ cm/s}^2)t^2]\hat{i} + (5.0\text{ cm/s})t\hat{j}$
At $t = 0$, $\vec{r} = (4.0\text{ cm})\,\hat{i}$.
At $t = 2.0$ s, $\vec{r} = (14.0\text{ cm})\,\hat{i} + (10.0\text{ cm})\,\hat{j}$.

$$v_{\text{av-}x} = \frac{\Delta x}{\Delta t} = \frac{10.0\text{ cm}}{2.0\text{ s}} = 5.0\text{ cm/s}.$$

$$v_{\text{av-}y} = \frac{\Delta y}{\Delta t} = \frac{10.0\text{ cm}}{2.0\text{ s}} = 5.0\text{ cm/s}.$$



$$v_{\text{av}} = \sqrt{(v_{\text{av}})_x^2 + (v_{\text{av}})_y^2} = 7.1\text{ cm/s}$$

$$\tan\alpha = \frac{(v_{\text{av}})_y}{(v_{\text{av}})_x} = 1.00$$

$$\theta = 45°.$$

Figure 3.3a

EVALUATE: Both x and y increase, so $\vec{v}_{\text{av}}$ is in the 1st quadrant.

(b) IDENTIFY and SET UP: Calculate $\vec{r}$ by taking the time derivative of $\vec{r}(t)$.

EXECUTE: $\vec{v} = \dfrac{d\vec{r}}{dt} = ([5.0\text{ cm/s}^2]t)\hat{i} + (5.0\text{ cm/s})\hat{j}$

$\underline{t=0}$: $v_x = 0$, $v_y = 5.0$ cm/s; $v = 5.0$ cm/s and $\theta = 90°$

$\underline{t = 1.0\text{ s}}$: $v_x = 5.0$ cm/s, $v_y = 5.0$ cm/s; $v = 7.1$ cm/s and $\theta = 45°$

$\underline{t = 2.0\text{ s}}$: $v_x = 10.0$ cm/s, $v_y = 5.0$ cm/s; $v = 11$ cm/s and $\theta = 27°$

(c) The trajectory is a graph of y versus x.

$x = 4.0\text{ cm} + (2.5\text{ cm/s}^2)t^2$, $y = (5.0\text{ cm/s})t$

For values of t between 0 and 2.0 s, calculate x and y and plot y versus x.

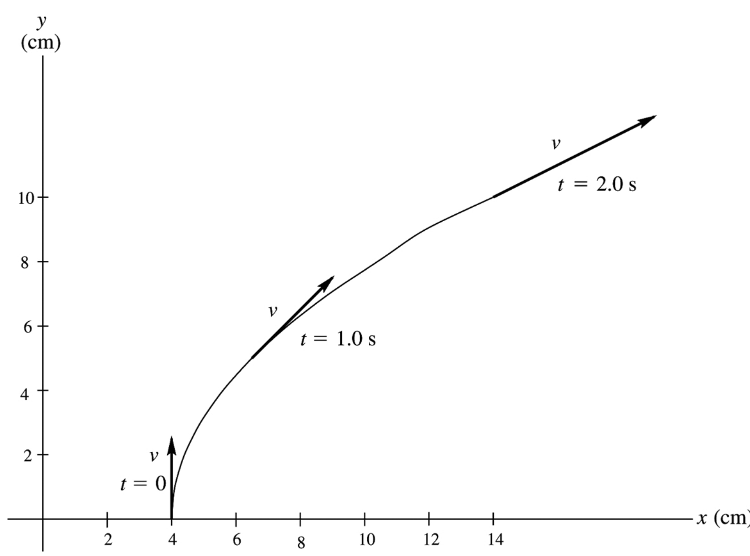


Figure 3.3b

EVALUATE: The sketch shows that the instantaneous velocity at any t is tangent to the trajectory.

3.4. **IDENTIFY:** Given the position vector of a squirrel, find its velocity components in general, and at a specific time find its velocity components and the magnitude and direction of its position vector and velocity.

SET UP: $v_x = dx/dt$ and $v_y = dy/dt$; the magnitude of a vector is $A = \sqrt{(A_x^2 + A_y^2)}$.

EXECUTE: **(a)** Taking the derivatives gives $v_x(t) = 0.280 \text{ m/s} + (0.0720 \text{ m/s}^2)t$ and $v_y(t) = (0.0570 \text{ m/s}^3)t^2$.

(b) Evaluating the position vector at $t = 5.00$ s gives $x = 2.30$ m and $y = 2.375$ m, which gives $r = 3.31$ m.

(c) At $t = 5.00$ s, $v_x = +0.64$ m/s, $v_y = 1.425$ m/s, which gives $v = 1.56$ m/s and $\tan\theta = \dfrac{1.425}{0.64}$ so the direction is $\theta = 65.8^\circ$ (counterclockwise from +x-axis)

EVALUATE: The acceleration is not constant, so we cannot use the standard kinematics formulas.

3.5. **IDENTIFY** and **SET UP:** Use Eq. $\vec{a}_{\text{av}} = \dfrac{\vec{v}_2 - \vec{v}_1}{t_2 - t_1}$ in component form to calculate $a_{\text{av-}x}$ and $a_{\text{av-}y}$.

EXECUTE: **(a)** The velocity vectors at $t_1 = 0$ and $t_2 = 30.0$ s are shown in Figure 3.5a.

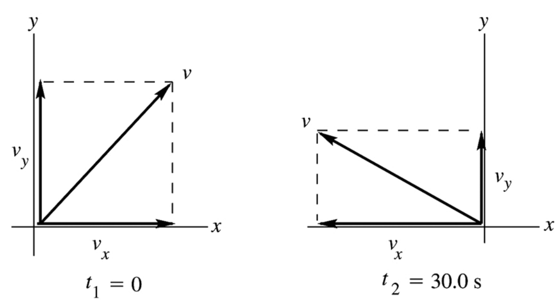

Figure 3.5a

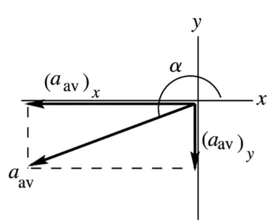
(b) $a_{\text{av-}x} = \dfrac{\Delta v_x}{\Delta t} = \dfrac{v_{2x} - v_{1x}}{t_2 - t_1} = \dfrac{-170 \text{ m/s} - 90 \text{ m/s}}{30.0 \text{ s}} = -8.67 \text{ m/s}^2$

$a_{\text{av-}y} = \dfrac{\Delta v_y}{\Delta t} = \dfrac{v_{2y} - v_{1y}}{t_2 - t_1} = \dfrac{40 \text{ m/s} - 110 \text{ m/s}}{30.0 \text{ s}} = -2.33 \text{ m/s}^2$

(c)



$a = \sqrt{(a_{\text{av-}x})^2 + (a_{\text{av-}y})^2} = 8.98 \text{ m/s}^2$

$\tan\alpha = \dfrac{a_{\text{av-}y}}{a_{\text{av-}x}} = \dfrac{-2.33 \text{ m/s}^2}{-8.67 \text{ m/s}^2} = 0.269$

$\alpha = 15^\circ + 180^\circ = 195^\circ$

Figure 3.5b

EVALUATE: The changes in v_x and v_y are both in the negative x or y direction, so both components of $\vec{a}_{\text{av}}$ are in the 3rd quadrant.

3.6. **IDENTIFY:** Use $\vec{a}_{\text{av}} = \dfrac{\vec{v}_2 - \vec{v}_1}{t_2 - t_1}$ in component form.

SET UP: $a_x = (0.45\text{ m/s}^2)\cos 31.0° = 0.39\text{ m/s}^2$, $a_y = (0.45\text{ m/s}^2)\sin 31.0° = 0.23\text{ m/s}^2$

EXECUTE: **(a)** $a_{\text{av-}x} = \dfrac{\Delta v_x}{\Delta t}$ and $v_x = 2.6\text{ m/s} + (0.39\text{ m/s}^2)(10.0\text{ s}) = 6.5\text{ m/s}$. $a_{\text{av-}y} = \dfrac{\Delta v_y}{\Delta t}$ and $v_y = -1.8\text{ m/s} + (0.23\text{ m/s}^2)(10.0\text{ s}) = 0.52\text{ m/s}$.

(b) $v = \sqrt{(6.5\text{ m/s})^2 + (0.52\text{ m/s})^2} = 6.52\text{ m/s}$, at an angle of $\arctan\left(\dfrac{0.52}{6.5}\right) = 4.6°$ counterclockwise from the $+x$-axis.

(c) The velocity vectors $\vec{v}_1$ and $\vec{v}_2$ are sketched in Figure 3.6. The two velocity vectors differ in magnitude and direction.

EVALUATE: $\vec{v}_1$ is at an angle of $35°$ below the $+x$-axis and has magnitude $v_1 = 3.2\text{ m/s}$, so $v_2 > v_1$ and the direction of $\vec{v}_2$ is rotated counterclockwise from the direction of $\vec{v}_1$.

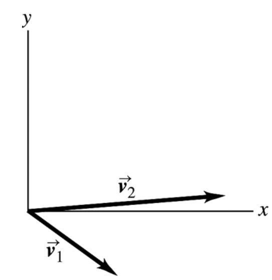


Figure 3.6

3.7. **IDENTIFY** and **SET UP:** Use $\vec{v} = \dfrac{d\vec{r}}{dt}$ and $\vec{a} = \dfrac{d\vec{v}}{dt}$ to find v_x, v_y, a_x, and a_y as functions of time. The magnitude and direction of $\vec{r}$ and $\vec{a}$ can be found once we know their components.

EXECUTE: **(a)** Calculate x and y for t values in the range 0 to 2.0 s and plot y versus x. The results are given in Figure 3.7a.

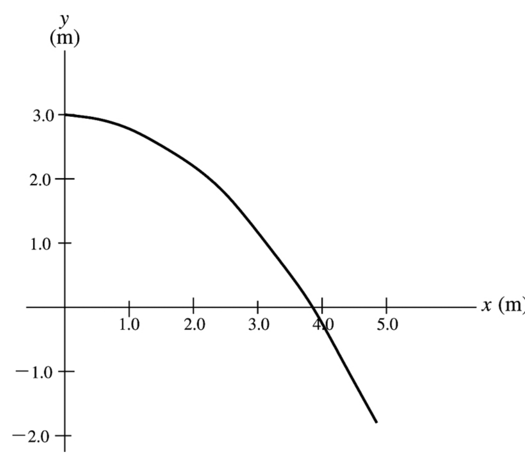

Figure 3.7a

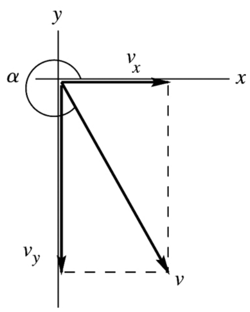
(b) $v_x = \dfrac{dx}{dt} = \alpha \quad v_y = \dfrac{dy}{dt} = -2\beta t$

$a_x = \dfrac{dv_x}{dt} = 0 \quad a_y = \dfrac{dv_y}{dt} = -2\beta$

Thus $\vec{v} = \alpha\hat{i} - 2\beta t\hat{j}$, $\vec{a} = -2\beta\hat{j}$

(c) Velocity: At $t = 2.0$ s, $v_x = 2.4$ m/s, $v_y = -2(1.2\ \text{m/s}^2)(2.0\ \text{s}) = -4.8$ m/s



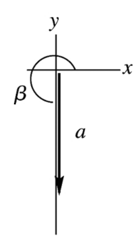
$$v = \sqrt{v_x^2 + v_y^2} = 5.4\ \text{m/s}$$

$$\tan\alpha = \frac{v_y}{v_x} = \frac{-4.8\ \text{m/s}}{2.4\ \text{m/s}} = -2.00$$

$$\alpha = -63.4° + 360° = 297°$$

Figure 3.7b

Acceleration: At $t = 2.0$ s, $a_x = 0$, $a_y = -2\,(1.2\ \text{m/s}^2) = -2.4\ \text{m/s}^2$



$$a = \sqrt{a_x^2 + a_y^2} = 2.4\ \text{m/s}^2$$

$$\tan\beta = \frac{a_y}{a_x} = \frac{-2.4\ \text{m/s}^2}{0} = -\infty$$

$$\beta = 270°$$

Figure 3.7c

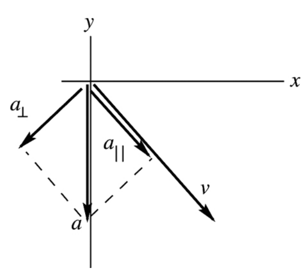


Figure 3.7d

EVALUATE: **(d)** $\vec{a}$ has a component $a_{\parallel}$ in the same direction as $\vec{v}$, so we know that v is increasing (the bird is speeding up). $\vec{a}$ also has a component $a_\perp$ perpendicular to $\vec{v}$, so that the direction of $\vec{v}$ is changing; the bird is turning toward the $-y$-direction (toward the right)

$\vec{v}$ is always tangent to the path; $\vec{v}$ at $t = 2.0$ s shown in part (c) is tangent to the path at this t, conforming to this general rule. $\vec{a}$ is constant and in the $-y$-direction; the direction of $\vec{v}$ is turning toward the $-y$-direction.

3.8. **IDENTIFY:** Use the velocity components of a car (given as a function of time) to find the acceleration of the car as a function of time and to find the magnitude and direction of the car's velocity and acceleration at a specific time.

SET UP: $a_x = dv_x/dt$ and $a_y = dv_y/dt$; the magnitude of a vector is $A = \sqrt{(A_x^2 + A_y^2)}$.

EXECUTE: **(a)** Taking the derivatives gives $a_x(t) = (-0.0360\ \text{m/s}^3)t$ and $a_y(t) = 0.550\ \text{m/s}^2$.

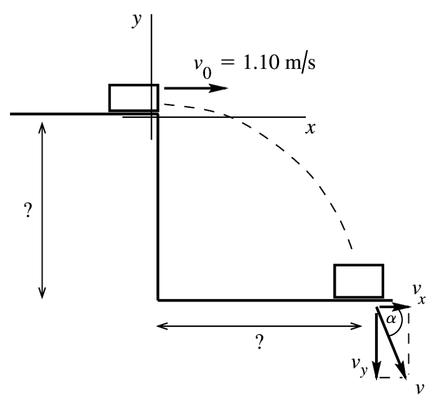
(b) Evaluating the velocity components at $t = 8.00$ s gives $v_x = 3.848$ m/s and $v_y = 6.40$ m/s, which gives $v = 7.47$ m/s. The direction is $\tan\theta = \dfrac{6.40}{3.848}$ so $\theta = 59.0°$ (counterclockwise from +x-axis).

(c) Evaluating the acceleration components at $t = 8.00$ s gives $a_x = 20.288$ m/s^2 and $a_y = 0.550$ m/s^2, which gives $a = 0.621$ m/s^2. The angle with the +y axis is given by $\tan\theta = \dfrac{0.288}{0.550}$, so $\theta = 27.6°$. The direction is therefore 118° counterclockwise from +x-axis.

EVALUATE: The acceleration is not constant, so we cannot use the standard kinematics formulas.

3.9. IDENTIFY: The book moves in projectile motion once it leaves the tabletop. Its initial velocity is horizontal.

SET UP: Take the positive y-direction to be upward. Take the origin of coordinates at the initial position of the book, at the point where it leaves the table top.



x-component:
$a_x = 0$, $v_{0x} = 1.10$ m/s,
$t = 0.480$ s
y-component:
$a_y = -9.80$ m/s^2, $v_{0y} = 0$,
$t = 0.480$ s

Figure 3.9a

Use constant acceleration equations for the x and y components of the motion, with $a_x = 0$ and $a_y = -g$.

EXECUTE: **(a)** $y - y_0 = ?$

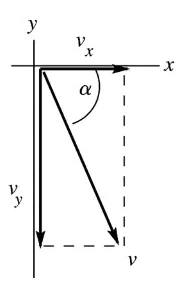
$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = 0 + \frac{1}{2}(-9.80 \text{ m/s}^2)(0.480 \text{ s})^2 = -1.129$ m. The tabletop is therefore 1.13 m above the floor.

(b) $x - x_0 = ?$

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (1.10 \text{ m/s})(0.480 \text{ s}) + 0 = 0.528$ m.

(c) $v_x = v_{0x} + a_x t = 1.10$ m/s (The x-component of the velocity is constant, since $a_x = 0$.)

$v_y = v_{0y} + a_y t = 0 + (-9.80 \text{ m/s}^2)(0.480 \text{ s}) = -4.704$ m/s



$v = \sqrt{v_x^2 + v_y^2} = 4.83$ m/s

$\tan\alpha = \dfrac{v_y}{v_x} = \dfrac{-4.704 \text{ m/s}}{1.10 \text{ m/s}} = -4.2764$

$\alpha = -76.8°$

Direction of $\vec{v}$ is 76.8° below the horizontal

Figure 3.9b

(d) The graphs are given in Figure 3.9c.

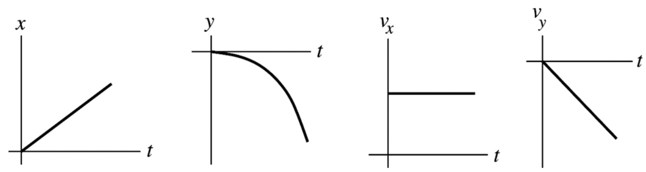


Figure 3.9c

EVALUATE: In the *x*-direction, $a_x = 0$ and v_x is constant. In the *y*-direction, $a_y = -9.80\ \text{m/s}^2$ and v_y is downward and increasing in magnitude since a_y and v_y are in the same directions. The *x* and *y* motions occur independently, connected only by the time. The time it takes the book to fall 1.13 m is the time it travels horizontally.

3.10. **IDENTIFY:** The person moves in projectile motion. She must travel 1.75 m horizontally during the time she falls 9.00 m vertically.

SET UP: Take $+y$ downward. $a_x = 0$, $a_y = +9.80\ \text{m/s}^2$. $v_{0x} = v_0$, $v_{0y} = 0$.

EXECUTE: Time to fall 9.00 m: $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = \sqrt{\frac{2(y - y_0)}{a_y}} = \sqrt{\frac{2(9.00\ \text{m})}{9.80\ \text{m/s}^2}} = 1.36\ \text{s}$.

Speed needed to travel 1.75 m horizontally during this time: $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives

$$v_0 = v_{0x} = \frac{x - x_0}{t} = \frac{1.75\ \text{m}}{1.36\ \text{s}} = 1.29\ \text{m/s}.$$

EVALUATE: If she increases her initial speed she still takes 1.36 s to reach the level of the ledge, but has traveled horizontally farther than 1.75 m.

3.11. **IDENTIFY:** Each object moves in projectile motion.

SET UP: Take $+y$ to be downward. For each cricket, $a_x = 0$ and $a_y = +9.80\ \text{m/s}^2$. For Chirpy, $v_{0x} = v_{0y} = 0$. For Milada, $v_{0x} = 0.950\ \text{m/s}$, $v_{0y} = 0$.

EXECUTE: Milada's horizontal component of velocity has no effect on her vertical motion. She also reaches the ground in 2.70 s. $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (0.950\ \text{m/s})(2.70\ \text{s}) = 2.57\ \text{m}$.

EVALUATE: The *x* and *y* components of motion are totally separate and are connected only by the fact that the time is the same for both.

3.12. **IDENTIFY:** The football moves in projectile motion.

SET UP: Let $+y$ be upward. $a_x = 0$, $a_y = -g$. At the highest point in the trajectory, $v_y = 0$.

EXECUTE: **(a)** $v_y = v_{0y} + a_y t$. The time t is $\frac{v_{0y}}{g} = \frac{12.0\ \text{m / s}}{9.80\ \text{m/s}^2} = 1.224\ \text{s}$, which we round to 1.22 s.

(b) Different constant acceleration equations give different expressions but the same numerical result:

$$\tfrac{1}{2}gt^2 = \tfrac{1}{2}v_{y0}t = \frac{v_{0y}^2}{2g} = 7.35\ \text{m}.$$

(c) Regardless of how the algebra is done, the time will be twice that found in part (a), which is 2(1.224 s) = 2.45 s.

(d) $a_x = 0$, so $x - x_0 = v_{0x}t = (20.0\ \text{m/s})(2.45\ \text{s}) = 49.0\ \text{m}$.

(e) The graphs are sketched in Figure 3.12.

EVALUATE: When the football returns to its original level, $v_x = 20.0\ \text{m/s}$ and $v_y = -12.0\ \text{m/s}$.

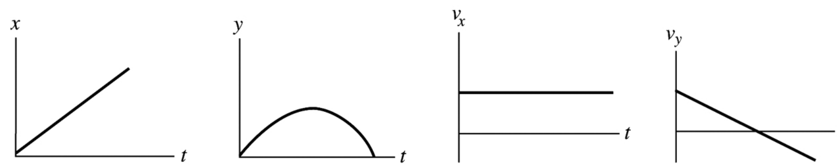

Figure 3.12

3.13. **IDENTIFY:** The car moves in projectile motion. The car travels $21.3\text{ m} - 1.80\text{ m} = 19.5\text{ m}$ downward during the time it travels 48.0 m horizontally.

SET UP: Take $+y$ to be downward. $a_x = 0$, $a_y = +9.80\text{ m/s}^2$. $v_{0x} = v_0$, $v_{0y} = 0$.

EXECUTE: **(a)** Use the vertical motion to find the time in the air:

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = \sqrt{\dfrac{2(y-y_0)}{a_y}} = \sqrt{\dfrac{2(19.5\text{ m})}{9.80\text{ m/s}^2}} = 1.995\text{ s}$

Then $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $v_0 = v_{0x} = \dfrac{x - x_0}{t} = \dfrac{48.0\text{ m}}{1.995\text{ s}} = 24.1\text{ m/s}$.

(b) $v_x = 24.06\text{ m/s}$ since $a_x = 0$. $v_y = v_{0y} + a_y t = -19.55\text{ m/s}$. $v = \sqrt{v_x^2 + v_y^2} = 31.0\text{ m/s}$.

EVALUATE: Note that the speed is considerably less than the algebraic sum of the x- and y-components of the velocity.

3.14. **IDENTIFY:** Knowing the maximum reached by the froghopper and its angle of takeoff, we want to find its takeoff speed and the horizontal distance it travels while in the air.

SET UP: Use coordinates with the origin at the ground and $+y$ upward. $a_x = 0$, $a_y = -9.80\text{ m/s}^2$. At the maximum height $v_y = 0$. The constant-acceleration formulas $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ and $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ apply.

EXECUTE: **(a)** $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$v_{0y} = \sqrt{-2a_y(y - y_0)} = \sqrt{-2(-9.80\text{ m/s}^2)(0.587\text{ m})} = 3.39\text{ m/s}$. $v_{0y} = v_0 \sin\theta_0$ so

$v_0 = \dfrac{v_{0y}}{\sin\theta_0} = \dfrac{3.39\text{ m/s}}{\sin 58.0°} = 4.00\text{ m/s}$.

(b) Use the vertical motion to find the time in the air. When the froghopper has returned to the ground, $y - y_0 = 0$. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = -\dfrac{2v_{0y}}{a_y} = -\dfrac{2(3.39\text{ m/s})}{-9.80\text{ m/s}^2} = 0.692\text{ s}$.

Then $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (v_0 \cos\theta_0)t = (4.00\text{ m/s})(\cos 58.0°)(0.692\text{ s}) = 1.47\text{ m}$.

EVALUATE: $v_y = 0$ when $t = -\dfrac{v_{0y}}{a_y} = -\dfrac{3.39\text{ m/s}}{-9.80\text{ m/s}^2} = 0.346\text{ s}$. The total time in the air is twice this.

3.15. **IDENTIFY:** The ball moves with projectile motion with an initial velocity that is horizontal and has magnitude v_0. The height h of the table and v_0 are the same; the acceleration due to gravity changes from $g_E = 9.80\text{ m/s}^2$ on earth to g_X on planet X.

SET UP: Let $+x$ be horizontal and in the direction of the initial velocity of the marble and let $+y$ be upward. $v_{0x} = v_0$, $v_{0y} = 0$, $a_x = 0$, $a_y = -g$, where g is either g_E or g_X.

EXECUTE: Use the vertical motion to find the time in the air: $y - y_0 = -h$. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = \sqrt{\dfrac{2h}{g}}$. Then $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $x - x_0 = v_{0x}t = v_0\sqrt{\dfrac{2h}{g}}$. $x - x_0 = D$ on earth and $2.76D$ on

Planet X. $(x-x_0)\sqrt{g}=v_0\sqrt{2h}$, which is constant, so $D\sqrt{g_E}=2.76D\sqrt{g_X}$.

$g_X=\dfrac{g_E}{(2.76)^2}=0.131g_E=1.28\text{ m/s}^2$.

EVALUATE: On Planet X the acceleration due to gravity is less, it takes the ball longer to reach the floor and it travels farther horizontally.

3.16. **IDENTIFY:** The shell moves in projectile motion.

SET UP: Let $+x$ be horizontal, along the direction of the shell's motion, and let $+y$ be upward. $a_x=0$, $a_y=-9.80\text{ m/s}^2$.

EXECUTE: **(a)** $v_{0x}=v_0\cos\alpha_0=(40.0\text{ m/s})\cos 60.0°=20.0\text{ m/s}$,
$v_{0y}=v_0\sin\alpha_0=(40.0\text{ m/s})\sin 60.0°=34.6\text{ m/s}$.

(b) At the maximum height $v_y=0$. $v_y=v_{0y}+a_yt$ gives $t=\dfrac{v_y-v_{0y}}{a_y}=\dfrac{0-34.6\text{ m/s}}{-9.80\text{ m/s}^2}=3.53\text{ s}$.

(c) $v_y^2=v_{0y}^2+2a_y(y-y_0)$ gives $y-y_0=\dfrac{v_y^2-v_{0y}^2}{2a_y}=\dfrac{0-(34.6\text{ m/s})^2}{2(-9.80\text{ m/s}^2)}=61.2\text{ m}$.

(d) The total time in the air is twice the time to the maximum height, so
$x-x_0=v_{0x}t+\frac{1}{2}a_xt^2=(20.0\text{ m/s})(2)(3.53\text{ s})=141\text{ m}$.

(e) At the maximum height, $v_x=v_{0x}=20.0\text{ m/s}$ and $v_y=0$. At all points in the motion, $a_x=0$ and $a_y=-9.80\text{ m/s}^2$.

EVALUATE: The equation for the horizontal range R derived in the text is $R=\dfrac{v_0^2\sin 2\alpha_0}{g}$. This gives $R=\dfrac{(40.0\text{ m/s})^2\sin(120.0°)}{9.80\text{ m/s}^2}=141\text{ m}$, which agrees with our result in part (d).

3.17. **IDENTIFY:** The baseball moves in projectile motion. In part (c) first calculate the components of the velocity at this point and then get the resultant velocity from its components.

SET UP: First find the x- and y-components of the initial velocity. Use coordinates where the $+y$-direction is upward, the $+x$-direction is to the right and the origin is at the point where the baseball leaves the bat.

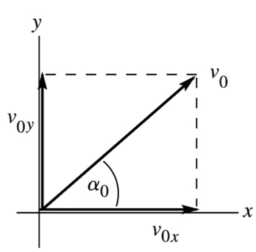

Figure 3.17a

$v_{0x}=v_0\cos\alpha_0=(30.0\text{ m/s})\cos 36.9°=24.0\text{ m/s}$

$v_{0y}=v_0\sin\alpha_0=(30.0\text{ m/s})\sin 36.9°=18.0\text{ m/s}$

Use constant acceleration equations for the x and y motions, with $a_x=0$ and $a_y=-g$.

EXECUTE: **(a)** y-component (vertical motion):

$y-y_0=+10.0\text{ m}$, $v_{0y}=18.0\text{ m/s}$, $a_y=-9.80\text{ m/s}^2$, $t=?$

$y-y_0=v_{0y}+\frac{1}{2}a_yt^2$

$10.0\text{ m}=(18.0\text{ m/s})t-(4.90\text{ m/s}^2)t^2$

$(4.90\ \text{m/s}^2)t^2 - (18.0\ \text{m/s})t + 10.0\ \text{m} = 0$

Apply the quadratic formula: $t = \frac{1}{9.80}\left[18.0 \pm \sqrt{(-18.0)^2 - 4\,(4.90)(10.0)}\right]\ \text{s} = (1.837 \pm 1.154)\ \text{s}$

The ball is at a height of 10.0 above the point where it left the bat at $t_1 = 0.683\ \text{s}$ and at $t_2 = 2.99\ \text{s}$. At the earlier time the ball passes through a height of 10.0 m as its way up and at the later time it passes through 10.0 m on its way down.

(b) $v_x = v_{0x} = +24.0\ \text{m/s}$, at all times since $a_x = 0$.

$v_y = v_{0y} + a_y t$

$\underline{t_1 = 0.683\ \text{s}}$: $v_y = +18.0\ \text{m/s} + (-9.80\ \text{m/s}^2)(0.683\ \text{s}) = +11.3\ \text{m/s}$. ($v_y$ is positive means that the ball is traveling upward at this point.)

$\underline{t_2 = 2.99\ \text{s}}$: $v_y = +18.0\ \text{m/s} + (-9.80\ \text{m/s}^2)(2.99\ \text{s}) = -11.3\ \text{m/s}$. ($v_y$ is negative means that the ball is traveling downward at this point.)

(c) $v_x = v_{0x} = 24.0\ \text{m/s}$

Solve for v_y:

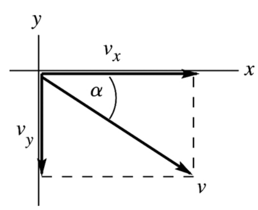
$v_y = ?$, $y - y_0 = 0$ (when ball returns to height where motion started),

$a_y = -9.80\ \text{m/s}^2$, $v_{0y} = +18.0\ \text{m/s}$

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$

$v_y = -v_{0y} = -18.0\ \text{m/s}$ (negative, since the baseball must be traveling downward at this point)

Now solve for the magnitude and direction of $\vec{v}$.



$v = \sqrt{v_x^2 + v_y^2}$

$v = \sqrt{(24.0\ \text{m/s})^2 + (-18.0\ \text{m/s})^2} = 30.0\ \text{m/s}$

$\tan\alpha = \dfrac{v_y}{v_x} = \dfrac{-18.0\ \text{m/s}}{24.0\ \text{m/s}}$

$\alpha = -36.9°$, $36.9°$ below the horizontal

Figure 3.17b

The velocity of the ball when it returns to the level where it left the bat has magnitude 30.0 m/s and is directed at an angle of $36.9°$ below the horizontal.

EVALUATE: The discussion in parts (a) and (b) explains the significance of two values of t for which $y - y_0 = +10.0\ \text{m}$. When the ball returns to its initial height, our results give that its speed is the same as its initial speed and the angle of its velocity below the horizontal is equal to the angle of its initial velocity above the horizontal; both of these are general results.

3.18. **IDENTIFY:** The shot moves in projectile motion.

SET UP: Let $+y$ be upward.

EXECUTE: **(a)** If air resistance is to be ignored, the components of acceleration are 0 horizontally and $-g = -9.80\ \text{m/s}^2$ vertically downward.

(b) The x-component of velocity is constant at $v_x = (12.0\ \text{m/s})\cos 51.0° = 7.55\ \text{m/s}$. The y-component is $v_{0y} = (12.0\ \text{m/s})\sin 51.0° = 9.32\ \text{m/s}$ at release and

$v_y = v_{0y} - gt = (9.32\ \text{m/s}) - (9.80\ \text{m/s})(2.08\ \text{s}) = -11.06\ \text{m/s}$ when the shot hits.

(c) $x - x_0 = v_{0x}t = (7.55\ \text{m/s})(2.08\ \text{s}) = 15.7\ \text{m}$.

(d) The initial and final heights are not the same.
(e) With $y = 0$ and v_{0y} as found above, the equation for $y - y_0$ as a function of time gives $y_0 = 1.81\text{m}$.
(f) The graphs are sketched in Figure 3.18.
EVALUATE: When the shot returns to its initial height, $v_y = -9.32$ m/s. The shot continues to accelerate downward as it travels downward 1.81 m to the ground and the magnitude of v_y at the ground is larger than 9.32 m/s.

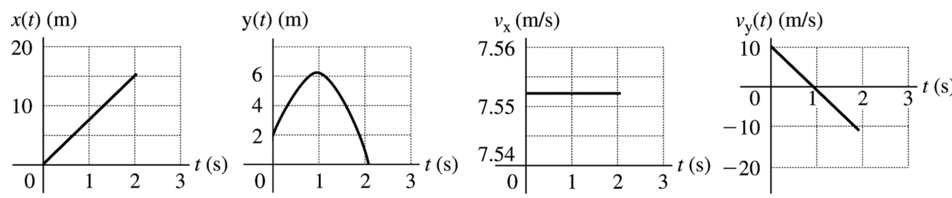


Figure 3.18

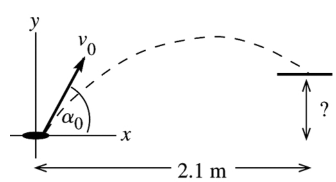
3.19. IDENTIFY: Take the origin of coordinates at the point where the quarter leaves your hand and take positive *y* to be upward. The quarter moves in projectile motion, with $a_x = 0$, and $a_y = -g$. It travels vertically for the time it takes it to travel horizontally 2.1 m.



$v_{0x} = v_0 \cos\alpha_0 = (6.4 \text{ m/s}) \cos 60°$
$v_{0x} = 3.20$ m/s
$v_{0y} = v_0 \sin\alpha_0 = (6.4 \text{ m/s}) \sin 60°$
$v_{0y} = 5.54$ m/s

Figure 3.19

(a) SET UP: Use the horizontal (*x*-component) of motion to solve for *t*, the time the quarter travels through the air:
$t = ?,\ x - x_0 = 2.1 \text{ m},\ v_{0x} = 3.2 \text{ m/s},\ a_x = 0$
$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = v_{0x}t,$ since $a_x = 0$

EXECUTE: $t = \dfrac{x - x_0}{v_{0x}} = \dfrac{2.1 \text{ m}}{3.2 \text{ m/s}} = 0.656 \text{ s}$

SET UP: Now find the vertical displacement of the quarter after this time:
$y - y_0 = ?,\ a_y = -9.80 \text{ m/s}^2,\ v_{0y} = +5.54 \text{ m/s},\ t = 0.656 \text{ s}$
$y - y_0 + v_{0y}t + \frac{1}{2}a_y t^2$

EXECUTE: $y - y_0 = (5.54 \text{ m/s})(0.656 \text{ s}) + \frac{1}{2}(-9.80 \text{ m/s}^2)(0.656 \text{ s})^2 = 3.63 \text{ m} - 2.11 \text{ m} = 1.5 \text{ m}.$

(b) SET UP: $v_y = ?,\ t = 0.656 \text{ s},\ a_y = -9.80 \text{ m/s}^2,\ v_{0y} = +5.54 \text{ m/s} \quad v_y = v_{0y} + a_y t$

EXECUTE: $v_y = 5.54 \text{ m/s} + (-9.80 \text{ m/s}^2)(0.656 \text{ s}) = -0.89 \text{ m/s}.$

EVALUATE: The minus sign for v_y indicates that the *y*-component of $\vec{v}$ is downward. At this point the quarter has passed through the highest point in its path and is on its way down. The horizontal range if it returned to its original height (it doesn't!) would be 3.6 m. It reaches its maximum height after traveling horizontally 1.8 m, so at $x - x_0 = 2.1$ m it is on its way down.

3.20. IDENTIFY: Consider the horizontal and vertical components of the projectile motion. The water travels 45.0 m horizontally in 3.00 s.

SET UP: Let $+y$ be upward. $a_x = 0$, $a_y = -9.80\ \text{m/s}^2$. $v_{0x} = v_0 \cos\theta_0$, $v_{0y} = v_0 \sin\theta_0$.

EXECUTE: **(a)** $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $x - x_0 = v_0(\cos\theta_0)t$ and $\cos\theta_0 = \dfrac{45.0\ \text{m}}{(25.0\ \text{m/s})(3.00\ \text{s})} = 0.600$; $\theta_0 = 53.1°$

(b) At the highest point $v_x = v_{0x} = (25.0\ \text{m/s})\cos 53.1° = 15.0\ \text{m/s}$, $v_y = 0$ and $v = \sqrt{v_x^2 + v_y^2} = 15.0\ \text{m/s}$. At all points in the motion, $a = 9.80\ \text{m/s}^2$ downward.

(c) Find $y - y_0$ when $t = 3.00\text{s}$:

$$y - y_0 = v_{0y}t + \tfrac{1}{2}a_y t^2 = (25.0\ \text{m/s})(\sin 53.1°)(3.00\ \text{s}) + \tfrac{1}{2}(-9.80\ \text{m/s}^2)(3.00\ \text{s})^2 = 15.9\ \text{m}$$

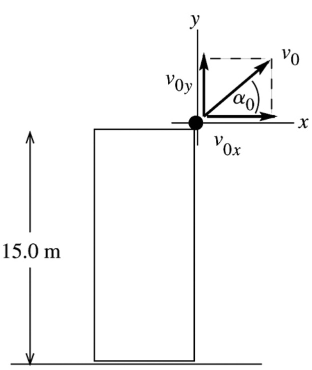
$v_x = v_{0x} = 15.0\ \text{m/s}$, $v_y = v_{0y} + a_y t = (25.0\ \text{m/s})(\sin 53.1°) - (9.80\text{m/s}^2)(3.00\ \text{s}) = -9.41\ \text{m/s}$, and

$$v = \sqrt{v_x^2 + v_y^2} = \sqrt{(15.0\ \text{m/s})^2 + (-9.41\ \text{m/s})^2} = 17.7\ \text{m/s}$$

EVALUATE: The acceleration is the same at all points of the motion. It takes the water $t = -\dfrac{v_{0y}}{a_y} = -\dfrac{20.0\ \text{m/s}}{-9.80\ \text{m/s}^2} = 2.04\ \text{s}$ to reach its maximum height. When the water reaches the building it has passed its maximum height and its vertical component of velocity is downward.

3.21. IDENTIFY: Take the origin of coordinates at the roof and let the $+y$-direction be upward. The rock moves in projectile motion, with $a_x = 0$ and $a_y = -g$. Apply constant acceleration equations for the x and y components of the motion.

SET UP:



$v_{0x} = v_0 \cos\alpha_0 = 25.2\ \text{m/s}$

$v_{0y} = v_0 \sin\alpha_0 = 16.3\ \text{m/s}$

Figure 3.21a

(a) At the maximum height $v_y = 0$.

$a_y = -9.80\ \text{m/s}^2$, . $v_y = 0$, . $v_{0y} = +16.3\ \text{m/s}$, $y - y_0 = ?$

$v_y^2 = v_{0y}^2 + 2a_y\,(y - y_0)$

EXECUTE: $y - y_0 = \dfrac{v_y^2 - v_{0y}^2}{2a_y} = \dfrac{0 - (16.3\ \text{m/s})^2}{2(-9.80\ \text{m/s}^2)} = +13.6\ \text{m}$

(b) SET UP: Find the velocity by solving for its x and y components.

$v_x = v_{0x} = 25.2\ \text{m/s}$ (since $a_x = 0$)

$v_y = ?,\ a_y = -9.80\ \text{m/s}^2,\ y - y_0 = -15.0\ \text{m}$ (negative because at the ground the rock is below its initial position), $v_{0y} = 16.3\ \text{m/s}$

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$

$v_y = -\sqrt{v_{0y}^2 + 2a_y(y - y_0)}$ (v_y is negative because at the ground the rock is traveling downward.)

EXECUTE: $v_y = -\sqrt{(16.3\ \text{m/s})^2 + 2(-9.80\ \text{m/s}^2)(-15.0\ \text{m})} = -23.7\ \text{m/s}$

Then $v = \sqrt{v_x^2 + v_y^2} = \sqrt{(25.2\ \text{m/s})^2 + (-23.7\ \text{m/s})^2} = 34.6\ \text{m/s}$.

(c) SET UP: Use the vertical motion (y-component) to find the time the rock is in the air:
$t = ?,\ v_y = -23.7\ \text{m/s}$ (from part (b)), $a_y = -9.80\ \text{m/s}^2,\ v_{0y} = +16.3\ \text{m/s}$

EXECUTE: $t = \dfrac{v_y - v_{0y}}{a_y} = \dfrac{-23.7\ \text{m/s} - 16.3\ \text{m/s}}{-9.80\ \text{m/s}^2} = +4.08\ \text{s}$

SET UP: Can use this t to calculate the horizontal range:
$t = 4.08\ \text{s},\ v_{0x} = 25.2\ \text{m/s},\ a_x = 0,\ x - x_0 = ?$

EXECUTE: $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (25.2\ \text{m/s})(4.08\ \text{s}) + 0 = 103\ \text{m}$

(d) Graphs of x versus t, y versus t, v_x versus t and v_y versus t:

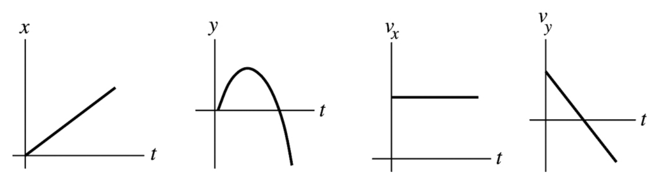


Figure 3.21b

EVALUATE: The time it takes the rock to travel vertically to the ground is the time it has to travel horizontally. With $v_{0y} = +16.3\ \text{m/s}$ the time it takes the rock to return to the level of the roof $(y = 0)$ is $t = 2v_{0y}/g = 3.33\ \text{s}$. The time in the air is greater than this because the rock travels an additional 15.0 m to the ground.

3.22. IDENTIFY: This is a problem in projectile motion. The acceleration is g downward with constant horizontal velocity. The constant-acceleration equations apply.

SET UP: We use $y = (v_0 \sin\alpha_0)t - \frac{1}{2}gt^2$ and $v_y = v_0 \sin\alpha_0 - gt$ for the vertical motion and $v_x = v_0 \cos\alpha_0$ for the horizontal motion. We want the time when $y = 5.00$ m.

EXECUTE: Use $y = (v_0 \sin\alpha_0)t - \frac{1}{2}gt^2$ to find the times.

$5.00\ \text{m} = (15.0\ \text{m/s})(\sin 53.0°)t - \frac{1}{2}(9.80\ \text{m/s}^2)t^2$

Using the quadratic formula to solve this equation gives $t = 0.534$ s and $t = 1.91$ s.
Now look at the horizontal velocity.
$v_x = v_0 \cos\alpha_0 = (15.0\ \text{m/s}) \cos 53.0° = 9.03\ \text{m/s}$ at both times.
At $t = 0.534$ s: $v_y = v_0 \sin\alpha_0 - gt = (15.0\ \text{m/s}) \sin 53.0° - (9.80\ \text{m/s}^2)(0.534\ \text{s}) = 6.75\ \text{m/s}$ upward.
At $t = 1.92$ s: $v_y = (15.0\ \text{m/s}) \sin 53.0° - (9.80\ \text{m/s}^2)(1.92\ \text{s}) = -6.75\ \text{m/s}$ downward.

EVALUATE: To check, use $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ to find v_y when y = 5.00 m, which gives $v_y^2 =$ [(15.0 m/s)(sin 53.0°)]^2 – 2(9.80 m/s^2)(5.00 m) $\rightarrow$ v_y = ±6.75 m/s, which agrees with our results. We get two answers because the rock is going upward at t = 0.534 s and downward at t = 1.91 s.

3.23. **IDENTIFY:** This is a problem in projectile motion. The acceleration is g downward with constant horizontal velocity. The constant-acceleration equations apply.

SET UP: Estimate: 75 ft which is about 25 m. The range of a projectile is $R = \dfrac{v_0^2}{g}\sin 2\alpha_0$. For the maximum range, $2\alpha_0$ = 90°, so α_0 = 45°, so we assume that we throw it at 45° above the horizontal.

EXECUTE: **(a)** Solve the range formula for v_0: $v_0 = \sqrt{Rg} = \sqrt{(25\text{ m})(9.80\text{ m/s}^2)}$ = 15.65 m/s, which rounds to 16 m/s.

(b) At the maximum height, v_y = 0. Using $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ with $y - y_0 = h$ gives 0 = [(15.65 m/s)(sin 45°)]^2 – 2(9.80 m/s^2)h $\rightarrow$ h = 6.5 m.

(c) Apply the range formula on Mars: $R = \dfrac{(15.65\text{ m/s})^2}{3.7\text{ m/s}^2}\sin 90°$ = 66 m.

EVALUATE: The range is inversely proportional to g, so $R_M/R_E = g_E/g_M$ = 9.8/3.7 = 2.65. So the range of Mars would be 2.65 times the range on earth, which is (2.65)(25 m) = 66 m, in agreement with our result.

3.24. **IDENTIFY:** The merry-go-round is rotating at a constant rate.

SET UP: Estimate: T = 5.0 s for one rotation. Convert units: R = 6.0 ft = 1.829 m. The radial acceleration is $a_{rad} = \dfrac{v^2}{R}$ and $v = 2\pi R/T$.

EXECUTE: **(a)** $v = 2\pi R/T = 2\pi(1.829\text{ m})/(5.0\text{ s})$ = 2.3 m/s.

(b) $a_{rad} = \dfrac{v^2}{R}$ = (2.3 m/s)^2/(1.829 m) = 2.9 m/s^2.

(c) If $T \rightarrow T/2$, $v \rightarrow 2v$ so $v^2 \rightarrow 4v^2$. Since $a_{rad} \propto v^2$, $a_{rad} \rightarrow 4a_{rad}$ = 4(2.9 m/s^2) = 12 m/s^2.

EVALUATE: The acceleration in part (b) is 2.9/9.8 g = 0.30g, which seems a bit large for a merry-go-round for young children. Perhaps the estimate of 5.0 s is too small. If we revise the estimate to 10 s, v will become 1.15 m/s and a_{rad} will become 0.72 m/s^2, which is 0.72/9.8 g = 0.074g. This is about 7.4% of g, which seems a bit more reasonable.

3.25. **IDENTIFY:** This problem deals with circular motion.

SET UP: Apply the equation $a_{rad} = 4\pi^2 R/T^2$, where T = 24 h.

EXECUTE: **(a)** $a_{rad} = \dfrac{4\pi^2(6.38\times10^6\text{ m})}{[(24\text{ h})(3600\text{ s/h})]^2} = 0.034\text{ m/s}^2 = 3.4\times10^{-3}g.$

(b) Solving the equation $a_{rad} = 4\pi^2 R/T^2$ for the period T with $a_{rad} = g$,

$$T = \sqrt{\frac{4\pi^2(6.38\times10^6\text{m})}{9.80\text{ m/s}^2}} = 5070\text{ s} = 1.4\text{ h}.$$

EVALUATE: a_{rad} is proportional to $1/T^2$, so to increase a_{rad} by a factor of $\dfrac{1}{3.4\times10^{-3}} = 294$ requires that T be multiplied by a factor of $\dfrac{1}{\sqrt{294}}$. $\dfrac{24\text{ h}}{\sqrt{294}} = 1.4\text{ h}.$

3.26. **IDENTIFY:** We want to find the acceleration of the inner ear of a dancer, knowing the rate at which she spins.

SET UP: $R = 0.070$ m. For 3.0 rev/s, the period T (time for one revolution) is $T = \dfrac{1.0 \text{ s}}{3.0 \text{ rev}} = 0.333$ s.

The speed is $v = d/T = (2\pi R)/T$, and $a_{\text{rad}} = v^2/R$.

EXECUTE: $a_{\text{rad}} = \dfrac{v^2}{R} = \dfrac{(2\pi R/T)^2}{R} = \dfrac{4\pi^2 R}{T^2} = \dfrac{4\pi^2(0.070 \text{ m})}{(0.333 \text{ s})^2} = 24.92 \text{ m/s}^2$, which rounds to 25 m/s^2 with two significant figures. As a fraction of g, this acceleration is $(24.92 \text{ m/s}^2)/(9.80 \text{ m/s}^2) = 2.54$, which rounds to 2.5 to two significant figures.

EVALUATE: The acceleration is large and the force on the fluid must be 2.5 times its weight.

3.27. **IDENTIFY:** The ball has no vertical acceleration, but it has a horizontal acceleration toward the center of the circle. This acceleration is the radial acceleration.

SET UP: $a_{\text{rad}} = \dfrac{4\pi^2 R}{T^2}$, $R = L \sin\theta$.

EXECUTE: Use $a_{\text{rad}} = \dfrac{4\pi^2 R}{T^2}$ with $R = L \sin\theta$. $a_{\text{rad}} = \dfrac{4\pi^2 L \sin\theta}{T^2}$. Using $L = 0.800$ m, $\theta = 37.0°$, and $T = 0.600$ s, this gives $a_{\text{rad}} = 52.8 \text{ m/s}^2$.

EVALUATE: Compare this acceleration to g: $a_{\text{rad}}/g = 52.8/9.80 = 5.39$, so $a_{\text{rad}} = 5.39g$, which is fairly large.

3.28. **IDENTIFY:** Each blade tip moves in a circle of radius $R = 3.40$ m and therefore has radial acceleration $a_{\text{rad}} = v^2/R$.

SET UP: 550 rev/min = 9.17 rev/s, corresponding to a period of $T = \dfrac{1}{9.17 \text{ rev/s}} = 0.109$ s.

EXECUTE: **(a)** $v = \dfrac{2\pi R}{T} = 196$ m/s.

(b) $a_{\text{rad}} = \dfrac{v^2}{R} = 1.13\times10^4 \text{ m/s}^2 = 1.15\times10^3 g$.

EVALUATE: $a_{\text{rad}} = \dfrac{4\pi^2 R}{T^2}$ gives the same results for a_{rad} as in part (b).

3.29. **IDENTIFY:** For the curved lowest part of the dive, the pilot's motion is approximately circular. We know the pilot's acceleration and the radius of curvature, and from this we want to find the pilot's speed.

SET UP: $a_{\text{rad}} = 5.5g = 53.9 \text{ m/s}^2$. 1 mph = 0.4470 m/s. $a_{\text{rad}} = \dfrac{v^2}{R}$.

EXECUTE: $a_{\text{rad}} = \dfrac{v^2}{R}$, so $v = \sqrt{Ra_{\text{rad}}} = \sqrt{(280 \text{ m})(53.9 \text{ m/s}^2)} = 122.8 \text{ m/s} = 274.8$ mph. Rounding these answers to 2 significant figures (because of $5.5g$), gives $v = 120$ m/s = 270 mph.

EVALUATE: This speed is reasonable for the type of plane flown by a test pilot.

3.30. **IDENTIFY:** The object has constant horizontal speed (but *not* constant velocity), so its acceleration points toward the center of the circle. This is the radial acceleration.

SET UP: We know v and T and we want a_{rad} in terms of v and T. $a_{\text{rad}} = \dfrac{v^2}{R}$ and $v = 2\pi R/T$.

EXECUTE: We want to express a_{rad} in terms of v and T. From $v = 2\pi R/T$ we get $R = vT/2\pi$, so

$$a_{\text{rad}} = \frac{v^2}{(vT/2\pi)} = 2\pi v/T.$$

(a) Using $a_{\text{rad}} = 2\pi v/T$, we see that if v doubles, T must also double to keep a_{rad} the same.

(b) First express a_{rad} in terms of R and T as $a_{rad} = \dfrac{4\pi^2 R}{T^2}$. If R doubles, the T^2 must also double to keep a_{rad} the same. Therefore T must increase by a factor of $\sqrt{2}$.

EVALUATE: Using $a_{rad} = 2\pi v/T$ would not be helpful in part (b) because the equation does not contain R.

3.31. **IDENTIFY:** Uniform circular motion.

SET UP: Since the magnitude of $\vec{v}$ is constant, $v_{tan} = \dfrac{d|\vec{v}|}{dt} = 0$ and the resultant acceleration is equal to the radial component. At each point in the motion the radial component of the acceleration is directed in toward the center of the circular path and its magnitude is given by v^2/R.

EXECUTE: **(a)** $a_{rad} = \dfrac{v^2}{R} = \dfrac{(6.00\text{ m/s})^2}{14.0\text{ m}} = 2.57\text{ m/s}^2$, upward.

(b) The radial acceleration has the same magnitude as in part (a), but now the direction toward the center of the circle is downward. The acceleration at this point in the motion is 2.57 m/s^2, downward.

(c) SET UP: The time to make one rotation is the period T, and the speed v is the distance for one revolution divided by T.

EXECUTE: $v = \dfrac{2\pi R}{T}$ so $T = \dfrac{2\pi R}{v} = \dfrac{2\pi\,(14.0\text{ m})}{6.00\text{ m/s}} = 14.7\text{ s}$.

EVALUATE: The radial acceleration is constant in magnitude since v is constant and is at every point in the motion directed toward the center of the circular path. The acceleration is perpendicular to $\vec{v}$ and is nonzero because the direction of $\vec{v}$ changes.

3.32. **IDENTIFY:** The roller coaster car is going in a circle. Its radial acceleration is always toward the center of the circle.

SET UP: $a_{rad} = \dfrac{v^2}{R}$

EXECUTE: **(a)** The radial acceleration is toward the center of the circle, which is directly downward when the car is at the top.

(b) By the same reasoning as in (a), the direction is vertically upward when the car is at the bottom.

(c) Use $a_{rad} = \dfrac{v^2}{R}$ and take the ratio of the accelerations: $\dfrac{a_{rad,bottom}}{a_{rad,top}} = \dfrac{v_2^2/R}{v_1^2/R} = (v_2/v_1)^2$.

EVALUATE: Our result shows that the acceleration is greater at the bottom since $v_2 > v_1$.

3.33. **IDENTIFY:** Each part of his body moves in uniform circular motion, with $a_{rad} = \dfrac{v^2}{R}$. The speed in rev/s is $1/T$, where T is the period in seconds (time for 1 revolution). The speed v increases with R along the length of his body but all of him rotates with the same period T.

SET UP: For his head $R = 8.84$ m and for his feet $R = 6.84$ m.

EXECUTE: **(a)** $v = \sqrt{Ra_{rad}} = \sqrt{(8.84\text{ m})(12.5)(9.80\text{ m/s}^2)} = 32.9\text{ m/s}$

(b) Use $a_{rad} = \dfrac{4\pi^2 R}{T^2}$. Since his head has $a_{rad} = 12.5g$ and $R = 8.84$ m,

$T = 2\pi\sqrt{\dfrac{R}{a_{rad}}} = 2\pi\sqrt{\dfrac{8.84\text{m}}{12.5(9.80\text{m/s}^2)}} = 1.688\text{s}$. Then his feet have $a_{rad} = \dfrac{R}{T^2} = \dfrac{4\pi^2(6.84\text{m})}{(1.688\text{s})^2} = 94.8\text{m/s}^2 =$ 9.67 g. The difference between the acceleration of his head and his feet is $12.5g - 9.67g = 2.83g = 27.7\text{ m/s}^2$.

(c) $\dfrac{1}{T} = \dfrac{1}{1.69\text{ s}} = 0.592\text{ rev/s} = 35.5\text{ rpm}$

EVALUATE: His feet have speed $v = \sqrt{Ra_{\text{rad}}} = \sqrt{(6.84\text{ m})(94.8\text{ m/s}^2)} = 25.5\text{ m/s}.$

3.34. **IDENTIFY:** Each planet moves in a circular orbit and therefore has acceleration $a_{\text{rad}} = v^2/R.$

SET UP: The radius of the earth's orbit is $r = 1.50 \times 10^{11}\text{ m}$ and its orbital period is $T = 365\text{ days} = 3.16 \times 10^7\text{ s}.$ For Mercury, $r = 5.79 \times 10^{10}\text{ m}$ and $T = 88.0\text{ days} = 7.60 \times 10^6\text{ s}.$

EXECUTE: **(a)** $v = \dfrac{2\pi r}{T} = 2.98 \times 10^4\text{ m/s}$

(b) $a_{\text{rad}} = \dfrac{v^2}{r} = 5.91 \times 10^{-3}\text{ m/s}^2.$

(c) $v = 4.79 \times 10^4\text{ m/s},$ and $a_{\text{rad}} = 3.96 \times 10^{-2}\text{ m/s}^2.$

EVALUATE: Mercury has a larger orbital velocity and a larger radial acceleration than earth.

3.35. **IDENTIFY:** Relative velocity problem. The time to walk the length of the moving sidewalk is the length divided by the velocity of the woman relative to the ground.

SET UP: Let W stand for the woman, G for the ground and S for the sidewalk. Take the positive direction to be the direction in which the sidewalk is moving.

The velocities are $v_{\text{W/G}}$ (woman relative to the ground), $v_{\text{W/S}}$ (woman relative to the sidewalk), and $v_{\text{S/G}}$ (sidewalk relative to the ground).

The equation for relative velocity becomes $v_{\text{W/G}} = v_{\text{W/S}} + v_{\text{S/G}}.$

The time to reach the other end is given by $t = \dfrac{\text{distance traveled relative to ground}}{v_{\text{W/G}}}$

EXECUTE: **(a)** $v_{\text{S/G}} = 1.0\text{ m/s}$

$v_{\text{W/S}} = +1.5\text{ m/s}$

$v_{\text{W/G}} = v_{\text{W/S}} + v_{\text{S/G}} = 1.5\text{ m/s} + 1.0\text{ m/s} = 2.5\text{ m/s}.$

$t = \dfrac{35.0\text{ m}}{v_{\text{W/G}}} = \dfrac{35.0\text{ m}}{2.5\text{ m/s}} = 14\text{ s}.$

(b) $v_{\text{S/G}} = 1.0\text{ m/s}$

$v_{\text{W/S}} = -1.5\text{ m/s}$

$v_{\text{W/G}} = v_{\text{W/S}} + v_{\text{S/G}} = -1.5\text{ m/s} + 1.0\text{ m/s} = -0.5\text{ m/s}.$ (Since $v_{\text{W/G}}$ now is negative, she must get on the moving sidewalk at the opposite end from in part (a).)

$t = \dfrac{-35.0\text{ m}}{v_{\text{W/G}}} = \dfrac{-35.0\text{ m}}{-0.5\text{ m/s}} = 70\text{ s}.$

EVALUATE: Her speed relative to the ground is much greater in part (a) when she walks with the motion of the sidewalk.

3.36. **IDENTIFY:** The relative velocities are $\vec{v}_{\text{S/F}}$, the velocity of the scooter relative to the flatcar, $\vec{v}_{\text{S/G}}$, the scooter relative to the ground and $\vec{v}_{\text{F/G}}$, the flatcar relative to the ground. $\vec{v}_{\text{S/G}} = \vec{v}_{\text{S/F}} + \vec{v}_{\text{F/G}}$. Carry out the vector addition by drawing a vector addition diagram.

SET UP: $\vec{v}_{\text{S/F}} = \vec{v}_{\text{S/G}} - \vec{v}_{\text{F/G}}$. $\vec{v}_{\text{F/G}}$ is to the right, so $-\vec{v}_{\text{F/G}}$ is to the left.

EXECUTE: In each case the vector addition diagram gives

(a) 5.0 m/s to the right

(b) 16.0 m/s to the left

(c) 13.0 m/s to the left.

EVALUATE: The scooter has the largest speed relative to the ground when it is moving to the right relative to the flatcar, since in that case the two velocities $\vec{v}_{\text{S/F}}$ and $\vec{v}_{\text{F/G}}$ are in the same direction and their magnitudes add.

3.37. **IDENTIFY:** Apply the relative velocity relation.
SET UP: The relative velocities are $\vec{v}_{\text{C/E}}$, the canoe relative to the earth, $\vec{v}_{\text{R/E}}$, the velocity of the river relative to the earth and $\vec{v}_{\text{C/R}}$, the velocity of the canoe relative to the river.
EXECUTE: $\vec{v}_{\text{C/E}} = \vec{v}_{\text{C/R}} + \vec{v}_{\text{R/E}}$ and therefore $\vec{v}_{\text{C/R}} = \vec{v}_{\text{C/E}} - \vec{v}_{\text{R/E}}$. The velocity components of $\vec{v}_{\text{C/R}}$ are $-0.50\text{ m/s} + (0.40\text{ m/s})/\sqrt{2}$, east and $(0.40\text{ m/s})/\sqrt{2}$, south, for a velocity relative to the river of 0.36 m/s, at $52.5°$ south of west.
EVALUATE: The velocity of the canoe relative to the river has a smaller magnitude than the velocity of the canoe relative to the earth.

3.38. **IDENTIFY:** Calculate the rower's speed relative to the shore for each segment of the round trip.
SET UP: The boat's speed relative to the shore is 6.8 km/h downstream and 1.2 km/h upstream.
EXECUTE: The walker moves a total distance of 3.0 km at a speed of 4.0 km/h, and takes a time of three fourths of an hour (45.0 min).
The total time the rower takes is $\dfrac{1.5\text{ km}}{6.8\text{ km/h}} + \dfrac{1.5\text{ km}}{1.2\text{ km/h}} = 1.47\text{ h} = 88.2\text{ min}.$
EVALUATE: It takes the rower longer, even though for half the distance his speed is greater than 4.0 km/h. The rower spends more time at the slower speed.

3.39. **IDENTIFY:** The resultant velocity, relative to the ground, is directly southward. This velocity is the sum of the velocity of the bird relative to the air and the velocity of the air relative to the ground.
SET UP: $v_{\text{B/A}} = 100\text{ km/h}$. $\vec{v}_{\text{A/G}} = 40\text{ km/h}$, east. $\vec{v}_{\text{B/G}} = \vec{v}_{\text{B/A}} + \vec{v}_{\text{A/G}}$.
EXECUTE: We want $\vec{v}_{\text{B/G}}$ to be due south. The relative velocity addition diagram is shown in Figure 3.39.

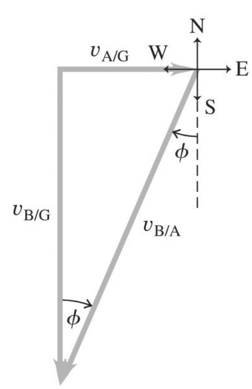

Figure 3.39

(a) $\sin\phi = \dfrac{v_{\text{A/G}}}{v_{\text{B/A}}} = \dfrac{40\text{ km/h}}{100\text{ km/h}}$, $\phi = 24°$, west of south.

(b) $v_{\text{B/G}} = \sqrt{v_{\text{B/A}}^2 - v_{\text{A/G}}^2} = 91.7\text{ km/h}$. $t = \dfrac{d}{v_{\text{B/G}}} = \dfrac{500\text{ km}}{91.7\text{ km/h}} = 5.5\text{ h}.$

EVALUATE: The speed of the bird relative to the ground is less than its speed relative to the air. Part of its velocity relative to the air is directed to oppose the effect of the wind.

3.40. **IDENTIFY:** Relative velocity problem in two dimensions.

(a) SET UP: $\vec{v}_{P/A}$ is the velocity of the plane relative to the air. The problem states that $\vec{v}_{P/A}$ has magnitude 35 m/s and direction south.

$\vec{v}_{A/E}$ is the velocity of the air relative to the earth. The problem states that $\vec{v}_{A/E}$ is to the southwest ($45°$ S of W) and has magnitude 10 m/s.

The relative velocity equation is $\vec{v}_{P/E} = \vec{v}_{P/A} + \vec{v}_{A/E}$.

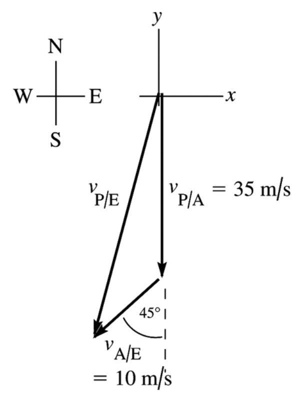

Figure 3.40a

EXECUTE: **(b)** $(v_{P/A})_x = 0,\ (v_{P/A})_y = -35$ m/s

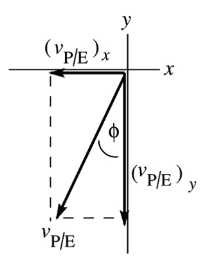
$(v_{A/E})_x = -(10 \text{ m/s})\cos 45° = -7.07$ m/s,

$(v_{A/E})_y = -(10 \text{ m/s})\sin 45° = -7.07$ m/s

$(v_{P/E})_x = (v_{P/A})_x + (v_{A/E})_x = 0 - 7.07 \text{ m/s} = -7.1$ m/s

$(v_{P/E})_y = (v_{P/A})_y + (v_{A/E})_y = -35 \text{ m/s} - 7.07 \text{ m/s} = -42$ m/s

(c)



$$v_{P/E} = \sqrt{(v_{P/E})_x^2 + (v_{P/E})_y^2}$$

$$v_{P/E} = \sqrt{(-7.1 \text{ m/s})^2 + (-42 \text{ m/s})^2} = 43 \text{ m/s}$$

$$\tan\phi = \frac{(v_{P/E})_x}{(v_{P/E})_y} = \frac{-7.1}{-42} = 0.169$$

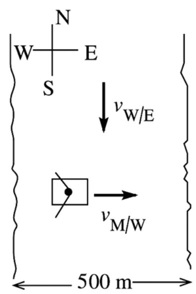
$\phi = 9.6°$; ($9.6°$ west of south)

Figure 3.40b

EVALUATE: The relative velocity addition diagram does not form a right triangle so the vector addition must be done using components. The wind adds both southward and westward components to the velocity of the plane relative to the ground.

3.41. **IDENTIFY:** Relative velocity problem in two dimensions. His motion relative to the earth (time displacement) depends on his velocity relative to the earth so we must solve for this velocity.

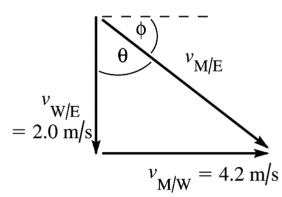
(a) SET UP: View the motion from above.



The velocity vectors in the problem are:
$\vec{v}_{M/E}$, the velocity of the man relative to the earth
$\vec{v}_{W/E}$, the velocity of the water relative to the earth
$\vec{v}_{M/W}$, the velocity of the man relative to the water
The rule for adding these velocities is
$\vec{v}_{M/E} = \vec{v}_{M/W} + \vec{v}_{W/E}$

Figure 3.41a

The problem tells us that $\vec{v}_{W/E}$ has magnitude 2.0 m/s and direction due south. It also tells us that $\vec{v}_{M/W}$ has magnitude 4.2 m/s and direction due east. The vector addition diagram is then as shown in Figure 3.41b.



This diagram shows the vector addition
$\vec{v}_{M/E} = \vec{v}_{M/W} + \vec{v}_{W/E}$
and also has $\vec{v}_{M/W}$ and $\vec{v}_{W/E}$ in their specified directions. Note that the vector diagram forms a right triangle.

Figure 3.41b

The Pythagorean theorem applied to the vector addition diagram gives $v_{M/E}^2 = v_{M/W}^2 + v_{W/E}^2$.

EXECUTE: $v_{M/E} = \sqrt{v_{M/W}^2 + v_{W/E}^2} = \sqrt{(4.2\text{ m/s})^2 + (2.0\text{ m/s})^2} = 4.7\text{ m/s}$; $\tan\theta = \dfrac{v_{M/W}}{v_{W/E}} = \dfrac{4.2\text{ m/s}}{2.0\text{ m/s}} = 2.10$; $\theta = 65°$; or $\phi = 90° - \theta = 25°$. The velocity of the man relative to the earth has magnitude 4.7 m/s and direction 25° S of E.

(b) This requires careful thought. To cross the river the man must travel 500 m due east relative to the earth. The man's velocity relative to the earth is $\vec{v}_{M/E}$. But, from the vector addition diagram the eastward component of $v_{M/E}$ equals $v_{M/W} = 4.2$ m/s.

Thus $t = \dfrac{x - x_0}{v_x} = \dfrac{500\text{ m}}{4.2\text{ m/s}} = 119\text{ s}$, which we round to 120 s.

(c) The southward component of $\vec{v}_{M/E}$ equals $v_{W/E} = 2.0$ m/s. Therefore, in the 120 s it takes him to cross the river, the distance south the man travels relative to the earth is

$$y - y_0 = v_y t = (2.0\text{ m/s})(119\text{ s}) = 240\text{ m}.$$

EVALUATE: If there were no current he would cross in the same time, $(500\text{ m})/(4.2\text{ m/s}) = 120\text{ s}$. The current carries him downstream but doesn't affect his motion in the perpendicular direction, from bank to bank.

3.42. **IDENTIFY:** Use the relation that relates the relative velocities.

SET UP: The relative velocities are the water relative to the earth, $\vec{v}_{W/E}$, the boat relative to the water, $\vec{v}_{B/W}$, and the boat relative to the earth, $\vec{v}_{B/E}$. $\vec{v}_{B/E}$ is due east, $\vec{v}_{W/E}$ is due south and has magnitude 2.0 m/s. $v_{B/W} = 4.2$ m/s. $\vec{v}_{B/E} = \vec{v}_{B/W} + \vec{v}_{W/E}$. The velocity addition diagram is given in Figure 3.42.

EXECUTE: **(a)** Find the direction of $\vec{v}_{B/W}$. $\sin\theta = \dfrac{v_{W/E}}{v_{B/W}} = \dfrac{2.0\text{ m/s}}{4.2\text{ m/s}}$. $\theta = 28.4°$, north of east.

(b) $v_{B/E} = \sqrt{v_{B/W}^2 - v_{W/E}^2} = \sqrt{(4.2\text{ m/s})^2 - (2.0\text{ m/s})^2} = 3.7\text{ m/s}$

(c) $t = \dfrac{800\text{ m}}{v_{B/E}} = \dfrac{800\text{ m}}{3.7\text{ m/s}} = 216\text{ s}.$

EVALUATE: It takes longer to cross the river in this problem than it did in Problem 3.41. In the direction straight across the river (east) the component of his velocity relative to the earth is less than 4.2 m/s.

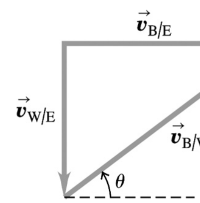


Figure 3.42

3.43. **IDENTIFY:** Use the relation that relates the relative velocities.

SET UP: The relative velocities are the velocity of the plane relative to the ground, $\vec{v}_{P/G}$, the velocity of the plane relative to the air, $\vec{v}_{P/A}$, and the velocity of the air relative to the ground, $\vec{v}_{A/G}$. $\vec{v}_{P/G}$ must be due west and $\vec{v}_{A/G}$ must be south. $v_{A/G} = 80\text{ km/h}$ and $v_{P/A} = 320\text{ km/h}$. $\vec{v}_{P/G} = \vec{v}_{P/A} + \vec{v}_{A/G}$. The relative velocity addition diagram is given in Figure 3.43.

EXECUTE: **(a)** $\sin\theta = \dfrac{v_{A/G}}{v_{P/A}} = \dfrac{80\text{ km/h}}{320\text{ km/h}}$ and $\theta = 14°$, north of west.

(b) $v_{P/G} = \sqrt{v_{P/A}^2 - v_{A/G}^2} = \sqrt{(320\text{ km/h})^2 - (80.0\text{ km/h})^2} = 310\text{ km/h}.$

EVALUATE: To travel due west the velocity of the plane relative to the air must have a westward component and also a component that is northward, opposite to the wind direction.

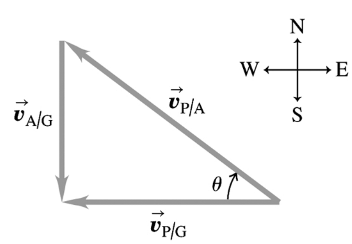

Figure 3.43

3.44. **IDENTIFY:** The dog runs away from a tree with a non-constant acceleration, so the constant-acceleration equations do not apply. We need to go to the basic definitions of *a* and *v* in terms of calculus.

SET UP: The dog starts from rest at the tree when $t = 0$, so $x_0 = 0$ and $v_0 = 0$. The dog's acceleration is given by $\vec{a} = (0.400\ \text{m/s}^2)\hat{i} - (0.180\ \text{m/s}^3)t\,\hat{j}$, so we see that $a_x = 0.400\ \text{m/s}^2$ and $a_y = -0.180\ \text{m/s}^3\ t$. The basic definitions are $a_x = dv_x/dt$ and $v_x = dx/dt$, and likewise for the y-components. We want to know how far the dog is from the tree at the end of 8.00 s of running. By integration of the acceleration we can find the x and y components of the dog's position vector at 8.00 s. From these components we can find the magnitude of the dog's position vector.

EXECUTE: First find the components of the dog's velocity using $a_x = dv_x/dt$ and $a_y = dv_y/dt$.

x-coordinate: We can save some time because $a_x = 0.400\ \text{m/s}^2$ is a constant. So we can use $x = x_0 + v_{0x}t + \frac{1}{2}a_x t^2$, which gives $x = \frac{1}{2}a_x t^2 = \frac{1}{2}(0.400\ \text{m/s}^2)(8.00\ \text{s})^2 = 12.80\ \text{m}$.

y-coordinate: First find v_y using $a_y = dv_y/dt$. This gives $v_y = \int a_y dt = \int kt\,dt = \frac{kt^2}{2}$, where we let $k = -0.180\ \text{m/s}^3$ for convenience. We have used $v_y = 0$ when $t = 0$. Now use $v_y = dy/dt$ to find $y(t)$.

$y = \int v_y dt = \int \frac{kt^2}{2} dt = \frac{kt^3}{6}$, where we have used $y = 0$ when $t = 0$. At 8.00 s, we have

$$y = \frac{(-0.180\ \text{m/s}^3)(8.00\ \text{s})^3}{6} = -15.36\ \text{m}.$$

Now use $A = \sqrt{A_x^2 + A_y^2}$ to find the dog's distance d from the tree. $d = \sqrt{(12.80\ \text{m})^2 + (-15.36\ \text{m})^2} = 20.0\ \text{m}$.

EVALUATE: The use of components makes the solution to this problem quite straightforward.

3.45. **IDENTIFY:** $\vec{v} = d\vec{r}/dt$. This vector will make a $45°$ angle with both axes when its x- and y-components are equal.

SET UP: $\dfrac{d(t^n)}{dt} = nt^{n-1}$.

EXECUTE: $\vec{v} = 2bt\hat{i} + 3ct^2\hat{j}$. $v_x = v_y$ gives $t = 2b/3c$.

EVALUATE: Both components of $\vec{v}$ change with t.

3.46. **IDENTIFY:** The acceleration is not constant but is known as a function of time.

SET UP: Integrate the acceleration to get the velocity and the velocity to get the position. At the maximum height $v_y = 0$.

EXECUTE: **(a)** $v_x = v_{0x} + \frac{\alpha}{3}t^3$, $v_y = v_{0y} + \beta t - \frac{\gamma}{2}t^2$, and $x = v_{0x}t + \frac{\alpha}{12}t^4$, $y = v_{0y}t + \frac{\beta}{2}t^2 - \frac{\gamma}{6}t^3$.

(b) Setting $v_y = 0$ yields a quadratic in t, $0 = v_{0y} + \beta t - \frac{\gamma}{2}t^2$. Using the numerical values given in the problem, this equation has as the positive solution $t = \frac{1}{\gamma}\left[\beta + \sqrt{\beta^2 + 2v_{0y}\gamma}\right] = 13.59\ \text{s}$. Using this time in the expression for $y(t)$ gives a maximum height of 341 m.

(c) $y = 0$ gives $0 = v_{0y}t + \frac{\beta}{2}t^2 - \frac{\gamma}{6}t^3$ and $\frac{\gamma}{6}t^2 - \frac{\beta}{2}t - v_{0y} = 0$. Using the numbers given in the problem, the positive solution is $t = 20.73$ s. For this t, $x = 3.85 \times 10^4$ m.

EVALUATE: We cannot use the constant-acceleration kinematics formulas, but calculus provides the solution.

3.47. **IDENTIFY:** Once the rocket leaves the incline it moves in projectile motion. The acceleration along the incline determines the initial velocity and initial position for the projectile motion.

SET UP: For motion along the incline let $+x$ be directed up the incline. $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives $v_x = \sqrt{2(1.90\text{ m/s}^2)(200\text{ m})} = 27.57\text{ m/s}$. When the projectile motion begins the rocket has $v_0 = 27.57\text{ m/s}$ at $35.0°$ above the horizontal and is at a vertical height of $(200.0\text{ m})\sin 35.0° = 114.7\text{ m}$. For the projectile motion let $+x$ be horizontal to the right and let $+y$ be upward. Let $y = 0$ at the ground. Then $y_0 = 114.7\text{ m}$, $v_{0x} = v_0\cos 35.0° = 22.57\text{ m/s}$, $v_{0y} = v_0 \sin 35.0° = 15.81\text{ m/s}$, $a_x = 0$, $a_y = -9.80\text{ m/s}^2$. Let $x = 0$ at point *A*, so $x_0 = (200.0\text{ m})\cos 35.0° = 163.8\text{ m}$.

EXECUTE: **(a)** At the maximum height $v_y = 0$. $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$y - y_0 = \dfrac{v_y^2 - v_{0y}^2}{2a_y} = \dfrac{0 - (15.81\text{ m/s})^2}{2(-9.80\text{ m/s}^2)} = 12.77\text{ m}$ and $y = 114.7\text{ m} + 12.77\text{ m} = 128\text{ m}$. The maximum height above ground is 128 m.

(b) The time in the air can be calculated from the vertical component of the projectile motion: $y - y_0 = -114.7\text{ m}$, $v_{0y} = 15.81\text{ m/s}$, $a_y = -9.80\text{ m/s}^2$. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $(4.90\text{ m/s}^2)t^2 - (15.81\text{ m/s})t - 114.7\text{ m}$. The quadratic formula gives $t = 6.713\text{ s}$ for the positive root. Then $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (22.57\text{ m/s})(6.713\text{ s}) = 151.6\text{ m}$ and $x = 163.8\text{ m} + 151.6\text{ m} = 315\text{ m}$. The horizontal range of the rocket is 315 m.

EVALUATE: The expressions for *h* and *R* derived in the range formula do not apply here. They are only for a projectile fired on level ground.

3.48. **IDENTIFY:** Use the position vector of a dragonfly to determine information about its velocity vector and acceleration vector.

SET UP: Use the definitions $v_x = dx/dt$, $v_y = dy/dt$, $a_x = dv_x/dt$, and $a_y = dv_y/dt$.

EXECUTE: **(a)** Taking derivatives of the position vector gives the components of the velocity vector: $v_x(t) = (0.180\text{ m/s}^2)t$, $v_y(t) = (-0.0450\text{ m/s}^3)t^2$. Use these components and the given direction:

$\tan 30.0° = \dfrac{(0.0450\text{ m/s}^3)t^2}{(0.180\text{ m/s}^2)t}$, which gives $t = 2.31\text{ s}$.

(b) Taking derivatives of the velocity components gives the acceleration components: $a_x = 0.180\text{ m/s}^2$, $a_y(t) = -(0.0900\text{ m/s}^3)t$. At $t = 2.31\text{ s}$, $a_x = 0.180\text{ m/s}^2$ and $a_y = -0.208\text{ m/s}^2$, giving $a = 0.275\text{ m/s}^2$. The direction is $\tan\theta = \dfrac{0.208}{0.180}$, so $\theta = 49.1°$ clockwise from +*x*-axis.

EVALUATE: The acceleration is not constant, so we cannot use the standard kinematics formulas.

3.49. **IDENTIFY:** The cannister moves in projectile motion. Its initial velocity is horizontal. Apply constant acceleration equations for the *x* and *y* components of motion.

SET UP:

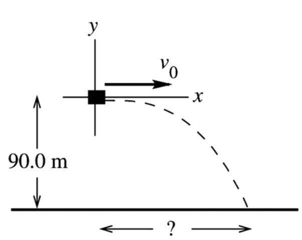

Figure 3.49

Take the origin of coordinates at the point where the cannister is released. Take $+y$ to be upward. The initial velocity of the cannister is the velocity of the plane, 64.0 m/s in the $+x$-direction.

Use the vertical motion to find the time of fall: $y-y_0=v_{0y}t+\frac{1}{2}a_yt^2$ where $t=?$, $v_{0y}=0$, $a_y=-9.80\ \text{m/s}^2$, $y-y_0=-90.0\ \text{m}$ (When the cannister reaches the ground it is 90.0 m *below* the origin.)

EXECUTE: Since $v_{0y}=0$, $t=\sqrt{\dfrac{2(y-y_0)}{a_y}}=\sqrt{\dfrac{2(-90.0\ \text{m})}{-9.80\ \text{m/s}^2}}=4.286\ \text{s}.$

SET UP: Then use the horizontal component of the motion to calculate how far the cannister falls in this time: $x-x_0=?$, a_x-0, $v_{0x}=64.0\ \text{m/s}$.

EXECUTE: $x-x_0=v_0t+\frac{1}{2}at^2=(64.0\ \text{m/s})(4.286\ \text{s})+0=274\ \text{m}.$

EVALUATE: The time it takes the cannister to fall 90.0 m, starting from rest, is the time it travels horizontally at constant speed.

3.50. **IDENTIFY:** $\vec{r}=\vec{r}_0+\int_0^t \vec{v}(t)dt$ and $\boldsymbol{a}=\dfrac{d\vec{v}}{dt}$.

SET UP: At $t=0$, $x_0=0$ and $y_0=0$.

EXECUTE: **(a)** Integrating, $\vec{r}=\left(\alpha t-\dfrac{\beta}{3}t^3\right)\hat{\boldsymbol{i}}+\left(\dfrac{\gamma}{2}t^2\right)\hat{\boldsymbol{j}}$. Differentiating, $\vec{a}=(-2\beta t)\hat{\boldsymbol{i}}+\gamma\hat{\boldsymbol{j}}$.

(b) The positive time at which $x=0$ is given by $t^2=3\alpha/\beta$. At this time, the y-coordinate is

$$y=\frac{\gamma}{2}t^2=\frac{3\alpha\gamma}{2\beta}=\frac{3(2.4\ \text{m/s})(4.0\ \text{m/s}^2)}{2(1.6\ \text{m/s}^3)}=9.0\ \text{m}.$$

EVALUATE: The acceleration is not constant.

3.51. **IDENTIFY:** The person moves in projectile motion. Her vertical motion determines her time in the air.

SET UP: Take $+y$ upward. $v_{0x}=15.0\ \text{m/s}$, $v_{0y}=+10.0\ \text{m/s}$, $a_x=0$, $a_y=-9.80\ \text{m/s}^2$.

EXECUTE: **(a)** Use the vertical motion to find the time in the air: $y-y_0=v_{0y}t+\frac{1}{2}a_yt^2$ with $y-y_0=-30.0\ \text{m}$ gives $-30.0\ \text{m}=(10.0\ \text{m/s})t-(4.90\ \text{m/s}^2)t^2$. The quadratic formula gives $t=\dfrac{1}{2(4.9)}\left(+10.0\pm\sqrt{(-10.0)^2-4(4.9)(-30)}\right)$ s. The positive solution is $t=3.70$ s. During this time she travels a horizontal distance $x-x_0=v_{0x}t+\frac{1}{2}a_xt^2=(15.0\ \text{m/s})(3.70\ \text{s})=55.5\ \text{m}$. She will land 55.5 m south of the point where she drops from the helicopter and this is where the mats should have been placed.

(b) The *x-t*, *y-t*, v_x *-t* and v_y *-t* graphs are sketched in Figure 3.51.

EVALUATE: If she had dropped from rest at a height of 30.0 m it would have taken her $t=\sqrt{\dfrac{2(30.0\ \text{m})}{9.80\ \text{m/s}^2}}=2.47\ \text{s}$. She is in the air longer than this because she has an initial vertical component of velocity that is upward.

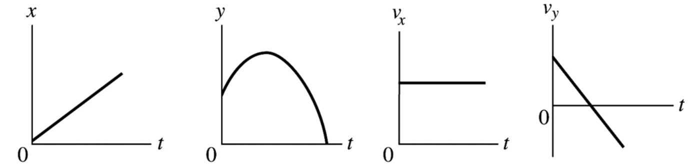

Figure 3.51

3.52. **IDENTIFY:** The shell moves as a projectile. To just clear the top of the cliff, the shell must have $y - y_0 = 25.0$ m when it has $x - x_0 = 60.0$ m.

SET UP: Let $+y$ be upward. $a_x = 0$, $a_y = -g$. $v_{0x} = v_0 \cos 43°$, $v_{0y} = v_0 \sin 43°$.

EXECUTE: **(a)** horizontal motion: $x - x_0 = v_{0x}t$ so $t = \dfrac{60.0 \text{ m}}{(v_0 \cos 43°)}$.

vertical motion: $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $25.0 \text{ m} = (v_0 \sin 43.0°)\, t + \frac{1}{2}(-9.80 \text{ m/s}^2)\, t^2$.

Solving these two simultaneous equations for v_0 and t gives $v_0 = 32.6$ m/s and $t = 2.51$ s.

(b) v_y when shell reaches cliff:

$$v_y = v_{0y} + a_y t = (32.6 \text{ m/s}) \sin 43.0° - (9.80 \text{ m/s}^2)(2.51 \text{ s}) = -2.4 \text{ m/s}$$

The shell is traveling downward when it reaches the cliff, so it lands right at the edge of the cliff.

EVALUATE: The shell reaches its maximum height at $t = -\dfrac{v_{0y}}{a_y} = 2.27$ s, which confirms that at $t = 2.51$ s it has passed its maximum height and is on its way down when it strikes the edge of the cliff.

3.53. **IDENTIFY:** Find the horizontal distance a rocket moves if it has a non-constant horizontal acceleration but a constant vertical acceleration of g downward.

SET UP: The vertical motion is g downward, so we can use the constant acceleration formulas for that component of the motion. We must use integration for the horizontal motion because the acceleration is not constant. Solving for t in the kinematics formula for y gives $t = \sqrt{\dfrac{2(y - y_0)}{a_y}}$. In the horizontal direction we must use $v_x(t) = v_{0x} + \int_0^t a_x(t')dt'$ and $x - x_0 = \int_0^t v_x(t')dt'$.

EXECUTE: Use vertical motion to find t. $t = \sqrt{\dfrac{2(y - y_0)}{a_y}} = \sqrt{\dfrac{2(30.0 \text{ m})}{9.80 \text{ m/s}^2}} = 2.474$ s.

In the horizontal direction we have

$v_x(t) = v_{0x} + \int_0^t a_x(t')dt' = v_{0x} + (0.800 \text{ m/s}^3)t^2 = 12.0 \text{ m/s} + (0.800 \text{ m/s}^3)t^2$. Integrating $v_x(t)$ gives $x - x_0 = (12.0 \text{ m/s})t + (0.2667 \text{ m/s}^3)t^3$. At $t = 2.474$ s, $x - x_0 = 29.69 \text{ m} + 4.04 \text{ m} = 33.7$ m.

EVALUATE: The vertical part of the motion is familiar projectile motion, but the horizontal part is not.

3.54. **IDENTIFY:** The equipment moves in projectile motion. The distance D is the horizontal range of the equipment plus the distance the ship moves while the equipment is in the air.

SET UP: For the motion of the equipment take $+x$ to be to the right and $+y$ to be upward. Then $a_x = 0$, $a_y = -9.80 \text{ m/s}^2$, $v_{0x} = v_0 \cos\alpha_0 = 7.50$ m/s and $v_{0y} = v_0 \sin\alpha_0 = 13.0$ m/s. When the equipment lands in the front of the ship, $y - y_0 = -8.75$ m.

EXECUTE: Use the vertical motion of the equipment to find its time in the air: $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = \dfrac{1}{9.80}\left(13.0 \pm \sqrt{(-13.0)^2 + 4(4.90)(8.75)}\right)$ s. The positive root is $t = 3.21$ s. The horizontal range of the equipment is $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (7.50 \text{ m/s})(3.21 \text{ s}) = 24.1$ m. In 3.21 s the ship moves a horizontal distance $(0.450 \text{ m/s})(3.21 \text{ s}) = 1.44$ m, so $D = 24.1 \text{ m} + 1.44 \text{ m} = 25.5$ m.

EVALUATE: The range equation $R = \dfrac{v_0^2 \sin 2\alpha_0}{g}$ cannot be used here because the starting and ending points of the projectile motion are at different heights.

3.55. **IDENTIFY:** Two-dimensional projectile motion.

SET UP: Let $+y$ be upward. $a_x = 0,\ a_y = -9.80\ \text{m/s}^2$. With $x_0 = y_0 = 0,$ algebraic manipulation of the equations for the horizontal and vertical motion shows that x and y are related by

$$y = (\tan\theta_0)x - \frac{g}{2v_0^2\cos^2\theta_0}x^2.$$

$\theta_0 = 60.0°.\ \ y = 8.00\ \text{m}$ when $x = 18.0\ \text{m}.$

EXECUTE: **(a)** Solving for v_0 gives $v_0 = \sqrt{\dfrac{gx^2}{2(\cos^2\theta_0)(x\tan\theta_0 - y)}} = 16.6\ \text{m/s}.$

(b) We find the horizontal and vertical velocity components:

$v_x = v_{0x} = v_0\cos\theta_0 = 8.3\ \text{m/s}.$

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$v_y = -\sqrt{(v_0\sin\theta_0)^2 + 2a_y(y - y_0)} = -\sqrt{(14.4\ \text{m/s})^2 + 2(-9.80\ \text{m/s}^2)(8.00\ \text{m})} = -7.1\ \text{m/s}$

$v = \sqrt{v_x^2 + v_y^2} = 10.9\ \text{m/s}.\ \ \tan\theta = \dfrac{|v_y|}{|v_x|} = \dfrac{7.1}{8.3}$ and $\theta = 40.5°,$ below the horizontal.

EVALUATE: We can check our calculated v_0.

$$t = \frac{x - x_0}{v_{0x}} = \frac{18.0\ \text{m}}{8.3\ \text{m/s}} = 2.17\ \text{s}.$$

Then $y - y_0 = v_{0y}t + \frac{1}{2}a_yt^2 = (14.4\ \text{m/s})(2.17\ \text{s}) - (4.9\ \text{m/s}^2)(2.17\ \text{s})^2 = 8\ \text{m},$ which checks.

3.56. **IDENTIFY:** While the hay falls 150 m with an initial upward velocity and with a downward acceleration of g, it must travel a horizontal distance (the target variable) with constant horizontal velocity.

SET UP: Use coordinates with $+y$ upward and $+x$ horizontal. The bale has initial velocity components $v_{0x} = v_0\cos\alpha_0 = (75\ \text{m/s})\cos 55° = 43.0\ \text{m/s}$ and $v_{0y} = v_0\sin\alpha_0 = (75\ \text{m/s})\sin 55° = 61.4\ \text{m/s}.\ \ y_0 = 150\ \text{m}$ and $y = 0.$ The equation $y - y_0 = v_{0y}t + \frac{1}{2}a_yt^2$ applies to the vertical motion and a similar equation to the horizontal motion.

EXECUTE: Use the vertical motion to find t: $y - y_0 = v_{0y}t + \frac{1}{2}a_yt^2$ gives $-150\ \text{m} = (61.4\ \text{m/s})t - (4.90\ \text{m/s}^2)t^2.$ The quadratic formula gives $t = 6.27 \pm 8.36\ \text{s}.$ The physical value is the positive one, and $t = 14.6\ \text{s}.$ Then $x - x_0 = v_{0x}t + \frac{1}{2}a_xt^2 = (43.0\ \text{m/s})(14.6\ \text{s}) = 630\ \text{m}.$

EVALUATE: If the airplane maintains constant velocity after it releases the bales, it will also travel horizontally 630 m during the time it takes the bales to fall to the ground, so the airplane will be directly over the impact spot when the bales land.

3.57. **IDENTIFY:** From the figure in the text, we can read off the maximum height and maximum horizontal distance reached by the grasshopper. Knowing its acceleration is g downward, we can find its initial speed and the height of the cliff (the target variables).

SET UP: Use coordinates with the origin at the ground and $+y$ upward. $a_x = 0,\ a_y = -9.80\ \text{m/s}^2.$ The constant-acceleration kinematics formulas $v_y^2 = v_{0y}^2 + 2a_y\,(y - y_0)$ and $x - x_0 = v_{0x}t + \frac{1}{2}a_xt^2$ apply.

EXECUTE: **(a)** $v_y = 0$ when $y - y_0 = 0.0674\ \text{m}.\ \ v_y^2 = v_{0y}^2 + 2a_y\,(y - y_0)$ gives

$v_{0y} = \sqrt{-2a_y\,(y - y_0)} = \sqrt{-2\,(-9.80\ \text{m/s}^2)(0.0674\ \text{m})} = 1.15\ \text{m/s}.\ \ v_{0y} = v_0\sin\alpha_0$ so

$v_0 = \dfrac{v_{0y}}{\sin\alpha_0} = \dfrac{1.15\ \text{m/s}}{\sin 50.0°} = 1.50\ \text{m/s}.$

(b) Use the horizontal motion to find the time in the air. The grasshopper travels horizontally $x - x_0 = 1.06$ m. $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $t = \dfrac{x - x_0}{v_{0x}} = \dfrac{x - x_0}{v_0 \cos 50.0°} = 1.10$ s. Find the vertical displacement of the grasshopper at $t = 1.10$ s:

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = (1.15 \text{ m/s})(1.10 \text{ s}) + \frac{1}{2}(-9.80 \text{ m/s}^2)(1.10 \text{ s})^2 = -4.66$ m. The height of the cliff is 4.66 m.

EVALUATE: The grasshopper's maximum height (6.74 cm) is physically reasonable, so its takeoff speed of 1.50 m/s must also be reasonable. Note that the equation $R = \dfrac{v_0^2 \sin 2\alpha_0}{g}$ does *not* apply here since the launch point is not at the same level as the landing point.

3.58. **IDENTIFY:** The water moves in projectile motion.

SET UP: Let $x_0 = y_0 = 0$ and take $+y$ to be positive. $a_x = 0$, $a_y = -g$.

EXECUTE: The equations of motions are $y = (v_0 \sin \alpha)t - \frac{1}{2}gt^2$ and $x = (v_0 \cos \alpha)t$. When the water goes in the tank for the *minimum* velocity, $y = 2D$ and $x = 6D$. When the water goes in the tank for the *maximum* velocity, $y = 2D$ and $x = 7D$. In both cases, $\sin \alpha = \cos \alpha = \sqrt{2}/2$.

To reach the *minimum* distance: $6D = \dfrac{\sqrt{2}}{2}v_0 t$, and $2D = \dfrac{\sqrt{2}}{2}v_0 t - \frac{1}{2}gt^2$. Solving the first equation for t gives $t = \dfrac{6D\sqrt{2}}{v_0}$. Substituting this into the second equation gives $2D = 6D - \frac{1}{2}g\left(\dfrac{6D\sqrt{2}}{v_0}\right)^2$. Solving this for v_0 gives $v_0 = 3\sqrt{gD}$.

To reach the *maximum* distance: $7D = \dfrac{\sqrt{2}}{2}v_0 t$, and $2D = \dfrac{\sqrt{2}}{2}v_0 t - \frac{1}{2}gt^2$. Solving the first equation for t gives $t = \dfrac{7D\sqrt{2}}{v_0}$. Substituting this into the second equation gives $2D = 7D - \frac{1}{2}g\left(\dfrac{7D\sqrt{2}}{v_0}\right)^2$. Solving this for v_0 gives $v_0 = \sqrt{49gD/5} = 3.13\sqrt{gD}$, which, as expected, is larger than the previous result.

EVALUATE: A launch speed of $v_0 = \sqrt{6}\sqrt{gD} = 2.45\sqrt{gD}$ is required for a horizontal range of $6D$. The minimum speed required is greater than this, because the water must be at a height of at least $2D$ when it reaches the front of the tank.

3.59. **IDENTIFY:** This is a projectile motion problem. The vertical acceleration is g downward and the horizontal acceleration is zero. The constant-acceleration equations apply.

SET UP: Apply the constant-acceleration formulas.

EXECUTE: **(a)** The object has only vertical motion, so $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $v = \sqrt{v_0^2 + 2gH}$.

(b) The procedure is exactly the as in part (a) except that $v_{0y} = -v_0$, so the result is the same.

(c) Use the same approach as in part (a). $v_x = v_0 \cos\alpha_0$ and $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $v_y^2 = \left(v_0 \sin\alpha_0\right)^2 + 2(-g)(-H)$, so $v_y = \sqrt{v_0^2 \sin^2\alpha_0 + 2gH}$. The speed is the magnitude of the velocity vector, so $v = \sqrt{v_x^2 + v_y^2} = \sqrt{\left(v_0^2 \cos^2\alpha_0\right) + \left(v_0^2 \sin^2\alpha_0 + 2gH\right)} = \sqrt{v_0^2 + 2gH}$.

EVALUATE: **(d)** From part (c), we see that v does not depend on α_0, so v stays the same as α_0 is changed.

3.60. **IDENTIFY:** To clear the bar the ball must have a height of 10.0 ft when it has a horizontal displacement of 36.0 ft. The ball moves as a projectile. When v_0 is very large, the ball reaches the goal posts in a very short time and the acceleration due to gravity causes negligible downward displacement.

SET UP: $36.0 \text{ ft} = 10.97 \text{ m}$; $10.0 \text{ ft} = 3.048 \text{ m}$. Let $+x$ be to the right and $+y$ be upward, so $a_x = 0$, $a_y = -g$, $v_{0x} = v_0 \cos\alpha_0$ and $v_{0y} = v_0 \sin\alpha_0$.

EXECUTE: **(a)** The ball cannot be aimed lower than directly at the bar. $\tan\alpha_0 = \dfrac{10.0 \text{ ft}}{36.0 \text{ ft}}$ and $\alpha_0 = 15.5°$.

(b) $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $t = \dfrac{x - x_0}{v_{0x}} = \dfrac{x - x_0}{v_0 \cos\alpha_0}$. Then $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives

$$y - y_0 = (v_0 \sin\alpha_0)\left(\frac{x - x_0}{v_0 \cos\alpha_0}\right) - \frac{1}{2}g\frac{(x - x_0)^2}{v_0^2 \cos^2\alpha_0} = (x - x_0)\tan\alpha_0 - \frac{1}{2}g\frac{(x - x_0)^2}{v_0^2 \cos^2\alpha_0}.$$

$$v_0 = \frac{(x - x_0)}{\cos\alpha_0}\sqrt{\frac{g}{2[(x - x_0)\tan\alpha_0 - (y - y_0)]}} = \frac{10.97 \text{ m}}{\cos 45.0°}\sqrt{\frac{9.80 \text{ m/s}^2}{2[10.97 \text{ m} - 3.048 \text{ m}]}} = 12.2 \text{ m/s} = 43.9 \text{ km/h}.$$

EVALUATE: With the v_0 and 45° launch angle in part (b), the horizontal range of the ball is $R = \dfrac{v_0^2 \sin 2\alpha_0}{g} = 15.2 \text{ m} = 49.9 \text{ ft}$. The ball reaches the highest point in its trajectory when $x - x_0 = R/2$, which is 25 ft, so when it reaches the goal posts it is on its way down.

3.61. **IDENTIFY:** The snowball moves in projectile motion. In part (a) the vertical motion determines the time in the air. In part (c), find the height of the snowball above the ground after it has traveled horizontally 4.0 m.

SET UP: Let $+y$ be downward. $a_x = 0$, $a_y = +9.80 \text{ m/s}^2$. $v_{0x} = v_0 \cos\theta_0 = 5.36 \text{ m/s}$, $v_{0y} = v_0 \sin\theta_0 = 4.50 \text{ m/s}$.

EXECUTE: **(a)** Use the vertical motion to find the time in the air: $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ with $y - y_0 = 14.0 \text{ m}$ gives $14.0 \text{ m} = (4.50 \text{ m/s})\,t + (4.9 \text{ m/s}^2)\,t^2$. The quadratic formula gives $t = \dfrac{1}{2(4.9)}\left(-4.50 \pm \sqrt{(4.50)^2 - 4\,(4.9)(-14.0)}\right)$ s. The positive root is $t = 1.29$ s. Then $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (5.36 \text{ m/s})(1.29 \text{ s}) = 6.91 \text{ m}$.

(b) The x-t, y-t, v_x-t and v_y-t graphs are sketched in Figure 3.61.

(c) $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $t = \dfrac{x - x_0}{v_{0x}} = \dfrac{4.0 \text{ m}}{5.36 \text{ m/s}} = 0.746 \text{ s}$. In this time the snowball travels downward a distance $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 = 6.08 \text{ m}$ and is therefore $14.0 \text{ m} - 6.08 \text{ m} = 7.9 \text{ m}$ above the ground. The snowball passes well above the man and doesn't hit him.

EVALUATE: If the snowball had been released from rest at a height of 14.0 m it would have reached the ground in $t = \sqrt{\dfrac{2(14.0 \text{ m})}{9.80 \text{ m/s}^2}} = 1.69 \text{ s}$. The snowball reaches the ground in a shorter time than this because of its initial downward component of velocity.

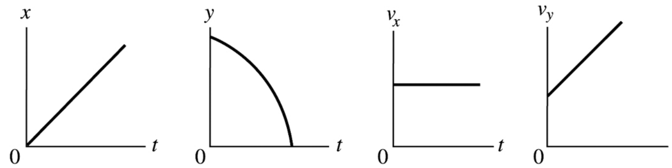

Figure 3.61

3.62. **IDENTIFY:** The ball moves in projectile motion.

SET UP: The woman and ball travel for the same time and must travel the same horizontal distance, so for the ball $v_{0x} = 6.00$ m/s.

EXECUTE: **(a)** $v_{0x} = v_0 \cos\theta_0$. $\cos\theta_0 = \dfrac{v_{0x}}{v_0} = \dfrac{6.00\text{ m/s}}{20.0\text{ m/s}}$ and $\theta_0 = 72.5°$. The ball is in the air for 5.55s and she runs a distance of $(6.00\text{ m/s})(5.55\text{ s}) = 33.3$ m.

(b) Relative to the ground the ball moves in a parabola. The ball and the runner have the same horizontal component of velocity, so relative to the runner the ball has only vertical motion. The trajectories as seen by each observer are sketched in Figure 3.62.

EVALUATE: The ball could be thrown with a different speed, so long as the angle at which it was thrown was adjusted to keep $v_{0x} = 6.00$ m/s.

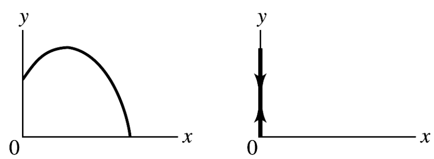

Figure 3.62

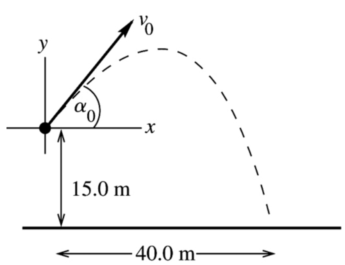
3.63. **(a) IDENTIFY:** Projectile motion.



Take the origin of coordinates at the top of the ramp and take $+y$ to be upward.

The problem specifies that the object is displaced 40.0 m to the right when it is 15.0 m below the origin.

Figure 3.63

We don't know *t*, the time in the air, and we don't know v_0. Write down the equations for the horizontal and vertical displacements. Combine these two equations to eliminate one unknown.

SET UP: <u>*y*-component</u>:

$y - y_0 = -15.0$ m, $a_y = -9.80$ m/s^2, $v_{0y} = v_0 \sin 53.0°$

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$

EXECUTE: $-15.0\text{ m} = (v_0 \sin 53.0°)\, t - (4.90\text{ m/s}^2)\, t^2$

SET UP: <u>*x*-component</u>:

$x - x_0 = 40.0 \text{ m}, \;\; a_x = 0, \;\; v_{0x} = v_0 \cos 53.0°$

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$

EXECUTE: $40.0 \text{ m} = (v_0 t)\cos 53.0°$

The second equation says $v_0 t = \dfrac{40.0 \text{ m}}{\cos 53.0°} = 66.47 \text{ m}.$

Use this to replace $v_0 t$ in the first equation:

$-15.0 \text{ m} = (66.47 \text{ m}) \sin 53° - (4.90 \text{ m/s}^2)\, t^2$

$$t = \sqrt{\frac{(66.47 \text{ m})\sin 53° + 15.0 \text{ m}}{4.90 \text{ m/s}^2}} = \sqrt{\frac{68.08 \text{ m}}{4.90 \text{ m/s}^2}} = 3.727 \text{ s}.$$

Now that we have t we can use the x-component equation to solve for v_0:

$$v_0 = \frac{40.0 \text{ m}}{t \cos 53.0°} = \frac{40.0 \text{ m}}{(3.727 \text{ s}) \cos 53.0°} = 17.8 \text{ m/s}.$$

EVALUATE: Using these values of v_0 and t in the $y = y_0 = v_{0y} + \frac{1}{2}a_y t^2$ equation verifies that $y - y_0 = -15.0 \text{ m}.$

(b) IDENTIFY: $v_0 = (17.8 \text{ m/s})/2 = 8.9 \text{ m/s}$

This is less than the speed required to make it to the other side, so he lands in the river.
Use the vertical motion to find the time it takes him to reach the water:

SET UP: $y - y_0 = -100 \text{ m}; \;\; v_{0y} = +v_0 \sin 53.0° = 7.11 \text{ m/s}; \;\; a_y = -9.80 \text{ m/s}^2$

$y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $-100 = 7.11t - 4.90t^2$

EXECUTE: $4.90t^2 - 7.11t - 100 = 0$ and $t = \frac{1}{9.80}\left(7.11 \pm \sqrt{(7.11)^2 - 4\,(4.90)(-100)}\right)$

$t = 0.726 \text{ s} \pm 4.57 \text{ s}$ so $t = 5.30 \text{ s}.$

The horizontal distance he travels in this time is
$x - x_0 = v_{0x}t = (v_0 \cos 53.0°)\, t = (5.36 \text{ m/s})(5.30 \text{ s}) = 28.4 \text{ m}.$

He lands in the river a horizontal distance of 28.4 m from his launch point.

EVALUATE: He has half the minimum speed and makes it only about halfway across.

3.64. IDENTIFY: The bagels move in projectile motion. Find Henrietta's location when the bagels reach the ground, and require the bagels to have this horizontal range.

SET UP: Let $+y$ be downward and let $x_0 = y_0 = 0.$ $a_x = 0,$ $a_y = +g.$ When the bagels reach the ground, $y = 38.0 \text{ m}.$

EXECUTE: **(a)** When she catches the bagels, Henrietta has been jogging for 9.00 s plus the time for the bagels to fall 38.0 m from rest. Get the time to fall: $y = \dfrac{1}{2}gt^2,$ $38.0 \text{ m} = \dfrac{1}{2}(9.80 \text{ m/s}^2)\, t^2$ and $t = 2.78 \text{ s}.$

So, she has been jogging for $9.00 \text{ s} + 2.78 \text{ s} = 11.78 \text{ s}.$ During this time she has gone $x = vt = (3.05 \text{ m/s})(11.78 \text{ s}) = 35.9 \text{ m}.$ Bruce must throw the bagels so they travel 35.9 m horizontally in 2.78 s. This gives $x = vt.$ $35.9 \text{ m} = v\,(2.78 \text{ s})$ and $v = 12.9 \text{ m/s}.$

(b) 35.9 m from the building.

EVALUATE: If $v > 12.9 \text{ m/s}$ the bagels land in front of her and if $v < 12.9 \text{ m/s}$ they land behind her. There is a range of velocities greater than 12.9 m/s for which she would catch the bagels in the air, at some height above the sidewalk.

3.65. IDENTIFY: The boulder moves in projectile motion.

SET UP: Take $+y$ downward. $v_{0x} = v_0,$ $a_x = 0,$ $a_x = 0,$ $a_y = +9.80 \text{ m/s}^2.$

EXECUTE: **(a)** Use the vertical motion to find the time for the boulder to reach the level of the lake: $y-y_0=v_{0y}t+\frac{1}{2}a_yt^2$ with $y-y_0=+20\text{ m}$ gives $t=\sqrt{\dfrac{2(y-y_0)}{a_y}}=\sqrt{\dfrac{2(20\text{ m})}{9.80\text{ m/s}^2}}=2.02\text{ s}$. The rock must travel horizontally 100 m during this time. $x-x_0=v_{0x}t+\frac{1}{2}a_xt^2$ gives

$$v_0=v_{0x}=\frac{x-x_0}{t}=\frac{100\text{ m}}{2.02\text{ s}}=49.5\text{ m/s}$$

(b) In going from the edge of the cliff to the plain, the boulder travels downward a distance of $y-y_0=45\text{ m}$. $t=\sqrt{\dfrac{2(y-y_0)}{a_y}}=\sqrt{\dfrac{2(45\text{ m})}{9.80\text{ m/s}^2}}=3.03\text{ s}$ and $x-x_0=v_{0x}t=(49.5\text{ m/s})(3.03\text{ s})=150\text{ m}$.

The rock lands $150\text{ m}-100\text{ m}=50\text{ m}$ beyond the foot of the dam.

EVALUATE: The boulder passes over the dam 2.02 s after it leaves the cliff and then travels an additional 1.01 s before landing on the plain. If the boulder has an initial speed that is less than 49 m/s, then it lands in the lake.

3.66. **IDENTIFY:** The water follows a parabolic trajectory since it is affected only by gravity, so we apply the principles of projectile motion to it.

SET UP: Use coordinates with $+y$ upward. Once the water leaves the cannon it is in free-fall and has $a_x=0$ and $a_y=-9.80\text{ m/s}^2$. The water has $v_{0x}=v_0\cos\theta_0=15.0\text{ m/s}$ and $v_{0y}=v_0\sin\theta_0=20.0\text{ m/s}$.

EXECUTE: Use the vertical motion to find t that gives $y-y_0=10.0\text{ m}$: $y-y_0=v_{0y}t+\frac{1}{2}a_yt^2$ gives $10.0\text{ m}=(20.0\text{ m/s})t-(4.90\text{ m/s}^2)t^2$.

The quadratic formula gives $t=2.04\pm1.45\text{ s}$, and $t=0.59\text{ s}$ or $t=3.49\text{ s}$. Both answers are physical.

For $t=0.59$ s: $x-x_0=v_{0x}t=(15.0\text{ m/s})(0.59\text{ s})=8.8\text{ m}$.

For $t=3.49$ s: $x-x_0=v_{0x}t=(15.0\text{ m/s})(3.49\text{ s})=52.4\text{ m}$.

When the cannon is 8.8 m from the building, the water hits this spot on the wall on its way up to its maximum height. When is it 52.4 m from the building it hits this spot after it has passed through its maximum height.

EVALUATE: The fact that we have two possible answers means that the firefighters have some choice on where to stand. If the fire is extremely fierce, they would no doubt prefer to stand at the more distant location.

3.67. **IDENTIFY:** This is a projectile motion problem. The vertical acceleration is g downward and the horizontal acceleration is zero. The constant-acceleration equations apply.

SET UP: Apply the constant-acceleration formulas. We know that the ball travels 50.0 m horizontally and has a speed of 8.0 m/s at its maximum height. We want to know how long the ball is in the air.

EXECUTE: The horizontal velocity is constant, so $v_x = 8.0$ m/s. The ball moves 50.0 m at this velocity, so $x = v_xt$ gives 50.0 m = (8.0 m/s)t → $t = 6.3$ s.

EVALUATE: The ball's vertical velocity keeps changing, but its horizontal velocity remains constant. At its highest point, the ball does *not stop*. Only its vertical velocity becomes zero there.

3.68. **IDENTIFY:** This is a projectile motion problem. The vertical acceleration is g downward and the horizontal acceleration is zero. The constant-acceleration equations apply.

SET UP: The box leaves the top of the ramp horizontally with speed v_0 and is in freefall until it hits the ramp. Fig. 3.68 illustrates the motion. When it hits the ramp, the box has been moving horizontally at speed v_0 for the same time that it has been falling vertically from rest. We want to know how far the box falls before hitting the ramp.

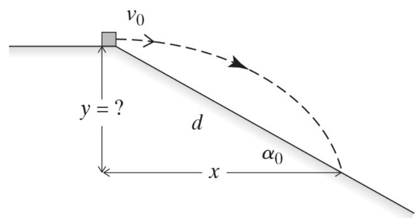


Figure 3.68

EXECUTE: When the box hits the ramp, the constant-acceleration equations give us $x = v_0 t$ and $y = \frac{1}{2}gt^2$. From the figure, we can see that $x = d\cos\alpha_0$ and $y = d\sin\alpha_0$. Therefore $v_0 t = d\cos\alpha_0$ and $\frac{1}{2}gt^2 = d\sin\alpha_0$. Combining the last two equations gives $t = (d\cos\alpha_0)/v_0$ so $\frac{1}{2}g\left(\frac{d\cos\alpha_0}{v_0}\right)^2 = d\sin\alpha_0$.

Solving for d gives $d = \frac{2v_0^2\sin\alpha_0}{g\cos^2\alpha_0}$. We want to find y, so we use the fact that $y = d\sin\alpha_0$ and use the value of d we just found, which gives

$$y = \frac{2v_0^2\sin\alpha_0}{g\cos^2\alpha_0}\cdot\sin\alpha_0 = \frac{2v_0^2\tan^2\alpha_0}{g}.$$

EVALUATE: Check some special cases. If $\alpha_0 \to 0$, the ramp is nearly vertical, so y gets very large. That is reasonable because the box would fall a very long distance before it hit the ramp. If $\alpha_0 \to 0°$, our result gives $y = 0$. This is reasonable because the box would already be on the ramp when it slid off the loading dock, so it would not have to fall any distance to reach the ramp.

3.69. **IDENTIFY:** The rock is in free fall once it is in the air, so it has only a downward acceleration of 9.80 m/s^2, and we apply the principles of two-dimensional projectile motion to it. The constant-acceleration kinematics formulas apply.

SET UP: The vertical displacement must be $\Delta y = y - y_0 = 5.00$ m – 1.60 m = 3.40 m at the instant that the horizontal displacement $\Delta x = x - x_0 = 14.0$ m, and $a_y = -9.80$ m/s^2 with $+y$ upward.

EXECUTE: **(a)** There is no horizontal acceleration, so 14.0 m = $v_0\cos(56.0°)t$, which gives $t = \frac{14.0\text{ m}}{v_0\cos 56.0°}$. Putting this quantity, along with the numerical quantities, into the equation $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ and solving for v_0 we get $v_0 = 13.3$ m/s.

(b) The initial horizontal velocity of the rock is (13.3 m/s)(cos 56.0°), and when it lands on the ground, $y - y_0 = -1.60$ m. Putting these quantities into the equation $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ leads to a quadratic equation in t. Using the positive square root, we get $t = 2.388$ s when the rock lands. The horizontal position at that instant is $x - x_0 =$ (13.3 m/s)(cos 56.0°)(2.388 s) = 17.8 m from the launch point. So the distance beyond the fence is 17.8 m – 14.0 m = 3.8 m.

EVALUATE: We cannot use the range formula to find the distance in (b) because the rock's motion does not start and end at the same height.

3.70. **IDENTIFY:** This is a projectile motion problem. The vertical acceleration is g downward and the horizontal acceleration is zero. The constant-acceleration equations apply.

SET UP: The horizontal range is $R = \frac{v_0^2}{g}\sin 2\alpha_0$.

EXECUTE: **(a)** We want to know how far the object has moved horizontally when it reaches its maximum height. At the maximum height, $v_y = 0$, so $v_y = v_0\sin\alpha_0 - gt$ gives

$t = \dfrac{v_0 \sin\alpha_0}{g}$ = (16.0 m/s)(sin 60.0°)/(9.80 m/s^2) = 1.414 s. This is the time to reach its maximum height.

The horizontal motion during that time gives
$x = (v_0 \cos\alpha_0)t$ = (16.0 m/s)(cos 60.0°)(1.414 s) = 11.3 m.

The horizontal range is $R = \dfrac{v_0^2}{g}\sin 2\alpha_0$ = (16.0 m/s)^2(sin 120°)/(9.80 m/s^2) = 22.6 m. So we see that at the highest point, the object's horizontal displacement is one-half of its horizontal range.

(b) In this case, $x = 0.800R$ = (0.800)(22.6 m) = 18.1 m. We want to know the vertical position of the object when it has traveled this far horizontally. To find the time to reach 18.1 m horizontally, apply $x = (v_0 \cos\alpha_0)t$ and solve for t, giving t = (18.1 m)/[(16.0 m/s)(cos 60.0°)] = 2.262 s. Now find the value of y at this time using $y = (v_0 \sin\alpha_0)t - \frac{1}{2}gt^2$. This gives

y = (16.0 m/s)(sin 60.0°)(2.262 s) – $y = (v_0 \sin\alpha_0)t - \frac{1}{2}gt^2$ = 6.27 m.

In part (a) we saw that the object reaches its maximum height in 1.414 s. Using $y = (v_0 \sin\alpha_0)t - \frac{1}{2}gt^2$, we get

y_{max} = (16.0 m/s)(sin 60.0°)(1.414 s) – $\frac{1}{2}$(9.80 m/s^2)(1.414 s)^2 = 9.80 m.

Comparing the height at 2.262 s to its maximum height gives h/h_{max} = (6.27 m)/(9.80 m) = 0.640, so it is at 64.0% of its maximum height.

(c) When $x - x_0 = \alpha R$, we want to find $\dfrac{y - y_0}{h_{max}}$. We use the same general approach as in part (b). First find h_{max} using the fact that $v_y = 0$ at that point. $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $0 = (v_0 \sin\alpha_0)^2 - 2gh_{max}$, so $h_{max} = \dfrac{v_0^2 \sin^2\alpha_0}{2g}$. Now use the horizontal motion to find t when $x - x_0 = \alpha R$, giving $v_0 \cos\alpha_0\, t$ = αR, so t = $t = \dfrac{\alpha R}{v_0 \cos\alpha_0}$. Using the range formula $R = \dfrac{2v_0^2 \sin\alpha_0 \cos\alpha_0}{g}$, the time becomes

$t = \dfrac{\alpha}{v_0 \cos\alpha_0}\left(\dfrac{2v_0^2 \sin\alpha_0 \cos\alpha_0}{g}\right) = \dfrac{2v_0 \alpha \sin\alpha_0}{g}$. Now get $y - y_0$ for this time. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2 =$ $v_0 \sin\alpha_0\left(\dfrac{2v_0\alpha \sin\alpha_0}{g}\right) - \dfrac{1}{2}g\left(\dfrac{2v_0 \sin\alpha_0}{g}\right)^2$. Simplifying gives $y - y_0 = \dfrac{2(v_0 \sin\alpha_0)^2}{g}\alpha(1-\alpha)$. Now find the ratio $\dfrac{y - y_0}{h_{max}}$ using our results above. $\dfrac{y - y_0}{h_{max}} = \dfrac{\dfrac{2(v_0 \sin\alpha_0)^2}{g}\alpha(1-\alpha)}{\dfrac{(v_0 \sin\alpha_0)^2}{2g}} = 4\alpha(\alpha - 1)$.

EVALUATE: Check our result in some special cases.

α = ½: $\dfrac{y - y_0}{h_{max}}$ = 4(½)(1 – ½) = 1. This is correct because x is half-way to R, so the object is at its highest point, which makes $y - y_0 = h_{max}$.

α = 0: $\dfrac{y - y_0}{h_{max}}$ = 0. This is reasonable because the object is at its take-off point at ground level.

α = 1: $\dfrac{y - y_0}{h_{max}}$ = 0. This is reasonable because the object is at $x = R$, so it has returned to the ground.

$\alpha = 0.800$: $\dfrac{y - y_0}{h_{\text{max}}} = 4(0.800)(1 - 0.800) = 0.640$. This agrees with our result in part (b).

3.71. **IDENTIFY:** Relative velocity problem. The plane's motion relative to the earth is determined by its velocity relative to the earth.

SET UP: Select a coordinate system where $+y$ is north and $+x$ is east.

The velocity vectors in the problem are:

$\vec{v}_{\text{P/E}}$, the velocity of the plane relative to the earth.

$\vec{v}_{\text{P/A}}$, the velocity of the plane relative to the air (the magnitude $v_{\text{P/A}}$ is the airspeed of the plane and the direction of $\vec{v}_{\text{P/A}}$ is the compass course set by the pilot).

$\vec{v}_{\text{A/E}}$, the velocity of the air relative to the earth (the wind velocity).

The rule for combining relative velocities gives $\vec{v}_{\text{P/E}} = \vec{v}_{\text{P/A}} + \vec{v}_{\text{A/E}}$.

(a) We are given the following information about the relative velocities:

$\vec{v}_{\text{P/A}}$ has magnitude 220 km/h and its direction is west. In our coordinates it has components $(v_{\text{P/A}})_x = -220$ km/h and $(v_{\text{P/A}})_y = 0$.

From the displacement of the plane relative to the earth after 0.500 h, we find that $\vec{v}_{\text{P/E}}$ has components in our coordinate system of

$$(v_{\text{P/E}})_x = -\frac{120\text{ km}}{0.500\text{ h}} = -240\text{ km/h (west)}$$

$$(v_{\text{P/E}})_y = -\frac{20\text{ km}}{0.500\text{ h}} = -40\text{ km/h (south)}$$

With this information the diagram corresponding to the velocity addition equation is shown in Figure 3.71a.

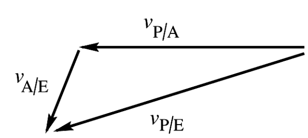

Figure 3.71a

We are asked to find $\vec{v}_{\text{A/E}}$, so solve for this vector:

$\vec{v}_{\text{P/E}} = \vec{v}_{\text{P/A}} + \vec{v}_{\text{A/E}}$ gives $\vec{v}_{\text{A/E}} = \vec{v}_{\text{P/E}} - \vec{v}_{\text{P/A}}$.

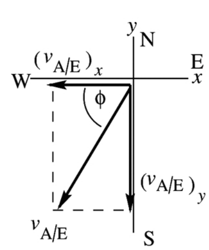
EXECUTE: The x-component of this equation gives

$(v_{\text{A/E}})_x = (v_{\text{P/E}})_x - (v_{\text{P/A}})_x = -240\text{ km/h} - (-220\text{ km/h}) = -20$ km/h.

The y-component of this equation gives

$(v_{\text{A/E}})_y = (v_{\text{P/E}})_y - (v_{\text{P/A}})_y = -40$ km/h.

Now that we have the components of $\vec{v}_{\text{A/E}}$ we can find its magnitude and direction.



$$v_{\text{A/E}} = \sqrt{(v_{\text{A/E}})_x^2 + (v_{\text{A/E}})_y^2}$$

$$v_{\text{A/E}} = \sqrt{(-20\text{ km/h})^2 + (-40\text{ km/h})^2} = 44.7\text{ km/h}$$

$$\tan\phi = \frac{40\text{ km/h}}{20\text{ km/h}} = 2.00;\quad \phi = 63.4^\circ$$

The direction of the wind velocity is 63.4° S of W, or 26.6° W of S.

Figure 3.71b

EVALUATE: The plane heads west. It goes farther west than it would without wind and also travels south, so the wind velocity has components west and south.

(b) SET UP: The rule for combining the relative velocities is still $\vec{v}_{P/E} = \vec{v}_{P/A} + \vec{v}_{A/E}$, but some of these velocities have different values than in part (a).

$\vec{v}_{P/A}$ has magnitude 220 km/h but its direction is to be found.

$\vec{v}_{A/E}$ has magnitude 40 km/h and its direction is due south.

The direction of $\vec{v}_{P/E}$ is west; its magnitude is not given.

The vector diagram for $\vec{v}_{P/E} = \vec{v}_{P/A} + \vec{v}_{A/E}$ and the specified directions for the vectors is shown in Figure 3.71c.

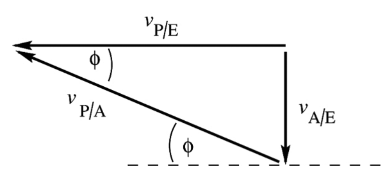


Figure 3.71c

The vector addition diagram forms a right triangle.

EXECUTE: $\sin\phi = \dfrac{v_{A/E}}{v_{P/A}} = \dfrac{40 \text{ km/h}}{220 \text{ km/h}} = 0.1818;\ \ \phi = 10.5°.$

The pilot should set her course $10.5°$ north of west.

EVALUATE: The velocity of the plane relative to the air must have a northward component to counteract the wind and a westward component in order to travel west.

3.72. **IDENTIFY:** Use the relation that relates the relative velocities.

SET UP: The relative velocities are the raindrop relative to the earth, $\vec{v}_{R/E}$, the raindrop relative to the train, $\vec{v}_{R/T}$, and the train relative to the earth, $\vec{v}_{T/E}$. $\vec{v}_{R/E} = \vec{v}_{R/T} + \vec{v}_{T/E}$. $\vec{v}_{T/E}$ is due east and has magnitude 12.0 m/s. $\vec{v}_{R/T}$ is $30.0°$ west of vertical. $\vec{v}_{R/E}$ is vertical. The relative velocity addition diagram is given in Figure 3.72.

EXECUTE: **(a)** $\vec{v}_{R/E}$ is vertical and has zero horizontal component. The horizontal component of $\vec{v}_{R/T}$ is $-\vec{v}_{T/E}$, so is 12.0 m/s westward.

(b) $v_{R/E} = \dfrac{v_{T/E}}{\tan 30.0°} = \dfrac{12.0 \text{ m/s}}{\tan 30.0°} = 20.8 \text{ m/s}.$ $v_{R/T} = \dfrac{v_{T/E}}{\sin 30.0°} = \dfrac{12.0 \text{ m/s}}{\sin 30.0°} = 24.0 \text{ m/s}.$

EVALUATE: The speed of the raindrop relative to the train is greater than its speed relative to the earth, because of the motion of the train.

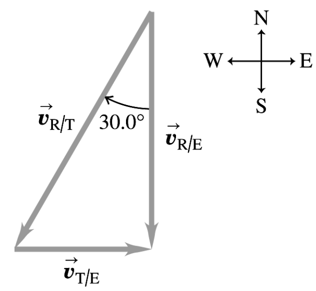

Figure 3.72

3.73. **IDENTIFY:** This is a relative velocity problem.

SET UP: The three relative velocities are:

$\vec{v}_{J/G}$: Juan relative to the ground. This velocity is due north and has magnitude $v_{J/G} = 8.00$ m/s.

$\vec{v}_{B/G}$: the ball relative to the ground. This vector is $37.0°$ east of north and has magnitude $v_{B/G} = 12.00$ m/s.

$\vec{v}_{B/J}$: the ball relative to Juan. We are asked to find the magnitude and direction of this vector.

The relative velocity addition equation is $\vec{v}_{B/G} = \vec{v}_{B/J} + \vec{v}_{J/G}$, so $\vec{v}_{B/J} = \vec{v}_{B/G} - \vec{v}_{J/G}$.

The relative velocity addition diagram does not form a right triangle so we must do the vector addition using components.

Take $+y$ to be north and $+x$ to be east.

EXECUTE: $v_{B/Jx} = +v_{B/G}\sin 37.0° = 7.222$ m/s

$v_{B/Jy} = +v_{B/G}\cos 37.0° - v_{J/G} = 1.584$ m/s

These two components give $v_{B/J} = 7.39$ m/s at $12.4°$ north of east.

EVALUATE: Since Juan is running due north, the ball's eastward component of velocity relative to him is the same as its eastward component relative to the earth. The northward component of velocity for Juan and the ball are in the same direction, so the component for the ball relative to Juan is the difference in their components of velocity relative to the ground.

3.74. **IDENTIFY:** This problem involves relative velocities and vector addition.

SET UP: The catcher is standing still, so the velocity of the ball relative to the catcher is the same as its velocity relative to the ground. We use $\vec{v}_{P/A} = \vec{v}_{P/B} + \vec{v}_{B/A}$. Fig. 3.74 shows the vector sum, where B refers to the baseball, S refers to the shortstop, and G is the ground.

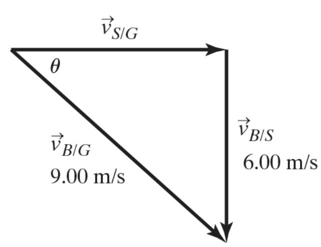

Figure 3.74

EXECUTE: From the figure, we see that $\sin\theta = \dfrac{6.00\text{ m/s}}{9.00\text{ m/s}} = 0.6667 \quad \rightarrow \quad \theta = 41.81°$. We also see that $v_{S/G}$ = (9.00 m/s) cos θ = (9.00 m/s) cos 41.81° = 6.71 m/s.

EVALUATE: As seen by the catcher, the ball is moving eastward at 6.71 m/s and southward at 6.00 m/s.

3.75. IDENTIFY: We need to use relative velocities.

SET UP: If B is moving relative to M and M is moving relative to E, the velocity of B relative to E is $\vec{v}_{B/E} = \vec{v}_{B/M} + \vec{v}_{M/E}$.

EXECUTE: Let $+x$ be east and $+y$ be north. We have $v_{B/M,x} = 2.50$ m/s, $v_{B/M,y} = -4.33$ m/s, $v_{M/E,x} = 0$, and $v_{M/E,y} = 6.00$ m/s. Therefore $v_{B/E,x} = v_{B/M,x} + v_{M/E,x} = 2.50$ m/s and $v_{B/E,y} = v_{B/M,y} + v_{M/E,y} = -4.33 \text{ m/s} + 6.00 \text{ m/s} = +1.67$ m/s. The magnitude is $v_{B/E} = \sqrt{(2.50 \text{ m/s})^2 + (1.67 \text{ m/s})^2} = 3.01$ m/s, and the direction is $\tan\theta = \dfrac{1.67}{2.50}$, which gives $\theta = 33.7^\circ$ north of east.

EVALUATE: Since Mia is moving, the velocity of the ball relative to her is different from its velocity relative to the ground or relative to Alice.

3.76. IDENTIFY: You have a graph showing the horizontal range of the rock as a function of the angle at which it was launched and want to find its initial velocity. Because air resistance is negligible, the rock is in free fall. The range formula applies since the rock rock was launced from the ground and lands at the ground.

SET UP: **(a)** The range formula is $R = \dfrac{v_0^2 \sin(2\theta)}{g}$, so a plot of R versus $\sin(2\theta_0)$ will give a straight line having slope equal to v_0^2/g. We can use that data in the graph in the problem to construct our graph by hand, or we can use graphing software. The resulting graph is shown in Figure 3.76.

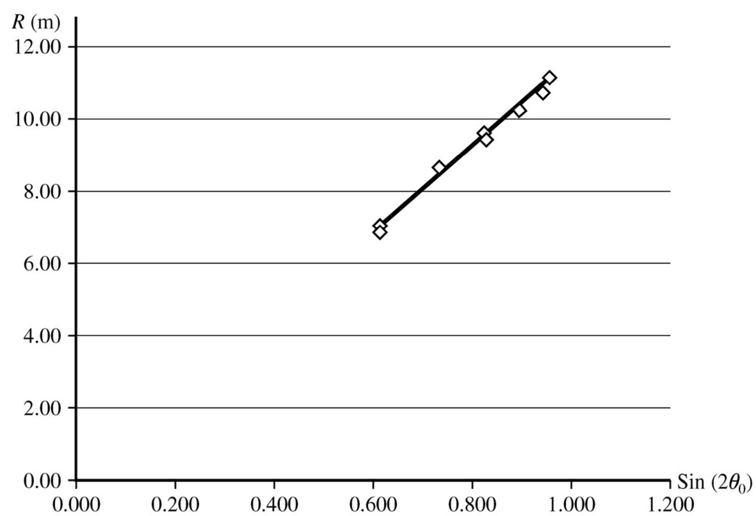

Figure 3.76

(b) The slope of the graph is 10.95 m, so 10.95 m = v_0^2/g. Solving for v_0 we get v_0 = 10.4 m/s.

(c) Solving the formula $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ for $y - y_0$ with $v_y = 0$ at the highest point, we get $y - y_0$ = 1.99 m.

EVALUATE: This approach to finding the launch speed v_0 requires only simple measurements: the range and the launch angle. It would be difficult and would require special equipment to measure v_0 directly.

3.77. **IDENTIFY:** The table gives data showing the horizontal range of the potato for various launch heights. You want to use this information to determine the launch speed of the potato, assuming negligible air resistance.

SET UP: The potatoes are launched horizontally, so $v_{0y} = 0$, and they are in free fall, so $a_y = 9.80\text{ m/s}^2$ downward and $a_x = 0$. The time a potato is in the air is just the time it takes for it to fall vertically from the launch point to the ground, a distance h.

EXECUTE: **(a)** For the vertical motion of a potato, we have $h = \frac{1}{2} gt^2$, so $t = \sqrt{2h/g}$. The horizontal range R is given by $R = v_0 t = v_0\sqrt{2h/g}$. Squaring gives $R^2 = \left(\dfrac{2v_0^2}{g}\right)h$. Graphing R^2 versus h will give a straight line with slope $2v_0^2/g$. We can graph the data from the table in the text by hand, or we could use graphing software. The result is shown in Figure 3.77.

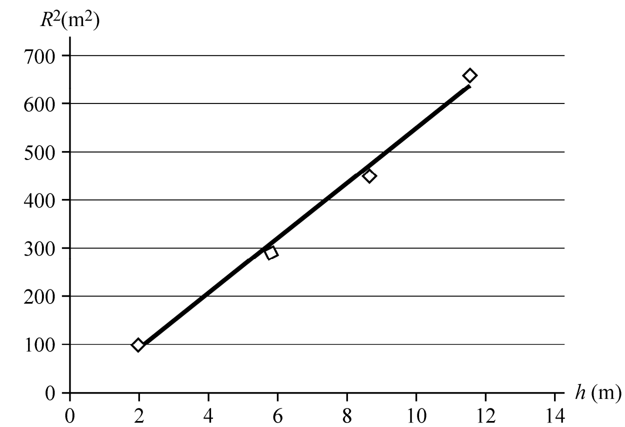

Figure 3.77

(b) The slope of the graph is 55.2 m, so $v_0 = \sqrt{\dfrac{(9.80\text{ m/s}^2)(55.2\text{ m})}{2}} = 16.4\text{ m/s}.$

(c) In this case, the potatoes are launched and land at ground level, so we can use the range formula with $\theta = 30.0°$ and $v_0 = 16.4$ m/s. The result is $R = \dfrac{v_0^2 \sin(2\theta)}{g} = 23.8\text{ m}.$

EVALUATE: This approach to finding the launch speed v_0 requires only simple measurements: the range and the launch height. It would be difficult and would require special equipment to measure v_0 directly.

3.78. **IDENTIFY:** This is a vector addition problem. The boat moves relative to the water and the water moves relative to the earth. We know the speed of the boat relative to the water and the times for the boat to go directly across the river, and from these things we want to find out how fast the water is moving and the width of the river.

SET UP: For both trips of the boat, $\vec{v}_{B/E} = \vec{v}_{B/W} + \vec{v}_{W/E}$, where the subscripts refer to the boat, earth, and water. The speed of the boat relative to the earth is $v_{B/E} = d/t$, where d is the width of the river and t is the time to cross the river, which is different in the two crossings.

EXECUTE: Figure 3.78 shows a vector sum for the first trip and for the return trip.

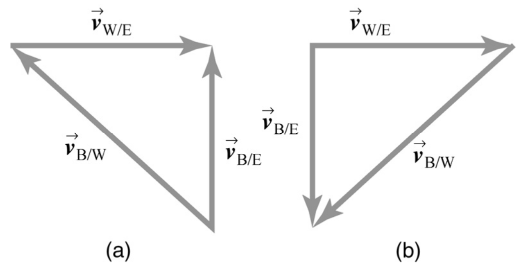

Figure 3.78a-b

(a) For both trips, the vectors in Figures 3.78 a & b form right triangles, so we can apply the Pythagorean theorem. $v_{B/E}^2 = v_{B/W}^2 - v_{W/E}^2$ and $v_{B/E} = d/t$. For the first trip, $v_{B/W} = 6.00$ m/s and $t = 20.1$ s, giving
$d^2/(20.1\text{ s})^2 = (60.00\text{ m/s}^2) - (v_{W/E})^2$. For the return trip, $v_{B/W} = 9.0$ m/s and $t = 11.2$ s, which gives $d^2/(11.2\text{ s})^2 = (9.00\text{ m/s}^2) - (v_{W/E})^2$. Solving these two equations together gives $d = 90.48$ m, which rounds to 90.5 m (the width of the river) and $v_{W/E} = 3.967$ m/s which rounds to 3.97 m/s (the speed of the current).
(b) The shortest time is when the boat heads perpendicular to the current, which is due north. Figure 3.78c illustrates this situation. The time to cross is $t = d/v_{B/W} = (90.48\text{ m})/(6.00\text{ m/s}) = 15.1$ s. The distance x east (down river) that you travel is $x = v_{W/E}t = (3.967\text{ m/s})(15.1\text{ s}) = 59.9$ m east of your starting point.

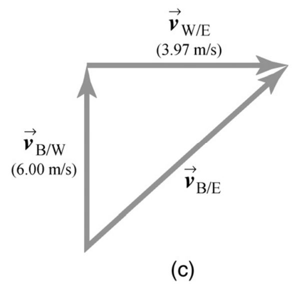

Figure 3.78c

EVALUATE: In part (a), the boat must have a velocity component up river to cancel out the current velocity. In part (b), velocity of the current has no effect on the crossing time, but it does affect the landing position of the boat.

3.79. **IDENTIFY:** Write an expression for the square of the distance (D^2) from the origin to the particle, expressed as a function of time. Then take the derivative of D^2 with respect to t, and solve for the value of t when this derivative is zero. If the discriminant is zero or negative, the distance D will never decrease.
SET UP: $D^2 = x^2 + y^2$, with $x(t)$ and $y(t)$ given by Eqs. (3.19) and (3.20).
EXECUTE: Following this process, $\sin^{-1}\sqrt{8/9} = 70.5°$.
EVALUATE: We know that if the object is thrown straight up it moves away from P and then returns, so we are not surprised that the projectile angle must be less than some maximum value for the distance to always increase with time.

3.80. **IDENTIFY:** Apply the relative velocity relation.

SET UP: Let $v_{\text{C/W}}$ be the speed of the canoe relative to water and $v_{\text{W/G}}$ be the speed of the water relative to the ground.

EXECUTE: **(a)** Taking all units to be in km and h, we have three equations. We know that heading upstream $v_{\text{C/W}} - v_{\text{W/G}} = 2.$ We know that heading downstream for a time t, $(v_{\text{C/W}} + v_{\text{W/G}})t = 5.$ We also know that for the bottle $v_{\text{W/G}}(t+1) = 3.$ Solving these three equations for $v_{\text{W/G}} = x$, $v_{\text{C/W}} = 2 + x$, therefore $(2 + x + x)t = 5$ or $(2 + 2x)t = 5.$ Also $t = 3/x - 1,$ so $(2+2x)\left(\dfrac{3}{x} - 1\right) = 5$ or $2x^2 + x - 6 = 0.$

The positive solution is $x = v_{\text{W/G}} = 1.5$ km/h.

(b) $v_{\text{C/W}} = 2\text{ km/h} + v_{\text{W/G}} = 3.5\text{ km/h}.$

EVALUATE: When they head upstream, their speed relative to the ground is $3.5\text{ km/h} - 1.5\text{ km/h} = 2.0\text{ km/h}.$ When they head downstream, their speed relative to the ground is $3.5\text{ km/h} + 1.5\text{ km/h} = 5.0\text{ km/h}.$ The bottle is moving downstream at 1.5 km/s relative to the earth, so they are able to overtake it.

3.81. **IDENTIFY:** The rocket has two periods of constant acceleration motion.

SET UP: Let $+y$ be upward. During the free-fall phase, $a_x = 0$ and $a_y = -g.$ After the engines turn on, $a_x = (3.00g)\cos 30.0°$ and $a_y = (3.00g)\sin 30.0°.$ Let *t* be the total time since the rocket was dropped and let *T* be the time the rocket falls before the engine starts.

EXECUTE: (i) The diagram is given in Figure 3.81 a.

(ii) The *x*-position of the plane is $(236\text{ m/s})t$ and the *x*-position of the rocket is $(236\text{ m/s})t + (1/2)(3.00)(9.80\text{ m/s}^2)\cos 30°(t-T)^2.$ The graphs of these two equations are sketched in Figure 3.81 b.

(iii) If we take $y = 0$ to be the altitude of the airliner, then $y(t) = -1/2gT^2 - gT(t-T) + 1/2(3.00)(9.80\text{ m/s}^2)(\sin 30°)(t-T)^2$ for the rocket. The airliner has constant *y*. The graphs are sketched in Figure 3.81b.

In each of the Figures 3.81a–c, the rocket is dropped at $t = 0$ and the time *T* when the motor is turned on is indicated.

By setting $y = 0$ for the rocket, we can solve for *t* in terms of *T*:

$0 = -(4.90\text{ m/s}^2)T^2 - (9.80\text{ m/s}^2)T(t-T) + (7.35\text{ m/s}^2)(t-T)^2.$ Using the quadratic formula for the variable $x = t - T$ we find $x = t - T = \dfrac{(9.80\text{ m/s}^2)T + \sqrt{(9.80\text{ m/s}^2T)^2 + (4)(7.35\text{ m/s}^2)(4.9)T^2}}{2(7.35\text{ m/s}^2)}$, or $t = 2.72\,T.$ Now, using the condition that $x_{\text{rocket}} - x_{\text{plane}} = 1000\text{ m},$ we find

$(236\text{ m/s})t + (12.7\text{ m/s}^2)(t-T)^2 - (236\text{ m/s})t = 1000\text{ m},$ or $(1.72T)^2 = 78.6\text{ s}^2.$ Therefore $T = 5.15\text{ s}.$

EVALUATE: During the free-fall phase the rocket and airliner have the same *x* coordinate but the rocket moves downward from the airliner. After the engines fire, the rocket starts to move upward and its horizontal component of velocity starts to exceed that of the airliner.

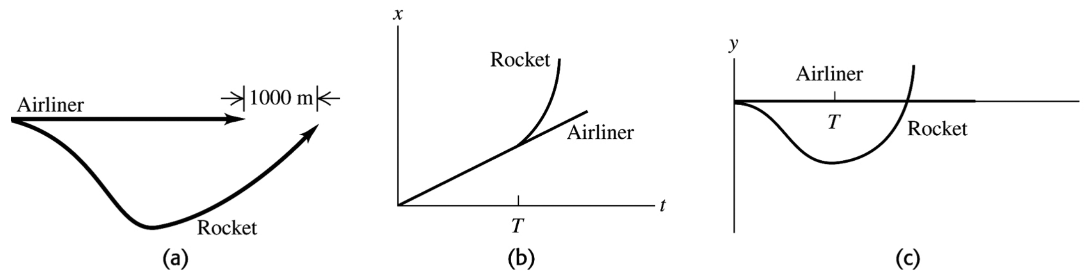

Figure 3. 81

3.82. **IDENTIFY:** We know the speed of the seeds and the distance they travel.
SET UP: We can treat the speed as constant over a very short distance, so $v = d/t$. The minimum frame rate is determined by the maximum speed of the seeds, so we use $v = 4.6$ m/s.
EXECUTE: Solving for t gives $t = d/v = (0.20 \times 10^{-3}\text{ s})/(4.6\text{ m/s}) = 4.3 \times 10^{-5}$ s per frame.
The frame rate is $1/(4.3 \times 10^{-5}$ s per frame) = 23,000 frames/second. Choice (c) 25,000 frames per second is closest to this result, so choice (c) is the best one.
EVALUATE: This experiment would clearly require high-speed photography.

3.83. **IDENTIFY:** A seed launched at 90° goes straight up. Since we are ignoring air resistance, its acceleration is 9.80 m/s^2 downward.
SET UP: For the highest possible speed $v_{0y} = 4.6$ m/s, and $v_y = 0$ at the highest point.
EXECUTE: $v_y = v_{0y} - gt$ gives $t = v_{0y}/g = (4.6\text{ m/s})/(9.80\text{ m/s}^2) = 0.47$ s, which is choice (b).
EVALUATE: Seeds are rather light and 4.6 m/s is fairly fast, so it might not be such a good idea to ignore air resistance. But doing so is acceptable to get a first approximation to the time.

3.84. **IDENTIFY:** A seed launched at 0° starts out traveling horizontally from a height of 20 cm above the ground. Since we are ignoring air resistance, its acceleration is 9.80 m/s^2 downward.
SET UP: Its horizontal distance is determined by the time it takes the seed to fall 20 cm, starting from rest vertically.
EXECUTE: The time to fall 20 cm is $0.20\text{ m} = \frac{1}{2}gt^2$, which gives $t = 0.202$ s. The horizontal distance traveled during this time is $x = (4.6\text{ m/s})(0.202\text{ s}) = 0.93\text{ m} = 93$ cm, which is choice (b).
EVALUATE: In reality the seed would travel a bit less distance due to air resistance.

3.85. **IDENTIFY:** About 2/3 of the seeds are launched between 6° and 56° above the horizontal, and the average for all the seeds is 31°. So clearly most of the seeds are launched above the horizontal.
SET UP and EXECUTE: For choice (a) to be correct, the seeds would need to cluster around 90°, which they do not. For choice (b), most seeds would need to launch below the horizontal, which is not the case. For choice (c), the launch angle should be around +45°. Since 31° is not far from 45°, this is the best choice. For choice (d), the seeds should go straight downward. This would require a launch angle of –90°, which is not the case.
EVALUATE: Evolutionarily it would be an advantage for the seeds to get as far from the parent plant as possible so the young plants would not compete with the parent for water and soil nutrients, so 45° is a biologically plausible result. Natural selection would tend to favor plants that launched their seeds at this angle over those that did not.

4

NEWTON'S LAWS OF MOTION

VP4.1.1. **IDENTIFY:** This is a problem about vector addition. We know the magnitude and direction of three forces and want to find the magnitude and direction of their resultant force.

SET UP: The components of a vector of magnitude A that make an angle θ with the $+x$-axis are $A_x = A \cos\theta$ and $A_y = A \sin\theta$. The magnitude and direction are $A = \sqrt{A_x^2 + A_y^2}$ and $\theta = \arctan\dfrac{A_y}{A_x}$. The components of the resultant are $R_x = A_x + B_x + C_x$ and $R_y = A_y + B_y + C_y$.

EXECUTE: For the three given vectors, the components of the resultant are

R_x = 40.0 N + 0 N + (60.0 N) cos 36.9° = 88.0 N

R_y = 0 N + (–80.0 N) + (60.0 N) sin 36.9° = –44.0 N

$R = \sqrt{(88.0\text{ N})^2 + (-44.0\text{ N})^2} = 98.4\text{ N}$.

θ = arctan [(–44.0 N)/(88.0 N)] = –26.6°. The minus sign tells us that θ is clockwise from the $+x$-axis.

EVALUATE: Since R_x is positive and R_y is negative, the resultant should point into the fourth quadrant, which agrees with our result.

VP4.1.2. **IDENTIFY:** This is a problem about vector addition. We know the magnitude and direction of three forces and want to find the magnitude and direction of their resultant force.

SET UP: The components of a vector of magnitude A that make an angle θ with the $+x$-axis are $A_x = A \cos\theta$ and $A_y = A \sin\theta$. The magnitude and direction are $A = \sqrt{A_x^2 + A_y^2}$ and $\theta = \arctan\dfrac{A_y}{A_x}$. The components of the resultant are $R_x = A_x + B_x + C_x$ and $R_y = A_y + B_y + C_y$.

EXECUTE: The components of the resultant are

R_x = 45.0 N + 0 N + (235 N) cos 143.1° = –143 N

R_y = 0 N + 105 N + 235 N sin 143.1° = 246 N

$R = \sqrt{(-143\text{ N})^2 + (246\text{ N})^2} = 285\text{ N}$.

θ = arctan[(246 N)/(–143 N)] = –60.0°, so θ = 120° counterclockwise from the $+x$-axis.

EVALUATE: The resultant has a negative x-component and a positive y-component, so it should point into the second quadrant, which is what our result shows.

VP4.1.3. **IDENTIFY:** This is a problem about vector addition. We know the magnitude and direction of three forces and want to find the magnitude and direction of their resultant force.

SET UP: The components of a vector of magnitude A that make an angle θ with the $+x$-axis are $A_x = A \cos\theta$ and $A_y = A \sin\theta$. The magnitude and direction are $A = \sqrt{A_x^2 + A_y^2}$ and $\theta = \arctan\dfrac{A_y}{A_x}$. The components of the resultant are $R_x = A_x + B_x + C_x$ and $R_y = A_y + B_y + C_y$.

EXECUTE: The components of the resultant are

R_x = 0 N + (60.0 N) cos 70.0° + (15.0 N) cos 160.0° = 6.4 N

R_y = –60.0 N + (60.0 N) sin 70.0° + (15.0 N) sin 160.0° = 1.5 N

$R = \sqrt{(6.4\text{ N})^2+(1.5\text{ N})^2} = 6.6\text{ N}$

θ = arctan[(1.5 N)/(64 N)] = 13° counterclockwise from the +x-axis.

EVALUATE: Since all the components of the resultant are positive, it should point into the first quadrant, which is what we found.

VP4.1.4. **IDENTIFY:** We know the resultant of three vectors, and we know two of them. We want to find the magnitude and direction of the unknown third vector.

SET UP: The components of a vector of magnitude A that make an angle θ with the +x-axis are $A_x = A \cos\theta$ and $A_y = A \sin\theta$. The magnitude and direction are $A = \sqrt{A_x^2 + A_y^2}$ and $\theta = \arctan\frac{A_y}{A_x}$. The components of the resultant are $R_x = A_x + B_x + C_x$ and $R_y = A_y + B_y + C_y$.

EXECUTE: Let T refer to Ernesto's force, K for Kamala's force, and T for Tsuroku's unknown force. The components of the resultant force are

R_x = 35.0 N + 0 N + T_x = (24.0 N) cos 210° $\rightarrow$ T_x = –55.8 N

R_y = 0 N + 50.0 N + T_y = (24.0 N) sin 210° $\rightarrow$ T_y = –62.0 N

$T = \sqrt{(-55.8\text{ N})^2+(-62.0\text{ N})^2} = 83.4\text{ N}$

θ = arctan[(–62.0 N)/(–55.8 N)] = 48.0°

Since both components of Tsuroku's force are negative, its direction is 48.0° below the –x-axis, which is 48.0° south of west.

EVALUATE: A graphical sum will confirm this result.

VP4.4.1. **IDENTIFY:** Apply Newton's second law to the box.

SET UP: Take the x-axis along the floor. Use $\sum F_x = ma_x$ to find a_x. The only horizontal force acting on the box is the force due to the worker.

EXECUTE: $\sum F_x = ma_x$ gives 25 N = (55 kg) a_x $\rightarrow$ a_x = 0.45 m/s^2. This acceleration is in the direction of the worker's force.

EVALUATE: Other forces act on the box, such as gravity downward and the upward push of the floor. But these do not affect the horizontal acceleration since they have no horizontal components.

VP4.4.2. **IDENTIFY:** Apply Newton's second law to the cheese.

SET UP: Take the x-axis along the surface of the table. Use $\sum F_x = ma_x$ to find a_x. The only horizontal force acting on the box is the 0.50-N force.

EXECUTE: **(a)** The forces are gravity acting vertically downward, the normal force due to the tabletop acting vertically upward, and the 0.50-N force due to your hand acting horizontally.

(b) $\sum F_x = ma_x$ gives 0.50 N = (2.0 kg) a_x $\rightarrow$ a_x = 0.25 m/s^2.

EVALUATE: The vertical forces do not affect the horizontal motion, so only the 0.50-N force causes the acceleration.

VP4.4.3. **IDENTIFY:** Apply Newton's second law to the puck.

SET UP: Take the x-axis along the direction of the horizontal hit on the puck. We know the acceleration of the puck, so use $\sum F_x = ma_x$ to find the force of the hit. The only horizontal force acting on the puck is the hit. For the vertical forces, use $\sum F_y = ma_y$.

EXECUTE: (a) With the x-axis horizontal, $\sum F_x = ma_x$ gives

F_x = (0.16 kg)(75 m/s^2) = 12 N.

(b) The vertical forces are gravity (the weight w) and the normal force n due to the ice. Using $\sum F_y = ma_y$, we have $n - w = 0$ since $a_y = 0$. So the normal force must be equal to the weight of the puck.

EVALUATE: The vertical forces do not affect the horizontal motion.

VP4.4.4. **IDENTIFY:** We apply Newton's second law to the plate. We know its horizontal acceleration and mass and one of the horizontal forces acting on it, so we can find the friction force, which is horizontal.

SET UP: Apply $\sum F_x = ma_x$ with the x-axis horizontal. The two horizontal forces are friction f and the push P.

EXECUTE: (a) $\sum F_x = ma_x$ = (0.800 kg)(12.0 m/s^2) = 9.60 N. This is the net force.

(b) $F_{\text{net}} = P - f$, so 9.60 N = 14.0 N – f, so f = 4.4 N. The direction is opposite to the push.

EVALUATE: Friction is less than the push, which it should be since the plate accelerates in the direction of the push.

VP4.5.1. **IDENTIFY:** The forces on the child are constant, so her acceleration is constant. Thus we can use the constant-acceleration motion equations to find her acceleration. Then apply Newton's second law to find the friction force.

SET UP: The formulas $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ and $\sum F_x = ma_x$ both apply.

EXECUTE: First find the girl's acceleration using $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$. Putting in the known numbers gives 0^2 = (3.00 m/s)^2 + $2a_x$(2.25 m), giving a_x = –2.00 m/s^2. The minus sign means that a_x is opposite to v_x. Now use $\sum F_x = ma_x$ to find the friction force. Since friction is the only horizontal force acting on her, it must be in the same direction as her acceleration. This gives $f = ma_x$ = (20.0 kg)(–2.00 m/s^2) = –40.0 N. The magnitude is 40.0 N and the direction is the same as the acceleration, which is opposite to the velocity.

EVALUATE: The other forces (gravity and the normal force due to the ice) are vertical, so they do not affect the horizontal motion.

VP4.5.2. **IDENTIFY:** This problem involves Newton's second law and motion with uniform acceleration. Thus we can use the constant-acceleration motion equations.

SET UP: First use $\sum F_x = ma_x$ to find the plane's acceleration. Then use $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ to find how far it travels while stopping.

EXECUTE: Using $\sum F_x = ma_x$ gives 2.90 N = (1.70×10^5 kg) a_x → a_x = 1.706 m/s^2. Now use $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ to find $x - x_0$. Call the +x-direction to be that of the velocity, so a_x will be negative. Thus

0^2 = (75.0 m/s)^2 + 2(–1.706 m/s^2)($x - x_0$) → $x - x_0$ = 1650 m = 1.65 km.

EVALUATE: This distance is about a mile, which is not so unreasonable for stopping a large plane landing at a fairly high speed.

VP4.5.3. **IDENTIFY:** This problem involves Newton's second law and motion with uniform acceleration. Thus we can use the constant-acceleration motion equations. We know the truck's mass, its initial speed, and the distance it travels while stopping. We want to find how long it takes to stop, its acceleration while stopping, and the braking force while stopping.

SET UP: The braking force is opposite to the truck's velocity but is in the same direction as the truck's acceleration. The equations $v_x = v_{0x} + a_x t$ and $\sum F_x = ma_x$ apply. In addition, the average velocity is $v_{av-x} = \dfrac{\Delta x}{\Delta t}$, and for uniform acceleration, it is also true that $v_{av} = \dfrac{v_0 + v}{2}$.

EXECUTE: **(a)** Combining the two equations for $v_{\text{av-}x}$ gives

$$\Delta t = \frac{\Delta x}{v_{av-x}} = \frac{\Delta x}{\left(\frac{v_0 + v}{2}\right)} = \frac{48.0 \text{ m}}{\frac{25.0 \text{ m/s} + 0}{2}} = 3.84 \text{ s.}$$

(b) Using $v_x = v_{0x} + a_x t$ gives $0 = 25.0$ m/s + a_x (3.84 s)

$a_x = -6.51$ m/s^2. The minus sign means that a_x is opposite to v_x. The magnitude is 6.51 m/s^2.

(c) $\sum F_x = ma_x$ = (2400 kg)(6.51 m/s^2) = 1.56×10^4 N.

EVALUATE: This may seem like a large force, but it is the only force stopping a massive object with a large acceleration.

VP4.5.4. **IDENTIFY:** This problem involves Newton's second law and motion with uniform acceleration. Thus we can use the constant-acceleration motion equations.

SET UP: The equations $\sum F_x = ma_x$ and $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ apply.

EXECUTE: **(a)** Gravity acts downward and the normal force due to the road acts upward. The horizontal forces are the push and the friction force from the road. The friction force is opposite to the push.

(b) Use $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ to find the acceleration of the car, giving

(1.40 m/s)^2 = 0 + 2a_x(5.00 m) $\rightarrow$ $a_x = 0.1960$ m/s^2. Now apply $\sum F_x = ma_x$.

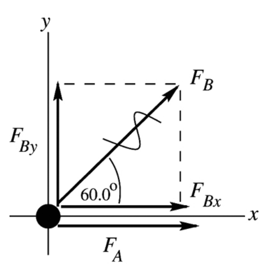
$P - f = ma_x$ $\rightarrow$ 8.00×10^2 N $- f = (1.15 \times 10^3$ kg)(0.1960 m/s^2) $\rightarrow$ $f = 575$ N.

EVALUATE: The push is 800 N and the opposing friction force is 575 N, so the car accelerates in the direction of the push.

4.1. **IDENTIFY:** Vector addition.

SET UP: Use a coordinate system where the $+x$-axis is in the direction of $\vec{F}_A$, the force applied by dog A. The forces are sketched in Figure 4.1.

EXECUTE:



$F_{Ax} = +270$ N, $F_{Ay} = 0$

$F_{Bx} = F_B \cos 60.0° = (300 \text{ N}) \cos 60.0° = +150$ N

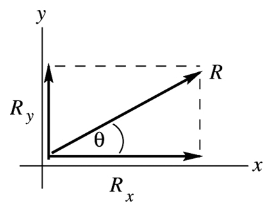
$F_{By} = F_B \sin 60.0° = (300 \text{ N}) \sin 60.0° = +260$ N

Figure 4.1a

$\vec{R} = \vec{F}_A + \vec{F}_B$

$R_x = F_{Ax} + F_{Bx} = +270 \text{ N} + 150 \text{ N} = +420$ N

$R_y = F_{Ay} + F_{By} = 0 + 260 \text{ N} = +260$ N



$$R = \sqrt{R_x^2 + R_y^2}$$
$$R = \sqrt{(420\text{ N})^2 + (260\text{ N})^2} = 494\text{ N}$$
$$\tan\theta = \frac{R_y}{R_x} = 0.619$$
$$\theta = 31.8°$$

Figure 4.1b

EVALUATE: The forces must be added as vectors. The magnitude of the resultant force is less than the sum of the magnitudes of the two forces and depends on the angle between the two forces.

4.2. **IDENTIFY:** We know the magnitudes and directions of three vectors and want to use them to find their components, and then to use the components to find the magnitude and direction of the resultant vector.
SET UP: Let $F_1 = 985$ N, $F_2 = 788$ N, and $F_3 = 411$ N. The angles θ that each force makes with the $+x$ axis are $\theta_1 = 31°$, $\theta_2 = 122°$, and $\theta_3 = 233°$. The components of a force vector are $F_x = F\cos\theta$ and $F_y = F\sin\theta$, and $R = \sqrt{R_x^2 + R_y^2}$ and $\tan\theta = \dfrac{R_y}{R_x}$.

EXECUTE: **(a)** $F_{1x} = F_1\cos\theta_1 = 844$ N, $F_{1y} = F_1\sin\theta_1 = 507$ N, $F_{2x} = F_2\cos\theta_2 = -418$ N, $F_{2y} = F_2\sin\theta_2 = 668$ N, $F_{3x} = F_3\cos\theta_3 = -247$ N, and $F_{3y} = F_3\sin\theta_3 = -328$ N.

(b) $R_x = F_{1x} + F_{2x} + F_{3x} = 179$ N; $R_y = F_{1y} + F_{2y} + F_{3y} = 847$ N. $R = \sqrt{R_x^2 + R_y^2} = 886$ N; $\tan\theta = \dfrac{R_y}{R_x}$ so $\theta = 78.1°$. $\vec{R}$ and its components are shown in Figure 4.2.

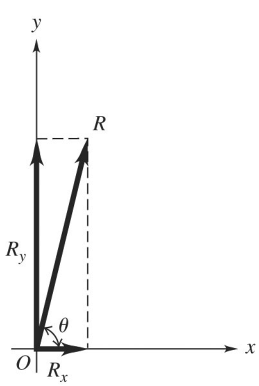


Figure 4.2

EVALUATE: A graphical sketch of the vector sum should agree with the results found in (b). Adding the forces as vectors gives a very different result from adding their magnitudes.

4.3. **IDENTIFY:** We know the resultant of two vectors of equal magnitude and want to find their magnitudes. They make the same angle with the vertical.

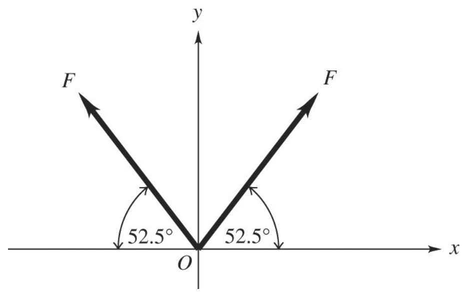

Figure 4.3

SET UP: Take $+y$ to be upward, so $\sum F_y = 5.00$ N. The strap on each side of the jaw exerts a force F directed at an angle of 52.5° above the horizontal, as shown in Figure 4.3.
EXECUTE: $\sum F_y = 2F \sin 52.5° = 5.00$ N, so $F = 3.15$ N.

EVALUATE: The resultant force has magnitude 5.00 N which is *not* the same as the sum of the magnitudes of the two vectors, which would be 6.30 N.

4.4. **IDENTIFY:** $F_x = F\cos\theta$, $F_y = F\sin\theta$.

SET UP: Let $+x$ be parallel to the ramp and directed up the ramp. Let $+y$ be perpendicular to the ramp and directed away from it. Then $\theta = 30.0°$.

EXECUTE: **(a)** $F = \dfrac{F_x}{\cos\theta} = \dfrac{90.0 \text{ N}}{\cos 30°} = 104$ N.

(b) $F_y = F\sin\theta = F_x \tan\theta = (90 \text{ N})(\tan 30°) = 52.0$ N.

EVALUATE: We can verify that $F_x^2 + F_y^2 = F^2$. The signs of F_x and F_y show their direction.

4.5. **IDENTIFY:** Add the two forces using components.
SET UP: $F_x = F\cos\theta$, $F_y = F\sin\theta$, where θ is the angle $\vec{F}$ makes with the $+x$ axis.

EXECUTE: **(a)** $F_{1x} + F_{2x} = (9.00 \text{ N})\cos 120° + (6.00 \text{ N})\cos(233.1°) = -8.10$ N

$F_{1y} + F_{2y} = (9.00 \text{ N})\sin 120° + (6.00 \text{ N})\sin(233.1°) = +3.00$ N.

(b) $R = \sqrt{R_x^2 + R_y^2} = \sqrt{(8.10 \text{ N})^2 + (3.00 \text{ N})^2} = 8.64$ N.

EVALUATE: Since $F_x < 0$ and $F_y > 0$, $\vec{F}$ is in the second quadrant.

4.6. **IDENTIFY:** Use constant acceleration equations to calculate a_x and t. Then use $\sum \vec{F} = m\vec{a}$ to calculate the net force.
SET UP: Let $+x$ be in the direction of motion of the electron.

EXECUTE: **(a)** $v_{0x} = 0$, $(x - x_0) = 1.80\times10^{-2}$ m, $v_x = 3.00\times10^6$ m/s. $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives

$$a_x = \frac{v_x^2 - v_{0x}^2}{2(x - x_0)} = \frac{(3.00\times10^6 \text{ m/s})^2 - 0}{2(1.80\times10^{-2} \text{ m})} = 2.50\times10^{14} \text{ m/s}^2$$

(b) $v_x = v_{0x} + a_x t$ gives $t = \dfrac{v_x - v_{0x}}{a_x} = \dfrac{3.00\times10^6 \text{ m/s} - 0}{2.50\times10^{14} \text{ m/s}^2} = 1.2\times10^{-8}$ s

(c) $\sum F_x = ma_x = (9.11\times10^{-31} \text{ kg})(2.50\times10^{14} \text{ m/s}^2) = 2.28\times10^{-16}$ N.

EVALUATE: The acceleration is in the direction of motion since the speed is increasing, and the net force is in the direction of the acceleration.

4.7. **IDENTIFY:** Friction is the only horizontal force acting on the skater, so it must be the one causing the acceleration. Newton's second law applies.

SET UP: Take $+x$ to be the direction in which the skater is moving initially. The final velocity is $v_x = 0$, since the skater comes to rest. First use the kinematics formula $v_x = v_{0x} + a_x t$ to find the acceleration, then apply $\sum \vec{F} = m\vec{a}$ to the skater.

EXECUTE: $v_x = v_{0x} + a_x t$ so $a_x = \dfrac{v_x - v_{0x}}{t} = \dfrac{0 - 2.40\text{ m/s}}{3.52\text{ s}} = -0.682\text{ m/s}^2$. The only horizontal force on the skater is the friction force, so $f_x = ma_x = (68.5\text{ kg})(-0.682\text{ m/s}^2) = -46.7\text{ N}$. The force is 46.7 N, directed opposite to the motion of the skater.

EVALUATE: Although other forces are acting on the skater (gravity and the upward force of the ice), they are vertical and therefore do not affect the horizontal motion.

4.8. **IDENTIFY:** The elevator and everything in it are accelerating upward, so we apply Newton's second law in the vertical direction.

SET UP: Your mass is $m = w/g = 63.8\text{ kg}$. Both you and the package have the same acceleration as the elevator. Take $+y$ to be upward, in the direction of the acceleration of the elevator, and apply $\sum F_y = ma_y$.

EXECUTE: **(a)** Your free-body diagram is shown in Figure 4.8a, where *n* is the scale reading. $\sum F_y = ma_y$ gives $n - w = ma$. Solving for *n* gives

$n = w + ma = 625\text{ N} + (63.8\text{ kg})(2.50\text{ m/s}^2) = 784\text{ N}$.

(b) The free-body diagram for the package is given in Figure 4.8b. $\sum F_y = ma_y$ gives $T - w = ma$, so $T = w + ma = (3.85\text{ kg})(9.80\text{ m/s}^2 + 2.50\text{ m/s}^2) = 47.4\text{ N}$.

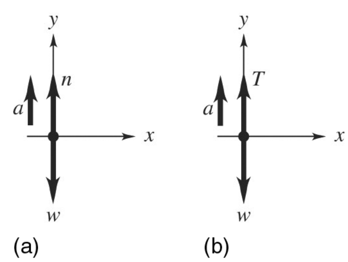

Figure 4.8

EVALUATE: The objects accelerate upward so for each of them the upward force is greater than the downward force.

4.9. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$ to the box.

SET UP: Let $+x$ be the direction of the force and acceleration. $\sum F_x = 48.0\text{ N}$.

EXECUTE: $\sum F_x = ma_x$ gives $m = \dfrac{\sum F_x}{a_x} = \dfrac{48.0\text{ N}}{2.20\text{ m/s}^2} = 21.8\text{ kg}$.

EVALUATE: The vertical forces sum to zero and there is no motion in that direction.

4.10. **IDENTIFY:** Use the information about the motion to find the acceleration and then use $\sum F_x = ma_x$ to calculate *m*.

SET UP: Let $+x$ be the direction of the force. $\sum F_x = 80.0\text{ N}$.

EXECUTE: **(a)** $x - x_0 = 11.0\text{ m}$, $t = 5.00\text{ s}$, $v_{0x} = 0$. $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives

$a_x = \dfrac{2(x - x_0)}{t^2} = \dfrac{2(11.0\text{ m})}{(5.00\text{ s})^2} = 0.880\text{ m/s}^2$. $m = \dfrac{\sum F_x}{a_x} = \dfrac{80.0\text{ N}}{0.880\text{ m/s}^2} = 90.9\text{ kg}$.

(b) $a_x = 0$ and v_x is constant. After the first 5.0 s, $v_x = v_{0x} + a_x t =$ (0.880 m/s^2) (5.00 s) = 4.40 m/s.

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 =$ (4.40 m/s)(5.00 s) = 22.0 m.

EVALUATE: The mass determines the amount of acceleration produced by a given force. The block moves farther in the second 5.00 s than in the first 5.00 s.

4.11. **IDENTIFY** and **SET UP:** Use Newton's second law in component form to calculate the acceleration produced by the force. Use constant acceleration equations to calculate the effect of the acceleration on the motion.

EXECUTE: **(a)** During this time interval the acceleration is constant and equal to

$$a_x = \frac{F_x}{m} = \frac{0.250\ \text{N}}{0.160\ \text{kg}} = 1.562\ \text{m/s}^2$$

We can use the constant acceleration kinematic equations from Chapter 2.

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = 0 + \frac{1}{2}(1.562\ \text{m/s}^2)(2.00\ \text{s})^2 = 3.12\ \text{m}$, so the puck is at $x = 3.12$ m.

$v_x = v_{0x} + a_x t = 0 + (1.562\ \text{m/s}^2)(2.00\ \text{s}) = 3.12\ \text{m/s}.$

(b) In the time interval from $t = 2.00$ s to 5.00 s the force has been removed so the acceleration is zero. The speed stays constant at $v_x = 3.12$ m/s. The distance the puck travels is

$x - x_0 = v_{0x}t = (3.12\ \text{m/s})(5.00\ \text{s} - 2.00\ \text{s}) = 9.36\ \text{m}.$ At the end of the interval it is at

$x = x_0 + 9.36\ \text{m} = 12.5\ \text{m}.$

In the time interval from $t = 5.00$ s to 7.00 s the acceleration is again $a_x = 1.562\ \text{m/s}^2$. At the start of this interval $v_{0x} = 3.12$ m/s and $x_0 = 12.5$ m.

$x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (3.12\ \text{m/s})(2.00\ \text{s}) + \frac{1}{2}(1.562\ \text{m/s}^2)(2.00\ \text{s})^2.$

$x - x_0 = 6.24\ \text{m} + 3.12\ \text{m} = 9.36\ \text{m}.$

Therefore, at $t = 7.00$ s the puck is at $x = x_0 + 9.36\ \text{m} = 12.5\ \text{m} + 9.36\ \text{m} = 21.9\ \text{m}.$

$v_x = v_{0x} = a_x t = 3.12\ \text{m/s} + (1.562\ \text{m/s}^2)(2.00\ \text{s}) = 6.24\ \text{m/s}.$

EVALUATE: The acceleration says the puck gains 1.56 m/s of velocity for every second the force acts. The force acts a total of 4.00 s so the final velocity is (1.56 m/s)(4.0 s) = 6.24 m/s.

4.12. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$. Then use a constant acceleration equation to relate the kinematic quantities.

SET UP: Let $+x$ be in the direction of the force.

EXECUTE: **(a)** $a_x = F_x / m$ = (14.0 N)/(32.5 kg) = 0.4308 m/s^2, which rounds to 0.431 m/s^2 for the final answer.

(b) $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$. With $v_{0x} = 0$, $x = \frac{1}{2}a_x t^2 = \frac{1}{2}(0.4308\ \text{m/s}^2)(10.0\ \text{s})^2 = 21.5\ \text{m}.$

(c) $v_x = v_{0x} + a_x t$. With $v_{0x} = 0$, $v_x = a_x t$ = (0.4308 m/s^2)(10.0 s) = 4.31 m/s.

EVALUATE: The acceleration connects the motion to the forces.

4.13. **IDENTIFY:** The force and acceleration are related by Newton's second law.

SET UP: $\sum F_x = ma_x$, where $\sum F_x$ is the net force. $m = 4.50$ kg.

EXECUTE: **(a)** The maximum net force occurs when the acceleration has its maximum value.

$\sum F_x = ma_x = (4.50\ \text{kg})(10.0\ \text{m/s}^2) = 45.0\ \text{N}.$ This maximum force occurs between 2.0 s and 4.0 s.

(b) The net force is constant when the acceleration is constant. This is between 2.0 s and 4.0 s.

(c) The net force is zero when the acceleration is zero. This is the case at $t = 0$ and $t = 6.0$ s.

EVALUATE: A graph of $\sum F_x$ versus t would have the same shape as the graph of a_x versus t.

4.14. **IDENTIFY:** The force and acceleration are related by Newton's second law. $a_x = \dfrac{dv_x}{dt}$, so a_x is the slope of the graph of v_x versus t.

SET UP: The graph of v_x versus t consists of straight-line segments. For $t = 0$ to $t = 2.00$ s, $a_x = 4.00\ \text{m/s}^2$. For $t = 2.00$ s to 6.00 s, $a_x = 0$. For $t = 6.00$ s to 10.0 s, $a_x = 1.00\ \text{m/s}^2$. $\sum F_x = ma_x$, with $m = 2.75$ kg. $\sum F_x$ is the net force.

EXECUTE: **(a)** The maximum net force occurs when the acceleration has its maximum value. $\sum F_x = ma_x = (2.75\ \text{kg})(4.00\ \text{m/s}^2) = 11.0$ N. This maximum occurs in the interval $t = 0$ to $t = 2.00$ s.

(b) The net force is zero when the acceleration is zero. This is between 2.00 s and 6.00 s.

(c) Between 6.00 s and 10.0 s, $a_x = 1.00\ \text{m/s}^2$, so $\sum F_x = (2.75\ \text{kg})(1.00\ \text{m/s}^2) = 2.75$ N.

EVALUATE: The net force is largest when the velocity is changing most rapidly.

4.15. **IDENTIFY:** The net force and the acceleration are related by Newton's second law. When the rocket is near the surface of the earth the forces on it are the upward force $\vec{F}$ exerted on it because of the burning fuel and the downward force $\vec{F}_{\text{grav}}$ of gravity. $F_{\text{grav}} = mg$.

SET UP: Let $+y$ be upward. The weight of the rocket is $F_{\text{grav}} = (8.00\ \text{kg})(9.80\ \text{m/s}^2) = 78.4$ N.

EXECUTE: **(a)** At $t = 0$, $F = A = 100.0$ N. At $t = 2.00$ s, $F = A + (4.00\ \text{s}^2)B = 150.0$ N and $B = \dfrac{150.0\ \text{N} - 100.0\ \text{N}}{4.00\ \text{s}^2} = 12.5\ \text{N/s}^2$.

(b) (i) At $t = 0$, $F = A = 100.0$ N. The net force is $\sum F_y = F - F_{\text{grav}} = 100.0\ \text{N} - 78.4\ \text{N} = 21.6$ N. $a_y = \dfrac{\sum F_y}{m} = \dfrac{21.6\ \text{N}}{8.00\ \text{kg}} = 2.70\ \text{m/s}^2$. (ii) At $t = 3.00$ s, $F = A + B(3.00\ \text{s})^2 = 212.5$ N. $\sum F_y = 212.5\ \text{N} - 78.4\ \text{N} = 134.1$ N. $a_y = \dfrac{\sum F_y}{m} = \dfrac{134.1\ \text{N}}{8.00\ \text{kg}} = 16.8\ \text{m/s}^2$.

(c) Now $F_{\text{grav}} = 0$ and $\sum F_y = F = 212.5$ N. $a_y = \dfrac{212.5\ \text{N}}{8.00\ \text{kg}} = 26.6\ \text{m/s}^2$.

EVALUATE: The acceleration increases as F increases.

4.16. **IDENTIFY:** Weight and mass are related by $w = mg$. The mass is constant but g and w depend on location.

SET UP: On earth, $g = 9.80\ \text{m/s}^2$.

EXECUTE: **(a)** $\dfrac{w}{g} = m$, which is constant, so $\dfrac{w_{\text{E}}}{g_{\text{E}}} = \dfrac{w_{\text{A}}}{g_{\text{A}}}$. $w_{\text{E}} = 17.5$ N, $g_{\text{E}} = 9.80\ \text{m/s}^2$, and $w_{\text{M}} = 3.24$ N. $g_{\text{M}} = \left(\dfrac{w_{\text{A}}}{w_{\text{E}}}\right) g_{\text{E}} = \left(\dfrac{3.24\ \text{N}}{17.5\ \text{N}}\right)(9.80\ \text{m/s}^2) = 1.81\ \text{m/s}^2$.

(b) $m = \dfrac{w_{\text{E}}}{g_{\text{E}}} = \dfrac{17.5\ \text{N}}{9.80\ \text{m/s}^2} = 1.79$ kg.

EVALUATE: The weight at a location and the acceleration due to gravity at that location are directly proportional.

4.17. **IDENTIFY** and **SET UP:** $F = ma$. We must use $w = mg$ to find the mass of the boulder.

EXECUTE: $m = \dfrac{w}{g} = \dfrac{2400\ \text{N}}{9.80\ \text{m/s}^2} = 244.9$ kg

Then $F = ma = (244.9\text{ kg})(12.0\text{ m/s}^2) = 2940\text{ N}$.

EVALUATE: We must use mass in Newton's second law. Mass and weight are proportional.

4.18. **IDENTIFY:** Find weight from mass and vice versa.

SET UP: Equivalencies we'll need are: $1\,\mu\text{g} = 10^{-6}\text{ g} = 10^{-9}\text{ kg}$, $1\text{ mg} = 10^{-3}\text{ g} = 10^{-6}\text{ kg}$, $1\text{ N} = 0.2248\text{ lb}$, and $g = 9.80\text{ m/s}^2 = 32.2\text{ ft/s}^2$.

EXECUTE: **(a)** $m = 210\,\mu\text{g} = 2.10\times10^{-7}\text{ kg}$. $w = mg = (2.10\times10^{-7}\text{ kg})(9.80\text{ m/s}^2) = 2.06\times10^{-6}\text{ N}$.

(b) $m = 12.3\text{ mg} = 1.23\times10^{-5}\text{ kg}$. $w = mg = (1.23\times10^{-5}\text{ kg})(9.80\text{ m/s}^2) = 1.21\times10^{-4}\text{ N}$.

(c) $(45\text{ N})\left(\dfrac{0.2248\text{ lb}}{1\text{ N}}\right) = 10.1\text{ lb}$. $m = \dfrac{w}{g} = \dfrac{45\text{ N}}{9.80\text{ m/s}^2} = 4.6\text{ kg}$.

EVALUATE: We are not converting mass to weight (or vice versa) since they are different types of quantities. We are finding what a given mass will weigh and how much mass a given weight contains.

4.19. **IDENTIFY** and **SET UP:** $w = mg$. The mass of the watermelon is constant, independent of its location. Its weight differs on earth and Jupiter's moon. Use the information about the watermelon's weight on earth to calculate its mass:

EXECUTE: **(a)** $w = mg$ gives that $m = \dfrac{w}{g} = \dfrac{44.0\text{ N}}{9.80\text{ m/s}^2} = 4.49\text{ kg}$.

(b) On Jupiter's moon, $m = 4.49\text{ kg}$, the same as on earth. Thus the weight on Jupiter's moon is $w = mg = (4.49\text{ kg})(1.81\text{ m/s}^2) = 8.13\text{ N}$.

EVALUATE: The weight of the watermelon is less on Io, since g is smaller there.

4.20. **IDENTIFY and SET UP:** This problem requires some estimation and a web search.

EXECUTE: Web search: The mass of a Sumo wrestler is approximately 148 kg, which is about 326 lb. Estimate: The average student in class weighs about 165 lb which is about 75 kg.

EVALUATE: These are average values.

4.21. **IDENTIFY:** Apply $\sum F_x = ma_x$ to find the resultant horizontal force.

SET UP: Let the acceleration be in the $+x$ direction.

EXECUTE: $\sum F_x = ma_x = (55\text{ kg})(15\text{ m/s}^2) = 825\text{ N}$. The force is exerted by the blocks. The blocks push on the sprinter because the sprinter pushes on the blocks.

EVALUATE: The force the blocks exert on the sprinter has the same magnitude as the force the sprinter exerts on the blocks. The harder the sprinter pushes, the greater the force on her.

4.22. **IDENTIFY:** Newton's third law applies.

SET UP: The car exerts a force on the truck and the truck exerts a force on the car.

EXECUTE: The force and the reaction force are always exactly the same in magnitude, so the force that the truck exerts on the car is 1600 N, by Newton's third law.

EVALUATE: Even though the truck is much larger and more massive than the car, it cannot exert a larger force on the car than the car exerts on it.

4.23. **IDENTIFY:** The system is accelerating so we use Newton's second law.

SET UP: The acceleration of the entire system is due to the 250-N force, but the acceleration of box B is due to the force that box A exerts on it. $\sum F = ma$ applies to the two-box system and to each box individually.

EXECUTE: For the two-box system: $a_x = \dfrac{250\text{ N}}{25.0\text{ kg}} = 10.0\text{ m/s}^2$. Then for box B, where F_A is the force exerted on B by A, $F_A = m_B a = (5.0\text{ kg})(10.0\text{ m/s}^2) = 50\text{ N}$.

EVALUATE: The force on B is less than the force on A.

4.24. IDENTIFY: The reaction forces in Newton's third law are always between a pair of objects. In Newton's second law all the forces act on a single object.
SET UP: Let $+y$ be downward. $m = w/g$.

EXECUTE: The reaction to the upward normal force on the passenger is the downward normal force, also of magnitude 620 N, that the passenger exerts on the floor. The reaction to the passenger's weight is the
gravitational force that the passenger exerts on the earth, upward and also of magnitude 650 N.
$\dfrac{\sum F_y}{m} = a_y$ gives $a_y = \dfrac{650\text{ N} - 620\text{ N}}{(650\text{ N})/(9.80\text{ m/s}^2)} = 0.452\text{ m/s}^2$. The passenger's acceleration is 0.452 m/s^2, downward.
EVALUATE: There is a net downward force on the passenger, and the passenger has a downward acceleration.

4.25. IDENTIFY: Apply Newton's second law to the earth.
SET UP: The force of gravity that the earth exerts on her is her weight,
$w = mg = (45\text{ kg})(9.8\text{ m/s}^2) = 441\text{ N}$. By Newton's third law, she exerts an equal and opposite force on the earth.
Apply $\sum\vec{F} = m\vec{a}$ to the earth, with $\left|\sum\vec{F}\right| = w = 441\text{ N}$, but must use the mass of the earth for m.

EXECUTE: $a = \dfrac{w}{m} = \dfrac{441\text{ N}}{6.0\times10^{24}\text{ kg}} = 7.4\times10^{-23}\text{ m/s}^2$.

EVALUATE: This is *much* smaller than her acceleration of 9.8 m/s^2. The force she exerts on the earth equals in magnitude the force the earth exerts on her, but the acceleration the force produces depends on the mass of the object and her mass is *much* less than the mass of the earth.

4.26. IDENTIFY: The surface of block B can exert both a friction force and a normal force on block A. The friction force is directed so as to oppose relative motion between blocks B and A. Gravity exerts a downward force w on block A.
SET UP: The pull is a force on B not on A.
EXECUTE: **(a)** If the table is frictionless there is a net horizontal force on the combined object of the two blocks, and block B accelerates in the direction of the pull. The friction force that B exerts on A is to the right, to try to prevent A from slipping relative to B as B accelerates to the right. The free-body diagram is sketched in Figure 4.26a (next page). f is the friction force that B exerts on A and n is the normal force that B exerts on A.
(b) The pull and the friction force exerted on B by the table cancel and the net force on the system of two blocks is zero. The blocks move with the same constant speed and B exerts no friction force on A. The free-body diagram is sketched in Figure 4.26b (next page).
EVALUATE: If in part (b) the pull force is decreased, block B will slow down, with an acceleration directed to the left. In this case the friction force on A would be to the left, to prevent relative motion between the two blocks by giving A an acceleration equal to that of B.

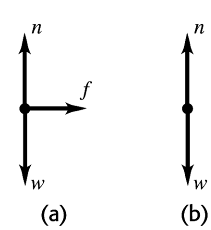

Figure 4.26

4.27. **IDENTIFY:** Identify the forces on each object.

SET UP: In each case the forces are the noncontact force of gravity (the weight) and the forces applied by objects that are in contact with each crate. Each crate touches the floor and the other crate, and some object applies $\vec{F}$ to crate A.

EXECUTE: **(a)** The free-body diagrams for each crate are given in Figure 4.27.

F_{AB} (the force on m_A due to m_B) and F_{BA} (the force on m_B due to m_A) form an action-reaction pair.

(b) Since there is no horizontal force opposing F, any value of F, no matter how small, will cause the crates to accelerate to the right. The weight of the two crates acts at a right angle to the horizontal, and is in any case balanced by the upward force of the surface on them.

EVALUATE: Crate B is accelerated by F_{BA} and crate A is accelerated by the net force $F - F_{AB}$. The greater the total weight of the two crates, the greater their total mass and the smaller will be their acceleration.

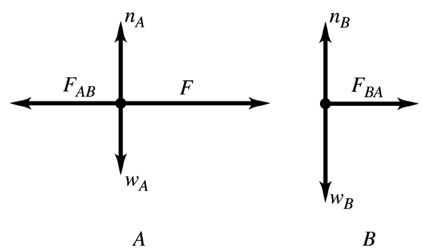

Figure 4.27

4.28. **IDENTIFY:** Use a constant acceleration equation to find the stopping time and acceleration. Then use $\sum\vec{F} = m\vec{a}$ to calculate the force.

SET UP: Let $+x$ be in the direction the bullet is traveling. $\vec{F}$ is the force the wood exerts on the bullet.

EXECUTE: **(a)** $v_{0x} = 350$ m/s, $v_x = 0$ and $(x - x_0) = 0.130$ m. $(x - x_0) = \left(\dfrac{v_{0x} + v_x}{2}\right)t$ gives

$$t = \frac{2(x - x_0)}{v_{0x} + v_x} = \frac{2(0.130\text{ m})}{350\text{ m/s}} = 7.43\times10^{-4}\text{ s}.$$

(b) $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives $a_x = \dfrac{v_x^2 - v_{0x}^2}{2(x - x_0)} = \dfrac{0 - (350\text{ m/s})^2}{2(0.130\text{ m})} = -4.71\times10^5\text{ m/s}^2$

$\sum F_x = ma_x$ gives $-F = ma_x$ and $F = -ma_x = -(1.80\times10^{-3}\text{ kg})(-4.71\times10^5\text{ m/s}^2) = 848$ N.

EVALUATE: The acceleration and net force are opposite to the direction of motion of the bullet.

4.29. **IDENTIFY:** Since the observer in the train sees the ball hang motionless, the ball must have the same acceleration as the train car. By Newton's second law, there must be a net force on the ball in the same direction as its acceleration.

SET UP: The forces on the ball are gravity, which is w, downward, and the tension $\vec{T}$ in the string, which is directed along the string.

EXECUTE: **(a)** The acceleration of the train is zero, so the acceleration of the ball is zero. There is no net horizontal force on the ball and the string must hang vertically. The free-body diagram is sketched in Figure 4.29a.

(b) The train has a constant acceleration directed east so the ball must have a constant eastward acceleration. There must be a net horizontal force on the ball, directed to the east. This net force must come from an eastward component of $\vec{T}$ and the ball hangs with the string displaced west of vertical. The free-body diagram is sketched in Figure 4.29b.

EVALUATE: When the motion of an object is described in an inertial frame, there must be a net force in the direction of the acceleration.

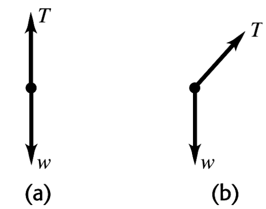

Figure 4.29

4.30. **IDENTIFY:** Identify the forces on the chair. The floor exerts a normal force and a friction force.
SET UP: Let $+y$ be upward and let $+x$ be in the direction of the motion of the chair.

EXECUTE: **(a)** The free-body diagram for the chair is given in Figure 4.30.
(b) For the chair, $a_y = 0$ so $\sum F_y = ma_y$ gives $n - mg - F\sin 37° = 0$ and $n = 142$ N.

EVALUATE: n is larger than the weight because $\vec{F}$ has a downward component.

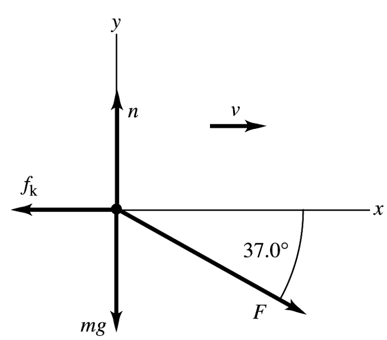

Figure 4.30

4.31. **IDENTIFY:** This problem requires some estimation and a web search.
SET UP: We want to find the force the pitcher exerts on a baseball while pitching a fastball. Estimate: The distance a pitcher moves the ball during a pitch is about twice an arm length, which is about 3.0 ft. Web search: A major league baseball weighs between 5.00 oz and 5.25 oz, so use an average of 5.125 oz, which is 0.320 lb with a mass of 1.0×10^{-2} slugs. The average speed of a pitched fastball is 92 mph which is 135 ft/s.
Assumptions: The ball moves in a straight horizontal line with constant acceleration during the pitch. We use the information above to calculate the acceleration of the ball during the pitch. Then apply Newton's second law to find the average force on the ball. $\sum F_x = ma_x$ applies to the ball and $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ for constant acceleration.

EXECUTE: Use $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ to find the acceleration: $(135 \text{ ft/s})^2 = 0 + 2a_x(3.0 \text{ ft})$, which gives $a_x = 3.0 \times 10^3 \text{ ft/s}^2$. Now apply $\sum F_x = ma_x$ to the ball. The only force accelerating it is the push P of the pitcher, so $P = ma = (1.0 \times 10^{-2} \text{ slugs})(3.0 \times 10^3 \text{ ft/s}^2) = 30$ lb. This push is about 130 N.
EVALUATE: A 30-lb push may not seem like much, but the ball has a rather small mass, so this push can produce a large acceleration. In this case, $a_x/g = (3000 \text{ ft/s}^2)/(32.2 \text{ ft/s}^2) = 93$, so a_x is nearly $100g$!

4.32. **IDENTIFY:** Use the motion of the ball to calculate g, the acceleration of gravity on the planet. Then $w = mg$.

SET UP: Let $+y$ be downward and take $y_0 = 0$. $v_{0y} = 0$ since the ball is released from rest.

EXECUTE: Get g on X: $y = \frac{1}{2}gt^2$ gives $10.0\text{ m} = \frac{1}{2}g(3.40\text{ s})^2$. $g = 1.73\text{ m/s}^2$ and then

$w_X = mg_X = (0.100\text{ kg})(1.73\text{ m/s}^2) = 0.173\text{ N}$.

EVALUATE: g on Planet X is smaller than on earth and the object weighs less than it would on earth.

4.33. **IDENTIFY:** Apply Newton's second law to the bucket and constant-acceleration kinematics.

SET UP: The minimum time to raise the bucket will be when the tension in the cord is a maximum since this will produce the greatest acceleration of the bucket.

EXECUTE: Apply Newton's second law to the bucket: $T - mg = ma$. For the maximum acceleration, the tension is greatest, so $a = \frac{T - mg}{m} = \frac{75.0\text{ N} - (5.60\text{ kg})(9.8\text{ m/s}^2)}{5.60\text{ kg}} = 3.593\text{ m/s}^2$.

The kinematics equation for $y(t)$ gives $t = \sqrt{\frac{2(y - y_0)}{a_y}} = \sqrt{\frac{2(12.0\text{ m})}{3.593\text{ m/s}^2}} = 2.58\text{ s}$.

EVALUATE: A shorter time would require a greater acceleration and hence a stronger pull, which would break the cord.

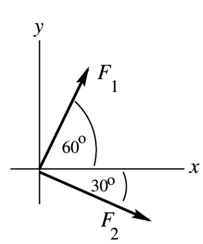
4.34. **IDENTIFY:** The pull accelerates both blocks, so we apply Newton's second law to each one.

SET UP: Apply $\sum F_x = ma_x$ to each block. Using B we can find the friction force on each block, which is also the friction force on A, by Newton's third law. Then using A we can find its acceleration. The target variable is the acceleration of block A.

EXECUTE: Block B: The friction force on B due to A opposes the pull. So $\sum F_x = ma_x$ gives $P - f = m_B a_B$, so $f = P - m_B a_B = 12.0\text{ N} - (6.00\text{ kg})(1.80\text{ m/s}^2) = 1.20\text{ N}$. Now apply $\sum F_x = ma_x$ to block A. Only friction accelerates this block forward, and it must be 1.20 N. Thus $f = m_A a_A$, which becomes $1.20\text{ N} = (2.00\text{ kg})a_A$, so $a_A = 0.600\text{ m/s}^2$.

EVALUATE: Block B accelerates forward at 1.80 m/s^2 but block A accelerates forward at only 0.600 m/s^2. Thus A is not keeping up with B, which means it is sliding *backward* as observed by a person moving with B.

4.35. **IDENTIFY:** If the box moves in the $+x$-direction it must have $a_y = 0$, so $\sum F_y = 0$.



The smallest force the child can exert and still produce such motion is a force that makes the y-components of all three forces sum to zero, but that doesn't have any x-component.

Figure 4.35

SET UP: $\vec{F}_1$ and $\vec{F}_2$ are sketched in Figure 4.35. Let $\vec{F}_3$ be the force exerted by the child.

$\sum F_y = ma_y$ implies $F_{1y} + F_{2y} + F_{3y} = 0$, so $F_{3y} = -(F_{1y} + F_{2y})$.

EXECUTE: $F_{1y} = +F_1 \sin 60° = (100\text{ N})\sin 60° = 86.6\text{ N}$

$F_{2y} = +F_2 \sin(-30°) = -F_2 \sin 30° = -(140\text{ N})\sin 30° = -70.0\text{ N}$

Then $F_{3y} = -(F_{1y} + F_{2y}) = -(86.6\text{ N} - 70.0\text{ N}) = -16.6\text{ N}$; $F_{3x} = 0$

The smallest force the child can exert has magnitude 17 N and is directed at $90°$ clockwise from the $+x$-axis shown in the figure.

(b) IDENTIFY and SET UP: Apply $\sum F_x = ma_x$. We know the forces and a_x so can solve for m. The force exerted by the child is in the $-y$-direction and has no x-component.

EXECUTE: $F_{1x} = F_1 \cos 60° = 50\ \text{N}$

$F_{2x} = F_2 \cos 30° = 121.2\ \text{N}$

$\sum F_x = F_{1x} + F_{2x} = 50\ \text{N} + 121.2\ \text{N} = 171.2\ \text{N}$

$$m = \frac{\sum F_x}{a_x} = \frac{171.2\ \text{N}}{2.00\ \text{m/s}^2} = 85.6\ \text{kg}$$

Then $w = mg = 840\ \text{N}$.

EVALUATE: In part (b) we don't need to consider the y-component of Newton's second law. $a_y = 0$ so the mass doesn't appear in the $\sum F_y = ma_y$ equation.

4.36. IDENTIFY: Use constant acceleration equations to calculate the acceleration a_x that would be required. Then use $\sum F_x = ma_x$ to find the necessary force.

SET UP: Let $+x$ be the direction of the initial motion of the auto.

EXECUTE: $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ with $v_x = 0$ gives $a_x = -\dfrac{v_{0x}^2}{2(x - x_0)}$. The force F is directed opposite

to

the motion and $a_x = -\dfrac{F}{m}$. Equating these two expressions for a_x gives

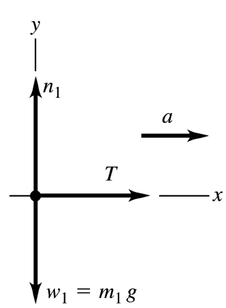
$$F = m\frac{v_{0x}^2}{2(x - x_0)} = (850\ \text{kg})\frac{(12.5\ \text{m/s})^2}{2(1.8\times10^{-2}\ \text{m})} = 3.7\times10^6\ \text{N}.$$

EVALUATE: A very large force is required to stop such a massive object in such a short distance.

4.37. IDENTIFY: Use Newton's second law to relate the acceleration and forces for each crate.

(a) SET UP: Since the crates are connected by a rope, they both have the same acceleration, $2.50\ \text{m/s}^2$.

(b) The forces on the 4.00 kg crate are shown in Figure 4.37a.



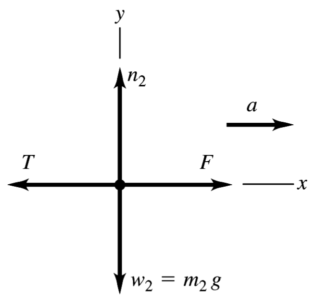
EXECUTE:

$\sum F_x = ma_x$

$T = m_1 a = (4.00\ \text{kg})(2.50\ \text{m/s}^2) = 10.0\ \text{N}.$

Figure 4.37a

(c) SET UP: Forces on the 6.00 kg crate are shown in Figure 4.37b.



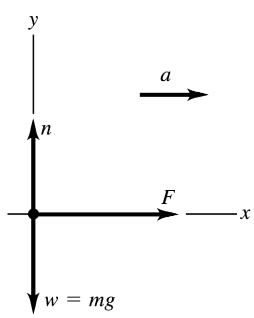
The crate The crate accelerates to the right, so the net force is to the right. F must be larger than T.

Figure 4.37b

(d) EXECUTE: $\sum F_x = ma_x$ gives $F - T = m_2 a$

$F = T + m_2 a = 10.0\text{ N} + (6.00\text{ kg})(2.50\text{ m/s}^2) = 10.0\text{ N} + 15.0\text{ N} = 25.0\text{ N}$

EVALUATE: We can also consider the two crates and the rope connecting them as a single object of mass $m = m_1 + m_2 = 10.0$ kg. The free-body diagram is sketched in Figure 4.37c.



$\sum F_x = ma_x$

$F = ma = (10.0\text{ kg})(2.50\text{ m/s}^2) = 25.0\text{ N}$

This agrees with our answer in part (d).

Figure 4.37c

4.38. **IDENTIFY:** Use kinematics to find the acceleration and then apply Newton's second law.
SET UP: The 60.0-N force accelerates both blocks, but only the tension in the rope accelerates block B. The force F is constant, so the acceleration is constant, which means that the standard kinematics formulas apply. There is no friction.
EXECUTE: **(a)** First use kinematics to find the acceleration of the system. Using $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ with $x - x_0 = 18.0$ m, $v_{0x} = 0$, and $t = 5.00$ s, we get $a_x = 1.44\text{ m/s}^2$. Now apply Newton's second law to the horizontal motion of block A, which gives $F - T = m_A a$. $T = 60.0\text{ N} - (15.0\text{ kg})(1.44\text{ m/s}^2) = 38.4$ N.
(b) Apply Newton's second law to block B, giving $T = m_B a$. $m_B = T/a = (38.4\text{ N})/(1.44\text{ m/s}^2) = 26.7$ kg.
EVALUATE: As an alternative approach, consider the two blocks as a single system, which makes the tension an internal force. Newton's second law gives $F = (m_A + m_B)a$. Putting in numbers gives $60.0\text{ N} = (15.0\text{ kg} + m_B)(1.44\text{ m/s}^2)$, and solving for m_B gives 26.7 kg. Now apply Newton's second law to either block A or block B and find the tension.

4.39. **IDENTIFY** and **SET UP:** Take derivatives of $x(t)$ to find v_x and a_x. Use Newton's second law to relate the acceleration to the net force on the object.
EXECUTE:
(a) $x = (9.0\times10^3\text{ m/s}^2)t^2 - (8.0\times10^4\text{ m/s}^3)t^3$

$x = 0$ at $t = 0$

When $t = 0.025$ s, $x = (9.0\times10^3\text{ m/s}^2)(0.025\text{ s})^2 - (8.0\times10^4\text{ m/s}^3)(0.025\text{ s})^3 = 4.4$ m.

The length of the barrel must be 4.4 m.

(b) $v_x = \dfrac{dx}{dt} = (18.0\times10^3 \text{ m/s}^2)t - (24.0\times10^4 \text{ m/s}^3)t^2$

At $t = 0,\ v_x = 0$ (object starts from rest).

At $t = 0.025$ s, when the object reaches the end of the barrel,

$v_x = (18.0\times10^3 \text{ m/s}^2)(0.025 \text{ s}) - (24.0\times10^4 \text{ m/s}^3)(0.025 \text{ s})^2 = 300 \text{ m/s}$

(c) $\sum F_x = ma_x$, so must find a_x.

$a_x = \dfrac{dv_x}{dt} = 18.0\times10^3 \text{ m/s}^2 - (48.0\times10^4 \text{ m/s}^3)t$

(i) At $t = 0,\ a_x = 18.0\times10^3 \text{ m/s}^2$ and $\sum F_x = (1.50 \text{ kg})(18.0\times10^3 \text{ m/s}^2) = 2.7\times10^4$ N.

(ii) At $t = 0.025$ s, $a_x = 18\times10^3 \text{ m/s}^2 - (48.0\times10^4 \text{ m/s}^3)(0.025 \text{ s}) = 6.0\times10^3 \text{ m/s}^2$ and

$\sum F_x = (1.50 \text{ kg})(6.0\times10^3 \text{ m/s}^2) = 9.0\times10^3$ N.

EVALUATE: The acceleration and net force decrease as the object moves along the barrel.

4.40. **IDENTIFY:** This problem involves Newton's second law. The rocket's motion occurs in two stages: during the first stage, its engines produce a constant upward force, and during the second stage the engines turn off. Gravity acts during both stages.

SET UP: Apply $\sum F_y = ma_y$ during both stages. During the first stage, the engine force F acts upward and gravity mg acts downward. During the second stage, only gravity acts on the rocket. The constant-acceleration formulas apply during both stages, but with different acceleration in each stage. Fig. 4.40 shows the information. The rocket stops moving at its highest point.

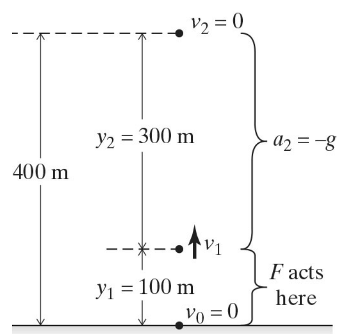


Figure 4.40

EXECUTE: Look at the stages one at a time.

First stage: Apply $\sum F_y = ma_y$. $T - mg = ma_1$ gives $a_1 = (F - mg)/m$. Now apply

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ to relate v_1 to F, using the a_1 we just found. This gives $v_1^2 = 0 + 2\left(\dfrac{F - mg}{m}\right)y_1$.

Second stage: Apply $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$. The v_{0y} for the second stage is v_1 from the first stage. Using the result for v_1^2 from the first stage, this equation gives $0 = 2\left(\dfrac{F - mg}{m}\right)y_1 - 2gy_2$.

Solving for F gives $F = \dfrac{mg}{y_1}(y_1 + y_2) = \dfrac{(400 \text{ kg})(9.80 \text{ m/s})}{100 \text{ m}}(400 \text{ m}) = 1.57\times10^4$ N.

EVALUATE: We cannot do this problem in a single step because the acceleration is different in the two stages. We cannot treat this as a single process using the average acceleration because the accelerations last for different times.

4.41. **IDENTIFY:** You observe that your weight is different from your normal weight in an elevator, so you must have acceleration. Apply $\sum \vec{F} = m\vec{a}$ to your body inside the elevator.

SET UP: The quantity $w = 683$ N is the force of gravity exerted on you, independent of your motion. Your mass is $m = w/g = 69.7$ kg. Use coordinates with $+y$ upward. Your free-body diagram is shown in Figure 4.41, where n is the scale reading, which is the force the scale exerts on you. You and the elevator have the same acceleration.

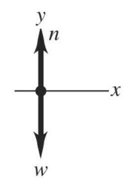

Figure 4.41

EXECUTE: $\sum F_y = ma_y$ gives $n - w = ma_y$ so $a_y = \dfrac{n-w}{m}$.

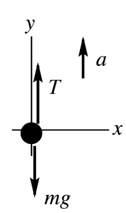
(a) $n = 725$ N, so $a_y = \dfrac{725\text{ N} - 683\text{ N}}{69.7\text{ kg}} = 0.603\text{ m/s}^2$. a_y is positive so the acceleration is upward.

(b) $n = 595$ N, so $a_y = \dfrac{595\text{ N} - 683\text{ N}}{69.7\text{ kg}} = -1.26\text{ m/s}^2$. a_y is negative so the acceleration is downward.

EVALUATE: If you appear to weigh less than your normal weight, you must be accelerating downward, but not necessarily *moving* downward. Likewise if you appear to weigh more than your normal weight, you must be acceleration upward, but you could be *moving* downward.

4.42. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$ to the elevator to relate the forces on it to the acceleration.

(a) SET UP: The free-body diagram for the elevator is sketched in Figure 4.42.



The net force is $T - mg$ (upward).

Figure 4.42

Take the +y-direction to be upward since that is the direction of the acceleration. The maximum upward acceleration is obtained from the maximum possible tension in the cables.

EXECUTE: $\sum F_y = ma_y$ gives $T - mg = ma$

$$a = \frac{T - mg}{m} = \frac{28{,}000\text{ N} - (2200\text{ kg})(9.80\text{ m/s}^2)}{2200\text{ kg}} = 2.93\text{ m/s}^2.$$

(b) What changes is the weight mg of the elevator.

$$a = \frac{T - mg}{m} = \frac{28{,}000\text{ N} - (2200\text{ kg})(1.62\text{ m/s}^2)}{2200\text{ kg}} = 11.1\text{ m/s}^2.$$

EVALUATE: The cables can give the elevator a greater acceleration on the moon since the downward force of gravity is less there and the same T then gives a greater net force.

4.43. **IDENTIFY:** The ball changes velocity, so it has acceleration. Therefore Newton's second law applies to it.

SET UP: Apply $\sum F_x = ma_x$ to the ball. Assume that the acceleration is constant, so we can use the constant-acceleration equation $v_x = v_{0x} + a_x t$. Call the x-axis horizontal with $+x$ in the direction of the ball's original velocity.

EXECUTE: First use $v_x = v_{0x} + a_x t$ to find the acceleration.

$-50.0\text{ m/s} = 40.0\text{ m/s} + a_x(8.00\times10^{-3}\text{ s}) \quad\rightarrow\quad a_x = -1.125\times10^{4}\text{ m/s}^2$.

Now apply $\sum F_x = ma_x$ to the ball. Only the bat exerts a horizontal force on the ball.

$F_{\text{bat}} = ma_x = (0.145\text{ kg})(-1.125\times10^{4}\text{ m/s}^2) = -1630\text{ N}$. The minus sign tells us that the force and the acceleration are directed opposite to the original velocity of the ball, which is away from the batter.

EVALUATE: Compare the acceleration to g: $a/g = (1.125\times10^{4}\text{ m/s}^2)/(9.80\text{ m/s}^2) = 1150$, so the acceleration is $1150g$ – a huge acceleration but for only a very brief time.

4.44. **IDENTIFY:** The object has acceleration, so Newton's second law applies to it. We need to find the acceleration using the equation for its position as a function of time.

SET UP: First find the acceleration using $v_x = dx/dt$ and $a_x = dv_x/dt$. Then apply $\sum F_x = ma_x$. We know that $x(t) = \alpha t^2 - 2\beta t$.

EXECUTE: $v_x = d(\alpha t^2 - 2\beta t)/dt = 2\alpha t - 2\beta$, $a_x = d($a $2\alpha t - 2\beta)/dt = 2\alpha$. Now apply $\sum F_x = ma_x$, giving $F_{\text{net}} = m(2\alpha) = 2\alpha m$.

EVALUATE: Check units: αt^2 must have SI units of m, so α has units of m/s^2. Thus the units of $2\alpha m$ are $(\text{m/s}^2)(\text{kg}) = \text{kg}\cdot\text{m/s}^2 = \text{N}$, so our answer has the proper units.

4.45. **IDENTIFY:** The system is accelerating, so we apply Newton's second law to each box and can use the constant acceleration kinematics for formulas to find the acceleration.

SET UP: First use the constant acceleration kinematics for formulas to find the acceleration of the system. Then apply $\sum F = ma$ to each box.

EXECUTE: **(a)** The kinematics formula $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives

$a_y = \dfrac{2(y-y_0)}{t^2} = \dfrac{2(12.0\text{ m})}{(4.0\text{ s})^2} = 1.5\text{ m/s}^2$. For box B, $mg - T = ma$ and

$m = \dfrac{T}{g-a} = \dfrac{36.0\text{ N}}{9.8\text{ m/s}^2 - 1.5\text{ m/s}^2} = 4.34\text{ kg}$.

(b) For box A, $T + mg - F = ma$ and $m = \dfrac{F-T}{g-a} = \dfrac{80.0\text{ N} - 36.0\text{ N}}{9.8\text{ m/s}^2 - 1.5\text{ m/s}^2} = 5.30\text{ kg}$.

EVALUATE: The boxes have the same acceleration but experience different forces because they have different masses.

4.46. **IDENTIFY:** Note that in this problem the mass of the rope is given, and that it is not negligible compared to the other masses. Apply $\sum\vec{F} = m\vec{a}$ to each object to relate the forces to the acceleration.

(a) SET UP: The free-body diagrams for each block and for the rope are given in Figure 4.46a.

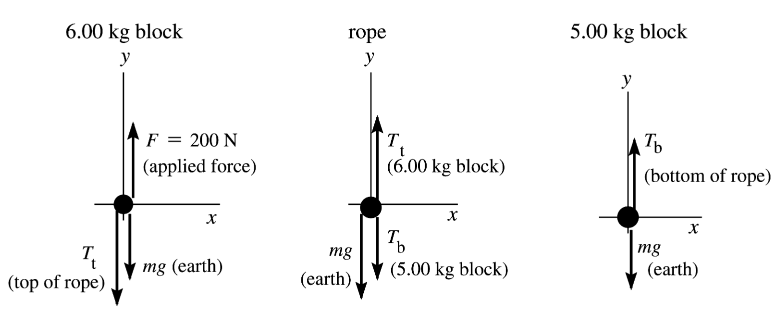


Figure 4.46a

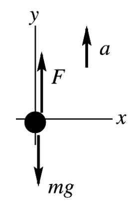
T_{t} is the tension at the top of the rope and T_{b} is the tension at the bottom of the rope.

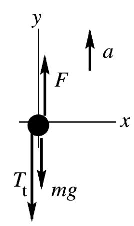
EXECUTE: (b) Treat the rope and the two blocks together as a single object, with mass $m = 6.00\text{ kg} + 4.00\text{ kg} + 5.00\text{ kg} = 15.0\text{ kg}$. Take $+y$ upward, since the acceleration is upward. The free-body diagram is given in Figure 4.46b.



$$\sum F_y = ma_y$$
$$F - mg = ma$$
$$a = \frac{F - mg}{m}$$
$$a = \frac{200\text{ N} - (15.0\text{ kg})(9.80\text{ m/s}^2)}{15.0\text{ kg}} = 3.53\text{ m/s}^2$$

Figure 4.46b

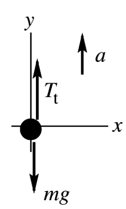
(c) Consider the forces on the top block $(m = 6.00\text{ kg})$, since the tension at the top of the rope (T_{t}) will be one of these forces.



$$\sum F_y = ma_y$$
$$F - mg - T_{\text{t}} = ma$$
$$T_{\text{t}} = F - m(g + a)$$
$$T_{\text{t}} = 200\text{ N} - (6.00\text{ kg})(9.80\text{ m/s}^2 + 3.53\text{ m/s}^2) = 120\text{ N}.$$

Figure 4.46c

Alternatively, you can consider the forces on the combined object rope plus bottom block $(m = 9.00\text{ kg})$:

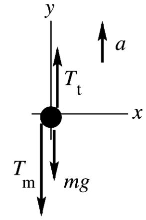


$$\sum F_y = ma_y$$
$$T_{\text{t}} - mg = ma$$
$$T_{\text{t}} = m(g + a) = 9.00\text{ kg}(9.80\text{ m/s}^2 + 3.53\text{ m/s}^2) = 120$$

which checks

Figure 4.46d

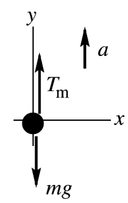
(d) One way to do this is to consider the forces on the top half of the rope $(m = 2.00\text{ kg})$. Let T_m be the tension at the midpoint of the rope.



$$\sum F_y = ma_y$$
$$T_{\text{t}} - T_{\text{m}} - mg = ma$$
$$T_{\text{m}} = T_{\text{t}} - m(g + a) = 120\text{ N} - 2.00\text{ kg}(9.80\text{ m/s}^2 + 3.53\text{ m/s}^2)$$

Figure 4.46e

To check this answer we can alternatively consider the forces on the bottom half of the rope plus the lower block taken together as a combined object $(m = 2.00\text{ kg} + 5.00\text{ kg} = 7.00\text{ kg})$:



$\sum F_y = ma_y$

$T_m - mg = ma$

$T_m = m(g + a) = 7.00\text{ kg}(9.80\text{ m/s}^2 + 3.53\text{ m/s}^2) = 93.$

which checks

Figure 4.46f

Evaluate: The tension in the rope is not constant but increases from the bottom of the rope to the top. The tension at the top of the rope must accelerate the rope as well the 5.00-kg block. The tension at the top of the rope is less than F; there must be a net upward force on the 6.00-kg block.

4.47. **Identify:** The rocket engines reduce the speed of the rocket, so Newton's second law applies to the rocket. Two vertical forces act on the rocket: gravity and the force F of the engines. The constant-acceleration equations apply because both F and gravity are constant, which makes the acceleration constant.

Set Up: The rocket needs to reduce its speed from 30.0 m/s to zero while traveling 80.0 m. We can find the acceleration from this information using $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$. Then we can apply $\sum F_y = ma_y$ to find the force F. Choose the $+y$-axis upward with the origin at the ground.

Execute: We know that $v_y = 0$ as the rocket reaches the ground. Using $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ we get $0 = (-30.0\text{ m/s})^2 + 2a_y(0 - 80.0\text{ m})$ $\rightarrow$ $a_y = 5.625\text{ m/s}^2$. Now apply $\sum F_y = ma_y$.

$F - mg = ma_y$ $\rightarrow$ $F - (20.0\text{ kg})(9.80\text{ m/s}^2) = (20.0\text{ kg})(5.625\text{ m/s}^2)$ $\rightarrow$ $F = 309\text{ N}$.

Evaluate: The weight of this rocket is $w = mg = (20.0\text{ kg})(9.80\text{ m/s}^2) = 196\text{ N}$, so we see that $F > w$. This is reasonable because the engine force must oppose gravity to reduce the rocket's speed. Notice that the rocket is moving downward but its acceleration is upward. This is reasonable because the rocket is slowing down, so its acceleration must be opposite to its velocity.

4.48. **Identify:** On the planet Newtonia, you make measurements on a tool by pushing on it and by dropping it. You want to use those results to find the weight of the object on that planet and on earth.

Set Up: Using $w = mg$, you could find the weight if you could calculate the mass of the tool and the acceleration due to gravity on Newtonia. Newton's laws of motion are applicable on Newtonia, as is your knowledge of falling objects. Let m be the mass of the tool. There is no appreciable friction. Use coordinates where $+x$ is horizontal, in the direction of the 12.0 N force, and let $+y$ be downward.

Execute: First find the mass m: $x - x_0 = 16.0\text{ m}$, $t = 2.00\text{ s}$, $v_{0x} = 0$. $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives

$a_x = \dfrac{2(x - x_0)}{t^2} = \dfrac{2(16.0\text{ m})}{(2.00\text{ s})^2} = 8.00\text{ m/s}^2$. Now apply Newton's second law to the tool. $\sum F_x = ma_x$

gives $F = ma_x$ and $m = \dfrac{F}{a_x} = \dfrac{12.0\text{ N}}{8.00\text{ m/s}^2} = 1.50\text{ kg}$. Find g_N, the acceleration due to gravity on

Newtonia. $y - y_0 = 10.0\text{ m}$, $v_{0y} = 0$, $t = 2.58\text{ s}$. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives

$a_y = \dfrac{2(y - y_0)}{t^2} = \dfrac{2(10.0\text{ m})}{(2.58\text{ s})^2} = 3.00\text{ m/s}^2$; $g_N = 3.00\text{ m/s}^2$. The weight on Newtonia is

$w_N = mg_N = (1.50\text{ kg})(3.00\text{ m/s}^2) = 4.50\text{ N}$. The weight on earth is

$w_E = mg_E = (1.50\text{ kg})(9.80\text{ m/s}^2) = 14.7\text{ N}$.

EVALUATE: The tool weighs about 1/3 on Newtonia of what it weighs on earth since the acceleration due to gravity on Newtonia is about 1/3 what it is on earth.

4.49. IDENTIFY: The rocket accelerates due to a variable force, so we apply Newton's second law. But the acceleration will not be constant because the force is not constant.

SET UP: We can use $a_x = F_x/m$ to find the acceleration, but must integrate to find the velocity and then the distance the rocket travels.

EXECUTE: Using $a_x = F_x/m$ gives $a_x(t) = \dfrac{(16.8\ \text{N/s})t}{45.0\ \text{kg}} = (0.3733\ \text{m/s}^3)t$. Now integrate the acceleration to get the velocity, and then integrate the velocity to get the distance moved. $v_x(t) = v_{0x} + \int_0^t a_x(t')dt' = (0.1867\ \text{m/s}^3)t^2$ and $x - x_0 = \int_0^t v_x(t')dt' = (0.06222\ \text{m/s}^3)t^3$. At $t = 5.00$ s, $x - x_0 = 7.78$ m.

EVALUATE: The distance moved during the next 5.0 s would be considerably greater because the acceleration is increasing with time.

4.50. IDENTIFY: A constant force is applied to an object, which gives it a constant acceleration. We apply Newton's second law and can use the constant-acceleration equations.

SET UP: The object starts from rest reaches a speed v_1 due to force F_1 which gives it an acceleration $a_1 = F_1/m$. $\sum F_x = ma_x$ applies to the object.

EXECUTE: **(a)** With F_1 acting, the object travels a distance d. Now with $F_2 = 2F_1$ acting, the object still travels a distance d but reaches speed v_2. We want to find v_2 in terms of v_1. In this case, twice the force acts over the same distance d. We know that $a_1 = F_1/m$ and $a_2 = F_2/m = 2F_1/m = 2a_1$. Applying $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ to both situations gives $v_1^2 = 2a_1 d$ and $v_2^2 = 2a_2 d$. Since $a_2 = 2a_1$, the last equation gives $v_2^2 = 2(2a_1)d = 2(2a_1 d)$, which tells us that $v_2^2 = 2v_1^2$, so $v_2 = \sqrt{2}v_1$.

(b) In this case, twice the force acts for the same amount of time T. As we saw above, $a_2 = 2a_1$. Applying $v_x = v_{0x} + a_x t$ to both situations gives $v_1 = a_1 T$ and $v_2 = a_2 T = (2a_1)T = 2(a_1 T) = 2v_2$, so we find that $v_2 = 2v_1$.

EVALUATE: We have seen in (a) that doubling the force over the same distance increases the speed by a factor of $\sqrt{2}$, but in (b) we saw that doubling the force for the same amount of time increases the speed by a factor of 2.

4.51. IDENTIFY: Kinematics will give us the average acceleration of each car, and Newton's second law will give us the average force that is accelerating each car.

SET UP: The cars start from rest and all reach a final velocity of 60 mph (26.8 m/s). We first use kinematics to find the average acceleration of each car, and then use Newton's second law to find the average force on each car.

EXECUTE: **(a)** We know the initial and final velocities of each car and the time during which this change in velocity occurs. The definition of average acceleration gives $a_{\text{av}} = \dfrac{\Delta v}{\Delta t}$. Then $F = ma$ gives the force on each car. For the Alpha Romeo, the calculations are $a_{\text{av}} = (26.8\ \text{m/s})/(4.4\ \text{s}) = 6.09\ \text{m/s}^2$. The force is $F = ma = (895\ \text{kg})(6.09\ \text{m/s}^2) = 5.451 \times 10^3\ \text{N} = 5.451$ kN, which we should round to 5.5 kN for 2 significant figures. Repeating this calculation for the other cars and rounding the force to 2 significant figures gives:

Alpha Romeo: $a = 6.09\ \text{m/s}^2$, $F = 5.5$ kN
Honda Civic: $a = 4.19\ \text{m/s}^2$, $F = 5.5$ kN
Ferrari: $a = 6.88\ \text{m/s}^2$, $F = 9.9$ kN
Ford Focus: $a = 4.97\ \text{m/s}^2$, $F = 7.3$ kN
Volvo: $a = 3.72\ \text{m/s}^2$, $F = 6.1$ kN

The smallest net force is on the Alpha Romeo and Honda Civic, to two-figure accuracy. The largest net force is on the Ferrari.
(b) The largest force would occur for the largest acceleration, which would be in the Ferrari. The smallest force would occur for the smallest acceleration, which would be in the Volvo.
(c) We use the same approach as in part (a), but now the final velocity is 100 mph (44.7 m/s).
a_{av} = (44.7 m/s)/(8.6 s) = 5.20 m/s^2, and $F = ma$ = (1435 kg)(5.20 m/s^2) = 7.5 kN. The average force is considerably smaller in this case. This is because air resistance increases with speed.
(d) As the speed increases, so does the air resistance. Eventually the air resistance will be equal to the force from the roadway, so the new force will be zero and the acceleration will also be zero, so the speed will remain constant.
EVALUATE: The actual forces and accelerations involved with auto dynamics can be quite complicated because the forces (and hence the accelerations) are not constant but depend on the speed of the car.

4.52. **IDENTIFY:** Calculate $\vec{a}$ from $\vec{a} = d^2\vec{r}/dt^2$. Then $\vec{F}_{\text{net}} = m\vec{a}$.
SET UP: $w = mg$
EXECUTE: Differentiating twice, the acceleration of the helicopter as a function of time is
$\vec{a} = (0.120\text{ m/s}^3)t\hat{\imath} - (0.12\text{ m/s}^2)\hat{k}$ and at $t = 5.0$ s, the acceleration is $\vec{a} = (0.60\text{ m/s}^2)\hat{\imath} - (0.12\text{ m/s}^2)\hat{k}$.
The force is then

$$\vec{F} = m\vec{a} = \frac{w}{g}\vec{a} = \frac{(2.75\times 10^5\text{ N})}{(9.80\text{ m/s}^2)}\left[(0.60\text{ m/s}^2)\hat{\imath} - (0.12\text{ m/s}^2)\hat{k}\right] = (1.7\times 10^4\text{ N})\hat{\imath} - (3.4\times 10^3\text{ N})\hat{k}$$

EVALUATE: The force and acceleration are in the same direction. They are both time dependent.

4.53. **IDENTIFY:** A block is accelerated upward by a force of magnitude F. For various forces, we know the time for the block to move upward a distance of 8.00 m starting from rest. Since the upward force is constant, so is the acceleration. Newton's second law applies to the accelerating block.
SET UP: The acceleration is constant, so $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ applies, and $\sum F_y = ma_y$ also applies to the block.
EXECUTE: **(a)** Using the above formula with $v_{0y} = 0$ and $y - y_0 = 8.00$ m, we get $a_y = (16.0\text{ m})/t^2$. We use this formula to calculate the acceleration for each value of the force F. For example, when F= 250 N, we have a = (16.0 m)/(3.3 s)^2 = 1.47 m/s^2. We make similar calculations for all six values of F and then graph F versus a. We can do this graph by hand or using graphing software. The result is shown in Figure 4.53.

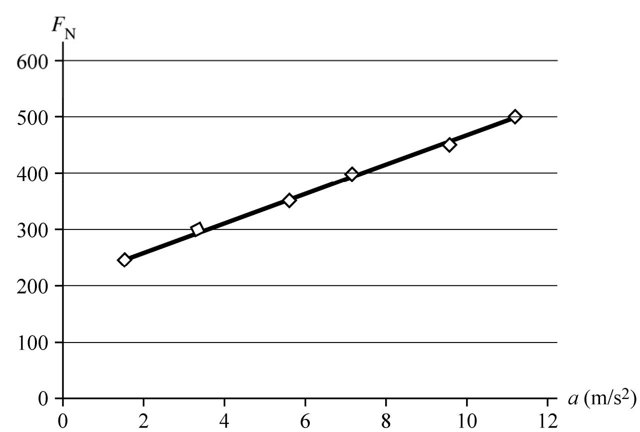


Figure 4.53

(b) Applying Newton's second law to the block gives $F - mg = ma$, so $F = mg + ma$. The equation of our best-fit graph in part (a) is $F = (25.58\text{ kg})a + 213.0\text{ N}$. The slope of the graph is the mass m, so the mass of the block is $m = 26$ kg. The y intercept is mg, so $mg = 213$ N, which gives $g = (213\text{ N})/(25.58\text{ kg}) = 8.3$ m/s^2 on the distant planet.

EVALUATE: The acceleration due to gravity on this planet is not too different from what it is on earth.

4.54. IDENTIFY: The box comes to a stop, so it must have acceleration, so Newton's second law applies. For constant acceleration, the standard kinematics formulas apply.

SET UP: For constant acceleration, $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ and $v_x = v_{0x} + a_x t$ apply. For any motion, $\vec{F}_{\text{net}} = m\vec{a}$.

EXECUTE: **(a)** If the box comes to rest with constant acceleration, its final velocity is zero so $v_{0x} = -a_x t$. And if during this time it travels a distance $x - x_0 = d$, the distance formula above can be put into the form
$d = (-a_x t) + \frac{1}{2} a_x t^2 = -\frac{1}{2} a_x t^2$. This gives $a_x = -2d/t^2$. For the first push on the box, this gives $a_x = -2(8.22\text{ m})/(2.8\text{ s})^2 = -2.1\text{ m/s}^2$. If the acceleration is constant, the distance the box should travel after the second push is $d = -\frac{1}{2} a_x t^2 = -(\frac{1}{2})(-2.1\text{ m/s}^2)(2.0\text{ s})^2 = 4.2$ m, which is in fact the distance the box did travel. Therefore the acceleration was constant.

(b) The total mass m_T of the box is the initial mass (8.00 kg) plus the added mass. Since $v_x = 0$ and $a_x = 2d/t^2$ as shown in part (a), the magnitude of the initial speed v_{0x} is $v_{0x} = a_x t = (2d/t^2)t = 2d/t$. For no added mass, this calculation gives $v_{0x} = 2(8.22\text{ m})/(2.8\text{ s}) = 5.87$ m/s. Similar calculations with added mass give

$m_T = 8.00$ kg, $v_{0x} = 5.87\text{ m/s} \approx 5.9$ m/s
$m_T = 11.00$ kg, $v_{0x} = 6.72\text{ m/s} \approx 6.7$ m/s
$m_T = 15.00$ kg, $v_{0x} = 6.30\text{ m/s} \approx 6.3$ m/s
$m_T = 20.00$ kg, $v_{0x} = 5.46\text{ m/s} \approx 5.5$ m/s

where all answers have been rounded to 2 significant figures. It is obvious that the initial speed was *not* the same in each case. The ratio of maximum speed to minimum speed is
$v_{0,\max}/v_{0,\min} = (6.72\text{ m/s})/(5.46\text{ m/s}) = 1.2$

(c) We calculate the magnitude of the force f using $f = ma$, getting a using $a = -2d/t^2$, as we showed in part (a). In each case the acceleration is 2.1 m/s^2. So for example, when $m = 11.00$ kg, the force is $f = (11.00\text{ kg})(2.1\text{ m/s}^2) = 23$ N. Similar calculations produce a set of values for f and m. These can be graphed by hand or using graphing software. The resulting graph is shown in Figure 4.54. The slope of this straight-line graph is 2.1 m/s^2 and it passes through the origin, so the slope-y intercept equation of the line is $f = (2.1\text{ m/s}^2)m$.

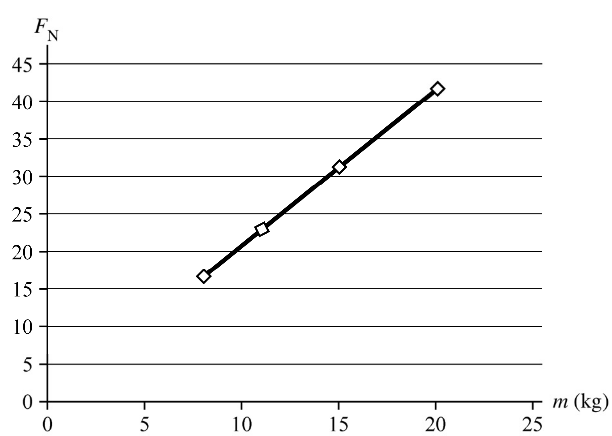

Figure 4.54

Evaluate: The results of the graph certainly agree with Newton's second law. A graph of F versus m should have slope equal to the acceleration a. This is in fact just what we get, since the acceleration is 2.1 m/s^2 which is the same as the slope of the graph.

4.55. **Identify:** The force on the block is a function of time, so the acceleration will also be a function of time. Therefore we cannot use the constant-acceleration formulas, but instead must use the basic velocity and acceleration definitions. We also need to apply Newton's second law.

Set Up: Using $\sum F_x = ma_x$ we can determine the acceleration and use it to find the velocity and position of the block. We use $a_x = dv_x/dt$ and $v_x = dx/dt$. We know that $F(t) = \beta - \alpha t$ and that the object starts from rest.

Execute: **(a)** We want the largest positive value of x. Using $\sum F_x = ma_x$ we can find $a_x(t)$, and from that we can find $v_x(t)$ and then find $x(t)$. First find a_x: $a_x(t) = F_x/m = (\beta - \alpha t)/m$.

Now use $a_x = dv_x/dt$ to find $v_x(t)$. $v_x = \int a_x dt = \int \dfrac{\beta - \alpha t}{m} dt = \dfrac{\beta t - \dfrac{\alpha t^2}{2}}{m}$, where we have used $v_x = 0$ when $t = 0$. Now use $v_x = dx/dt$ to find $x(t)$. $x(t) = \int v_x dt = \int \dfrac{\beta t - \dfrac{\alpha t^2}{2}}{m} dt = \dfrac{\dfrac{\beta t^2}{2} - \dfrac{\alpha t^3}{6}}{m}$, where we have used $x = 0$ when $t = 0$. The largest value of x will occur when $v_x = 0$ because the block will go no further.

Equating v_x to zero gives $v_x = \dfrac{\beta t - \dfrac{\alpha t^2}{2}}{m} = 0$. Solving for t and calling it $t_{\max}$ gives $t_{\max} = 2\beta/\alpha$.

Now use $t_{\max}$ in our equation for $x(t)$ to find the largest value of x. This gives

$$x(t_{\max}) = \frac{\dfrac{\beta(2\beta/\alpha)^2}{2} - \dfrac{\alpha(2\beta/\alpha)^3}{6}}{m} = \frac{2\beta^3}{3m\alpha^2}.$$

The force at $t_{\max}$ is $F_x = \beta - \alpha t_{\max} = \beta - \alpha\left(\dfrac{2\beta}{\alpha}\right) = -\beta$.

Putting in the values for α and β gives the following results:

$t_{\max} = 2\beta/\alpha = 2(4.00\text{ N})/(6.00\text{ N/s}) = 1.33$ s.

$x_{\max} = \dfrac{2\beta^3}{3m\alpha^2} = \dfrac{2(4.00\text{ N})^3}{3(2.00\text{ kg})(6.00\text{ N/s})^2} = 0.593$ m.

$F_{\max} = -\beta = -4.00$ N, but we only want the magnitude, so $F_{\max} = 4.00$ N.

(b) When $x = 0$, the block has returned to where it started. Using our equation for $x(t)$, we get

$x(t) = \dfrac{\dfrac{\beta t^2}{2} - \dfrac{\alpha t^3}{6}}{m} = 0$, which gives $t = 3\beta/\alpha = 3(4.00\text{ N})/(6.00\text{ N/s}) = 2.00$ s.

Using our equation for $v_x(t)$ and evaluating it at $t = 2.00$ s gives

$v_x = \dfrac{\beta t - \dfrac{\alpha t^2}{2}}{m} = \dfrac{(4.00\text{ N})(2.00\text{ s}) - \dfrac{(6.00\text{ N/s})(2.00\text{ s})^2}{2}}{(2.00\text{ kg})} = -2.00$ m/s. Its speed is 2.00 m/s.

Evaluate: The constant-acceleration equations would be of no help with this type of time-dependent force.

4.56. **Identify:** $x = \int_0^t v_x dt$ and $v_x = \int_0^t a_x dt$, and similar equations apply to the y-component.

Set Up: In this situation, the x-component of force depends explicitly on the y-component of position. As the y-component of force is given as an explicit function of time, v_y and y can be found as functions of time and used in the expression for $a_x(t)$.

EXECUTE: $a_y = (k_3/m)t$, so $v_y = (k_3/2m)t^2$ and $y = (k_3/6m)t^3$, where the initial conditions $v_{0y} = 0, y_0 = 0$ have been used. Then, the expressions for a_x, v_x, and x are obtained as functions of time:

$$a_x = \frac{k_1}{m} + \frac{k_2 k_3}{6m^2}t^3, \quad v_x = \frac{k_1}{m}t + \frac{k_2 k_3}{24m^2}t^4 \text{ and } x = \frac{k_1}{2m}t^2 + \frac{k_2 k_3}{120m^2}t^5.$$

In vector form, $\vec{r} = \left(\frac{k_1}{2m}t^2 + \frac{k_2 k_3}{120m^2}t^5\right)\hat{\boldsymbol{i}} + \left(\frac{k_3}{6m}t^3\right)\hat{\boldsymbol{j}}$ and $\vec{v} = \left(\frac{k_1}{m}t + \frac{k_2 k_3}{24m^2}t^4\right)\hat{\boldsymbol{i}} + \left(\frac{k_3}{2m}t^2\right)\hat{\boldsymbol{j}}$.

EVALUATE: a_x depends on time because it depends on y, and y is a function of time.

4.57. **IDENTIFY:** Newton's second law applies to the dancer's head.

SET UP: We use $a_{\text{av}} = \frac{\Delta v}{\Delta t}$ and $\vec{F}_{\text{net}} = m\vec{a}$.

EXECUTE: First find the average acceleration: $a_{\text{av}} = (4.0 \text{ m/s})/(0.20 \text{ s}) = 20 \text{ m/s}^2$. Now apply Newton's second law to the dancer's head. Two vertical forces act on the head: $F_{\text{neck}} - mg = ma$, so $F_{\text{neck}} = m(g + a)$, which gives $F_{\text{neck}} = (0.094)(65 \text{ kg})(9.80 \text{ m/s}^2 + 20 \text{ m/s}^2) = 180 \text{ N}$, which is choice (d).

EVALUATE: The neck force is not simply ma because the neck must balance her head against gravity, even if the head were not accelerating. That error would lead one to incorrectly select choice (c).

4.58. **IDENTIFY:** Newton's third law of motion applies.

SET UP: The force the neck exerts on her head is the same as the force the head exerts on the neck.

EXECUTE: Choice (a) is correct.

EVALUATE: These two forces form an action-reaction pair.

4.59. **IDENTIFY:** The dancer is in the air and holding a pose, so she is in free fall.

SET UP: The dancer, including all parts of her body, are in free fall, so they all have the same downward acceleration of 9.80 m/s^2.

EXECUTE: Since her head and her neck have the same downward acceleration, and that is produced by gravity, her neck does not exert any force on her head, so choice (a) 0 N is correct.

EVALUATE: During falling motion such as this, a person (including her head) is often described as being "weightless."

4.60. **IDENTIFY:** The graph shows the vertical force that a force plate exerts on her body.

SET UP and **EXECUTE:** When the dancer is not moving, the force that the force plate exerts on her will be her weight, which appears to be about 650 N. Between 0.0 s and 0.4 s, the force on her is less than her weight and is decreasing, so she must be accelerating downward. At 0.4 s, the graph reaches a relative minimum of around 300 N and then begins to increase after that. Only choice (a) is consistent with this part of the graph.

EVALUATE: At the high points in the graph, the force on her is over twice her weight.

5

APPLYING NEWTON'S LAWS

VP5.5.1. **IDENTIFY:** The cart and bucket move with constant speed, so their acceleration is zero, which means that the forces on each of them must balance.

SET UP: Apply $\sum F_x = 0$ and $\sum F_y = 0$ to the cart and the bucket. For the cart, take the +x-axis parallel to the surface of the incline pointing upward. For the bucket, take the +y-axis vertically upward.

EXECUTE: **(a)** Isolate the bucket and apply $\sum F_y = 0$. $T - w = 0 \quad \rightarrow \quad T = w = 255$ N.

Now apply $\sum F_x = 0$ to the cart. $T - w \sin 36.9° = 0$. $255 \text{ N} - w \sin 36.9° = 0$. $w = 425$ N.

(b) From above, $T = 255$ N.

EVALUATE: The bucket can balance a much heavier cart because it only needs to balance the component of the cart's weight that is parallel to the surface of the incline.

VP5.5.2. **IDENTIFY:** The cart and bucket are at rest, which means that the forces on each of them must balance.

SET UP: Apply $\sum F_x = 0$ and $\sum F_y = 0$ to the cart and the bucket. For the cart, take the +x-axis parallel to the surface of the incline pointing upward. For the bucket, take the +y-axis vertically upward.

EXECUTE: **(a)** Apply $\sum F_x = 0$ to the cart, giving $T - w_C \sin 25.0° = 0$.

$155 \text{ N} - w_C \sin 25.0°$, so $w_C = 367$ N.

(b) Isolate the bucket and apply $\sum F_y = 0$. $T - w_B = 0$, so $w_B = T = 367$ N.

The total weight is 367 N + 155 N = 522 N.

EVALUATE: A light bucket can balance a heavy cart because it must balance only the weight component of the cart that is parallel to the surface of the incline.

VP5.5.3. **IDENTIFY:** The cart and bucket move with constant speed, so their acceleration is zero, which means that the forces on each of them must balance.

SET UP: Apply $\sum F_x = 0$ and $\sum F_y = 0$ to the cart and the bucket. For the cart, take the +x-axis parallel to the surface of the incline pointing upward. For the bucket, take the +y-axis vertically upward. We want to find the angle θ of the slope. Call T the tension in the cable.

EXECUTE: **(a)** Applying $\sum F_y = 0$ to the bucket gives $T = w_B$. Applying $\sum F_x = 0$ to the cart gives $T = w_C \sin \theta$. Equating the two expressions for T gives $w_B = w_C \sin \theta$, which tells us

$\sin\theta = \dfrac{w_B}{w_C} = \dfrac{m_B g}{m_C g} = \dfrac{65.0 \text{ kg}}{175 \text{ kg}} = 0.371$, so $\theta = 21.8°$.

(b) From part (a), $T = w_B = (65.0 \text{ kg})(9.80 \text{ m/s}^2) = 637$ N.

EVALUATE: It must also be true that $T = w_C \sin\theta$. $T = (175 \text{ kg})(9.80 \text{ m/s}^2) \sin 21.8° = 637$ N, which agrees with our answer in (b).

VP5.5.4. **IDENTIFY:** The cart and bucket remain at rest, so the forces on each of them must balance.

SET UP: Apply $\sum F_x = 0$ and $\sum F_y = 0$ to the cart and the bucket. For the cart, take the +*x*-axis parallel to the surface of the incline pointing upward. For the bucket, take the +*y*-axis vertically upward. We want to find the angle θ of the slope. Call *T* the tension in the cable and *f* the friction force. If there were no friction, the cart would slide *up* the incline because $w > w \sin\theta$. Since friction opposes motion, it must act *down* the incline.

EXECUTE: Applying $\sum F_y = 0$ to the bucket gives $T = w_B = w$. Applying $\sum F_x = 0$ to the cart gives $T - w_C \sin\theta - f = 0$, which becomes $T - w_C \sin\theta - f = 0$. Combining the results gives $f = w(1 - \sin\theta)$. Since $\sin\theta < 1$, we know that $f < w$.

EVALUATE: The weight of the bucket must now balance *two* forces: the weight of the cart acting down the incline and the friction force down the incline.

VP5.15.1. **IDENTIFY:** The crate moves at constant velocity, so the forces on it must balance.

SET UP: Apply $\sum F_x = 0$ and $\sum F_y = 0$ to the crate. Take the *x*-axis horizontal and the *y*-axis vertical. Make a free-body diagram as in Fig. VP5.15.1.

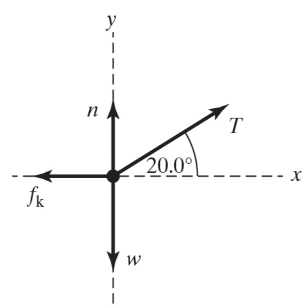

Figure VP5.15.1

EXECUTE: **(a)** Using the notation in Fig. VP5.15.1, $\sum F_x = 0$ gives $T \cos 20.0° - f_k = 0$ and $\sum F_y = 0$ gives $T \sin 20.0° + n - w = 0$, so $n = w - T \sin 20.0°$. For sliding friction $f_k = \mu_k n$. Combining these results gives $T \cos 20.0° - \mu_k (w - T \sin 20.0°) = 0$. Putting in the numbers:

$T \cos 20.0° - (0.250)(325\text{ N}) + (0.250)T \sin 20.0° = 0 \quad \rightarrow \quad T = 79.3\text{ N}$.

(b) $n = w - T \sin 20.0° = 325\text{ N} - (79.3\text{ N}) \sin 20.0° = 298\text{ N}$.

EVALUATE: We find that $n < w$. This is reasonable because the upward component of the tension balances part of the weight of the crate.

VP5.15.2. **IDENTIFY:** The crate moves at constant velocity, so the forces on it must balance.

SET UP: Apply $\sum F_x = 0$ and $\sum F_y = 0$ to the crate. Take the *x*-axis horizontal and the *y*-axis vertical. Make a free-body diagram as in Fig. 5.15.2.

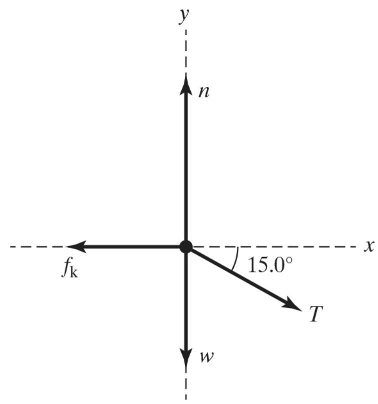

Figure VP5.15.2

Execute: The procedure is exactly the same as for VP5.15.1 *except* that the tension is now directed at 15.0° *below* the horizontal.

(a) $\sum F_x = 0$ gives $n - w - T\sin 15.0° = 0$, so $n = w + T\sin 15.0°$.

$\sum F_y = 0$ gives $T\cos 15.0° - f_k = T\cos 15.0° - \mu_k n = 0$.

Combining these equations and solving for T gives $T = 90.2$ N.

(b) $n = w + T\sin 15.0° = 325\text{ N} + (90.2\text{ N})\sin 15.0° = 348$ N.

Evaluate: The normal force must balance the downward component of the tension in addition to the weight of the crate, so it is greater than the weight.

VP5.15.3. **Identify:** The sled is accelerated horizontally, so Newton's second law applies to it.

Set Up: $\sum F_x = ma_x$ applies to the horizontal motion and $\sum F_y = 0$ applies to the vertical motion. Use $\sum F_y = 0$ to find the normal force n. The kinetic friction force is $f_k = \mu_k n$. Call P the magnitude of the pull and w the weight of the sled. Take the $+x$-axis to be horizontal in the direction of the horizontal component of the pull.

Execute: **(a)** $\sum F_y = 0$: $T\sin 12.0° + n - w = 0$.

$n = w - T\sin 12.0° = 475\text{ N} - (125\text{ N})\sin 12.0° = 449$ N.

(b) $\sum F_x = ma_x$: $P\cos 12.0° - f_k = ma_x = P\cos 12.0° - \mu_k n$

$(125\text{ N})\cos 12.0° - (0.200)(449\text{ N} = [(475\text{ N})/(9.80\text{ m/s}^2)]\, a_x \rightarrow a_x = 0.670\text{ m/s}^2$. We have chosen the $+x$-axis in the same direction as the horizontal component of the pull. Since a_x is positive, the acceleration is in the same direction as that pull, so the sled is *speeding up*.

Evaluate: If the sled were slowing down, that would mean that friction was greater than the horizontal component of the pull. In that case, the sled could never have started moving in the first place, so our answer is reasonable.

VP5.15.4. **Identify:** Before it slides, the forces on the box must balance.

Set Up: For the minimum pull, the box is just ready to slide, so static friction is at its maximum, which is $f_s = \mu_s n$. Apply $\sum F_x = 0$ and $\sum F_y = 0$ to the box just as it is ready to slide.

Execute: $\sum F_x = 0$: $T_{min}\cos\theta - f_s = 0 \rightarrow T_{min}\cos\theta - \mu_s n = 0$.

$\sum F_y = 0$: $T_{min}\sin\theta + n - mg = 0 \rightarrow n = mg - T_{min}\sin\theta$.

Combine these results and solve for μ_s.

$$T_{min}\cos\theta - \mu_s(mg - T_{min}\sin\theta) = 0 \rightarrow \mu_s = \frac{T_{min}\cos\theta}{mg - T_{min}\sin\theta}.$$

Evaluate: If the box is *not* just ready to slide, our analysis is not valid. The forces still balance, but $f_s \neq \mu_s n$ in that case.

VP5.22.1. **IDENTIFY:** The pendulum bob is moving in a horizontal circle at constant speed. Therefore it has horizontal acceleration toward the center of the circle, but it has no vertical acceleration. The vertical forces on it must balance, but we need to use Newton's second law for the horizontal motion.

SET UP: Vertically $\sum F_y = 0$ and horizontally $\sum F_x = ma_x$, where a_x is the radial acceleration $a_{rad} = v^2/R$. Therefore horizontally we use $\sum F = m\frac{v^2}{R}$. The speed is $v = 2\pi R/t$, where t is the time for one cycle (do not use T for the period to avoid confusion with the tension T). Make a free-body diagram like Fig. 5.32b in the text.

EXECUTE: **(a)** $R = L \sin\beta = (0.800\text{ m}) \sin 20.0° = 0.274\text{ m}$.

(b) $\sum F = m\frac{v^2}{R}$ gives $T\sin\beta = m\frac{v^2}{R}$. Using $v = 2\pi R/t$, this becomes $T\sin\beta = \frac{m}{R}\left(\frac{2\pi R}{t}\right)^2$. Solving for t we get $t = \sqrt{\frac{4\pi^2 Rm}{T\sin\beta}}$, so we need to find T.

(c) $\sum F_y = 0$ gives $T\cos\beta = W = mg \rightarrow T = (0.250\text{ kg})(9.80\text{ m/s}^2)/(\cos 20.0°) = 2.61\text{ N}$. Now return to part (b) to find the time $t = \sqrt{\frac{4\pi^2 Rm}{T\sin\beta}}$. Putting in the numbers gives

Ita $t = 2\pi\sqrt{\frac{(0.274\text{ m})(0.250\text{ kg})}{(2.61\text{ N})(\sin 20.0°)}} = 1.74\text{ s}$.

EVALUATE: Even though the bob has constant speed, the horizontal forces do not balance because its *velocity* is changing direction, so it has acceleration.

VP5.22.2. **IDENTIFY:** The cyclist is moving in a horizontal circle at constant speed. Therefore she has horizontal acceleration toward the center of the circle, but no vertical acceleration. The vertical forces on her must balance, but we need to use Newton's second law for her horizontal motion.

SET UP: Vertically $\sum F_y = 0$ and horizontally $\sum F_x = ma_x$, where a_x is the radial acceleration $a_{rad} = v^2/R$. Therefore horizontally we use $\sum F = m\frac{v^2}{R}$. Make a free-body diagram as shown in Fig. VP5.22.2.

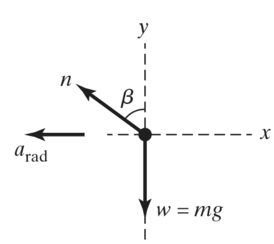

Figure VP5.22.2

EXECUTE: **(a)** $\sum F_x = ma_x = n\sin\beta = mv^2/R$

$\sum F_y = 0 = n\cos\beta - mg$.

Combining these two equations gives $\tan\beta = v^2/Rg$, which gives

$R = v^2/(g\tan\beta) = (12.5\text{ m/s})^2/[(9.80\text{ m/s}^2)(\tan 40.0°)] = 19.0\text{ m}$.

(b) $a_{rad} = v^2/R = (12.5\text{ m/s})^2/(19.0\text{ m}) = 8.22\text{ m/s}^2$.

(c) Using $n\cos\beta - mg = 0$, we get $n = mg/\cos\beta = (64.0\text{ kg})(9.80\text{ m/s}^2)/(\cos 40.0°) = 819\text{ N}$.

EVALUATE: We found that $n > w$. This is reasonable since only the vertical component of n balances her weight, which means that n has to be greater then w.

VP5.22.3. **IDENTIFY:** The plane is moving in a horizontal circle at constant speed. Therefore it has horizontal acceleration toward the center of the circle, but no vertical acceleration. The vertical forces on it must balance, but we need to use Newton's second law for its horizontal motion.

SET UP: Vertically $\sum F_y = 0$ and horizontally $\sum F_x = ma_x$, where a_x is the radial acceleration $a_{rad} = v^2/R$. Therefore horizontally we use $\sum F = m\dfrac{v^2}{R}$. Make a free-body diagram like Fig. 5.35 in the text.

EXECUTE: **(a)** $\sum F_x = ma_x = n \sin\beta = mv^2/R$

$\sum F_y = 0 = n\cos\beta - mg$.

Combining these two equations gives $\tan\beta = v^2/Rg = (80.0\text{ m/s})^2/[(175\text{ m})(9.80\text{ m/s}^2)]$, which gives $\beta = 75.0°$.

(b) The pilot's apparent weight will be the force n due to the seat. Using $\sum F_y = 0$ gives $w = n\cos\beta$, so $n = w/\cos\beta = (80.0\text{ kg})(9.80\text{ m/s}^2)/(\cos 75.0°) = 3.03\times10^3$ N.

$w_{apparent}/w_{actual} = (3.03\times10^3\text{ N})/[(80.0\text{ kg})(9.80\text{ m/s}^2)] = 3.86$, which means that is apparent weight is 3.86 times great than his actual weight.

EVALUATE: Notice that $\tan\beta \propto v^2$, so a large speed means a large bank angle. We also saw that $n = w/\cos\beta$, so as v gets larger and larger, β gets closer and closer to 90°, and $\cos\beta$ gets closer and closer to zero. Therefore n gets larger and larger. This can be dangerous for pilots in high speed turns. The effects from such turns can cause a pilot to black out if the speed is great enough.

VP5.22.4. **IDENTIFY:** The driver is moving in a horizontal circle at constant speed. Therefore she has horizontal acceleration toward the center of the circle, but no vertical acceleration. The vertical forces on her must balance, but we need to use Newton's second law for her horizontal motion.

SET UP: Vertically $\sum F_y = 0$ and horizontally $\sum F_x = ma_x$, where a_x is the radial acceleration $a_{rad} = v^2/R$. Therefore horizontally we use $\sum F = m\dfrac{v^2}{R}$. Make a free-body diagram like Fig. 5.34b in the textbook. Her apparent weight x times her actual weight, which means that the normal force n on her due to the seat is $n = xmg$.

EXECUTE: **(a)** Using $\sum F = m\dfrac{v^2}{R}$, we see that the net force on her is $F_{net} = ma_x = mv^2/R$. From the free-body diagram, we see that $F_{rad} = n\sin\beta$. So $F_{net} = F_{rad} = n\sin\beta = xmg\sin\beta$. Use $\sum F_y = 0$ to find β: $n\cos\beta - mg = 0 \quad\rightarrow\quad \cos\beta = mg/n = mg/xmg = 1/x$. This means that $\sin\beta = \dfrac{\sqrt{x^2-1}}{x}$.

We showed that $F_{net} = xmg\sin\beta$, so $F_{net} = xmg\dfrac{\sqrt{x^2-1}}{x} = mg\sqrt{x^2-1}$.

(b) $F_{rad} = F_{net} = mv^2/R$. Use the result from (a) for F_{net}.

$mg\sqrt{x^2-1} = mv^2/R \quad\rightarrow\quad R = \dfrac{v^2}{g\sqrt{x^2-1}}$.

EVALUATE: Our result in (b) says that as x gets larger and larger, R gets smaller and smaller. This is reasonable, since the larger x is, the greater the apparent weight of the driver. So for a given speed, a sharper turn will produce a greater apparent weight than a wide turn.

5.1. **IDENTIFY:** $a = 0$ for each object. Apply $\Sigma F_y = ma_y$ to each weight and to the pulley.

SET UP: Take $+y$ upward. The pulley has negligible mass. Let T_r be the tension in the rope and let T_c be the tension in the chain.

EXECUTE: **(a)** The free-body diagram for each weight is the same and is given in Figure 5.1a. $\Sigma F_y = ma_y$ gives $T_r = w = 25.0$ N.

(b) The free-body diagram for the pulley is given in Figure 5.1b. $T_c = 2T_r = 50.0$ N.

EVALUATE: The tension is the same at all points along the rope.

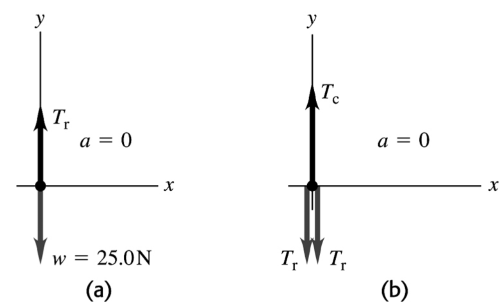

Figure 5.1

5.2. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each weight.

SET UP: Two forces act on each mass: w down and $T(= w)$ up.

EXECUTE: In all cases, each string is supporting a weight w against gravity, and the tension in each string is w.

EVALUATE: The tension is the same in all three cases.

5.3. **IDENTIFY:** Both objects are at rest and $a = 0$. Apply Newton's first law to the appropriate object. The maximum tension T_{max} is at the top of the chain and the minimum tension is at the bottom of the chain.

SET UP: Let $+y$ be upward. For the maximum tension take the object to be the chain plus the ball. For the minimum tension take the object to be the ball. For the tension T three-fourths of the way up from the bottom of the chain, take the chain below this point plus the ball to be the object. The free-body diagrams in each of these three cases are sketched in Figure 5.3. $m_{\text{b+c}} = 75.0\text{ kg} + 26.0\text{ kg} = 101.0\text{ kg}$. $m_{\text{b}} = 75.0$ kg. m is the mass of three-fourths of the chain: $m = \frac{3}{4}(26.0\text{ kg}) = 19.5\text{ kg}$.

EXECUTE: **(a)** From Figure 5.3a, $\Sigma F_y = 0$ gives $T_{\text{max}} - m_{\text{b+c}}g = 0$ and $T_{\text{max}} = (101.0\text{ kg})(9.80\text{ m/s}^2) = 990$ N. From Figure 5.3b, $\Sigma F_y = 0$ gives $T_{\text{min}} - m_{\text{b}}g = 0$ and $T_{\text{min}} = (75.0\text{ kg})(9.80\text{ m/s}^2) = 735$ N.

(b) From Figure 5.3c, $\Sigma F_y = 0$ gives $T - (m + m_{\text{b}})g = 0$ and $T = (19.5\text{ kg} + 75.0\text{ kg})(9.80\text{ m/s}^2) = 926$ N.

EVALUATE: The tension in the chain increases linearly from the bottom to the top of the chain.

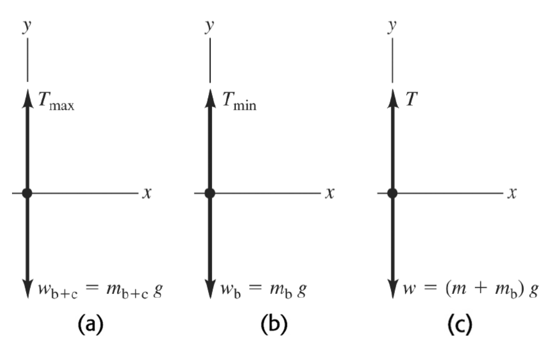

Figure 5.3

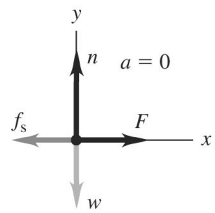
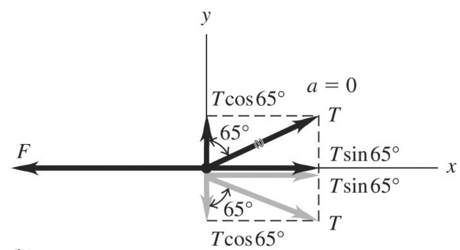
5.4. **IDENTIFY:** For the maximum tension, the patient is just ready to slide so static friction is at its maximum and the forces on him add to zero.

SET UP: **(a)** The free-body diagram for the person is given in Figure 5.4a. F is magnitude of the traction force along the spinal column and $w = mg$ is the person's weight. At maximum static friction, $f_s = \mu_s n$.

(b) The free-body diagram for the collar where the cables are attached is given in Figure 5.4b. The tension in each cable has been resolved into its x- and y-components.



(a)



(b)

Figure 5.4

EXECUTE: **(a)** $n = w$ and $F = f_s = \mu_s n = 0.75w = 0.75(9.80\text{ m/s}^2)(78.5\text{ kg}) = 577\text{ N}$.

(b) $2T\sin 65° - F = 0$ so $T = \dfrac{F}{2\sin 65°} = \dfrac{0.75w}{2\sin 65°} = 0.41w = (0.41)(9.80\text{ m/s}^2)(78.5\text{ kg}) = 315\text{ N}$.

EVALUATE: The two tensions add up to 630 N, which is more than the traction force, because the cables do not pull directly along the spinal column.

5.5. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the frame.

SET UP: Let w be the weight of the frame. Since the two wires make the same angle with the vertical, the tension is the same in each wire. $T = 0.75w$.

EXECUTE: The vertical component of the force due to the tension in each wire must be half of the weight, and this in turn is the tension multiplied by the cosine of the angle each wire makes with the vertical. $\dfrac{w}{2} = \dfrac{3w}{4}\cos\theta$ and $\theta = \arccos\frac{2}{3} = 48°$.

EVALUATE: If $\theta = 0°$, $T = w/2$ and $T \to \infty$ as $\theta \to 90°$. Therefore, there must be an angle where $T = 3w/4$.

5.6. **IDENTIFY:** Apply Newton's first law to the wrecking ball. Each cable exerts a force on the ball, directed along the cable.

SET UP: The force diagram for the wrecking ball is sketched in Figure 5.6.

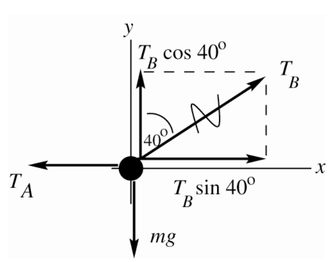


Figure 5.6

EXECUTE: **(a)** $\Sigma F_y = ma_y$

$T_B\cos 40° - mg = 0$

$$T_B = \frac{mg}{\cos 40°} = \frac{(3620\text{ kg})(9.80\text{ m/s}^2)}{\cos 40°} = 4.63\times 10^4\text{ N} = 46.3\text{ kN}$$

(b) $\Sigma F_x = ma_x$

$T_B \sin 40° - T_A = 0$

$T_A = T_B \sin 40° = 2.98 \times 10^4 \text{ N} = 29.8 \text{ kN}$

EVALUATE: If the angle 40° is replaced by 0° (cable B is vertical), then $T_B = mg$ and $T_A = 0$.

5.7. **IDENTIFY:** Apply $\Sigma \vec{F} = m\vec{a}$ to the object and to the knot where the cords are joined.

SET UP: Let $+y$ be upward and $+x$ be to the right.

EXECUTE: **(a)** $T_C = w$, $T_A \sin 30° + T_B \sin 45° = T_C = w$, and $T_A \cos 30° - T_B \cos 45° = 0$. Since $\sin 45° = \cos 45°$, adding the last two equations gives $T_A(\cos 30° + \sin 30°) = w$, and so

$T_A = \dfrac{w}{1.366} = 0.732w$. Then, $T_B = T_A \dfrac{\cos 30°}{\cos 45°} = 0.897w$.

(b) Similar to part (a), $T_C = w$, $-T_A \cos 60° + T_B \sin 45° = w$, and $T_A \sin 60° - T_B \cos 45° = 0$.

Adding these two equations, $T_A = \dfrac{w}{(\sin 60° - \cos 60°)} = 2.73w$, and $T_B = T_A \dfrac{\sin 60°}{\cos 45°} = 3.35w$.

EVALUATE: In part (a), $T_A + T_B > w$ since only the vertical components of T_A and T_B hold the object against gravity. In part (b), since T_A has a downward component T_B is greater than w.

5.8. **IDENTIFY:** Apply Newton's first law to the hanging weight and to each knot. The tension force at each end of a string is the same.

(a) Let the tensions in the three strings be T, T', and T'', as shown in Figure 5.8a.

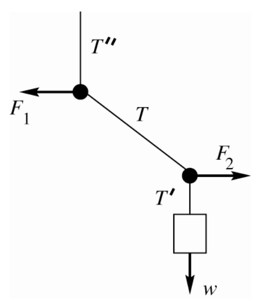

Figure 5.8a

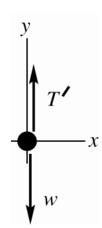
SET UP: The free-body diagram for the block is given in Figure 5.8b.



EXECUTE:

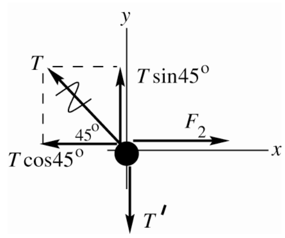
$\Sigma F_y = 0$

$T' - w = 0$

$T' = w = 60.0 \text{ N}$

Figure 5.8b

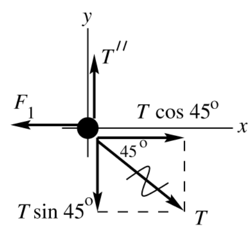
SET UP: The free-body diagram for the lower knot is given in Figure 5.8c.



EXECUTE:
$\Sigma F_y = 0$
$T\sin 45° - T' = 0$
$T = \dfrac{T'}{\sin 45°} = \dfrac{60.0\text{ N}}{\sin 45°} = 84.9\text{ N}$

Figure 5.8c

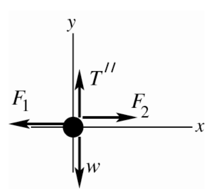
(b) Apply $\Sigma F_x = 0$ to the force diagram for the lower knot:
$\Sigma F_x = 0$
$F_2 = T\cos 45° = (84.9\text{ N})\cos 45° = 60.0\text{ N}$
SET UP: The free-body diagram for the upper knot is given in Figure 5.8d.



EXECUTE:
$\Sigma F_x = 0$
$T\cos 45° - F_1 = 0$
$F_1 = (84.9\text{ N})\cos 45°$
$F_1 = 60.0\text{ N}$

Figure 5.8d

Note that $F_1 = F_2$.
EVALUATE: Applying $\Sigma F_y = 0$ to the upper knot gives $T'' = T\sin 45° = 60.0\text{ N} = w$. If we treat the whole system as a single object, the force diagram is given in Figure 5.8e.



$\Sigma F_x = 0$ **gives** $F_2 = F_1$, **which checks**
$\Sigma F_y = 0$ **gives** $T'' = w$, **which checks**

Figure 5.8e

5.9. **IDENTIFY:** Since the velocity is constant, apply Newton's first law to the piano. The push applied by the man must oppose the component of gravity down the incline.
SET UP: The free-body diagrams for the two cases are shown in Figure 5.9. $\vec{F}$ is the force applied by the man. Use the coordinates shown in the figure.
EXECUTE: **(a)** $\Sigma F_x = 0$ gives $F - w\sin 19.0° = 0$ and $F = (180\text{ kg})(9.80\text{ m/s}^2)\sin 19.0° = 574\text{ N}$.
(b) $\Sigma F_y = 0$ gives $n\cos 19.0° - w = 0$ and $n = \dfrac{w}{\cos 19.0°}$. $\Sigma F_x = 0$ gives $F - n\sin 19.0° = 0$ and $F = \left(\dfrac{w}{\cos 19.0°}\right)\sin 19.0° = w\tan 19.0° = 607\text{ N}$.

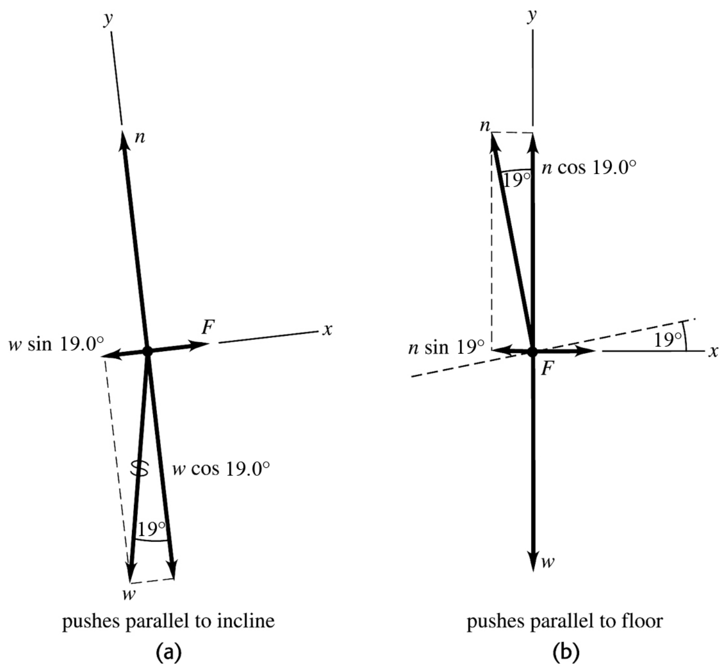


Figure 5.9

EVALUATE: When pushing parallel to the floor only part of the push is up the ramp to balance the weight of the piano, so you need a larger push in this case than if you push parallel to the ramp.

5.10. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the composite object of elevator plus student $(m_{\text{tot}} = 850 \text{ kg})$ and also to the student $(w = 550 \text{ N})$. The elevator and the student have the same acceleration.

SET UP: Let $+y$ be upward. The free-body diagrams for the composite object and for the student are given in Figure 5.10. T is the tension in the cable and n is the scale reading, the normal force the scale exerts on the student. The mass of the student is $m = w/g = 56.1$ kg.

EXECUTE: **(a)** $\Sigma F_y = ma_y$ applied to the student gives $n - mg = ma_y$.

$a_y = \dfrac{n - mg}{m} = \dfrac{450 \text{ N} - 550 \text{ N}}{56.1 \text{ kg}} = -1.78 \text{ m/s}^2$. The elevator has a downward acceleration of 1.78 m/s^2.

(b) $a_y = \dfrac{670 \text{ N} - 550 \text{ N}}{56.1 \text{ kg}} = 2.14 \text{ m/s}^2$.

(c) $n = 0$ means $a_y = -g$. The student should worry; the elevator is in free fall.

(d) $\Sigma F_y = ma_y$ applied to the composite object gives $T - m_{\text{tot}}g = m_{\text{tot}}a_y$. $T = m_{\text{tot}}(a_y + g)$. In part (a), $T = (850 \text{ kg})(-1.78 \text{ m/s}^2 + 9.80 \text{ m/s}^2) = 6820$ N. In part (c), $a_y = -g$ and $T = 0$.

EVALUATE: In part (b), $T = (850 \text{ kg})(2.14 \text{ m/s}^2 + 9.80 \text{ m/s}^2) = 10{,}150$ N. The weight of the composite object is 8330 N. When the acceleration is upward the tension is greater than the weight and when the acceleration is downward the tension is less than the weight.

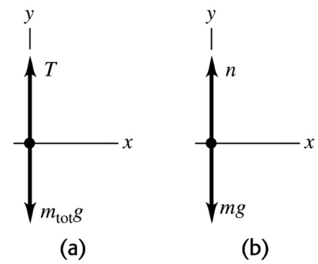

Figure 5.10

5.11. **IDENTIFY:** We apply Newton's second law to the rocket and the astronaut in the rocket. A constant force means we have constant acceleration, so we can use the standard kinematics equations.

SET UP: The free-body diagrams for the rocket (weight w_r) and astronaut (weight w) are given in Figure 5.11. F_T is the thrust and n is the normal force the rocket exerts on the astronaut. The speed of sound is 331 m/s. We use $\Sigma F_y = ma_y$ and $v = v_0 + at$.

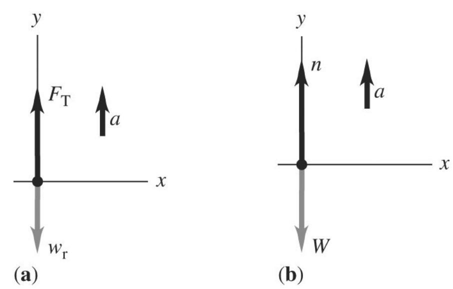

Figure 5.11

EXECUTE: **(a)** Apply $\Sigma F_y = ma_y$ to the rocket: $F_T - w_r = ma$. $a = 4g$ and $w_r = mg$, so $F = m\,(5g) = (2.25\times 10^6\text{ kg})\,(5)\,(9.80\text{ m/s}^2) = 1.10\times 10^8\text{ N}$.

(b) Apply $\Sigma F_y = ma_y$ to the astronaut: $n - w = ma$. $a = 4g$ and $m = \dfrac{w}{g}$, so $n = w + \left(\dfrac{w}{g}\right)(4g) = 5w$.

(c) $v_0 = 0$, $v = 331$ m/s and $a = 4g = 39.2\text{ m/s}^2$. $v = v_0 + at$ gives $t = \dfrac{v - v_0}{a} = \dfrac{331\text{ m/s}}{39.2\text{ m/s}^2} = 8.4\text{ s}$.

EVALUATE: The 8.4 s is probably an unrealistically short time to reach the speed of sound because you would not want your astronauts at the brink of blackout during a launch.

5.12. **IDENTIFY:** Apply Newton's second law to the rocket plus its contents and to the power supply. Both the rocket and the power supply have the same acceleration.

SET UP: The free-body diagrams for the rocket and for the power supply are given in Figure 5.12. Since the highest altitude of the rocket is 120 m, it is near to the surface of the earth and there is a downward gravity force on each object. Let $+y$ be upward, since that is the direction of the acceleration. The power supply has mass $m_{ps} = (15.5\text{ N})/(9.80\text{ m/s}^2) = 1.58\text{ kg}$.

EXECUTE: **(a)** $\Sigma F_y = ma_y$ applied to the rocket gives $F - m_r g = m_r a$.

$$a = \frac{F - m_r g}{m_r} = \frac{1720\text{ N} - (125\text{ kg})(9.80\text{ m/s}^2)}{125\text{ kg}} = 3.96\text{ m/s}^2.$$

(b) $\Sigma F_y = ma_y$ applied to the power supply gives $n - m_{ps}g = m_{ps}a$.

$n = m_{ps}(g + a) = (1.58\text{ kg})(9.80\text{ m/s}^2 + 3.96\text{ m/s}^2) = 21.7\text{ N}$.

EVALUATE: The acceleration is constant while the thrust is constant, and the normal force is constant while the acceleration is constant. The altitude of 120 m is not used in the calculation.

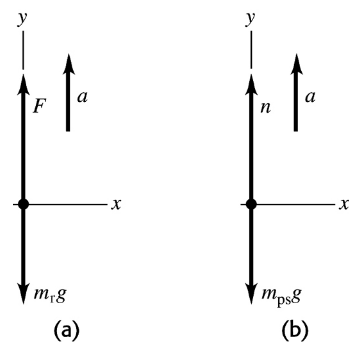

Figure 5.12

5.13. **IDENTIFY:** Use the kinematic information to find the acceleration of the capsule and the stopping time. Use Newton's second law to find the force *F* that the ground exerted on the capsule during the crash.

SET UP: Let $+y$ be upward. $311 \text{ km/h} = 86.4 \text{ m/s}$. The free-body diagram for the capsule is given in Figure 5.13.

EXECUTE: $y - y_0 = -0.810 \text{ m}$, $v_{0y} = -86.4 \text{ m/s}$, $v_y = 0$. $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$$a_y = \frac{v_y^2 - v_{0y}^2}{2(y - y_0)} = \frac{0 - (-86.4 \text{ m/s})^2}{2(-0.810) \text{ m}} = 4610 \text{ m/s}^2 = 470g.$$

(b) $\Sigma F_y = ma_y$ applied to the capsule gives $F - mg = ma$ and

$$F = m(g + a) = (210 \text{ kg})(9.80 \text{ m/s}^2 + 4610 \text{ m/s}^2) = 9.70 \times 10^5 \text{ N} = 471w.$$

(c) $y - y_0 = \left(\dfrac{v_{0y} + v_y}{2}\right)t$ gives $t = \dfrac{2(y - y_0)}{v_{0y} + v_y} = \dfrac{2(-0.810 \text{ m})}{-86.4 \text{ m/s} + 0} = 0.0187 \text{ s}$

EVALUATE: The upward force exerted by the ground is much larger than the weight of the capsule and stops the capsule in a short amount of time. After the capsule has come to rest, the ground still exerts a force *mg* on the capsule, but the large 9.70×10^5 N force is exerted only for 0.0187 s.

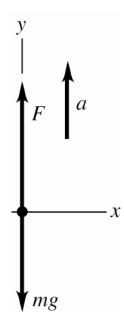

Figure 5.13

5.14. **IDENTIFY:** Apply Newton's second law to the three sleds taken together as a composite object and to each individual sled. All three sleds have the same horizontal acceleration *a*.

SET UP: The free-body diagram for the three sleds taken as a composite object is given in Figure 5.14a and for each individual sled in Figures 5.14b–d. Let $+x$ be to the right, in the direction of the acceleration. $m_{tot} = 60.0$ kg.

Execute: **(a)** $\Sigma F_x = ma_x$ for the three sleds as a composite object gives $P = m_{\text{tot}}a$ and
$a = \dfrac{P}{m_{\text{tot}}} = \dfrac{190 \text{ N}}{60.0 \text{ kg}} = 3.17 \text{ m/s}^2$.

(b) $\Sigma F_x = ma_x$ applied to the 10.0 kg sled gives $P - T_A = m_{10}a$ and
$T_A = P - m_{10}a = 190 \text{ N} - (10.0 \text{ kg})(3.17 \text{ m/s}^2) = 158 \text{ N}$. $\Sigma F_x = ma_x$ applied to the 30.0 kg sled gives
$T_B = m_{30}a = (30.0 \text{ kg})(3.17 \text{ m/s}^2) = 95.1 \text{ N}$.

Evaluate: If we apply $\Sigma F_x = ma_x$ to the 20.0 kg sled and calculate a from T_A and T_B found in part (b), we get $T_A - T_B = m_{20}a$. $a = \dfrac{T_A - T_B}{m_{20}} = \dfrac{158 \text{ N} - 95.1 \text{ N}}{20.0 \text{ kg}} = 3.15 \text{ m/s}^2$, which agrees closely with the value we calculated in part (a), the difference being due to rounding.

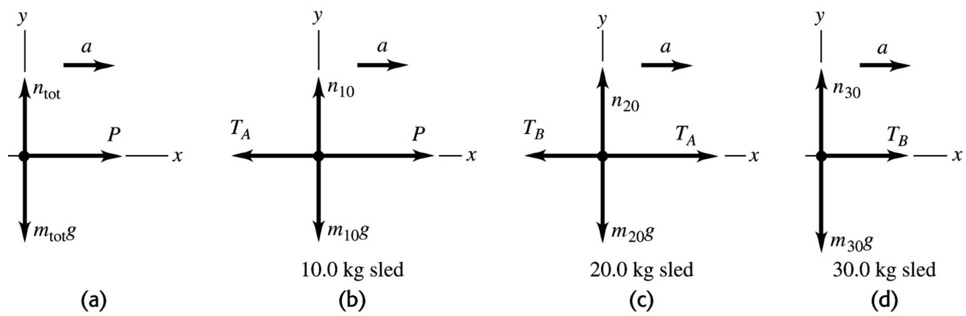

Figure 5.14

5.15. **Identify:** Apply $\Sigma \vec{F} = m\vec{a}$ to the load of bricks and to the counterweight. The tension is the same at each end of the rope. The rope pulls up with the same force (T) on the bricks and on the counterweight. The counterweight accelerates downward and the bricks accelerate upward; these accelerations have the same magnitude.

(a) Set Up: The free-body diagrams for the bricks and counterweight are given in Figure 5.15.

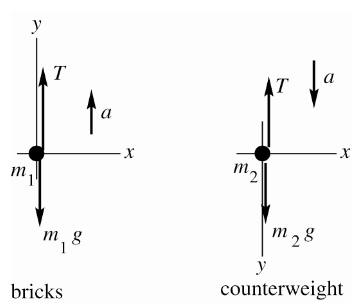

Figure 5.15

(b) Execute: Apply $\Sigma F_y = ma_y$ to each object. The acceleration magnitude is the same for the two objects. For the bricks take $+y$ to be upward since $\vec{a}$ for the bricks is upward. For the counterweight take $+y$ to be downward since $\vec{a}$ is downward.

<u>bricks</u>: $\Sigma F_y = ma_y$

$T - m_1 g = m_1 a$

<u>counterweight</u>: $\Sigma F_y = ma_y$

$m_2 g - T = m_2 a$

Add these two equations to eliminate T:

$$(m_2 - m_1)g = (m_1 + m_2)a$$

$$a = \left(\frac{m_2 - m_1}{m_1 + m_2}\right)g = \left(\frac{28.0\text{ kg} - 15.0\text{ kg}}{15.0\text{ kg} + 28.0\text{ kg}}\right)(9.80\text{ m/s}^2) = 2.96\text{ m/s}^2$$

(c) $T - m_1 g = m_1 a$ gives $T = m_1(a + g) = (15.0\text{ kg})(2.96\text{ m/s}^2 + 9.80\text{ m/s}^2) = 191\text{ N}$

As a check, calculate T using the other equation.

$m_2 g - T = m_2 a$ gives $T = m_2(g - a) = 28.0\text{ kg}(9.80\text{ m/s}^2 - 2.96\text{ m/s}^2) = 191\text{ N}$, which checks.

EVALUATE: The tension is 1.30 times the weight of the bricks; this causes the bricks to accelerate upward. The tension is 0.696 times the weight of the counterweight; this causes the counterweight to accelerate downward. If $m_1 = m_2$, $a = 0$ and $T = m_1 g = m_2 g$. In this special case the objects don't move. If $m_1 = 0$, $a = g$ and $T = 0$; in this special case the counterweight is in free fall. Our general result is correct in these two special cases.

5.16. IDENTIFY: In part (a) use the kinematic information and the constant acceleration equations to calculate the acceleration of the ice. Then apply $\Sigma\vec{F} = m\vec{a}$. In part (b) use $\Sigma\vec{F} = m\vec{a}$ to find the acceleration and use this in the constant acceleration equations to find the final speed.

SET UP: Figure 5.16 gives the free-body diagrams for the ice both with and without friction. Let $+x$ be directed down the ramp, so $+y$ is perpendicular to the ramp surface. Let ϕ be the angle between the ramp and the horizontal. The gravity force has been replaced by its x- and y-components.

EXECUTE: **(a)** $x - x_0 = 1.50\text{ m}$, $v_{0x} = 0$. $v_x = 2.50\text{ m/s}$. $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives

$a_x = \dfrac{v_x^2 - v_{0x}^2}{2(x - x_0)} = \dfrac{(2.50\text{ m/s})^2 - 0}{2(1.50\text{ m})} = 2.08\text{ m/s}^2$. $\Sigma F_x = ma_x$ gives $mg\sin\phi = ma$ and

$\sin\phi = \dfrac{a}{g} = \dfrac{2.08\text{ m/s}^2}{9.80\text{ m/s}^2}$. $\phi = 12.3°$.

(b) $\Sigma F_x = ma_x$ gives $mg\sin\phi - f = ma$ and

$a = \dfrac{mg\sin\phi - f}{m} = \dfrac{(8.00\text{ kg})(9.80\text{ m/s}^2)\sin 12.3° - 10.0\text{ N}}{8.00\text{ kg}} = 0.838\text{ m/s}^2$.

Then $x - x_0 = 1.50\text{ m}$, $v_{0x} = 0$. $a_x = 0.838\text{ m/s}^2$ and $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives

$$v_x = \sqrt{2a_x(x - x_0)} = \sqrt{2(0.838\text{ m/s}^2)(1.50\text{ m})} = 1.59\text{ m/s}$$

EVALUATE: With friction present the speed at the bottom of the ramp is less.

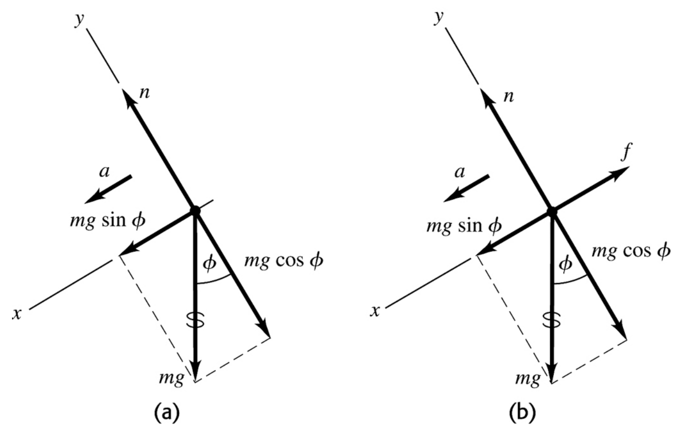

Figure 5.16

5.17. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each block. Each block has the same magnitude of acceleration a.

SET UP: Assume the pulley is to the right of the 4.00 kg block. There is no friction force on the 4.00 kg block; the only force on it is the tension in the rope. The 4.00 kg block therefore accelerates to the right and the suspended block accelerates downward. Let $+x$ be to the right for the 4.00 kg block, so for it $a_x = a$, and let $+y$ be downward for the suspended block, so for it $a_y = a$.

EXECUTE: **(a)** The free-body diagrams for each block are given in Figures 5.17a and b.

(b) $\Sigma F_x = ma_x$ applied to the 4.00 kg block gives $T = (4.00\text{ kg})a$ and

$$a = \frac{T}{4.00\text{ kg}} = \frac{15.0\text{ N}}{4.00\text{ kg}} = 3.75\text{ m/s}^2.$$

(c) $\Sigma F_y = ma_y$ applied to the suspended block gives $mg - T = ma$ and

$$m = \frac{T}{g-a} = \frac{15.0\text{ N}}{9.80\text{ m/s}^2 - 3.75\text{ m/s}^2} = 2.48\text{ kg}.$$

(d) The weight of the hanging block is $mg = (2.48\text{ kg})(9.80\text{ m/s}^2) = 24.3\text{ N}$. This is greater than the tension in the rope; $T = 0.617mg$.

EVALUATE: Since the hanging block accelerates downward, the net force on this block must be downward and the weight of the hanging block must be greater than the tension in the rope. Note that the blocks accelerate no matter how small m is. It is not necessary to have $m > 4.00\text{ kg}$, and in fact in this problem m is less than 4.00 kg.

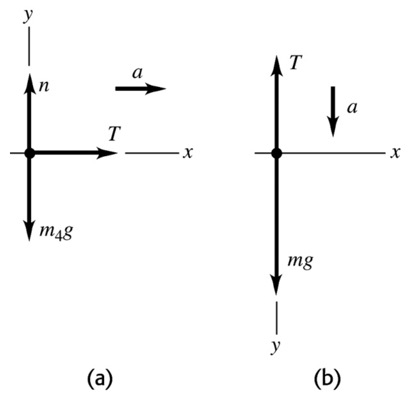

Figure 5.17

5.18. **IDENTIFY:** **(a)** Consider both gliders together as a single object, apply $\Sigma\vec{F} = m\vec{a}$, and solve for a. Use a in a constant acceleration equation to find the required runway length.

(b) Apply $\Sigma\vec{F} = m\vec{a}$ to the second glider and solve for the tension T_g in the towrope that connects the two gliders.

SET UP: In part (a), set the tension T_t in the towrope between the plane and the first glider equal to its maximum value, $T_t = 12{,}000$ N.

EXECUTE: **(a)** The free-body diagram for both gliders as a single object of mass $2m = 1400$ kg is given in Figure 5.18a. $\Sigma F_x = ma_x$ gives $T_t - 2f = (2m)a$ and $a = \dfrac{T_t - 2f}{2m} = \dfrac{12{,}000\text{ N} - 5000\text{ N}}{1400\text{ kg}} = 5.00\text{ m/s}^2$. Then $a_x = 5.00\text{ m/s}^2$, $v_{0x} = 0$ and $v_x = 40$ m/s in $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives $(x - x_0) = \dfrac{v_x^2 - v_{0x}^2}{2a_x} = 160$ m.

(b) The free-body diagram for the second glider is given in Figure 5.18b.
$\Sigma F_x = ma_x$ gives $T_g - f = ma$ and $T_g = f + ma = 2500\text{ N} + (700\text{ kg})(5.00\text{ m/s}^2) = 6000$ N.

EVALUATE: We can verify that $\Sigma F_x = ma_x$ is also satisfied for the first glider.

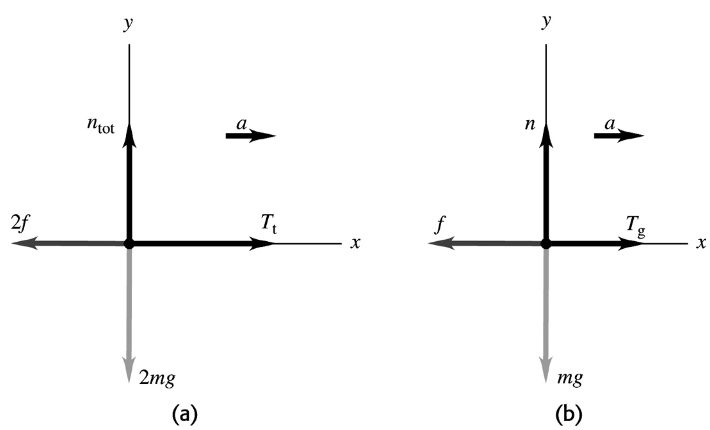

Figure 5.18

5.19. IDENTIFY: While the person is in contact with the ground, he is accelerating upward and experiences two forces: gravity downward and the upward force of the ground. Once he is in the air, only gravity acts on him so he accelerates downward. Newton's second law applies during the jump (and at all other times).

SET UP: Take $+y$ to be upward. After he leaves the ground the person travels upward 60 cm and his acceleration is $g = 9.80\text{ m/s}^2$, downward. His weight is w so his mass is w/g. $\Sigma F_y = ma_y$ and $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ apply to the jumper.

EXECUTE: **(a)** $v_y = 0$ (at the maximum height), $y - y_0 = 0.60\text{ m}$, $a_y = -9.80\text{ m/s}^2$.

$v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $v_{0y} = \sqrt{-2a_y(y - y_0)} = \sqrt{-2(-9.80\text{ m/s}^2)(0.60\text{ m})} = 3.4\text{ m/s}$.

(b) The free-body diagram for the person while he is pushing up against the ground is given in Figure 5.19.

(c) For the jump, $v_{0y} = 0$, $v_y = 3.4\text{ m/s}$ (from part (a)), and $y - y_0 = 0.50\text{ m}$. $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $a_y = \dfrac{v_y^2 - v_{0y}^2}{2(y - y_0)} = \dfrac{(3.4\text{ m/s})^2 - 0}{2(0.50\text{ m})} = 11.6\text{ m/s}^2$. $\Sigma F_y = ma_y$ gives $n - w = ma$.

$$n = w + ma = w\left(1 + \frac{a}{g}\right) = 2.2w.$$

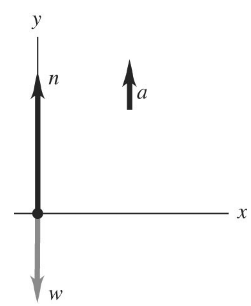

Figure 5.19

EVALUATE: To accelerate the person upward during the jump, the upward force from the ground must exceed the downward pull of gravity. The ground pushes up on him because he pushes down on the ground.

5.20. IDENTIFY: Acceleration and velocity are related by $a_y = \dfrac{dv_y}{dt}$. Apply $\Sigma\vec{F} = m\vec{a}$ to the rocket.

SET UP: Let $+y$ be upward. The free-body diagram for the rocket is sketched in Figure 5.20. $\vec{F}$ is the thrust force.

EXECUTE: **(a)** $v_y = At + Bt^2$. $a_y = A + 2Bt$. At $t = 0$, $a_y = 1.50\text{ m/s}^2$ so $A = 1.50\text{ m/s}^2$. Then $v_y = 2.00\text{ m/s}$ at $t = 1.00\text{ s}$ gives $2.00\text{ m/s} = (1.50\text{ m/s}^2)(1.00\text{ s}) + B(1.00\text{ s})^2$ and $B = 0.50\text{ m/s}^3$.

(b) At $t = 4.00\text{ s}$, $a_y = 1.50\text{ m/s}^2 + 2(0.50\text{ m/s}^3)(4.00\text{ s}) = 5.50\text{ m/s}^2$.

(c) $\Sigma F_y = ma_y$ applied to the rocket gives $T - mg = ma$ and

$T = m(a + g) = (2540\text{ kg})(9.80\text{ m/s}^2 + 5.50\text{ m/s}^2) = 3.89 \times 10^4\text{ N}$. $T = 1.56w$.

(d) When $a = 1.50\text{ m/s}^2$, $T = (2540\text{ kg})(9.80\text{ m/s}^2 + 1.50\text{ m/s}^2) = 2.87 \times 10^4\text{ N}$.

EVALUATE: During the time interval when $v(t) = At + Bt^2$ applies the magnitude of the acceleration is increasing, and the thrust is increasing.

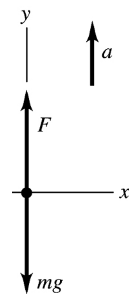

Figure 5.20

5.21. **IDENTIFY:** We know the external forces on the box and want to find the distance it moves and its speed. The force is not constant, so the acceleration will not be constant, so we cannot use the standard constant-acceleration kinematics formulas. But Newton's second law will apply.

SET UP: First use Newton's second law to find the acceleration as a function of time: $a_x(t) = \dfrac{F_x}{m}$. Then integrate the acceleration to find the velocity as a function of time, and next integrate the velocity to find the position as a function of time.

EXECUTE: Let $+x$ be to the right. $a_x(t) = \dfrac{F_x}{m} = \dfrac{(-6.00\ \text{N/s}^2)t^2}{2.00\ \text{kg}} = -(3.00\ \text{m/s}^4)t^2$. Integrate the acceleration to find the velocity as a function of time: $v_x(t) = -(1.00\ \text{m/s}^4)t^3 + 9.00\ \text{m/s}$. Next integrate the velocity to find the position as a function of time: $x(t) = -(0.250\ \text{m/s}^4)t^4 + (9.00\ \text{m/s})t$. Now use the given values of time.

(a) $v_x = 0$ when $(1.00\ \text{m/s}^4)t^3 = 9.00\ \text{m/s}$. This gives $t = 2.08\ \text{s}$. At $t = 2.08\ \text{s}$,
$x = (9.00\ \text{m/s})(2.08\ \text{s}) - (0.250\ \text{m/s}^4)(2.08\ \text{s})^4 = 18.72\ \text{m} - 4.68\ \text{m} = 14.0\ \text{m}$.

(b) At $t = 3.00\ \text{s}$, $v_x(t) = -(1.00\ \text{m/s}^4)(3.00\ \text{s})^3 + 9.00\ \text{m/s} = -18.0\ \text{m/s}$, so the speed is $18.0\ \text{m/s}$.

EVALUATE: The box starts out moving to the right. But because the acceleration is to the left, it reverses direction and v_x is negative in part (b).

5.22. **IDENTIFY:** We know the position of the crate as a function of time, so we can differentiate to find its acceleration. Then we can apply Newton's second law to find the upward force.

SET UP: $v_y(t) = dy/dt$, $a_y(t) = dv_y/dt$, and $\Sigma F_y = ma_y$.

EXECUTE: Let $+y$ be upward. $dy/dt = v_y(t) = 2.80\ \text{m/s} + (1.83\ \text{m/s}^3)t^2$ and $dv_y/dt = a_y(t) = (3.66\ \text{m/s}^3)t$. At $t = 4.00\ \text{s}$, $a_y = 14.64\ \text{m/s}^2$. Newton's second law in the y direction gives $F - mg = ma$. Solving for F gives $F = 49\ \text{N} + (5.00\ \text{kg})(14.64\ \text{m/s}^2) = 122\ \text{N}$.

EVALUATE: The force is greater than the weight since it is accelerating the crate upward.

5.23. **IDENTIFY:** At the maximum tilt angle, the patient is just ready to slide down, so static friction is at its maximum and the forces on the patient balance.

SET UP: Take $+x$ to be down the incline. At the maximum angle $f_s = \mu_s n$ and $\Sigma F_x = ma_x = 0$.

EXECUTE: The free-body diagram for the patient is given in Figure 5.23. $\Sigma F_y = ma_y$ gives $n = mg\cos\theta$. $\Sigma F_x = 0$ gives $mg\sin\theta - \mu_s n = 0$. $mg\sin\theta - \mu_s mg\cos\theta = 0$. $\tan\theta = \mu_s$ so $\theta = 50°$.

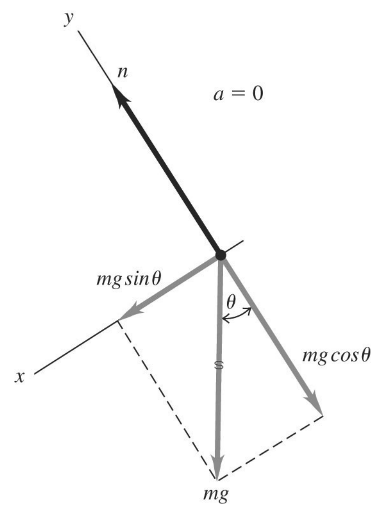

Figure 5.23

EVALUATE: A larger angle of tilt would cause more blood to flow to the brain, but it would also cause the patient to slide down the bed.

5.24. **IDENTIFY:** $f_s \le \mu_s n$ and $f_k = \mu_k n.$ The normal force n is determined by applying $\Sigma\vec{F} = m\vec{a}$ to the block. Normally, $\mu_k \le \mu_s$. f_s is only as large as it needs to be to prevent relative motion between the two surfaces.

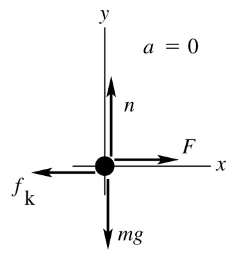
SET UP: Since the table is horizontal, with only the block present $n = 135$ N. With the brick on the block,
$n = 270$ N.

EXECUTE: **(a)** The friction is static for $P = 0$ to $P = 75.0$ N. The friction is kinetic for $P > 75.0$ N.
(b) The maximum value of f_s is $\mu_s n.$ From the graph the maximum f_s is $f_s = 75.0$ N, so
$\mu_s = \dfrac{\max f_s}{n} = \dfrac{75.0\text{ N}}{135\text{ N}} = 0.556.$ $f_k = \mu_k n.$ From the graph, $f_k = 50.0$ N and $\mu_k = \dfrac{f_k}{n} = \dfrac{50.0\text{ N}}{135\text{ N}} = 0.370.$
(c) When the block is moving the friction is kinetic and has the constant value $f_k = \mu_k n,$ independent of P. This is why the graph is horizontal for $P > 75.0$ N. When the block is at rest, $f_s = P$ since this prevents relative motion. This is why the graph for $P < 75.0$ N has slope $+1$.
(d) max f_s and f_k would double. The values of f on the vertical axis would double but the shape of the graph would be unchanged.

EVALUATE: The coefficients of friction are independent of the normal force.

5.25. **(a) IDENTIFY:** Constant speed implies $a = 0$. Apply Newton's first law to the box. The friction force is directed opposite to the motion of the box.

SET UP: Consider the free-body diagram for the box, given in Figure 5.25a. Let $\vec{F}$ be the horizontal force applied by the worker. The friction is kinetic friction since the box is sliding along the surface.



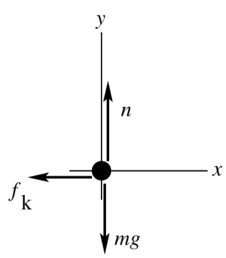
EXECUTE:
$\Sigma F_y = ma_y$
$n - mg = 0$
$n = mg$
so $f_k = \mu_k n = \mu_k mg$

Figure 5.25a

$\Sigma F_x = ma_x$
$F - f_k = 0$
$F = f_k = \mu_k mg = (0.20)(16.8\text{ kg})(9.80\text{ m/s}^2) = 33\text{ N}$

(b) IDENTIFY: Now the only horizontal force on the box is the kinetic friction force. Apply Newton's second law to the box to calculate its acceleration. Once we have the acceleration, we can find the distance using a constant acceleration equation. The friction force is $f_k = \mu_k mg$, just as in part (a).

SET UP: The free-body diagram is sketched in Figure 5.25b.



EXECUTE:
$\Sigma F_x = ma_x$
$-f_k = ma_x$
$-\mu_k mg = ma_x$
$a_x = -\mu_k g = -(0.20)(9.80\text{ m/s}^2) = -1.96\text{ m/s}^2$

Figure 5.25b

Use the constant acceleration equations to find the distance the box travels:
$v_x = 0,\ v_{0x} = 3.50\text{ m/s},\ a_x = -1.96\text{ m/s}^2,\ x - x_0 = ?$
$v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$
$$x - x_0 = \frac{v_x^2 - v_{0x}^2}{2a_x} = \frac{0 - (3.50\text{ m/s})^2}{2(-1.96\text{ m/s}^2)} = 3.1\text{ m}$$

EVALUATE: The normal force is the component of force exerted by a surface perpendicular to the surface. Its magnitude is determined by $\Sigma\vec{F} = m\vec{a}$. In this case *n* and *mg* are the only vertical forces and $a_y = 0$, so $n = mg$. Also note that f_k and *n* are proportional in magnitude but perpendicular in direction.

5.26. IDENTIFY: Apply $\Sigma\vec{F} = m\vec{a}$ to the box.

SET UP: Since the only vertical forces are *n* and *w*, the normal force on the box equals its weight. Static friction is as large as it needs to be to prevent relative motion between the box and the surface, up to its maximum possible value of $f_s^{\max} = \mu_s n$. If the box is sliding then the friction force is $f_k = \mu_k n$.

EXECUTE: **(a)** If there is no applied force, no friction force is needed to keep the box at rest.

(b) $f_s^{\max} = \mu_s n = (0.40)(40.0\text{ N}) = 16.0\text{ N}$. If a horizontal force of 6.0 N is applied to the box, then $f_s = 6.0\text{ N}$ in the opposite direction.

(c) The monkey must apply a force equal to f_s^{max}, 16.0 N.

(d) Once the box has started moving, a force equal to $f_k = \mu_k n = 8.0\text{ N}$ is required to keep it moving at constant velocity.

(e) $f_k = 8.0\text{ N}$. $a = (18.0\text{ N} - 8.0\text{ N})/(40.0\text{ N}/9.80\text{ m/s}^2) = 2.45\text{ m/s}^2$

EVALUATE: $\mu_k < \mu_s$ and less force must be applied to the box to maintain its motion than to start it moving.

5.27. IDENTIFY: Apply $\Sigma\vec{F} = m\vec{a}$ to the crate. $f_s \le \mu_s n$ and $f_k = \mu_k n$.

SET UP: Let $+y$ be upward and let $+x$ be in the direction of the push. Since the floor is horizontal and the push is horizontal, the normal force equals the weight of the crate: $n = mg = 441\text{ N}$. The force it takes to start the crate moving equals max f_s and the force required to keep it moving equals f_k.

EXECUTE: (a) max $f_s = 313\text{ N}$, so $\mu_s = \dfrac{313\text{ N}}{441\text{ N}} = 0.710$. $f_k = 208\text{ N}$, so $\mu_k = \dfrac{208\text{ N}}{441\text{ N}} = 0.472$.

(b) The friction is kinetic. $\Sigma F_x = ma_x$ gives $F - f_k = ma$ and

$F = f_k + ma = 208\text{ N} + (45.0\text{ kg})(1.10\text{ m/s}^2) = 258\text{ N}$.

(c) (i) The normal force now is $mg = 72.9\text{ N}$. To cause it to move,

$F = \max f_s = \mu_s n = (0.710)(72.9\text{ N}) = 51.8\text{ N}$.

(ii) $F = f_k + ma$ and $a = \dfrac{F - f_k}{m} = \dfrac{258\text{ N} - (0.472)(72.9\text{ N})}{45.0\text{ kg}} = 4.97\text{ m/s}^2$

EVALUATE: The kinetic friction force is independent of the speed of the object. On the moon, the mass of the crate is the same as on earth, but the weight and normal force are less.

5.28. IDENTIFY: On the level floor and on the ramp the box moves with constant velocity, so its acceleration is zero. Therefore the forces on it must balance. In addition to your push, kinetic friction and gravity act on the box.

SET UP: Estimate: Heaviest box is about 150 lb with sustained effort. $\sum F_x = 0$, $\sum F_y = 0$, and the kinetic friction force is $f_k = \mu_k n$.

EXECUTE: To push a 150-lb box on a horizontal surface, the force needed would be equal to the kinetic friction force, which is $f_k = \mu_k n = (0.50)(150\text{ lb}) = 75\text{ lb}$. We now exert this push on a box on a ramp and want to know the weight of the heaviest box we can push up the ramp at constant speed. μ_k is the same on the ramp as it is on the level floor. Fig. 5.28 shows a free-body diagram of the box on the ramp. Take the *x*-axis parallel to the ramp surface pointing up the ramp, and call β the angle the ramp makes above the horizontal .

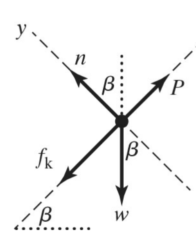


Figure 5.28

Using the notation in Fig. 5.28, $\sum F_y = 0$ gives $n - w\cos\beta = 0$, so $n = w\cos\beta$.

$\sum F_x = 0$ gives $P - f_k - w\sin\beta = 0$. We also have $f_k = \mu_k n$, so the last equation becomes

$P - \mu_k w \cos\beta - w \sin\beta = 0$. Solve for w: $w = \dfrac{P}{\mu_k \cos\beta + \sin\beta} = \dfrac{75 \text{ lb}}{(0.50)\cos 60° + \sin 60°}$, so $w = 67$ lb.

EVALUATE: This weight is less than you can push on a level surface because you need to balance the weight component down the ramp in addition to the friction force.

5.29. **IDENTIFY:** The children are accelerated as they move down the slide, so Newton's second law applies. The acceleration is constant, so the constant-acceleration formulas apply.

SET UP: Estimations: The height of the slide is about 6 ft or 2.0 m, and it rises at an angle of 30° above the horizontal. The forces on the child are gravity, the normal force due to the slide, and friction. Apply $\sum F_x = ma_x$ with the x-axis is along the surface of the slide pointing downward, and $\sum F_y = 0$ with the y-axis perpendicular to the slide surface. Fig. 5.29 shows free-body diagrams of the child with and without friction.

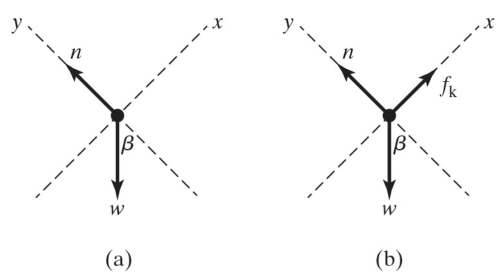

Figure 5.29

EXECUTE: **(a)** First find the acceleration and then use it to find the velocity at the bottom of the slide. Use $\sum F_x = ma_x$ with the notation in Fig. 5.29a. $mg \sin\beta = ma_x$, so $a_x = g \sin\beta = g \sin 30° = g/2$. Now use $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ to find v_x at the bottom. The distance $x - x_0 = (2.0 \text{ m})/(\sin\beta) = (2.0 \text{ m})/(\sin 30°) = 4.0$ m. This gives $v_x^2 = 0 + 2(g/2)(4.0 \text{ m})$, so $v_x = 6.3$ m/s.

(b) Now friction is acting up the slide, as shown in Fig. 5.29b, and we want to find μ_k. In this case, v_x is half of what it was without friction, so $v_x = (0.50)(6.3 \text{ m/s}) = 3.13$ m/s. Now use $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ to find the acceleration. $(3.13 \text{ m/s})^2 = 2a_x(4.0 \text{ m}) \quad \rightarrow \quad a_x = 1.225 \text{ m/s}^2$. Using $\sum F_x = ma_x$ gives $mg \sin\beta - f_k = mg \sin\beta - \mu_k n = ma_x$. Now use $\sum F_y = 0$ to find the normal force. $n - mg \cos\beta = 0$, so $n = mg \cos\beta$. Combining these two results gives

$mg \sin\beta - \mu_k mg \cos\beta = ma_x$. Solving for μ_k gives $\mu_k = \dfrac{g \sin\beta - a_x}{g \cos\beta}$. Using $a_x = 1.225 \text{ m/s}^2$ and $\beta = 30°$, we get $\mu_k = 0.43$.

(c) We now have static friction. For μ_s to have its minimum value, the child must be just ready to slide, so static friction is at its maximum value, which is $f_s = \mu_s n$. As before, $n = mg \cos\beta$. Now we have $\sum F_x = 0$, giving $\mu_s mg \cos\beta - mg \sin\beta = 0$, so $\mu_s = \tan\beta = \tan 30° = 0.58$.

EVALUATE: Table 5.1 shows that 0.58 is a reasonable value for μ_s, and it is larger than the value for μ_k we used in part (b).

5.30. **IDENTIFY:** Newton's second law applies to the rocks on the hill. When they are moving, kinetic friction acts on them, but when they are at rest, static friction acts.

SET UP: Use coordinates with axes parallel and perpendicular to the incline, with $+x$ in the direction of the acceleration. $\Sigma F_x = ma_x$ and $\Sigma F_y = ma_y = 0$.

EXECUTE: With the rock sliding up the hill, the friction force is down the hill. The free-body diagram is given in Figure 5.30a.

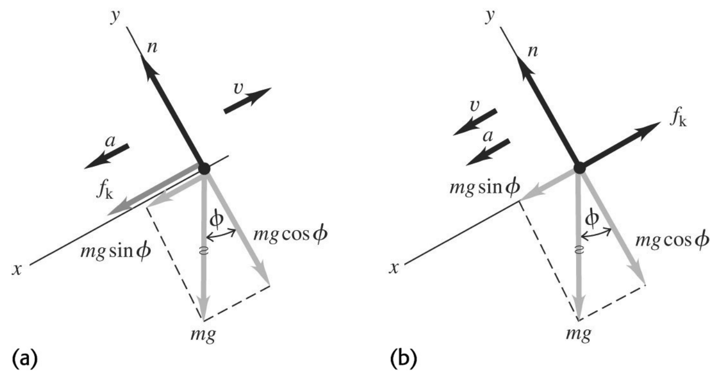

Figure 5.30

$\Sigma F_y = ma_y = 0$ gives $n = mg\cos\phi$ and $f_k = \mu_k n = \mu_k mg\cos\phi$. $\Sigma F_x = ma_x$ gives $mg\sin\phi + \mu_k mg\cos\phi = ma$.

$a = g(\sin\phi + \mu_k\cos\phi) = (9.80\text{ m/s}^2)[\sin 36° + (0.45)\cos 36°]$. $a = 9.33\text{ m/s}^2$, down the incline.

(b) The component of gravity down the incline is $mg\sin\phi = 0.588mg$. The maximum possible static friction force is $f_s = \mu_s n = \mu_s mg\cos\phi = 0.526mg$. f_s can't be as large as $mg\sin\phi$ and the rock slides back down. As the rock slides down, f_k is up the incline. The free-body diagram is given in Figure 5.30b. $\Sigma F_y = ma_y = 0$ gives $n = mg\cos\phi$ and $f_k = \mu_k n = \mu_k mg\cos\phi$. $\Sigma F_x = ma_x$ gives $mg\sin\phi - \mu_k mg\cos\phi = ma$, so $a = g(\sin\phi - \mu_k\cos\phi) = 2.19\text{ m/s}^2$, down the incline.

EVALUATE: The acceleration down the incline in (a) is greater than that in (b) because in (a) the static friction and gravity are both acting down the incline, whereas in (b) friction is up the incline, opposing gravity which still acts down the incline.

5.31. **IDENTIFY:** A 10.0-kg box is pushed on a ramp, causing it to accelerate. Newton's second law applies.

SET UP: Choose the x-axis along the surface of the ramp and the y-axis perpendicular to the surface. The only acceleration of the box is in the x-direction, so $\Sigma F_x = ma_x$ and $\Sigma F_y = 0$. The external forces acting on the box are the push P along the surface of the ramp, friction f_k, gravity mg, and the normal force n. The ramp rises at 55.0° above the horizontal, and $f_k = \mu_k n$. The friction force opposes the sliding, so it is directed up the ramp in part (a) and down the ramp in part (b).

EXECUTE: **(a)** Applying $\Sigma F_y = 0$ gives $n = mg\cos(55.0°)$, so the force of kinetic friction is $f_k = \mu_k n =$ (0.300)(10.0 kg)(9.80 m/s^2)(cos 55.0°) = 16.86 N. Call the +x-direction down the ramp since that is the direction of the acceleration of the box. Applying $\Sigma F_x = ma_x$ gives $P + mg\sin(55.0°) - f_k = ma$. Putting in the numbers gives (10.0 kg)a = 120 N + (98.0 N)(sin 55.0°) – 16.86 N; a = 18.3 m/s^2.

(b) Now P is up the up the ramp and f_k is down the ramp, but the other force components are unchanged, so f_k = 16.86 N as before. We now choose +x to be up the ramp, so $\Sigma F_x = ma_x$ gives $P - mg\sin(55.0°) - f_k = ma$. Putting in the same numbers as before gives a = 2.29 m/s^2.

EVALUATE: Pushing up the ramp produces a much smaller acceleration than pushing down the ramp because gravity helps the downward push but opposes the upward push.

5.32. **IDENTIFY:** For the shortest time, the acceleration is a maximum, so the toolbox is just ready to slide relative to the bed of the truck. The box is at rest relative to the truck, but it is accelerating relative to the ground because the truck is accelerating. Therefore Newton's second law will be useful.

SET UP: If the truck accelerates to the right the static friction force on the box is to the right, to try to prevent the box from sliding relative to the truck. The free-body diagram for the box is given in Figure 5.32. The maximum acceleration of the box occurs when f_s has its maximum value, so $f_s = \mu_s n$. If the box doesn't slide, its acceleration equals the acceleration of the truck. The constant-acceleration equation $v_x = v_{0x} + a_x t$ applies.

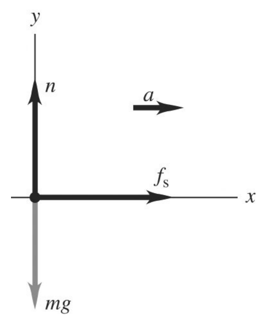

Figure 5.32

EXECUTE: $n = mg$. $\Sigma F_x = ma_x$ gives $f_s = ma$ so $\mu_s mg = ma$ and $a = \mu_s g = 6.37\ \text{m/s}^2$. $v_{0x} = 0$, $v_x = 30.0$ m/s. $v_x = v_{0x} + a_x t$ gives $t = \dfrac{v_x - v_{0x}}{a_x} = \dfrac{30.0\ \text{m/s} - 0}{6.37\ \text{m/s}^2} = 4.71$ s.

EVALUATE: If the truck has a smaller acceleration it is still true that $f_s = ma$, but now $f_s < \mu_s n$.

5.33. **IDENTIFY:** Apply $\Sigma \vec{F} = m\vec{a}$ to the composite object consisting of the two boxes and to the top box. The friction the ramp exerts on the lower box is kinetic friction. The upper box doesn't slip relative to the lower box, so the friction between the two boxes is static. Since the speed is constant the acceleration is zero.

SET UP: Let $+x$ be up the incline. The free-body diagrams for the composite object and for the upper box are given in Figure 5.33. The slope angle ϕ of the ramp is given by $\tan\phi = \dfrac{2.50\ \text{m}}{4.75\ \text{m}}$, so $\phi = 27.76°$. Since the boxes move down the ramp, the kinetic friction force exerted on the lower box by the ramp is directed up the incline. To prevent slipping relative to the lower box the static friction force on the upper box is directed up the incline. $m_{\text{tot}} = 32.0\ \text{kg} + 48.0\ \text{kg} = 80.0\ \text{kg}$.

EXECUTE: **(a)** $\Sigma F_y = ma_y$ applied to the composite object gives $n_{\text{tot}} = m_{\text{tot}} g\cos\phi$ and $f_k = \mu_k m_{\text{tot}} g\cos\phi$. $\Sigma F_x = ma_x$ gives $f_k + T - m_{\text{tot}} g\sin\phi = 0$ and

$T = (\sin\phi - \mu_k\cos\phi)m_{\text{tot}} g = (\sin 27.76° - [0.444]\cos 27.76°)(80.0\ \text{kg})(9.80\ \text{m/s}^2) = 57.1\ \text{N}$.

The person must apply a force of 57.1 N, directed up the ramp.

(b) $\Sigma F_x = ma_x$ applied to the upper box gives $f_s = mg\sin\phi = (32.0\ \text{kg})(9.80\ \text{m/s}^2)\sin 27.76° = 146\ \text{N}$, directed up the ramp.

EVALUATE: For each object the net force is zero.

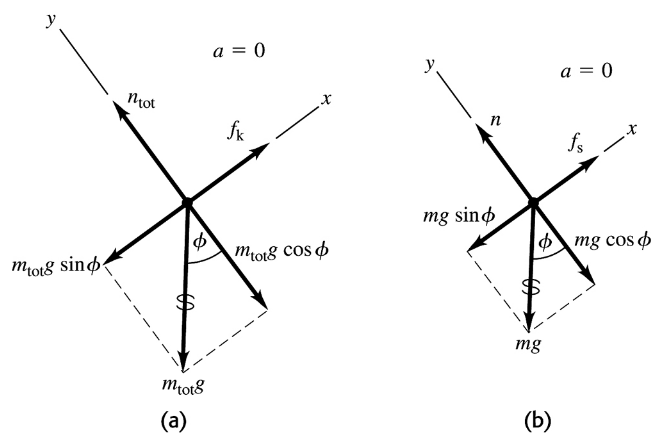

Figure 5.33

5.34. **IDENTIFY:** Constant speed means zero acceleration for each block. If the block is moving, the friction force the tabletop exerts on it is kinetic friction. Apply $\Sigma\vec{F} = m\vec{a}$ to each block.

SET UP: The free-body diagrams and choice of coordinates for each block are given by Figure 5.34. $m_A = 4.59$ kg and $m_B = 2.55$ kg.

EXECUTE: **(a)** $\Sigma F_y = ma_y$ with $a_y = 0$ applied to block *B* gives $m_B g - T = 0$ and $T = 25.0$ N. $\Sigma F_x = ma_x$ with $a_x = 0$ applied to block *A* gives $T - f_k = 0$ and $f_k = 25.0$ N. $n_A = m_A g = 45.0$ N and $\mu_k = \dfrac{f_k}{n_A} = \dfrac{25.0\text{ N}}{45.0\text{ N}} = 0.556.$

(b) Now let *A* be block *A* plus the cat, so $m_A = 9.18$ kg. $n_A = 90.0$ N and $f_k = \mu_k n = (0.556)(90.0\text{ N}) = 50.0$ N. $\sum F_x = ma_x$ for *A* gives $T - f_k = m_A a_x$. $\sum F_y = ma_y$ for block *B* gives $m_B g - T = m_B a_y$. a_x for *A* equals a_y for *B*, so adding the two equations gives $m_B g - f_k = (m_A + m_B)a_y$ and $a_y = \dfrac{m_B g - f_k}{m_A + m_B} = \dfrac{25.0\text{ N} - 50.0\text{ N}}{9.18\text{ kg} + 2.55\text{ kg}} = -2.13\text{ m/s}^2$. The acceleration is upward and block *B* slows down.

EVALUATE: The equation $m_B g - f_k = (m_A + m_B)a_y$ has a simple interpretation. If both blocks are considered together then there are two external forces: $m_B g$ that acts to move the system one way and f_k that acts oppositely. The net force of $m_B g - f_k$ must accelerate a total mass of $m_A + m_B$.

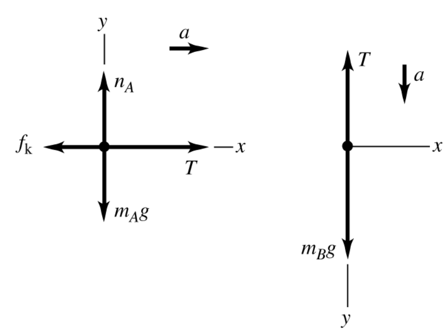

Figure 5.34

5.35. **IDENTIFY:** Use $\Sigma\vec{F} = m\vec{a}$ to find the acceleration that can be given to the car by the kinetic friction force. Then use a constant acceleration equation.

SET UP: Take $+x$ in the direction the car is moving.

EXECUTE: **(a)** The free-body diagram for the car is shown in Figure 5.35. $\Sigma F_y = ma_y$ gives $n = mg$. $\Sigma F_x = ma_x$ gives $-\mu_k n = ma_x$. $-\mu_k mg = ma_x$ and $a_x = -\mu_k g$. Then $v_x = 0$ and $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives $(x - x_0) = -\dfrac{v_{0x}^2}{2a_x} = +\dfrac{v_{0x}^2}{2\mu_k g} = \dfrac{(28.7\text{ m/s})^2}{2(0.80)(9.80\text{ m/s}^2)} = 52.5\text{ m}$.

(b) $v_{0x} = \sqrt{2\mu_k g(x - x_0)} = \sqrt{2(0.25)(9.80\text{ m/s}^2)52.5\text{ m}} = 16.0\text{ m/s}$

EVALUATE: For constant stopping distance $\dfrac{v_{0x}^2}{\mu_k}$ is constant and v_{0x} is proportional to $\sqrt{\mu_k}$. The answer to part (b) can be calculated as $(28.7\text{ m/s})\sqrt{0.25/0.80} = 16.0\text{ m/s}$.

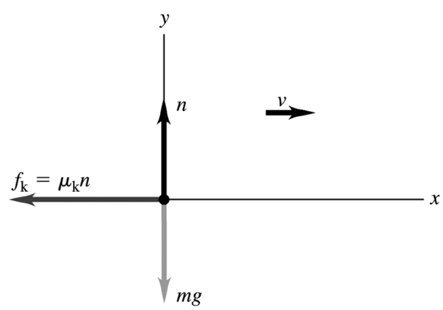

Figure 5.35

5.36. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the box. When the box is ready to slip the static friction force has its maximum possible value, $f_s = \mu_s n$.

SET UP: Use coordinates parallel and perpendicular to the ramp.

EXECUTE: **(a)** The normal force will be $w\cos\alpha$ and the component of the gravitational force along the ramp is $w\sin\alpha$. The box begins to slip when $w\sin\alpha > \mu_s w\cos\alpha$, or $\tan\alpha > \mu_s = 0.35$, so slipping occurs at $\alpha = \arctan(0.35) = 19.3°$.

(b) When moving, the friction force along the ramp is $\mu_k w\cos\alpha$, the component of the gravitational force along the ramp is $w\sin\alpha$, so the acceleration is

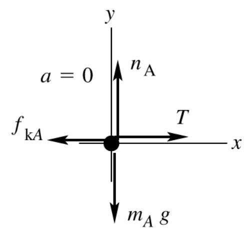
$$(w\sin\alpha - w\mu_k\cos\alpha)/m = g(\sin\alpha - \mu_k\cos\alpha) = 0.92\text{ m/s}^2.$$

(c) Since $v_{0x} = 0$, $2ax = v^2$, so $v = (2ax)^{1/2}$, or $v = [(2)(0.92\text{ m/s}^2)(5\text{ m})]^{1/2} = 3\text{ m/s}$.

EVALUATE: When the box starts to move, friction changes from static to kinetic and the friction force becomes smaller.

5.37. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each crate. The rope exerts force T to the right on crate A and force T to the left on crate B. The target variables are the forces T and F. Constant v implies $a = 0$.

SET UP: The free-body diagram for A is sketched in Figure 5.37a.

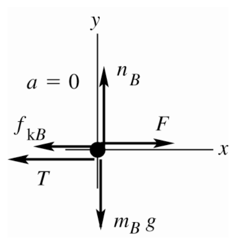


EXECUTE:
$\Sigma F_y = ma_y$
$n_A - m_A g = 0$
$n_A = m_A g$
$f_{kA} = \mu_k n_A = \mu_k m_A g$

Figure 5.37a

$\Sigma F_x = ma_x$
$T - f_{kA} = 0$
$T = \mu_k m_A g$

SET UP: The free-body diagram for *B* is sketched in Figure 5.37b.



EXECUTE:
$\Sigma F_y = ma_y$
$n_B - m_B g = 0$
$n_B = m_B g$
$f_{kB} = \mu_k n_B = \mu_k m_B g$

Figure 5.37b

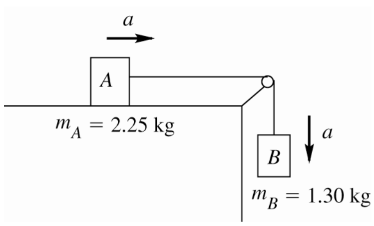
$\Sigma F_x = ma_x$
$F - T - f_{kB} = 0$
$F = T + \mu_k m_B g$
Use the first equation to replace *T* in the second:
$F = \mu_k m_A g + \mu_k m_B g.$
(a) $F = \mu_k (m_A + m_B) g$
(b) $T = \mu_k m_A g$
EVALUATE: We can also consider both crates together as a single object of mass $(m_A + m_B)$. $\Sigma F_x = ma_x$ for this combined object gives $F = f_k = \mu_k (m_A + m_B) g,$ in agreement with our answer in part (a).

5.38. **IDENTIFY:** Apply $\Sigma \vec{F} = m\vec{a}$ to the box.
SET UP: Let $+y$ be upward and $+x$ be horizontal, in the direction of the acceleration. Constant speed means $a = 0$.
EXECUTE: **(a)** There is no net force in the vertical direction, so $n + F\sin\theta - w = 0,$ or $n = w - F\sin\theta = mg - F\sin\theta.$ The friction force is $f_k = \mu_k n = \mu_k (mg - F\sin\theta).$ The net horizontal force is $F\cos\theta - f_k = F\cos\theta - \mu_k (mg - F\sin\theta),$ and so at constant speed,

$$F = \frac{\mu_k mg}{\cos\theta + \mu_k \sin\theta}$$

(b) Using the given values, $F = \dfrac{(0.35)(90\text{ kg})(9.80\text{ m/s}^2)}{(\cos 25° + (0.35)\sin 25°)} = 290\text{ N}.$
EVALUATE: If $\theta = 0°$, $F = \mu_k mg.$

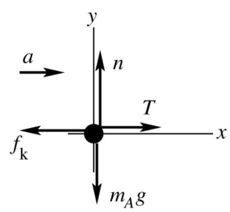
5.39. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each block. The target variables are the tension T in the cord and the acceleration a of the blocks. Then a can be used in a constant acceleration equation to find the speed of each block. The magnitude of the acceleration is the same for both blocks.
SET UP: The system is sketched in Figure 5.39a.



For each block take a positive coordinate direction to be the direction of the block's acceleration.

Figure 5.39a

Block on the table: The free-body is sketched in Figure 5.39b (next page).

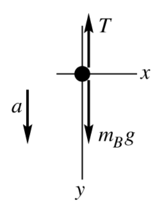


EXECUTE:
$\Sigma F_y = ma_y$
$n - m_A g = 0$
$n = m_A g$
$f_k = \mu_k n = \mu_k m_A g$

Figure 5.39b

$\Sigma F_x = ma_x$
$T - f_k = m_A a$
$T - \mu_k m_A g = m_A a$

SET UP: Hanging block: The free-body is sketched in Figure 5.39c.



EXECUTE:
$\Sigma F_y = ma_y$
$m_B g - T = m_B a$
$T = m_B g - m_B a$

Figure 5.39c

(a) Use the second equation in the first

$$m_B g - m_B a - \mu_k m_A g = m_A a$$

$$(m_A + m_B)a = (m_B - \mu_k m_A)g$$

$$a = \frac{(m_B - \mu_k m_A)g}{m_A + m_B} = \frac{(1.30\text{ kg} - (0.45)(2.25\text{ kg}))(9.80\text{ m/s}^2)}{2.25\text{ kg} + 1.30\text{ kg}} = 0.7937\text{ m/s}^2$$

SET UP: Now use the constant acceleration equations to find the final speed. Note that the blocks have the same speeds. $x - x_0 = 0.0300$ m, $a_x = 0.7937\text{ m/s}^2$, $v_{0x} = 0$, $v_x = ?$
$v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$

EXECUTE: $v_x = \sqrt{2a_x(x - x_0)} = \sqrt{2(0.7937\ \text{m/s}^2)(0.0300\ \text{m})} = 0.218\ \text{m/s} = 21.8\ \text{cm/s}.$

(b) $T = m_B g - m_B a = m_B(g - a) = 1.30\ \text{kg}(9.80\ \text{m/s}^2 - 0.7937\ \text{m/s}^2) = 11.7\ \text{N}$

Or, to check, $T - \mu_k m_A g = m_A a$.

$T = m_A(a + \mu_k g) = 2.25\ \text{kg}(0.7937\ \text{m/s}^2 + (0.45)(9.80\ \text{m/s}^2)) = 11.7\ \text{N},$ which checks.

EVALUATE: The force T exerted by the cord has the same value for each block. $T < m_B g$ since the hanging block accelerates downward. Also, $f_k = \mu_k m_A g = 9.92\ \text{N}$. $T > f_k$ and the block on the table accelerates in the direction of T.

5.40. **IDENTIFY:** Apply $\Sigma \vec{F} = m\vec{a}$ to the ball. At the terminal speed, $f = mg$.

SET UP: The fluid resistance is directed opposite to the velocity of the object. At half the terminal speed, the magnitude of the frictional force is one-fourth the weight.

EXECUTE: **(a)** If the ball is moving up, the frictional force is down, so the magnitude of the net force is $(5/4)w$ and the acceleration is $(5/4)g$, down.

(b) While moving down, the frictional force is up, and the magnitude of the net force is $(3/4)w$ and the acceleration is $(3/4)g$, down.

EVALUATE: The frictional force is less than mg in each case and in each case the net force is downward and the acceleration is downward.

5.41. **(a) IDENTIFY:** Apply $\Sigma \vec{F} = m\vec{a}$ to the crate. Constant v implies $a = 0$. Crate moving says that the friction is kinetic friction. The target variable is the magnitude of the force applied by the woman.

SET UP: The free-body diagram for the crate is sketched in Figure 5.41.

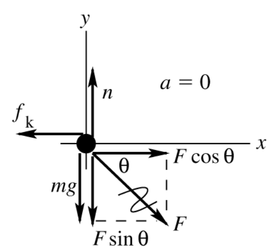


Figure 5.41

EXECUTE:

$\Sigma F_y = ma_y$

$n - mg - F\sin\theta = 0$

$n = mg + F\sin\theta$

$f_k = \mu_k n = \mu_k mg + \mu_k F\sin\theta$

$\Sigma F_x = ma_x$

$F\cos\theta - f_k = 0$

$F\cos\theta - \mu_k mg - \mu_k F\sin\theta = 0$

$F(\cos\theta - \mu_k \sin\theta) = \mu_k mg$

$$F = \frac{\mu_k mg}{\cos\theta - \mu_k \sin\theta}$$

(b) IDENTIFY and **SET UP:** "Start the crate moving" means the same force diagram as in part (a), except that μ_k is replaced by μ_s. Thus $F = \dfrac{\mu_s mg}{\cos\theta - \mu_s \sin\theta}$.

EXECUTE: $F \to \infty$ if $\cos\theta - \mu_s \sin\theta = 0$. This gives $\mu_s = \dfrac{\cos\theta}{\sin\theta} = \dfrac{1}{\tan\theta}$.

EVALUATE: $\vec{F}$ has a downward component so $n > mg$. If $\theta = 0$ (woman pushes horizontally), $n = mg$ and $F = f_k = \mu_k mg$.

5.42. **IDENTIFY:** You are accelerated toward the center of the circle, so Newton's second law applies. Static friction is the force preventing you from sliding off the disk.

SET UP: $\sum F = m\dfrac{v^2}{R}$ applies to circular motion. Static friction is at its maximum in this case, so we can use $f_S = \mu_s n$, with $n = mg$. Our target variable is the time for one revolution.

EXECUTE: **(a)** The speed is $v = 2\pi R/T$, so $\sum F = m\dfrac{v^2}{R}$ becomes $f_S = m(2\pi R/T)^2/R$, which becomes $\mu_s mg = m(4\pi^2 R/T^2)$. Solving for T gives $T = \sqrt{\dfrac{4\pi^2 R}{g\mu_s}} = \sqrt{\dfrac{4\pi^2(3.00\text{ m})}{(9.80\text{ m/s}^2)(0.400)}} = 5.50\text{ s}$.

(b) Since $T = \sqrt{\dfrac{4\pi^2 R}{g\mu_s}}$, the period does not depend on the mass (or weight) of the person, so the answer is the same: $T = 5.50$ s.

EVALUATE: In part (a) we could use the formula $a_{\text{rad}} = \dfrac{4\pi^2 R}{T^2}$ which leads to the same result.

5.43. **IDENTIFY:** Since the stone travels in a circular path, its acceleration is $a_{\text{rad}} = v^2/R$, directed toward the center of the circle. The only horizontal force on the stone is the tension of the string. Set the tension in the string equal to its maximum value.

SET UP: $\sum F_x = ma_x$ gives $T = m\dfrac{v^2}{R}$.

EXECUTE: **(a)** The free-body diagram for the stone is given in Figure 5.43 (next page). In the diagram the stone is at a point to the right of the center of the path.

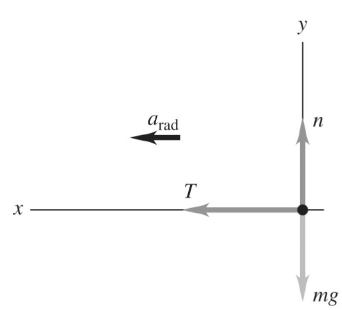

Figure 5.43

(b) Solving for v gives $v = \sqrt{\dfrac{TR}{m}} = \sqrt{\dfrac{(60.0\text{ N})(0.90\text{ m})}{0.80\text{ kg}}} = 8.2\text{ m/s}$.

EVALUATE: The tension is directed toward the center of the circular path of the stone. Gravity plays no role in this case because it is a vertical force and the acceleration is horizontal.

5.44. **IDENTIFY:** The wrist exerts a force on the hand causing the hand to move in a horizontal circle. Newton's second law applies to the hand.

SET UP: Each hand travels in a circle of radius 0.750 m and has mass (0.0125)(52 kg) = 0.65 kg and weight 6.4 N. The period for each hand is $T = (1.0\text{ s})/(2.0) = 0.50$ s. Let $+x$ be toward the center of the circular path. The speed of the hand is $v = 2\pi R/T$, the radial acceleration is $a_{\text{rad}} = \dfrac{v^2}{R} = \dfrac{4\pi^2 R}{T^2}$, and $\sum F_x = ma_x = ma_{\text{rad}}$.

EXECUTE: **(a)** The free-body diagram for one hand is given in Figure 5.44. $\vec{F}$ is the force exerted on the hand by the wrist. This force has both horizontal and vertical components.

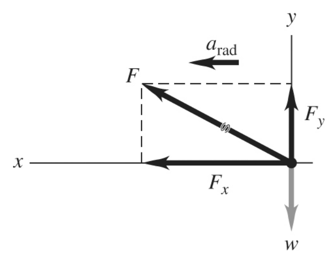

Figure 5.44

(b) $a_{rad} = \dfrac{4\pi^2 R}{T^2} = \dfrac{4\pi^2(0.750\text{ m})}{(0.50\text{ s})^2} = 118\text{ m/s}^2$, so $F_x = ma_{rad} = (0.65\text{ kg})(118\text{ m/s}^2) = 77\text{ N}$.

(c) $\dfrac{F}{w} = \dfrac{77\text{ N}}{6.4\text{ N}} = 12$, so the horizontal force from the wrist is 12 times the weight of the hand.

EVALUATE: The wrist must also exert a vertical force on the hand equal to the weight of the hand.

5.45. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the car. It has acceleration $\vec{a}_{rad}$, directed toward the center of the circular path.

SET UP: The analysis is the same as in Example 5.23.

EXECUTE: **(a)** $F_A = m\left(g + \dfrac{v^2}{R}\right) = (1.60\text{ kg})\left(9.80\text{ m/s}^2 + \dfrac{(12.0\text{ m/s})^2}{5.00\text{ m}}\right) = 61.8\text{ N}.$

(b) $F_B = m\left(g - \dfrac{v^2}{R}\right) = (1.60\text{ kg})\left(9.80\text{ m/s}^2 - \dfrac{(12.0\text{ m/s})^2}{5.00\text{ m}}\right) = -30.4\text{ N}$, where the minus sign indicates that the track pushes down on the car. The magnitude of this force is 30.4 N.

EVALUATE: $|F_A| > |F_B|$. $|F_A| - 2mg = |F_B|$.

5.46. **IDENTIFY:** The acceleration of the car at the top and bottom is toward the center of the circle, and Newton's second law applies to it.

SET UP: Two forces are acting on the car, gravity and the normal force. At point B (the top), both forces are toward the center of the circle, so Newton's second law gives $mg + n_B = ma$. At point A (the bottom), gravity is downward but the normal force is upward, so $n_A - mg = ma$.

EXECUTE: Solving the equation at B for the acceleration gives
$a = \dfrac{mg + n_B}{m} = \dfrac{(0.800\text{ kg})(9.8\text{ m/s}^2) + 6.00\text{ N}}{0.800\text{ kg}} = 17.3\text{ m/s}^2$. Solving the equation at A for the normal force gives $n_A = m(g + a) = (0.800\text{ kg})(9.8\text{ m/s}^2 + 17.3\text{ m/s}^2) = 21.7\text{ N}$.

EVALUATE: The normal force at the bottom is greater than at the top because it must balance the weight in addition to accelerating the car toward the center of its track.

5.47. **IDENTIFY:** A model car travels in a circle so it has radial acceleration, and Newton's second law applies to it.

SET UP: We use $\Sigma\vec{F} = m\vec{a}$, where the acceleration is $a_{rad} = \dfrac{v^2}{R}$ and the time T for one revolution is $T = 2\pi R/v$.

EXECUTE: At the bottom of the track, taking $+y$ upward, $\Sigma\vec{F} = m\vec{a}$ gives $n - mg = ma$, where n is the normal force. This gives $2.50mg - mg = ma$, so $a = 1.50g$. The acceleration is $a_{\text{rad}} = \dfrac{v^2}{R}$, so

$v = \sqrt{aR} = \sqrt{(1.50)(9.80\ \text{m/s}^2)(5.00\ \text{m})} = 8.573$ m/s, so $T = 2\pi R/v = 2\pi(5.00\ \text{m})/(8.573\ \text{m}) = 3.66$ s.

EVALUATE: We never need the mass of the car because we know the acceleration as a fraction of g and the force as a fraction of mg.

5.48. **IDENTIFY:** Since the car travels in an arc of a circle, it has acceleration $a_{\text{rad}} = v^2/R$, directed toward the center of the arc. The only horizontal force on the car is the static friction force exerted by the roadway. To calculate the minimum coefficient of friction that is required, set the static friction force equal to its maximum value, $f_s = \mu_s n$. Friction is static friction because the car is not sliding in the radial direction.

SET UP: The free-body diagram for the car is given in Figure 5.48 (next page). The diagram assumes the center of the curve is to the left of the car.

EXECUTE: **(a)** $\Sigma F_y = ma_y$ gives $n = mg$. $\Sigma F_x = ma_x$ gives $\mu_s n = m\dfrac{v^2}{R}$. $\mu_s mg = m\dfrac{v^2}{R}$ and

$$\mu_s = \frac{v^2}{gR} = \frac{(25.0\ \text{m/s})^2}{(9.80\ \text{m/s}^2)(170\ \text{m})} = 0.375$$

(b) $\dfrac{v^2}{\mu_s} = Rg = \text{constant}$, so $\dfrac{v_1^2}{\mu_{s1}} = \dfrac{v_2^2}{\mu_{s2}}$. $v_2 = v_1\sqrt{\dfrac{\mu_{s2}}{\mu_{s1}}} = (25.0\ \text{m/s})\sqrt{\dfrac{\mu_{s1}/3}{\mu_{s1}}} = 14.4$ m/s.

EVALUATE: A smaller coefficient of friction means a smaller maximum friction force, a smaller possible acceleration and therefore a smaller speed.

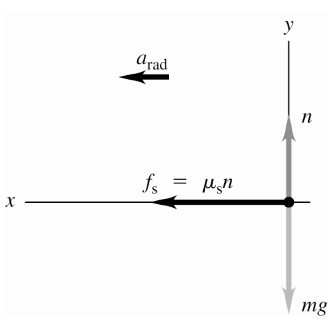

Figure 5.48

5.49. **IDENTIFY:** Apply Newton's second law to the car in circular motion, assume friction is negligible.

SET UP: The acceleration of the car is $a_{\text{rad}} = v^2/R$. As shown in the text, the banking angle β is given by $\tan\beta = \dfrac{v^2}{gR}$. Also, $n = mg/\cos\beta$. $65.0\ \text{mi/h} = 29.1\ \text{m/s}$.

EXECUTE: **(a)** $\tan\beta = \dfrac{(29.1\ \text{m/s})^2}{(9.80\ \text{m/s}^2)(225\ \text{m})}$ and $\beta = 21.0°$. The expression for $\tan\beta$ does not involve the mass of the vehicle, so the truck and car should travel at the same speed.

(b) For the car, $n_{\text{car}} = \dfrac{(1125\ \text{kg})(9.80\ \text{m/s}^2)}{\cos 21.0°} = 1.18\times10^4$ N and $n_{\text{truck}} = 2n_{\text{car}} = 2.36\times10^4$ N, since $m_{\text{truck}} = 2m_{\text{car}}$.

EVALUATE: The vertical component of the normal force must equal the weight of the vehicle, so the normal force is proportional to m.

5.50. **IDENTIFY:** The acceleration of the person is $a_{\text{rad}} = v^2/R$, directed horizontally to the left in the figure in the problem. The time for one revolution is the period $T = \dfrac{2\pi R}{v}$. Apply $\Sigma\vec{F} = m\vec{a}$ to the person.

SET UP: The person moves in a circle of radius $R = 3.00\text{ m} + (5.00\text{ m})\sin 30.0° = 5.50\text{ m}$. The free-body diagram is given in Figure 5.50. $\vec{F}$ is the force applied to the seat by the rod.

EXECUTE: **(a)** $\Sigma F_y = ma_y$ gives $F\cos 30.0° = mg$ and $F = \dfrac{mg}{\cos 30.0°}$. $\Sigma F_x = ma_x$ gives $F\sin 30.0° = m\dfrac{v^2}{R}$. Combining these two equations gives

$v = \sqrt{Rg\tan\theta} = \sqrt{(5.50\text{ m})(9.80\text{ m/s}^2)\tan 30.0°} = 5.58\text{ m/s}$. Then the period is

$$T = \frac{2\pi R}{v} = \frac{2\pi(5.50\text{ m})}{5.58\text{ m/s}} = 6.19\text{ s}.$$

(b) The net force is proportional to m so in $\Sigma\vec{F} = m\vec{a}$ the mass divides out and the angle for a given rate of rotation is independent of the mass of the passengers.

EVALUATE: The person moves in a horizontal circle so the acceleration is horizontal. The net inward force required for circular motion is produced by a component of the force exerted on the seat by the rod.

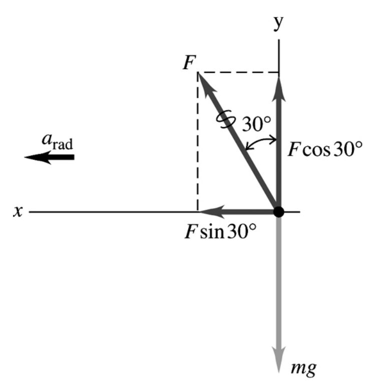

Figure 5.50

5.51. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the composite object of the person plus seat. This object moves in a horizontal circle and has acceleration a_{rad}, directed toward the center of the circle.

SET UP: The free-body diagram for the composite object is given in Figure 5.51. Let $+x$ be to the right, in the direction of $\vec{a}_{\text{rad}}$. Let $+y$ be upward. The radius of the circular path is $R = 7.50\text{ m}$. The total mass is $(255\text{ N} + 825\text{ N})/(9.80\text{ m/s}^2) = 110.2\text{ kg}$. Since the rotation rate is

$28.0\text{ rev/min} = 0.4667\text{ rev/s}$, the period T is $\dfrac{1}{0.4667\text{ rev/s}} = 2.143\text{ s}$.

EXECUTE: $\Sigma F_y = ma_y$ gives $T_A\cos 40.0° - mg = 0$ and $T_A = \dfrac{mg}{\cos 40.0°} = \dfrac{255\text{ N} + 825\text{ N}}{\cos 40.0°} = 1410\text{ N}$.

$\Sigma F_x = ma_x$ gives $T_A\sin 40.0° + T_B = ma_{\text{rad}}$ and

$$T_B = m\frac{4\pi^2 R}{T^2} - T_A\sin 40.0° = (110.2\text{ kg})\frac{4\pi^2(7.50\text{ m})}{(2.143\text{ s})^2} - (1410\text{ N})\sin 40.0° = 6200\text{ N}$$

The tension in the horizontal cable is 6200 N and the tension in the other cable is 1410 N.

EVALUATE: The weight of the composite object is 1080 N. The tension in cable A is larger than this since its vertical component must equal the weight. The tension in cable B is less than ma_{rad} because part of the required inward force comes from a component of the tension in cable A.

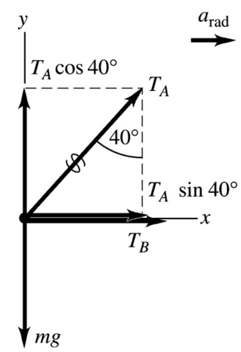

Figure 5.51

5.52. IDENTIFY: Newton's second law applies to the steel ball. Gravity and the tension in the rope are the forces acting on it.

SET UP: $\sum F = m\dfrac{v^2}{R}$

EXECUTE: **(a)** At the lowest point, the tension T is upward and the weight $w = mg$ is downward. $\sum F = m\dfrac{v^2}{R}$ gives $T - mg = ma$, which becomes $3mg - mg = \dfrac{mv^2}{R}$. Solving for v gives $v = \sqrt{2Rg} = \sqrt{2(15.0\text{ m})(9.80\text{ m/s}^2)} = 17.1$ m/s.

(b) If $T = mg$, the vertical forces balance, so $\sum F = m\dfrac{v^2}{R} = 0$, which tells us that the speed is zero.

EVALUATE: If $T = mg$, the ball is just hanging by the rope.

5.53. IDENTIFY: The acceleration due to circular motion is $a_{\text{rad}} = \dfrac{4\pi^2 R}{T^2}$.

SET UP: $R = 400$ m. $1/T$ is the number of revolutions per second.

EXECUTE: **(a)** Setting $a_{\text{rad}} = g$ and solving for the period T gives

$$T = 2\pi\sqrt{\frac{R}{g}} = 2\pi\sqrt{\frac{400\text{ m}}{9.80\text{ m/s}^2}} = 40.1\text{ s},$$

so the number of revolutions per minute is $(60\text{ s/min})/(40.1\text{ s}) = 1.5$ rev/min.

(b) The lower acceleration corresponds to a longer period, and hence a lower rotation rate, by a factor of the square root of the ratio of the accelerations, $T' = (1.5\text{ rev/min}) \times \sqrt{3.70/9.8} = 0.92$ rev/min.

EVALUATE: In part (a) the tangential speed of a point at the rim is given by $a_{\text{rad}} = \dfrac{v^2}{R}$, so $v = \sqrt{Ra_{\text{rad}}} = \sqrt{Rg} = 62.6$ m/s; the space station is rotating rapidly.

5.54. IDENTIFY: $T = \dfrac{2\pi R}{v}$. The apparent weight of a person is the normal force exerted on him by the seat he is sitting on. His acceleration is $a_{\text{rad}} = v^2/R$, directed toward the center of the circle.

SET UP: The period is $T = 60.0$ s. The passenger has mass $m = w/g = 90.0$ kg.

EXECUTE: **(a)** $v = \dfrac{2\pi R}{T} = \dfrac{2\pi(50.0 \text{ m})}{60.0 \text{ s}} = 5.24 \text{ m/s}.$ Note that $a_{\text{rad}} = \dfrac{v^2}{R} = \dfrac{(5.24 \text{ m/s})^2}{50.0 \text{ m}} = 0.549 \text{ m/s}^2.$

(b) The free-body diagram for the person at the top of his path is given in Figure 5.54a. The acceleration is downward, so take $+y$ downward. $\Sigma F_y = ma_y$ gives $mg - n = ma_{\text{rad}}$.

$n = m(g - a_{\text{rad}}) = (90.0 \text{ kg})(9.80 \text{ m/s}^2 - 0.549 \text{ m/s}^2) = 833 \text{ N}.$

The free-body diagram for the person at the bottom of his path is given in Figure 5.54b. The acceleration is upward, so take $+y$ upward. $\Sigma F_y = ma_y$ gives $n - mg = ma_{\text{rad}}$ and

$n = m(g + a_{\text{rad}}) = 931 \text{ N}.$

(c) Apparent weight $= 0$ means $n = 0$ and $mg = ma_{\text{rad}}$. $g = \dfrac{v^2}{R}$ and $v = \sqrt{gR} = 22.1 \text{ m/s}.$ The time for one revolution would be $T = \dfrac{2\pi R}{v} = \dfrac{2\pi(50.0 \text{ m})}{22.1 \text{ m/s}} = 14.2 \text{ s}.$ Note that $a_{\text{rad}} = g$.

(d) $n = m(g + a_{\text{rad}}) = 2mg = 2(882 \text{ N}) = 1760 \text{ N},$ twice his true weight.

EVALUATE: At the top of his path his apparent weight is less than his true weight and at the bottom of his path his apparent weight is greater than his true weight.

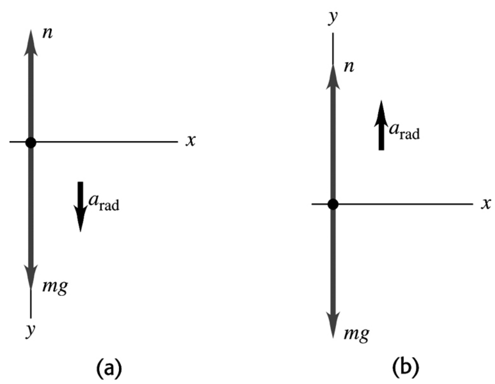

Figure 5.54

5.55. **IDENTIFY:** Newton's second law applies to the rock moving in a vertical circle of radius L. Gravity and the tension in the string are the forces acting on it.

SET UP: $\sum F = m\dfrac{v^2}{R}$, where $R = L$ in this case.

EXECUTE: **(a)** Apply $\sum F = m\dfrac{v^2}{R}$ at the top of the circle. Both gravity and the tension act downward, so $T + mg = mv^2/L$. The smallest that T can be is zero, in which case $mg = mv^2/L$, so $v = \sqrt{Lg}$.

(b) In this case, $v = 2\sqrt{Lg}$. $\sum F = m\dfrac{v^2}{R}$ gives $T - mg = \dfrac{mv^2}{L} = \dfrac{m\left(2\sqrt{Lg}\right)^2}{L} = 4mg$, so $T = 5mg$.

EVALUATE: Note in (a) that the rock does *not stop* at the top of the circle. If it did, it would just fall down and not complete the rest of the circle.

5.56. **IDENTIFY:** $a_{\text{rad}} = v^2/R$, directed toward the center of the circular path. At the bottom of the dive, $\vec{a}_{\text{rad}}$ is upward. The apparent weight of the pilot is the normal force exerted on her by the seat on which she is sitting.

SET UP: The free-body diagram for the pilot is given in Figure 5.56.

EXECUTE: **(a)** $a_{\text{rad}} = \dfrac{v^2}{R}$ gives $R = \dfrac{v^2}{a_{\text{rad}}} = \dfrac{(95.0\text{ m/s})^2}{4.00(9.80\text{ m/s}^2)} = 230\text{ m}.$

(b) $\Sigma F_y = ma_y$ gives $n - mg = ma_{\text{rad}}$.

$n = m(g + a_{\text{rad}}) = m(g + 4.00g) = 5.00mg = (5.00)(50.0\text{ kg})(9.80\text{ m/s}^2) = 2450\text{ N}$

EVALUATE: Her apparent weight is five times her true weight, the force of gravity the earth exerts on her.

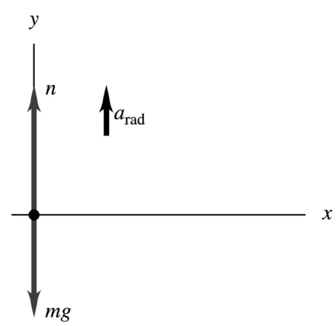

Figure 5.56

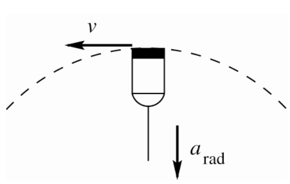
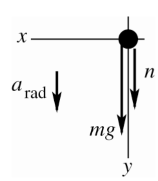
5.57. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the water. The water moves in a vertical circle. The target variable is the speed v; we will calculate a_{rad} and then get v from $a_{\text{rad}} = v^2/R$.

SET UP: Consider the free-body diagram for the water when the pail is at the top of its circular path, as shown in Figures 5.57a and b.



The radial acceleration is in toward the center of the circle so at this point is downward. *n* is the downward normal force exerted on the water by the bottom of the pail.

Figure 5.57a



EXECUTE:

$\Sigma F_y = ma_y$

$n + mg = m\dfrac{v^2}{R}$

Figure 5.57b

At the minimum speed the water is just ready to lose contact with the bottom of the pail, so at this speed, $n \to 0$. (Note that the force n cannot be upward.)

With $n \to 0$ the equation becomes $mg = m\dfrac{v^2}{R}$. $v = \sqrt{gR} = \sqrt{(9.80\text{ m/s}^2)(0.600\text{ m})} = 2.42\text{ m/s}.$

EVALUATE: At the minimum speed $a_{\text{rad}} = g$. If v is less than this minimum speed, gravity pulls the water (and bucket) out of the circular path.

5.58. **IDENTIFY:** The ball has acceleration $a_{\text{rad}} = v^2/R$, directed toward the center of the circular path. When the ball is at the bottom of the swing, its acceleration is upward.

SET UP: Take $+y$ upward, in the direction of the acceleration. The bowling ball has mass $m = w/g = 7.27\text{ kg}$.

EXECUTE: **(a)** $a_{\text{rad}} = \dfrac{v^2}{R} = \dfrac{(4.20\text{ m/s})^2}{3.80\text{ m}} = 4.64\text{ m/s},$ upward.

(b) The free-body diagram is given in Figure 5.58. $\Sigma F_y = ma_y$ gives $T - mg = ma_{\text{rad}}$.

$T = m(g + a_{\text{rad}}) = (7.27\text{ kg})(9.80\text{ m/s}^2 + 4.64\text{ m/s}^2) = 105\text{ N}$

EVALUATE: The acceleration is upward, so the net force is upward and the tension is greater than the weight.

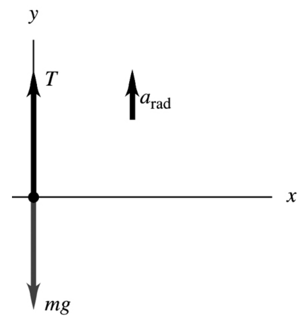


Figure 5.58

5.59. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the knot.

SET UP: $a = 0$. Use coordinates with axes that are horizontal and vertical.

EXECUTE: **(a)** The free-body diagram for the knot is sketched in Figure 5.59.

T_1 is more vertical so supports more of the weight and is larger. You can also see this from $\Sigma F_x = ma_x$:

$T_2\cos 40° - T_1\cos 60° = 0.$ $T_2\cos 40° - T_1\cos 60° = 0.$

(b) T_1 is larger so set $T_1 = 5000\text{ N}$. Then $T_2 = T_1/1.532 = 3263.5\text{ N}$. $\Sigma F_y = ma_y$ gives

$T_1\sin 60° + T_2\sin 40° = w$ and $w = 6400\text{ N}$.

EVALUATE: The sum of the vertical components of the two tensions equals the weight of the suspended object. The sum of the tensions is greater than the weight.

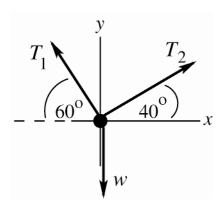

Figure 5.59

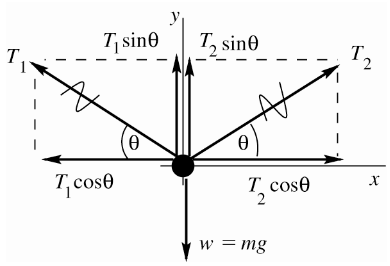
5.60. **IDENTIFY:** Apply Newton's first law to the person. Each half of the rope exerts a force on him, directed along the rope and equal to the tension T in the rope.

SET UP: **(a)** The force diagram for the person is given in Figure 5.60.



T_1 and T_2 are the tensions in each half of the rope.

Figure 5.60

EXECUTE: $\Sigma F_x = 0$

$T_2 \cos\theta - T_1 \cos\theta = 0$

This says that $T_1 = T_2 = T$ (The tension is the same on both sides of the person.)

$\Sigma F_y = 0$

$T_1 \sin\theta + T_2 \sin\theta - mg = 0$

But $T_1 = T_2 = T$, so $2T\sin\theta = mg$

$$T = \frac{mg}{2\sin\theta} = \frac{(90.0\text{ kg})(9.80\text{ m/s}^2)}{2\sin 10.0°} = 2540\text{ N}$$

(b) The relation $2T\sin\theta = mg$ still applies but now we are given that $T = 2.50\times10^4$ N (the breaking strength) and are asked to find θ.

$$\sin\theta = \frac{mg}{2T} = \frac{(90.0\text{ kg})(9.80\text{ m/s}^2)}{2(2.50\times10^4\text{ N})} = 0.01764,\quad \theta = 1.01°.$$

EVALUATE: $T = mg/(2\sin\theta)$ says that $T = mg/2$ when $\theta = 90°$ (rope is vertical).

$T \to \infty$ when $\theta \to 0$ since the upward component of the tension becomes a smaller fraction of the tension.

5.61. **IDENTIFY:** The engine is hanging at rest, so its acceleration is zero which means that the forces on it must balance. We balance horizontal components and vertical components.

SET UP: In addition to the tensions in the four cables shown in the text, gravity also acts on the engine. Call $+x$ horizontally to the right and $+y$ vertically upward, and call θ the angle that cable C makes with cable D. The mass of the engine is 409 kg and the tension T_A in cable A is 722 N.

EXECUTE: The tension in cable D is the only force balancing gravity on the engine, so $T_D = mg$. In the x-direction, we have $T_A = T_C \sin\theta$, which gives $T_C = T_A/\sin\theta$ = (722 N)/(sin 37.1°) = 1197 N. In the y-direction, we have $T_B - T_D - T_C \cos\theta = 0$, which gives T_B = (409 kg)(9.80 m/s^2) + (1197 N)cos(37.1°) = 4963 N. Rounding to 3 significant figures gives T_B = 4960 N and T_C = 1200 N.

EVALUATE: The tension in cable B is greater than the weight of the engine because cable C has a downward component that B must also balance.

5.62. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each object. Constant speed means $a = 0$.

SET UP: The free-body diagrams are sketched in Figure 5.62. T_1 is the tension in the lower chain, T_2 is the tension in the upper chain and $T = F$ is the tension in the rope.

EXECUTE: The tension in the lower chain balances the weight and so is equal to w. The lower pulley must have no net force on it, so twice the tension in the rope must be equal to w and the tension in the rope, which equals F, is $w/2$. Then, the downward force on the upper pulley due to the rope is also w, and so the upper chain exerts a force w on the upper pulley, and the tension in the upper chain is also w.

EVALUATE: The pulley combination allows the worker to lift a weight w by applying a force of only $w/2$.

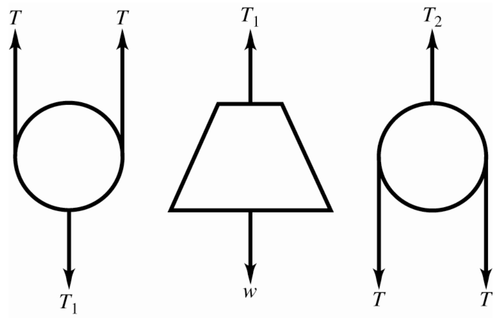


Figure 5.62

5.63. **IDENTIFY:** Newton's second law applies to the block. Gravity, kinetic friction, and the normal force due to the board act upon it.

SET UP: Apply $\sum F_x = ma_x$ and $\sum F_y = 0$ to the block. Choose the +*x*-axis along the surface of the board pointing downward. At the maximum angle α_0 just before slipping, tan α_0 = μ_s = 0.600, so α_0 = 30.96°. Fig. 5.63 shows a free-body diagram of the block after it has slipped.

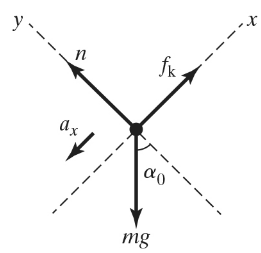

Figure 5.63

EXECUTE: First find the acceleration using Newton's laws. $\sum F_y = 0$ gives $n = mg\cos\alpha_0$ $\sum F_x = ma_x$ gives

$mg\sin\alpha_0 - f_k = ma_x$

$mg\sin\alpha_0 - \mu_k mg\cos\alpha_0 = ma_x$

$a_x = g(\sin\alpha_0 - \mu_k\cos\alpha_0) = (9.80\text{ m/s}^2)[\sin 30.96° - (0.400)\cos 30.96°] = 1.681\text{ m/s}^2$. Now use

$v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ to find the speed at the bottom of the board.

$v_x^2 = 0 + 2(1.681\text{ m/s}^2)(3.00\text{ m}) \quad \rightarrow \quad v_x = 3.18\text{ m/s}$.

EVALUATE: We chose the +*x*-axis to be downward because that is the direction of the acceleration. In most cases, it is easiest to make that choice if the direction of the acceleration is known.

5.64. **IDENTIFY:** Apply Newton's first law to the ball. Treat the ball as a particle.

SET UP: The forces on the ball are gravity, the tension in the wire and the normal force exerted by the surface. The normal force is perpendicular to the surface of the ramp. Use *x*- and *y*-axes that are horizontal and vertical.

EXECUTE: **(a)** The free-body diagram for the ball is given in Figure 5.64 (next page). The normal force has been replaced by its *x* and *y* components.

(b) $\Sigma F_y = 0$ gives $n\cos 35.0° - w = 0$ and $n = \dfrac{mg}{\cos 35.0°} = 1.22mg$.

(c) $\Sigma F_x = 0$ gives $T - n\sin 35.0° = 0$ and $T = (1.22mg)\sin 35.0° = 0.700mg$.

EVALUATE: Note that the normal force is greater than the weight, and increases without limit as the angle of the ramp increases toward $90°$. The tension in the wire is $w\tan\phi$, where ϕ is the angle of the ramp and T also increases without limit as $\phi \to 90°$.

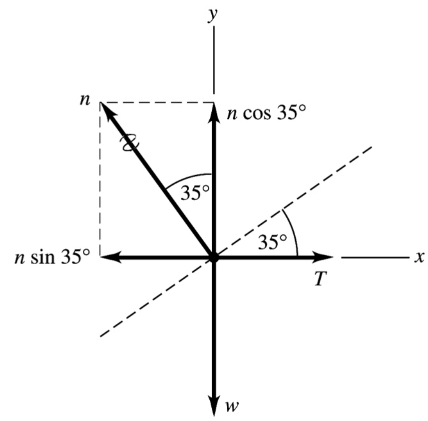

Figure 5.64

5.65. **IDENTIFY:** Newton's second law applies to the accelerating box. The forces acting on it are the force F, gravity, the normal force due to the surface, and kinetic friction.

SET UP: Apply $\sum F_y = 0$ and $\sum F_x = ma_x$. Fig. 5.65 shows a free-body diagram of the box. Choose the $+x$-axis in the direction of the acceleration.

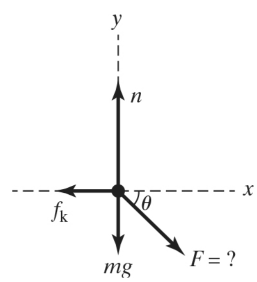

Figure 5.65

EXECUTE: **(a)** We want to find the magnitude of the force F. First use $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ to find a_x.

$(6.00\text{ m/s})^2 = 0 + 2a_x(8.00\text{ m}) \quad \to \quad a_x = 2.250\text{ m/s}^2$.

Now apply $\sum F_x = ma_x$: $F\cos\theta - f_k = ma_x$

We also have $f_k = \mu_k n$

Apply $\sum F_y = 0$: $n - mg - F\sin\theta = 0$

Combine these three results and solve for F: $F = \dfrac{m(a_x + \mu_k g)}{\cos\theta - \mu_k \sin\theta}$. Using $m = 12.0$ kg, $a_x = 2.250\text{ m/s}^2$, $\mu_k = 0.300$, and $\theta = 37.0°$, we get $F = 101$ N.

(b) If $f_k = 0$, we have $F\cos\theta = ma_x \quad \to \quad F\cos 37.0° = (12.0\text{ kg})(2.250\text{ m/s}^2) \quad \to \quad F = 33.8$ N.

(c) If F is horizontal, $\theta = 0°$, $n = mg$, and $f_k = \mu_k mg$, so $F = m(a_x + \mu_k g) = 62.3$ N.

EVALUATE: We see that F is least when there is no friction and greatest when it has a downward component. These results are reasonable since a downward component increases the normal force which increases friction. And the fact that it has a downward component means that there is less horizontal component to cause acceleration.

5.66. **IDENTIFY:** In each rough patch, the kinetic friction (and hence the acceleration) is constant, but the constants are different in the two patches. Newton's second law applies, as well as the constant-acceleration kinematics formulas in each patch.

SET UP: Choose the $+y$-axis upward and the $+x$-axis in the direction of the velocity.

EXECUTE: **(a)** Find the velocity and time when the box is at $x = 2.00$ m. Newton's second law tells us that $n = mg$ and $-f_k = ma_x$ which gives $-\mu_k mg = ma_x$; $a_x = -\mu_k g = -(0.200)(9.80\text{ m/s}^2) = -1.96\text{ m/s}^2$. Now use the kinematics equations involving v_x. Using $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ we get

$v_x = \sqrt{(4.00\text{ m/s})^2 + 2(-1.96\text{ m/s}^2)(2.00\text{ m})} = 2.857$ m/s. Now solve the equation $v_x = v_{0x} + a_x t$ for t to get $t = (2.857\text{ m/s} - 4.00\text{ m/s})/(-1.96\text{ m/s}^2) = 0.5834$ s.

Now look at the motion in the section for which $\mu_k = 0.400$: $a_x = -(0.400)(9.80\text{ m/s}^2) = -3.92\text{ m/s}^2$, $v_x = 0$, $v_{0x} =$ 2.857 m/s. Solving $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ for $x - x_0$ gives $x - x_0 = -(2.857\text{ m/s})^2/[2(-3.92\text{ m/s}^2)] = 1.041$ m.

The box is at the point $x = 2.00\text{ m} + 1.041\text{ m} = 3.04$ m.

Solving $v_x = v_{0x} + a_x t$ for t gives $t = (-2.857\text{ m/s})/(-3.92\text{ m/s}^2) = 0.7288$ s. The total time is $0.5834\text{ s} + 0.7288\text{ s} = 1.31$ s.

EVALUATE: We cannot do this problem in a single process because the acceleration, although constant in each patch, is different in the two patches.

5.67. **IDENTIFY:** Kinematics will give us the acceleration of the person, and Newton's second law will give us the force (the target variable) that his arms exert on the rest of his body.

SET UP: Let the person's weight be W, so $W = 680$ N. Assume constant acceleration during the speeding up motion and assume that the body moves upward 15 cm in 0.50 s while speeding up. The constant-acceleration kinematics formula $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ and $\Sigma F_y = ma_y$ apply. The free-body diagram for the person is given in Figure 5.67. F is the force exerted on him by his arms.

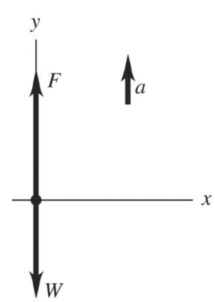

Figure 5.67

EXECUTE: $v_{0y} = 0$, $y - y_0 = 0.15$ m, $t = 0.50$ s. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives

$$a_y = \frac{2(y - y_0)}{t^2} = \frac{2(0.15\text{ m})}{(0.50\text{ s})^2} = 1.2\text{ m/s}^2.\quad \Sigma F_y = ma_y \text{ gives } F - W = ma.\quad m = \frac{W}{g}, \text{ so}$$

$$F = W\left(1 + \frac{a}{g}\right) = 1.12W = 762\text{ N}.$$

EVALUATE: The force is greater than his weight, which it must be if he is to accelerate upward.

5.68. **IDENTIFY:** The force is time-dependent, so the acceleration is not constant. Therefore we must use calculus instead of the standard kinematics formulas. Newton's second law applies.

SET UP: The acceleration is the time derivative of the velocity and $\Sigma F_y = ma_y$.

EXECUTE: Differentiating the velocity gives $a_y = dv_y/dt = 2.00\text{ m/s}^2 + (1.20\text{ m/s}^3)t$. Find the time when $v_y = 9.00$ m/s: $9.00\text{ m/s} = (2.00\text{ m/s}^2)t + (0.600\text{ m/s}^3)t^2$. Solving this quadratic for t and taking the positive value gives $t = 2.549$ s. At this time the acceleration is $a = 2.00\text{ m/s}^2 + (1.20\text{ m/s}^3)(2.549\text{ s}) = 5.059\text{ m/s}^2$.

Now apply Newton's second law to the box, calling T the tension in the rope: $T - mg = ma$, which gives $T = m(g + a) = (2.00\text{ kg})(9.80\text{ m/s}^2 + 5.059\text{ m/s}^2) = 29.7$ N.

EVALUATE: The tension is greater than the weight of the box, which it must be to accelerate the box upward. As time goes on, the acceleration, and hence the tension, would increase.

5.69. **IDENTIFY:** We know the forces on the box and want to find information about its position and velocity. Newton's second law will give us the box's acceleration.

SET UP: $a_y(t) = \dfrac{\Sigma F_y}{m}$. We can integrate the acceleration to find the velocity and the velocity to find the position. At an altitude of several hundred meters, the acceleration due to gravity is essentially the same as it is at the earth's surface.

EXECUTE: Let $+y$ be upward. Newton's second law gives $T - mg = ma_y$, so $a_y(t) = (12.0\text{ m/s}^3)t - 9.8\text{ m/s}^2$. Integrating the acceleration gives $v_y(t) = (6.00\text{ m/s}^3)t^2 - (9.8\text{ m/s}^2)t$.

(a) (i) At $t = 1.00$ s, $v_y = -3.80$ m/s. (ii) At $t = 3.00$ s, $v_y = 24.6$ m/s.

(b) Integrating the velocity gives $y - y_0 = (2.00\text{ m/s}^3)t^3 - (4.9\text{ m/s}^2)t^2$. $v_y = 0$ at $t = 1.63$ s. At $t = 1.63$ s, $y - y_0 = 8.71\text{ m} - 13.07\text{ m} = -4.36$ m.

(c) Setting $y - y_0 = 0$ and solving for t gives $t = 2.45$ s.

EVALUATE: The box accelerates and initially moves downward until the tension exceeds the weight of the box. Once the tension exceeds the weight, the box will begin to accelerate upward and will eventually move upward, as we saw in part (b).

5.70. **IDENTIFY:** We can use the standard kinematics formulas because the force (and hence the acceleration) is constant, and we can use Newton's second law to find the force needed to cause that acceleration. Kinetic friction, not static friction, is acting.

SET UP: From kinematics, we have $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ and $\Sigma F_x = ma_x$ applies. Forces perpendicular to the ramp balance. The force of kinetic friction is $f_k = \mu_k mg\cos\theta$.

EXECUTE: Call $+x$ upward along the surface of the ramp. Kinematics gives $a_x = \dfrac{2(x - x_0)}{t^2} = \dfrac{2(8.00\text{ m})}{(6.00\text{ s})^2} = 0.4444\text{ m/s}^2$. $\Sigma F_x = ma_x$ gives $F - mg\sin\theta - \mu_k mg\cos\theta = ma_x$. Solving for F and putting in the numbers for this problem gives
$F = m(a_x + g\sin\theta + \mu_k mg\cos\theta) = (5.00\text{ kg})(0.4444\text{ m/s}^2 + 4.9\text{ m/s}^2 + 3.395\text{ m/s}^2) = 43.7$ N.

EVALUTE: As long as the box is moving, only kinetic friction, not static friction, acts on it. The force is less than the weight of the box because only part of the box's weight acts down the ramp. We should also investigate if the force is great enough to start the box moving in the first place. In that case, static friction would have it maximum value, so $f_s = \mu_s n$. The force F in this would be $F = \mu_s mg\cos(30°) + mg\sin(30°) = mg(\mu_s\cos30° + \sin30°) = (5.00\text{ kg})(9.80\text{ m/s}^2)[(0.43)(\cos30°) + \sin30°] = 42.7$ N. Since the force we found is 43.7 N, it is great enough to overcome static friction and cause the box to move.

5.71. **IDENTIFY:** Newton's second law applies to the accelerating crate. The forces acting on it are the vertical force $\vec{F}$, gravity, the normal force due to the surface, and kinetic friction.

SET UP: Apply $\sum F_x = ma_x$. Fig. 5.71 shows a free-body diagram of the crate. Choose the +*x*-axis in the direction of the acceleration, which is down the surface of the ramp. Call α the angle the ramp makes above the horizontal. We want to find the magnitude of $\vec{F}$ that will give the crate an acceleration of 9.8 m/s^2 down the ramp.

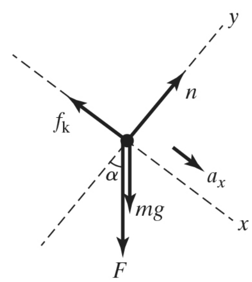

Figure 5.71

EXECUTE: First apply $\sum F_x = ma_x$ without the force $\vec{F}$ and then apply it with $\vec{F}$. Without $\vec{F}$ the normal force is $n = mg\cos\alpha$ and with $\vec{F}$ it is $n = (mg+F)\cos\alpha$.

Without the force: $mg\sin\alpha - \mu_k mg\cos\alpha = ma_1$.

With the force: $(mg+F)\sin\alpha - \mu_k(mg+F)\cos\alpha = ma_2$.

We know that $a_2/a_1 = (9.80\ \text{m/s}^2)/(4.9\ \text{m/s}^2) = 2$, so take the ratio of the equations, giving
$\dfrac{a_2}{a_1} = \dfrac{(mg+F)\sin\alpha - \mu_k(mg+F)\cos\alpha}{mg\sin\alpha - \mu_k mg\cos\alpha} = \dfrac{(mg+F)(\sin\alpha - \mu_k\cos\alpha)}{mg(\sin\alpha - \mu_k\cos\alpha)} = \dfrac{mg+F}{mg} = 2$. Solving for F gives $F = mg = (25.0\ \text{kg})(9.80\ \text{m/s}^2) = 245$ N. The force F is equal to the weight of the crate.

EVALUATE: The addition of the force F doubles the acceleration of the crate. Since F and mg are both downward, we need twice the force to double the acceleration, which tells us that F must be equal to the weight. So our result is reasonable. The addition of $F = mg$ effectively doubles the weight without changing the mass, so it doubles the acceleration.

5.72. **IDENTIFY:** The forces acting on the crate are the force F, gravity, the normal force due to the floor, and static friction. The crate is at rest, so the forces on it must balance. The crate is just ready to slide, so static friction force is a maximum.

SET UP: Apply $\sum F_x = 0$ and $\sum F_y = 0$. Fig. 5.72 shows a free-body diagram of the box. Choose the +*x*-axis horizontally to the right. At its maximum, $f_s = \mu_s n$. We want to find the mass m of the crate.

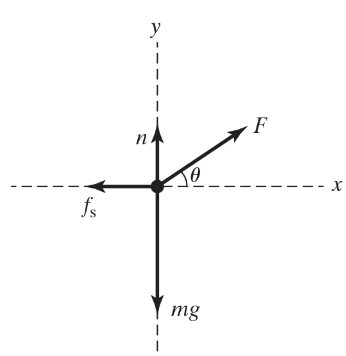

Figure 5.72

EXECUTE: $\sum F_x = 0$: $F\cos\theta - f_s = F\cos\theta - \mu_s n = 0$

$\sum F_y = 0$: $F\sin\theta + n - mg = 0$

Combine these two equations and solve for m: $m = \dfrac{F(\cos\theta + \mu_s \sin\theta)}{\mu_s g}$. Using $F = 380$ N, $\theta = 30.0°$, and $\mu_s = 0.400$ gives $m = 103$ kg.

EVALUATE: If the crate were not just ready to slide, we could *not* use $f_s = \mu_s n$.

5.73. **IDENTIFY:** Newton's second law applies to the box.

SET UP: $f_k = \mu_k n$, $\Sigma F_x = ma_x$, and $\Sigma F_y = ma_y$ apply to the box. Take the $+x$-axis down the surface of the ramp and the $+y$-axis perpendicular to the surface upward.

EXECUTE: $\Sigma F_y = ma_y$ gives $n + F\sin(33.0°) - mg\cos(33.0°) = 0$, which gives $n = 51.59$ N. The friction force is $f_k = \mu_k n = (0.300)(51.59\text{ N}) = 15.48$ N. Parallel to the surface we have $\Sigma F_x = ma_x$ which gives $F\cos(33.0°) + mg\sin(33.0°) - f_k = ma$, which gives $a = 6.129\text{ m/s}^2$. Finally the velocity formula gives us $v_x = v_{0x} + a_x t = 0 + (6.129\text{ m/s}^2)(2.00\text{ s}) = 12.3$ m/s.

EVALUATE: Even though F is horizontal and mg is vertical, it is best to choose the axes as we have done, rather than horizontal-vertical, because the acceleration is then in the x-direction. Taking x and y to be horizontal-vertical would give the acceleration x- and y-components, which would complicate the solution.

5.74. **IDENTIFY:** This is a system having constant acceleration, so we can use the standard kinematics formulas as well as Newton's second law to find the unknown mass m_2.

SET UP: Newton's second law applies to each block. The standard kinematics formulas can be used to find the acceleration because the acceleration is constant. The normal force on m_1 is $m_1 g\cos\alpha$, so the force of friction on it is $f_k = \mu_k m_1 g\cos\alpha$.

EXECUTE: Standard kinematics gives the acceleration of the system to be

$a_y = \dfrac{2(y-y_0)}{t^2} = \dfrac{2(12.0\text{ m})}{(3.00\text{ s})^2} = 2.667\text{ m/s}^2$. For m_1, $n = m_1 g\cos\alpha = 117.7$ N, so the friction force on m_1 is $f_k = (0.40)(117.7\text{ N}) = 47.08$ N. Applying Newton's second law to m_1 gives $T - f_k - m_1 g\sin\alpha = m_1 a$, where T is the tension in the cord. Solving for T gives $T = f_k + m_1 g\sin\alpha + m_1 a = 47.08\text{ N} + 156.7\text{ N} + 53.34\text{ N} = 257.1$ N. Newton's second law for m_2 gives $m_2 g - T = m_2 a$, so $m_2 = \dfrac{T}{g-a} = \dfrac{257.1\text{ N}}{9.8\text{ m/s}^2 - 2.667\text{ m/s}^2} = 36.0$ kg.

EVALUATE: We could treat these blocks as a two-block system. Newton's second law would then give $m_2 g - m_1 g\sin\alpha - \mu_k m_1 g\cos\alpha = (m_1 + m_2)a$, which gives the same result as above.

5.75. **IDENTIFY:** Newton's second law applies, as do the constant-acceleration kinematics equations.

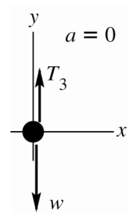
SET UP: Call the $+x$-axis horizontal and to the right and the $+y$-axis vertically upward. $\Sigma F_y = ma_y$ and $\Sigma F_x = ma_x$ both apply to the book.

EXECUTE: The book has no horizontal motion, so $\Sigma F_x = ma_x = 0$, which gives us the normal force n: $n = F\cos(60.0°)$. The kinetic friction force is $f_k = \mu_k n = (0.300)(96.0\text{ N})(\cos 60.0°) = 14.4$ N. In the vertical direction, we have $\Sigma F_y = ma_y$, which gives $F\sin(60.0°) - mg - f_k = ma$. Solving for a gives us $a = [(96.0\text{ N})(\sin 60.0°) - 49.0\text{ N} - 14.4\text{ N}]/(5.00\text{ kg}) = 3.948\text{ m/s}^2$ upward. Now the velocity formula $v_y^2 = v_{0y}^2 + 2a_y(y-y_0)$ gives $v_y = \sqrt{2(3.948\text{ m/s}^2)(0.400\text{ m})} = 1.78$ m/s.

EVALUATE: Only the upward component of the force F makes the book accelerate upward, while the horizontal component of T is the magnitude of the normal force.

5.76. **Identify:** The system is in equilibrium. Apply Newton's first law to block *A*, to the hanging weight and to the knot where the cords meet. Target variables are the two forces.

(a) Set Up: The free-body diagram for the hanging block is given in Figure 5.76a.



Execute:

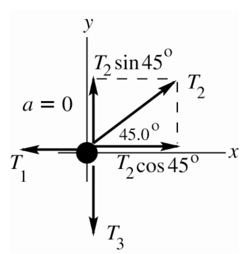
$\Sigma F_y = ma_y$

$T_3 - w = 0$

$T_3 = 12.0\text{ N}$

Figure 5.76a

Set Up: The free-body diagram for the knot is given in Figure 5.76b.



Execute:

$\Sigma F_y = ma_y$

$T_2 \sin 45.0° - T_3 = 0$

$T_2 = \dfrac{T_3}{\sin 45.0°} = \dfrac{12.0\text{ N}}{\sin 45.0°}$

$T_2 = 17.0\text{ N}$

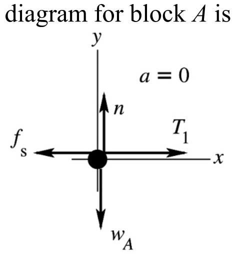
Figure 5.76b

$\Sigma F_x = ma_x$

$T_2 \cos 45.0° - T_1 = 0$

$T_1 = T_2 \cos 45.0° = 12.0\text{ N}$

Set Up: The free-body diagram for block *A* is given in Figure 5.76c.



Execute:

$\Sigma F_x = ma_x$

$T_1 - f_s = 0$

$f_s = T_1 = 12.0\text{ N}$

Figure 5.76c

Evaluate: Also can apply $\Sigma F_y = ma_y$ to this block:

$$n - w_A = 0$$

$$n = w_A = 60.0\text{ N}$$

Then $\mu_s n = (0.25)(60.0\text{ N}) = 15.0\text{ N};$ this is the maximum possible value for the static friction force. We see that $f_s < \mu_s n;$ for this value of *w* the static friction force can hold the blocks in place.

(b) Set Up: We have all the same free-body diagrams and force equations as in part (a) but now the static friction force has its largest possible value, $f_s = \mu_s n = 15.0\text{ N}.$ Then $T_1 = f_s = 15.0\text{ N}.$

Execute: From the equations for the forces on the knot

$T_2 \cos 45.0° - T_1 = 0$ implies $T_2 = T_1/\cos 45.0° = \dfrac{15.0\text{ N}}{\cos 45.0°} = 21.2\text{ N}$

$T_2 \sin 45.0° - T_3 = 0$ implies $T_3 = T_2 \sin 45.0° = (21.2 \text{ N}) \sin 45.0° = 15.0$ N

And finally $T_3 - w = 0$ implies $w = T_3 = 15.0$ N.

EVALUATE: Compared to part (a), the friction is larger in part (b) by a factor of $(15.0/12.0)$ and w is larger by this same ratio.

5.77. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each block.

SET UP: Constant speed means $a = 0$. When the blocks are moving, the friction force is f_k and when they are at rest, the friction force is f_s.

EXECUTE: **(a)** The tension in the cord must be $m_2 g$ in order that the hanging block move at constant speed. This tension must overcome friction and the component of the gravitational force along the incline, so $m_2 g = (m_1 g \sin\alpha + \mu_k m_1 g \cos\alpha)$ and $m_2 = m_1(\sin\alpha + \mu_k \cos\alpha)$.

(b) In this case, the friction force acts in the same direction as the tension on the block of mass m_1, so $m_2 g = (m_1 g \sin\alpha - \mu_k m_1 g \cos\alpha)$, or $m_2 = m_1(\sin\alpha - \mu_k \cos\alpha)$.

(c) Similar to the analysis of parts (a) and (b), the largest m_2 could be is $m_1(\sin\alpha + \mu_s \cos\alpha)$ and the smallest m_2 could be is $m_1(\sin\alpha - \mu_s \cos\alpha)$.

EVALUATE: In parts (a) and (b) the friction force changes direction when the direction of the motion of m_1 changes. In part (c), for the largest m_2 the static friction force on m_1 is directed down the incline and for the smallest m_2 the static friction force on m_1 is directed up the incline.

5.78. **IDENTIFY:** The net force at any time is $F_{\text{net}} = ma$.

SET UP: At $t = 0$, $a = 62g$. The maximum acceleration is 140g at $t = 1.2$ ms.

EXECUTE: **(a)** $F_{\text{net}} = ma = 62mg = 62(210\times10^{-9} \text{ kg})(9.80 \text{ m/s}^2) = 1.3\times10^{-4}$ N. This force is 62 times the flea's weight.

(b) $F_{\text{net}} = 140mg = 2.9\times10^{-4}$ N, at $t = 1.2$ ms.

(c) Since the initial speed is zero, the maximum speed is the area under the $a_x - t$ graph. This gives 1.2 m/s.

EVALUATE: a is much larger than g and the net external force is much larger than the flea's weight.

5.79. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each block. Use Newton's third law to relate forces on A and on B.

SET UP: Constant speed means $a = 0$.

EXECUTE: **(a)** Treat A and B as a single object of weight $w = w_A + w_B = 1.20$ N + 3.60 N = 4.80 N. The free-body diagram for this combined object is given in Figure 5.79a. $\Sigma F_y = ma_y$ gives $n = w = 4.80$ N. $f_k = \mu_k n = (0.300)(4.80 \text{ N}) = 1.44$ N. $\Sigma F_x = ma_x$ gives $F = f_k = 1.44$ N.

(b) The free-body force diagrams for blocks A and B are given in Figure 5.79b. n and f_k are the normal and friction forces applied to block B by the tabletop and are the same as in part (a). f_{kB} is the friction force that A applies to B. It is to the right because the force from A opposes the motion of B. n_B is the downward force that A exerts on B. f_{kA} is the friction force that B applies to A. It is to the left because block B wants A to move with it. n_A is the normal force that block B exerts on A. By Newton's third law, $f_{kB} = f_{kA}$ and these forces are in opposite directions. Also, $n_A = n_B$ and these forces are in opposite directions.

$\Sigma F_y = ma_y$ for block A gives $n_A = w_A = 1.20$ N, so $n_B = 1.20$ N.

$f_{kA} = \mu_k n_A = (0.300)(1.20 \text{ N}) = 0.360$ N, and $f_{kB} = 0.360$ N.

$\Sigma F_x = ma_x$ for block A gives $T = f_{kA} = 0.360$ N.

$\Sigma F_x = ma_x$ for block B gives $F = f_{kB} + f_k = 0.360\text{ N} + 1.44\text{ N} = 1.80$ N.

EVALUATE: In part (a) block A is at rest with respect to B and it has zero acceleration. There is no horizontal force on A besides friction, and the friction force on A is zero. A larger force F is needed in part (b), because of the friction force between the two blocks.

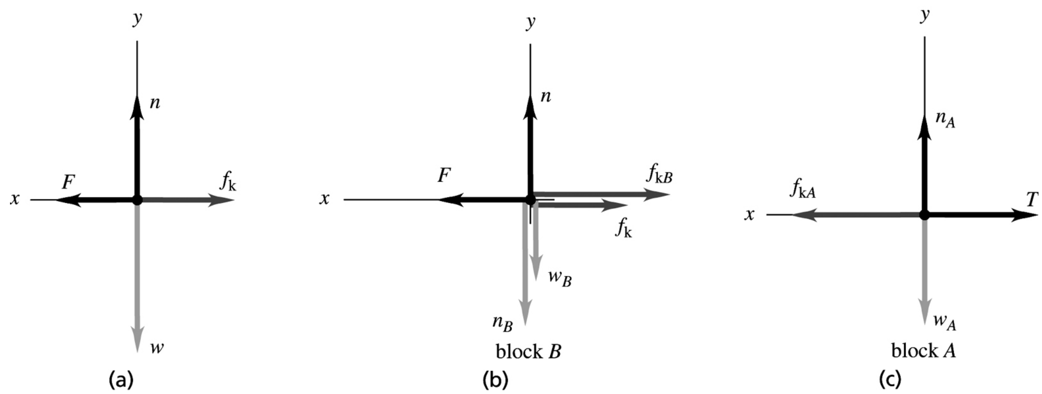


Figure 5.79

5.80. IDENTIFY: Apply $\Sigma \vec{F} = m\vec{a}$ to the passenger to find the maximum allowed acceleration. Then use a constant acceleration equation to find the maximum speed.

SET UP: The free-body diagram for the passenger is given in Figure 5.80.

EXECUTE: $\Sigma F_y = ma_y$ gives $n - mg = ma$. $n = 1.6mg$, so $a = 0.60g = 5.88\text{ m/s}^2$.

$y - y_0 = 3.0$ m, $a_y = 5.88\text{ m/s}^2$, $v_{0y} = 0$ so $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $v_y = 5.9$ m/s.

EVALUATE: A larger final speed would require a larger value of a_y, which would mean a larger normal force on the person.

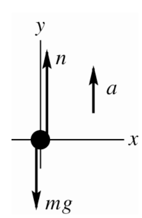

Figure 5.80

5.81. IDENTIFY: $a = dv/dt$. Apply $\Sigma \vec{F} = m\vec{a}$ to yourself.

SET UP: The reading of the scale is equal to the normal force the scale applies to you.

EXECUTE: The elevator's acceleration is $a = \dfrac{dv(t)}{dt} = 3.0\text{ m/s}^2 + 2(0.20\text{ m/s}^3)t = 3.0\text{ m/s}^2 + (0.40\text{ m/s}^3)t$.

At $t = 4.0$ s, $a = 3.0\text{ m/s}^2 + (0.40\text{ m/s}^3)(4.0\text{ s}) = 4.6\text{ m/s}^2$. From Newton's second law, the net force on you is $F_{\text{net}} = F_{\text{scale}} - w = ma$ and $F_{\text{scale}} = w + ma = (64\text{ kg})(9.8\text{ m/s}^2) + (64\text{ kg})(4.6\text{ m/s}^2) = 920$ N.

EVALUATE: a increases with time, so the scale reading is increasing.

5.82. **IDENTIFY:** The blocks are moving together with the same acceleration, so Newton's second law applies to each of them.

SET UP: For block A take the $+x$-axis horizontally to the right, and for B take the $+y$-axis vertically downward. Our choice for B has two advantages: it is in the direction of the acceleration of B and a positive acceleration of A gives a positive acceleration of B. Both blocks have the same acceleration, which we shall simply call a. $\sum F = ma$ applies to both blocks. We want to find the tension T in the rope and the coefficient of kinetic friction μ_k between A and the tabletop.

EXECUTE: **(a)** We know the speed of A and the distance it moved, so use $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ to find its horizontal acceleration. $(3.30 \text{ m/s})^2 = 0 + 2a(2.00 \text{ m})$, so $a = 2.7225 \text{ m/s}^2$. Now look at B to find the tension. $\sum F_y = ma_y$ gives $w_B - T = m_B a = (w_B/g)a$. Solving for T gives $T = w_B\left(1 - \dfrac{a}{g}\right) =$

$$(25.0 \text{ N})\left(1 - \frac{2.7225 \text{ m/s}^2}{9.80 \text{ m/s}^2}\right) = 18.1 \text{ N}.$$

Now look at block A. Balancing vertical forces tells us that $n = w_A$. The friction force is $f_k = \mu_k n = \mu_k w_A$. $\sum F_x = ma_x$ gives $T - f_k = m_A a \quad \rightarrow \quad T - \mu_k w_A = (w_A/g)a$. Solving for μ_k gives $\mu_k = \dfrac{T - (w_A/g)a}{w_A}$. Using $w_A = 45.0$ N, $a = 2.7225 \text{ m/s}^2$, and $T = 18.1$ N gives $\mu_k = 0.123$.

EVALUATE: According to Table 5.1 in the text, 0.123 is not an unreasonable coefficient of kinetic friction.

5.83. **IDENTIFY:** The blocks move together with the same acceleration. Newton's second law applies to each of them. The forces acting on each block are gravity downward the upward tension in the rope.

SET UP: $\sum F_y = ma_y$ applies to each block. The heavier block accelerates downward while the lighter one accelerates upward, both with acceleration a. Call the $+y$-axis downward for the heavier block and upward for the lighter block. We want to find the mass of each block.

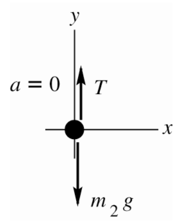
EXECUTE: Heavier block: First find the acceleration using $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$, which gives us $y = \frac{1}{2}at^2$, so $5.00 \text{ m} = \frac{1}{2}a(2.00 \text{ s})^2 \quad \rightarrow \quad a = 2.50 \text{ m/s}^2$. Now apply $\sum F_y = ma_y$ to this block, which gives $m_2 g - T = m_2 a$. Now olve for m_2: $m_2 = \dfrac{T}{g - a} = \dfrac{16.0 \text{ N}}{9.80 \text{ m/s}^2 - 2.50 \text{ m/s}^2} = 2.19$ kg.

Lighter block: $\sum F_y = ma_y$ gives $T - m_1 g = m_1 a$, so $m_1 = \dfrac{T}{a + g} = 1.30$ kg.

EVALUATE: As a check, consider the two blocks as a singe system The only external force causing the acceleration is $m_2 g - m_1 g$, so $\sum F_y = ma_y$ gives $m_2 g - m_1 g = (m_1 + m_2)a$. Solving for a using our results for the two masses gives $a = 2.50 \text{ m/s}^2$, which agrees with our result.

5.84. **IDENTIFY:** Apply Newton's first law to the rope. Let m_1 be the mass of that part of the rope that is on the table, and let m_2 be the mass of that part of the rope that is hanging over the edge. ($m_1 + m_2 = m$, the total mass of the rope). Since the mass of the rope is not being neglected, the tension in the rope varies along the length of the rope. Let T be the tension in the rope at that point that is at the edge of the table.

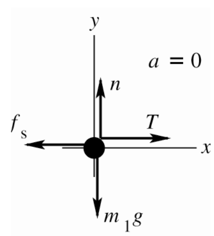
SET UP: The free-body diagram for the hanging section of the rope is given in Figure 5.84a.



EXECUTE:
$\Sigma F_y = ma_y$
$T - m_2 g = 0$
$T = m_2 g$

Figure 5.84a

SET UP: The free-body diagram for that part of the rope that is on the table is given in Figure 5.84b.



EXECUTE:
$\Sigma F_y = ma_y$
$n - m_1 g = 0$
$n = m_1 g$

Figure 5.84b

When the maximum amount of rope hangs over the edge the static friction has its maximum value:
$f_s = \mu_s n = \mu_s m_1 g$
a $\Sigma F_x = ma_x$
$T - f_s = 0$
$T = \mu_s m_1 g$
Use the first equation to replace T:
$m_2 g = \mu_s m_1 g$
$m_2 = \mu_s m_1$
The fraction that hangs over is $\dfrac{m_2}{m} = \dfrac{\mu_s m_1}{m_1 + \mu_s m_1} = \dfrac{\mu_s}{1+\mu_s}.$

EVALUATE: As $\mu_s \to 0,$ the fraction goes to zero and as $\mu_s \to \infty,$ the fraction goes to unity.

5.85. IDENTIFY: Apply $\Sigma \vec{F} = m\vec{a}$ to the point where the three wires join and also to one of the balls. By symmetry the tension in each of the 35.0 cm wires is the same.
SET UP: The geometry of the situation is sketched in Figure 5.85a. The angle ϕ that each wire makes with the vertical is given by $\sin\phi = \dfrac{12.5 \text{ cm}}{47.5 \text{ cm}}$ and $\phi = 15.26°.$ Let T_A be the tension in the vertical wire and let T_B be the tension in each of the other two wires. Neglect the weight of the wires. The free-body diagram for the left-hand ball is given in Figure 5.85b and for the point where the wires join in Figure 5.85c. n is the force one ball exerts on the other.
EXECUTE: (a) $\Sigma F_y = ma_y$ applied to the ball gives $T_B \cos\phi - mg = 0.$

$T_B = \dfrac{mg}{\cos\phi} = \dfrac{(15.0 \text{ kg})(9.80 \text{ m/s}^2)}{\cos 15.26°} = 152 \text{ N}.$ Then $\Sigma F_y = ma_y$ applied in Figure 5.85c gives

$T_A - 2T_B \cos\phi = 0$ and $T_A = 2(152 \text{ N})\cos\phi = 249 \text{ N}.$
(b) $\Sigma F_x = ma_x$ applied to the ball gives $n - T_B \sin\phi = 0$ and $n = (152 \text{ N})\sin 15.26° = 40.0 \text{ N}.$
EVALUATE: T_A equals the total weight of the two balls.

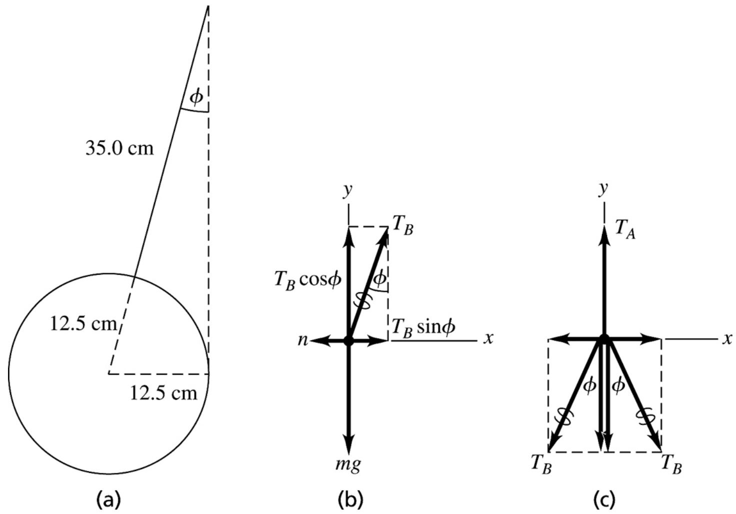


Figure 5.85

5.86. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the car to calculate its acceleration. Then use a constant acceleration equation to find the initial speed.

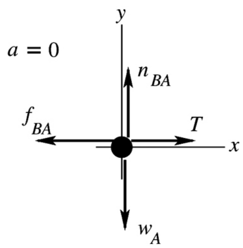
SET UP: Let $+x$ be in the direction of the car's initial velocity. The friction force f_k is then in the $-x$-direction. $192\text{ ft} = 58.52\text{ m}$.

EXECUTE: $n = mg$ and $f_k = \mu_k mg$. $\Sigma F_x = ma_x$ gives $-\mu_k mg = ma_x$ and $a_x = -\mu_k g = -(0.750)(9.80\text{ m/s}^2) = -7.35\text{ m/s}^2$. $v_x = 0$ (stops), $x - x_0 = 58.52\text{ m}$. $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives $v_{0x} = \sqrt{-2a_x(x - x_0)} = \sqrt{-2(-7.35\text{ m/s}^2)(58.52\text{ m})} = 29.3\text{ m/s} = 65.5\text{ mi/h}$. He was guilty.

EVALUATE: $x - x_0 = \dfrac{v_x^2 - v_{0x}^2}{2a_x} = -\dfrac{v_{0x}^2}{2a_x}$. If his initial speed had been 45 mi/h he would have stopped in $\left(\dfrac{45\text{ mi/h}}{65.5\text{ mi/h}}\right)^2 (192\text{ ft}) = 91\text{ ft}$.

5.87. **IDENTIFY:** Apply $-\left(\dfrac{M+m}{M}\right)\tan\alpha$ to each block. Forces between the blocks are related by Newton's third law. The target variable is the force F. Block B is pulled to the left at constant speed, so block A moves to the right at constant speed and $a = 0$ for each block.

SET UP: The free-body diagram for block A is given in Figure 5.87a. n_{BA} is the normal force that B exerts on A. $f_{BA} = \mu_k n_{BA}$ is the kinetic friction force that B exerts on A. Block A moves to the right relative to B, and f_{BA} opposes this motion, so f_{BA} is to the left. Note also that F acts just on B, not on A.



EXECUTE:
$\Sigma F_y = ma_y$
$n_{BA} - w_A = 0$
$n_{BA} = 1.90\text{ N}$
$f_{BA} = \mu_k n_{BA} = (0.30)(1.90\text{ N}) = 0.57\text{ N}$

Figure 5.87a

$\Sigma F_x = ma_x$. $T - f_{BA} = 0$. $T = f_{BA} = 0.57\text{ N}$.

SET UP: The free-body diagram for block *B* is given in Figure 5.87b.

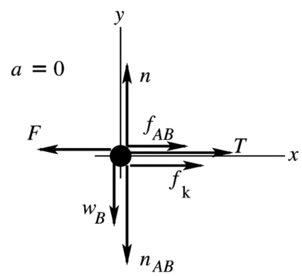


Figure 5.87b

EXECUTE: n_{AB} is the normal force that block *A* exerts on block *B*. By Newton's third law n_{AB} and n_{BA} are equal in magnitude and opposite in direction, so $n_{AB} = 1.90\text{ N}$. f_{AB} is the kinetic friction force that *A* exerts on *B*. Block *B* moves to the left relative to *A* and f_{AB} opposes this motion, so f_{AB} is to the right. $f_{AB} = \mu_k n_{AB} = (0.30)(1.90\text{ N}) = 0.57\text{ N}$. *n* and f_k are the normal and friction force exerted by the floor on block *B*; $f_k = \mu_k n$. Note that block *B* moves to the left relative to the floor and f_k opposes this motion, so f_k is to the right.

$\Sigma F_y = ma_y$: $n - w_B - n_{AB} = 0$. $n = w_B + n_{AB} = 4.20\text{ N} + 1.90\text{ N} = 6.10\text{ N}$. Then
$f_k = \mu_k n = (0.30)(6.10\text{ N}) = 1.83\text{ N}$. $\Sigma F_x = ma_x$: $f_{AB} + T + f_k - F = 0$.
$F = T + f_{AB} + f_k = 0.57\text{ N} + 0.57\text{ N} + 1.83\text{ N} = 3.0\text{ N}$.

EVALUATE: Note that f_{AB} and f_{BA} are a third law action-reaction pair, so they must be equal in magnitude and opposite in direction and this is indeed what our calculation gives.

5.88. **IDENTIFY:** Both blocks accelerate together. The force *P* accelerates the two-block system, but only static friction accelerates block *B*. Newton's second law applies to each block as well as the entire system.

SET UP: When *P* is the largest, block *A* is just ready to slide over block *B* so static friction is at its maximum, which is $f_s = \mu_s n$. Apply $\sum F_x = ma_x$. We want the largest value of *P* for which the blocks move together.

EXECUTE: Isolate *A*: $n = m_A g$ and $f_s = \mu_s m_A g$. $\sum F_x = ma_x$ gives $P - \mu_s m_A g = m_A a_x$. We need a_x. Treat the two blocks as a single system: $\sum F_x = ma_x$ gives $P = (m_A + m_B)a_x$. Now solve for a_x to get $a_x = P/(m_A + m_B)$.

Now use this value of a_x in the equation for block A, giving $P - \mu_s m_A g = m_A\left(\dfrac{P}{m_A + m_B}\right)$. Solving for P and using $m_A = 2.00$ kg, $m_B = 5.00$ kg, and $\mu_s = 0.400$ gives $P = 11.0$ N.

EVALUATE: If P were to exceed 11.0 N, slipping would occur, the friction force would be kinetic friction, and the blocks would not have the same acceleration.

5.89. **IDENTIFY:** Apply $-\left(\dfrac{M+m}{M}\right)\tan\alpha$ to each block. Parts (a) and (b) will be done together.

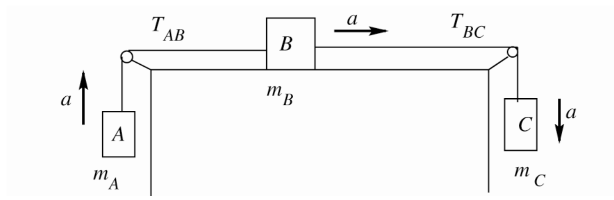

Figure 5.89a

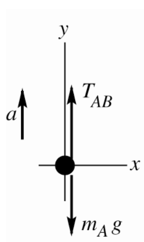
Note that each block has the same magnitude of acceleration, but in different directions. For each block let the direction of $\vec{a}$ be a positive coordinate direction.

SET UP: The free-body diagram for block A is given in Figure 5.89b.



EXECUTE:

$\Sigma F_y = ma_y$

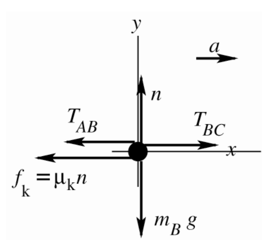
$T_{AB} - m_A g = m_A a$

$T_{AB} = m_A(a + g)$

$T_{AB} = 4.00\text{ kg}(2.00\text{ m/s}^2 + 9.80\text{ m/s}^2) = 47.2\text{ N}$

Figure 5.89b

SET UP: The free-body diagram for block B is given in Figure 5.89c.



EXECUTE:

$\Sigma F_y = ma_y$

$n - m_B g = 0$

$n = m_B g$

Figure 5.89c

$f_k = \mu_k n = \mu_k m_B g = (0.25)(12.0\text{ kg})(9.80\text{ m/s}^2) = 29.4\text{ N}$

$\Sigma F_x = ma_x$

$T_{BC} - T_{AB} - f_k = m_B a$

$T_{BC} = T_{AB} + f_k + m_B a = 47.2\text{ N} + 29.4\text{ N} + (12.0\text{ kg})(2.00\text{ m/s}^2)$

$T_{BC} = 100.6\text{ N}$

SET UP: The free-body diagram for block C is sketched in Figure 5.89d (next page).

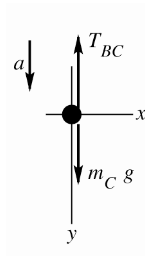


Figure 5.89d

EXECUTE:

$$\Sigma F_y = ma_y$$

$$m_C g - T_{BC} = m_C a$$

$$m_C(g-a) = T_{BC}$$

$$m_C = \frac{T_{BC}}{g-a} = \frac{100.6\ \text{N}}{9.80\ \text{m}/s^2 - 2.00\ \text{m/s}^2} = 12.9\ \text{kg}$$

EVALUATE: If all three blocks are considered together as a single object and $-\left(\frac{M+m}{M}\right)\tan\alpha$ is applied to this combined object, $m_C g - m_A g - \mu_k m_B g = (m_A + m_B + m_C)a$. Using the values for μ_k, m_A and m_B given in the problem and the mass m_C we calculated, this equation gives $a = 2.00\ \text{m/s}^2$, which checks.

5.90. **IDENTIFY:** Apply $-\left(\frac{M+m}{M}\right)\tan\alpha$ to each block. They have the same magnitude of acceleration, a.

SET UP: Consider positive accelerations to be to the right (up and to the right for the left-hand block, down and to the right for the right-hand block).

EXECUTE: **(a)** The forces along the inclines and the accelerations are related by $T - (100\ \text{kg})g\sin 30.0° = (100\ \text{kg})a$ and $(50\ \text{kg})g\sin 53.1° - T = (50\ \text{kg})a$, where T is the tension in the cord and a the mutual magnitude of acceleration. Adding these relations, $(50\ \text{kg}\sin 53.1° - 100\ \text{kg}\sin 30.0°)g = (50\ \text{kg} + 100\ \text{kg})a$, or $a = -0.067g$. Since a comes out negative, the blocks will slide to the left; the 100-kg block will slide down. Of course, if coordinates had been chosen so that positive accelerations were to the left, a would be $+0.067g$.

(b) $a = 0.067(9.80\ \text{m/s}^2) = 0.658\ \text{m/s}^2$.

(c) Substituting the value of a (including the proper sign, depending on choice of coordinates) into either of the above relations involving T yields 424 N.

EVALUATE: For part (a) we could have compared $mg\sin\theta$ for each block to determine which direction the system would move.

5.91. **IDENTIFY:** Let the tensions in the ropes be T_1 and T_2.

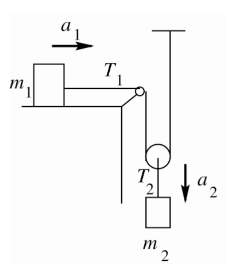

Figure 5.91a

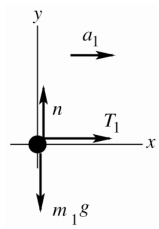
Consider the forces on each block. In each case take a positive coordinate direction in the direction of the acceleration of that block.

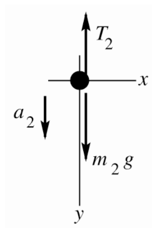
SET UP: The free-body diagram for m_1 is given in Figure 5.91b.



EXECUTE:
$\Sigma F_x = ma_x$
$T_1 = m_1a_1$

Figure 5.91b

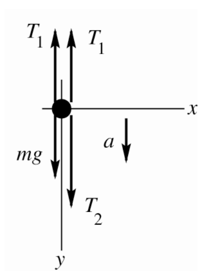
SET UP: The free-body diagram for m_2 is given in Figure 5.91c.



EXECUTE:
$\Sigma F_y = ma_y$
$m_2g - T_2 = m_2a_2$

Figure 5.91c

This gives us two equations, but there are four unknowns (T_1, T_2, a_1 and a_2) so two more equations are required.
SET UP: The free-body diagram for the moveable pulley (mass *m*) is given in Figure 5.91d.



EXECUTE:
$\Sigma F_y = ma_y$
$mg + T_2 - 2T_1 = ma$

Figure 5.91d

But our pulleys have negligible mass, so $mg = ma = 0$ and $T_2 = 2T_1$. Combine these three equations to eliminate T_1 and T_2: $m_2g - T_2 = m_2a_2$ gives $m_2g - 2T_1 = m_2a_2$. And then with $T_1 = m_1a_1$ we have $m_2g - 2m_1a_1 = m_2a_2$.
SET UP: There are still two unknowns, a_1 and a_2. But the accelerations a_1 and a_2 are related. In any time interval, if m_1 moves to the right a distance *d*, then in the same time m_2 moves downward a distance $d/2$. One of the constant acceleration kinematic equations says $x - x_0 = v_{0x}t + \frac{1}{2}a_xt^2$, so if m_2 moves half the distance it must have half the acceleration of m_1: $a_2 = a_1/2$, or $a_1 = 2a_2$.
EXECUTE: This is the additional equation we need. Use it in the previous equation and get
$m_2g - 2m_1(2a_2) = m_2a_2$.
$a_2(4m_1 + m_2) = m_2g$

$$a_2 = \frac{m_2 g}{4m_1 + m_2} \text{ and } a_1 = 2a_2 = \frac{2m_2 g}{4m_1 + m_2}.$$

EVALUATE: If $m_2 \to 0$ or $m_1 \to \infty$, $a_1 = a_2 = 0$. If $m_2 \gg m_1$, $a_2 = g$ and $a_1 = 2g$.

5.92. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to block B, to block A and B as a composite object, and to block C. If A and B slide together all three blocks have the same magnitude of acceleration.

SET UP: If A and B don't slip, the friction between them is static. The free-body diagrams for block B, for blocks A and B, and for C are given in Figure 5.92. Block C accelerates downward and A and B accelerate to the right. In each case take a positive coordinate direction to be in the direction of the acceleration. Since block A moves to the right, the friction force f_s on block B is to the right, to prevent relative motion between the two blocks. When C has its largest mass, f_s has its largest value: $f_s = \mu_s n$.

EXECUTE: $\Sigma F_x = ma_x$ applied to the block B gives $f_s = m_B a$. $n = m_B g$ and $f_s = \mu_s m_B g$. $\mu_s m_B g = m_B a$ and $a = \mu_s g$. $\Sigma F_x = ma_x$ applied to blocks $A + B$ gives $T = m_{AB} a = m_{AB} \mu_s g$. $\Sigma F_y = ma_y$ applied to block C gives $m_C g - T = m_C a$. $m_C g - m_{AB} \mu_s g = m_C \mu_s g$.

$$m_C = \frac{m_{AB}\mu_s}{1-\mu_s} = (5.00 \text{ kg} + 8.00 \text{ kg})\left(\frac{0.750}{1-0.750}\right) = 39.0 \text{ kg}.$$

EVALUATE: With no friction from the tabletop, the system accelerates no matter how small the mass of C is. If m_C is less than 39.0 kg, the friction force that A exerts on B is less than $\mu_s n$. If m_C is greater than 39.0 kg, blocks C and A have a larger acceleration than friction can give to block B, and A accelerates out from under B.

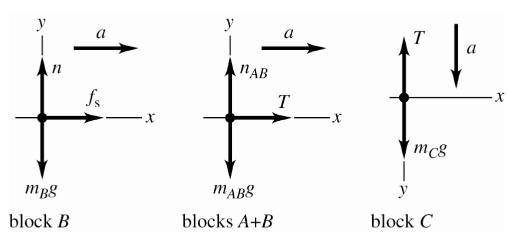


Figure 5.92

5.93. **IDENTIFY:** Both blocks accelerate together. The force F accelerates the two-block system, and the blocks exert kinetic friction forces on each other. Newton's second law applies to each block as well as the entire system.

SET UP: We apply $\sum F_x = ma_x$ and $\sum F_y = 0$ to each block. Block A accelerates to the right and B accelerates to the left. Call the direction of acceleration the $+x$-direction in each case, and call each acceleration a. Fig. 5.93 shows free-body diagrams of each block. It is important to realize two things immediately: the normal force that A exerts on B is equal and opposite to the normal force that B exerts on A, and the blocks exert equal but opposite friction forces on each other. Both of these points are due to Newton's third law (action-reaction). We want to find the tension in the cord and the coefficient of kinetic friction between A and B.

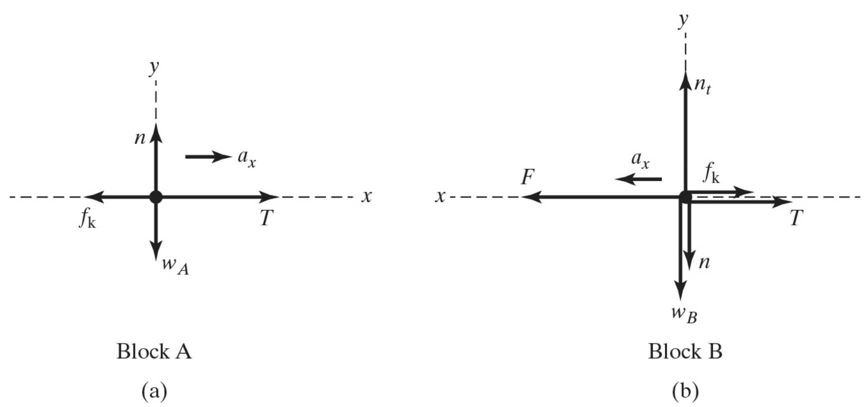

Figure 5.93

EXECUTE: **(a) & (b)** Isolate block A: Call n the normal force that the blocks exert on each other and f_k the kinetic friction force they exert on each other. From Fig. 5.93a, $\sum F_y = 0$ gives $n = w_A$ and $\sum F_x = ma_x$ gives $T - f_k = m_A a$, which becomes $T - \mu_k w_A = m_A a$. (Eq. 1)

Isolate block B: Call n_t the normal force due to the table. From Fig. 5.93b wee see that $\sum F_x = ma_x$ gives $T + f_k - F = m_B a$, which becomes $F - T - \mu_k w_A = m_B a$. (Eq. 2)

Combining Eq. 1 and Eq. 2 and solve for μ_k gives $F - 2\mu_k w_A = (m_A + m_B)a$. Solving for μ_k gives $\mu_k = \dfrac{F - (m_A + m_B)a}{2m_A g}$. Using the given masses, force, and acceleration gives $\mu_k = 0.242$.

Now use Eq. 1 (or Eq. 2) to find T: $T = m_A a + \mu_k m_A g = 7.75$ N.

EVALUATE: The tension is less than the force F, which is reasonable because B could never accelerate if T were greater than F. Also, from Table 5.1 we see that 0.242 is a reasonable coefficient of kinetic friction.

5.94. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the box.

SET UP: The box has an upward acceleration of $a = 1.90 \text{ m/s}^2$.

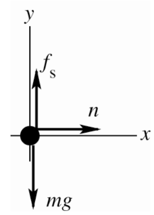
EXECUTE: The floor exerts an upward force n on the box, obtained from $n - mg = ma$, or $n = m(a + g)$. The friction force that needs to be balanced is

$$\mu_k n = \mu_k m(a + g) = (0.32)(36.0 \text{ kg})(1.90 \text{ m/s}^2 + 9.80 \text{ m/s}^2) = 135 \text{ N}.$$

EVALUATE: If the elevator were not accelerating the normal force would be $n = mg$ and the friction force that would have to be overcome would be 113 N. The upward acceleration increases the normal force and that increases the friction force.

5.95. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the block. The cart and the block have the same acceleration. The normal force exerted by the cart on the block is perpendicular to the front of the cart, so is horizontal and to the right. The friction force on the block is directed so as to hold the block up against the downward pull of gravity. We want to calculate the minimum a required, so take static friction to have its maximum value, $f_s = \mu_s n$.

SET UP: The free-body diagram for the block is given in Figure 5.95.



EXECUTE:
$\Sigma F_x = ma_x$
$n = ma$
$f_s = \mu_s n = \mu_s ma$

Figure 5.95

$\Sigma F_y = ma_y$: $f_s - mg = 0$
$\mu_s ma = mg$, so $a = g/\mu_s$.

EVALUATE: An observer on the cart sees the block pinned there, with no reason for a horizontal force on it because the block is at rest relative to the cart. Therefore, such an observer concludes that $n = 0$ and thus $f_s = 0$, and he doesn't understand what holds the block up against the downward force of gravity. The reason for this difficulty is that $\Sigma\vec{F} = m\vec{a}$ does not apply in a coordinate frame attached to the cart. This reference frame is accelerated, and hence not inertial. The smaller μ_s is, the larger *a* must be to keep the block pinned against the front of the cart.

5.96. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each block.
SET UP: Use coordinates where $+x$ is directed down the incline.
EXECUTE: **(a)** Since the larger block (the trailing block) has the larger coefficient of friction, it will need to be pulled down the plane; i.e., the larger block will not move faster than the smaller block, and the blocks will have the same acceleration. For the smaller block, $(4.00\text{ kg})g(\sin 30° - (0.25)\cos 30°) - T = (4.00\text{ kg})a$, or $11.11\text{ N} - T = (4.00\text{ kg})a$, and similarly for the larger, $15.44\text{ N} + T = (8.00\text{ kg})a$. Adding these two relations, $26.55\text{ N} = (12.00\text{ kg})a$, $a = 2.21\text{ m/s}^2$.
(b) Substitution into either of the above relations gives $T = 2.27\text{ N}$.
(c) The string will be slack. The 4.00-kg block will have $a = 2.78\text{ m/s}^2$ and the 8.00-kg block will have $a = 1.93\text{ m/s}^2$, until the 4.00-kg block overtakes the 8.00-kg block and collides with it.
EVALUATE: If the string is cut the acceleration of each block will be independent of the mass of that block and will depend only on the slope angle and the coefficient of kinetic friction. The 8.00-kg block would have a smaller acceleration even though it has a larger mass, since it has a larger μ_k.

5.97. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the block and to the plank.
SET UP: Both objects have $a = 0$.
EXECUTE: Let n_B be the normal force between the plank and the block and n_A be the normal force between the block and the incline. Then, $n_B = w\cos\theta$ and $n_A = n_B + 3w\cos\theta = 4w\cos\theta$. The net frictional force on the block is $\mu_k(n_A + n_B) = \mu_k 5w\cos\theta$. To move at constant speed, this must balance the component of the block's weight along the incline, so $3w\sin\theta = \mu_k 5w\cos\theta$, and $\mu_k = \frac{3}{5}\tan\theta = \frac{3}{5}\tan 37° = 0.452$.
EVALUATE: In the absence of the plank the block slides down at constant speed when the slope angle and coefficient of friction are related by $\tan\theta = \mu_k$. For $\theta = 36.9°$, $\mu_k = 0.75$. A smaller μ_k is needed when the plank is present because the plank provides an additional friction force.

5.98. **IDENTIFY:** Apply Newton's second law to Jack in the Ferris wheel.
SET UP: $\Sigma\vec{F} = m\vec{a}$ and Jack's acceleration is $a_{rad} = v^2/R$, and $v = 2\pi R/T$. At the highest point, the normal force that the chair exerts on Jack is ¼ of his weight, or $0.25mg$. Take $+y$ downward.

EXECUTE: $\Sigma F_y = ma_y$ gives $mg - n = mv^2/R$. $mg - 0.25mg = mv^2/R$, so $v^2/R = 0.75g$. Using $T = 2\pi R/T$, we get $v^2/R = 4\pi^2 R/T^2$. Therefore $4\pi^2 R/T^2 = 0.750g$. $T = 1/(0.100 \text{ rev/s}) = 10.0$ s/rev, so $R = (0.750g)T^2/(4\pi^2) = (0.750)(9.80 \text{ m/s}^2)[(10.0 \text{ s})/(2\pi)]^2 = 18.6$ m.

EVALUATE: This Ferris wheel would be about 120 ft in diameter, which is certainly large but not impossible.

5.99. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the person. The person moves in a horizontal circle so his acceleration is $a_{\text{rad}} = v^2/R$, directed toward the center of the circle. The target variable is the coefficient of static friction between the person and the surface of the cylinder.

$$v = (0.60 \text{ rev/s})\left(\frac{2\pi R}{1 \text{ rev}}\right) = (0.60 \text{ rev/s})\left(\frac{2\pi(2.5 \text{ m})}{1 \text{ rev}}\right) = 9.425 \text{ m/s}$$

(a) SET UP: The problem situation is sketched in Figure 5.99a.

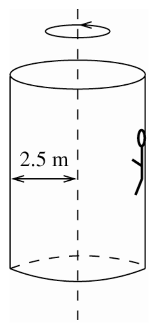


Figure 5.99a

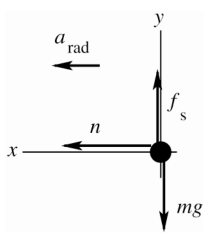

The free-body diagram for the person is sketched in Figure 5.99b.
The person is held up against gravity by the static friction force exerted on him by the wall. The acceleration of the person is a_{rad}, directed in toward the axis of rotation.

Figure 5.99b

(b) EXECUTE: To calculate the minimum μ_s required, take f_s to have its maximum value, $f_s = \mu_s n$.

$\Sigma F_y = ma_y$: $f_s - mg = 0$

$\mu_s n = mg$

$\Sigma F_x = ma_x$: $n = mv^2/R$

Combine these two equations to eliminate n: $\mu_s mv^2/R = mg$

$$\mu_s = \frac{Rg}{v^2} = \frac{(2.5 \text{ m})(9.80 \text{ m/s}^2)}{(9.425 \text{ m/s})^2} = 0.28$$

(c) EVALUATE: No, the mass of the person divided out of the equation for μ_s. Also, the smaller μ_s is, the larger v must be to keep the person from sliding down. For smaller μ_s the cylinder must rotate faster to make n large enough.

5.100. IDENTIFY: The ice is traveling in a circular arc, so Newton's second law applies to it. The radial acceleration is toward the center of the circle, which is downward at the top of the arc.

SET UP: $\sum F = m\dfrac{v^2}{R}$.

EXECUTE: At the top of the arc $\sum F = m\dfrac{v^2}{R}$ gives $mg - n = mv^2/R$. Using $n = mg/2$ gives

$mg - mg/2 = mv^2/R \quad \rightarrow \quad v = \sqrt{\dfrac{Rg}{2}}$.

EVALUATE: The smallest the normal force could be is zero, in which case $v = \sqrt{Rg}$, which is greater than our result. So our answer is reasonable.

5.101. IDENTIFY: The race car is accelerated toward the center of the circle of the curve. If the car goes at the proper speed for the banking angle, there will be no friction force on it, and will not tend to slide either up or down the road. In this case, it is going faster than the proper speed, so it will tend to slide up the road, so the friction force will be down the road. Newton's second law applies to the car.
SET UP: At the maximum speed so the car will not slide up the road, static friction from the road on the tires is at its maximum value, so $f_s = \mu_s n$ and its direction is down the road. Fig. 5.101 shows a free-body diagram of the car. Call the $+x$-axis horizontal pointing toward the center of the circular curve, and the y-axis perpendicular to the road surface. This is one of the few times that it is better *not* to take the x-axis parallel to the surface of the incline. The reason is that the acceleration is horizontal, not parallel to the surface. Apply $\sum F_x = ma_x$ and $\sum F_y = 0$ letting β be the banking angle.

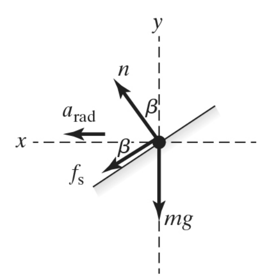

Figure 5.101

EXECUTE: **(a)** Start with $\sum F_x = ma_{rad}$. From the free-body diagram, we see that
$\sum F_x = n \sin\beta + f_s \cos\beta = n \sin\beta + \mu_s n \cos\beta$, so
$ma_{rad} = n(\sin\beta + \mu_s \cos\beta)$ (Eq. 1)
$\sum F_y = 0 = n \cos\beta - f_s \sin\beta - mg = n \cos\beta - \mu_s n \sin\beta - mg = 0$, which gives
$mg = n(\cos\beta - \mu_s \sin\beta)$ (Eq. 2)

Solving for n gives $n = \dfrac{mg}{\cos\beta - \mu_s \sin\beta} = \dfrac{(1200\text{ kg})(9.80\text{ m/s}^2)}{\cos 18.0° - (0.400)\sin 18.0°} = 1.42\times 10^4$ N.

(b) Divide Eq. 1 by Eq. 2, giving $a_{rad} = \left(\dfrac{\sin\beta + \mu_s \cos\beta}{\cos\beta - \mu_s \sin\beta}\right)g$. Using $\beta = 18.0°$ and $\mu_s = 0.400$ gives $a_{rad} = 8.17\text{ m/s}^2$.

(c) $a_{rad} = v^2/R$, so $v = \sqrt{Ra_{rad}} = \sqrt{(90.0\text{ m})(8.17\text{ m/s}^2)} = 27.1$ m/s.

EVALUATE: Check our result in (b) for a very smooth road in which $\mu_s = 0$. This gives $a_{rad} = g\tan\beta$, so $\frac{v^2}{R} = g\tan\beta$, or $\tan\beta = \frac{v^2}{Rg}$. This result give the familiar angle for a properly banked road for speed v. If there were no friction, a car would have to go at the proper speed to avoid slipping. So our result in this special case checks out. The proper speed for $\beta = 18.0°$ should be $v = \sqrt{Rg\tan\beta} = \sqrt{(90.0\text{ m})(9.80\text{ m/s}^2)\tan 18.0°} = 16.9$ m/s, so the speed we just found is obviously much greater than the proper speed.

5.102. **IDENTIFY:** The race car is accelerated toward the center of the circle of the curve. If the car goes at the proper speed for the banking angle, there will be no friction force on it, and will not tend to slide either up or down the road. In this case, it is going slower than the proper speed, so it will tend to slide down the road, so the friction force will be up the road. Newton's second law applies to the car.

SET UP: At the maximum speed so the car will not slide down the road, static friction from the road on the tires is at its maximum value, so $f_S = \mu_s n$ and its direction is up the road. Figure 5.102 shows a free-body diagram of the car. Call the $+x$-axis horizontal pointing toward the center of the circular curve, and the y-axis perpendicular to the road surface. This is one of the few times that it is better *not* to take the x-axis parallel to the surface of the incline. The reason is that the acceleration is horizontal, not parallel to the surface. Apply $\sum F_x = ma_x$ and $\sum F_y = 0$ letting β be the banking angle.

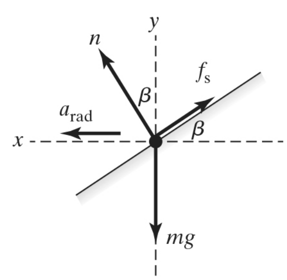

Figure 5.102

EXECUTE: **(a)** The procedure is the same as for problem 5.101 except that f_S is *up* the road surface instead of down. Using the same steps as in 5.101 leads to

$$\frac{mv^2}{R} = n(\sin\beta - \mu_s\cos\beta) \quad \text{(Eq. 1)}$$

$$n(\cos\beta + \mu_s\sin\beta) = mg \quad \text{(Eq. 2)}$$

Solving for n gives $n = \frac{mg}{\cos\beta + \mu_s\sin\beta} = \frac{(900\text{ kg})(9.80\text{ m/s}^2)}{\cos 18.0° + (0.300)\sin 18.0°} = 8450$ N.

(b) Combining Eq. 1 and Eq. 2 we get $v^2 = \left(\frac{\sin\beta - \mu_s\cos\beta}{\cos\beta + \mu_s\sin\beta}\right)Rg$. Using $\mu_s = 0.300$, $\beta = 18.0°$, and $R = 120.0$ m gives $v = 5.17$ m/s.

EVALUATE: The proper speed for a banking angle of 18.0° is given by $\tan\beta = \frac{v^2}{Rg}$, so the proper speed for this angle is $v = \sqrt{Rg\tan\beta} = \sqrt{(120.0\text{ m})(9.80\text{ m/s}^2)\tan 18.0°} = 19.5$ m/s, so the speed we just found is much slower.

5.103. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each block.

SET UP: For block B use coordinates parallel and perpendicular to the incline. Since they are connected by ropes, blocks A and B also move with constant speed.

EXECUTE: **(a)** The free-body diagrams are sketched in Figure 5.103.

(b) The blocks move with constant speed, so there is no net force on block A; the tension in the rope connecting A and B must be equal to the frictional force on block A, $T_1 = (0.35)(25.0\text{ N}) = 8.8\text{ N}$.

(c) The weight of block C will be the tension in the rope connecting B and C; this is found by considering the forces on block B. The components of force along the ramp are the tension in the first rope (8.8 N, from part (b)), the component of the weight along the ramp, the friction on block B and the tension in the second rope. Thus, the weight of block C is

$$w_C = 8.8\text{ N} + w_B(\sin 36.9° + \mu_k \cos 36.9°) = 8.8\text{ N} + (25.0\text{ N})(\sin 36.9° + (0.35)\cos 36.9°) = 30.8\text{ N}$$

The intermediate calculation of the first tension may be avoided to obtain the answer in terms of the common weight w of blocks A and B, $w_C = w(\mu_k + (\sin\theta + \mu_k \cos\theta))$, giving the same result.

(d) Applying Newton's second law to the remaining masses (B and C) gives:

$$a = g(w_C - \mu_k w_B \cos\theta - w_B \sin\theta)/(w_B + w_C) = 1.54\text{ m/s}^2.$$

EVALUATE: Before the rope between A and B is cut the net external force on the system is zero. When the rope is cut the friction force on A is removed from the system and there is a net force on the system of blocks B and C.

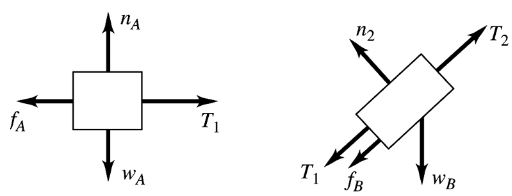

Figure 5.103

5.104. **IDENTIFY:** The block has acceleration $a_{\text{rad}} = v^2/r$, directed to the left in the figure in the problem. Apply $\Sigma\vec{F} = m\vec{a}$ to the block.

SET UP: The block moves in a horizontal circle of radius $r = \sqrt{(1.25\text{ m})^2 - (1.00\text{ m})^2} = 0.75\text{ m}$. Each string makes an angle θ with the vertical. $\cos\theta = \dfrac{1.00\text{ m}}{1.25\text{ m}}$, so $\theta = 36.9°$. The free-body diagram for the block is given in Figure 5.104. Let $+x$ be to the left and let $+y$ be upward.

EXECUTE: **(a)** $\Sigma F_y = ma_y$ gives $T_u \cos\theta - T_l \cos\theta - mg = 0$.

$$T_l = T_u - \frac{mg}{\cos\theta} = 80.0\text{ N} - \frac{(4.00\text{ kg})(9.80\text{ m/s}^2)}{\cos 36.9°} = 31.0\text{ N}.$$

(b) $\Sigma F_x = ma_x$ gives $(T_u + T_l)\sin\theta = m\dfrac{v^2}{r}$.

$v = \sqrt{\dfrac{r(T_u + T_l)\sin\theta}{m}} = \sqrt{\dfrac{(0.75\text{ m})(80.0\text{ N} + 31.0\text{ N})\sin 36.9°}{4.00\text{ kg}}} = 3.53\text{ m/s}.$ The number of revolutions per second is $\dfrac{v}{2\pi r} = \dfrac{3.53\text{ m/s}}{2\pi(0.75\text{ m})} = 0.749\text{ rev/s} = 44.9\text{ rev/min}.$

(c) If $T_l \to 0$, $T_u \cos\theta = mg$ and $T_u = \dfrac{mg}{\cos\theta} = \dfrac{(4.00\text{ kg})(9.80\text{ m/s}^2)}{\cos 36.9°} = 49.0\text{ N}$. $T_u \sin\theta = m\dfrac{v^2}{r}$.

$v = \sqrt{\dfrac{rT_u \sin\theta}{m}} = \sqrt{\dfrac{(0.75\text{ m})(49.0\text{ N})\sin 36.9°}{4.00\text{ kg}}} = 2.35\text{ m/s}$. The number of revolutions per minute is

$(44.9\text{ rev/min})\left(\dfrac{2.35\text{ m/s}}{3.53\text{ m/s}}\right) = 29.9\text{ rev/min}$.

EVALUATE: The tension in the upper string must be greater than the tension in the lower string so that together they produce an upward component of force that balances the weight of the block.

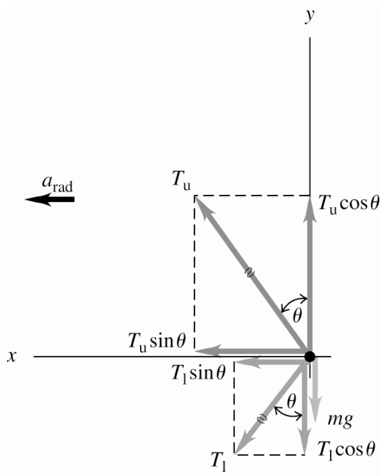

Figure 5.104

5.105. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$, with $f = kv$.

SET UP: Follow the analysis that leads to the equation $v_y = v_t[1 - e^{-(k/m)t}]$, except now the initial speed is $v_{0y} = 3mg/k = 3v_t$ rather than zero.

EXECUTE: The separated equation of motion has a lower limit of $3v_t$ instead of zero; specifically,

$$\int_{3v_t}^{v} \frac{dv}{v - v_t} = \ln\frac{v_t - v}{-2v_t} = \ln\left(\frac{v}{2v_t} - \frac{1}{2}\right) = -\frac{k}{m}t, \text{ or } v = 2v_t\left[\frac{1}{2} + e^{-(k/m)t}\right]$$

where $v_t = mg/k$.

EVALUATE: As $t \to \infty$ the speed approaches v_t. The speed is always greater than v_t and this limit is approached from above.

5.106. **IDENTIFY:** The box on the ramp slows down on the way up and speeds up on the way down. Newton's second law applies to both the upward and downward motion, but the acceleration will not be the same for both parts of the motion.

SET UP: On the way up, kinetic friction acts down the ramp, but on the way down it acts up the ramp. Yet gravity acts down the ramp in both cases. Therefore the acceleration will not be the same in both on the upward motion as on the downward motion. We must break this problem up into two segments: motion up the ramp and motion down the ramp. Fig. 5.106(a) shows a free-body diagram for the upward part of the motion. The free-body diagram for the downward segment is shown in Fig. 5.106(b). It is the same as for the upward motion except that friction acts up the ramp. We appy $\sum F_x = ma_x$ in both segments and use the constant-acceleration equations as needed. In both segments, the acceleration is down the ramp, so we call that the $+x$-axis in both parts. We use $\sum F_y = 0$ and $f_k = \mu_k n$ in both segments. At its highest point, the speed of the box is zero. We want to find μ_k in terms of α.

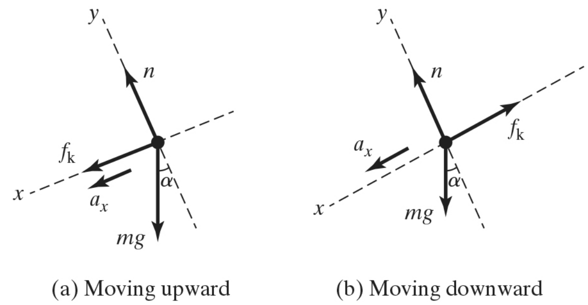

Figure 5.106

EXECUTE: First find the acceleration of the box on both segments of the motion. Call a_{up} the magnitude of the acceleration on the upward segment and a_{down} the magnitude of the acceleration on the downward segment.

Upward segment: Use $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ with $v = 0$ at the highest point. This gives $0 = v_0^2 + 2a_{up}(-d)$. Note that we used $-d$ because down the ramp is positive and the displacement d is up the ramp. This gives $a_{up} = v_0^2 / 2d$.

Downward segment: $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$ gives $\left(\dfrac{v_0}{2}\right)^2 = 0 + 2a_{down}d$. The displacement is down the ramp so we use $+d$ this time, so we get $a_{down} = v_0^2 / 8d$.

Now apply $\sum F_x = ma_x$ and $\sum F_y = 0$ for both segments. Referring to Fig. 5.106 shows us the components.

Upward segment: $\sum F_y = 0$ gives $n = mg\cos\alpha$

$\sum F_x = ma_x$ gives $mg\sin\alpha + f_k = ma_{up}$ $\rightarrow$ $mg\sin\alpha + \mu_k mg\cos\alpha = ma_{up} = mv_0^2 / 2d$. This simplifies to $g(\sin\alpha + \mu_k\cos\alpha) = \dfrac{v_0^2}{2d}$. (Eq. 1)

Downward segment: The normal force is the same as before, as is the magnitude of the friction force. But now the friction force acts *up* the ramp and $a_{down} = v_0^2 / 8d$. $\sum F_x = ma_x$ gives

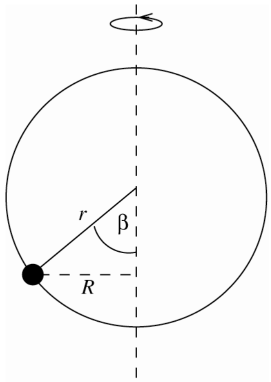
$g(\sin\alpha - \mu_k\cos\alpha) = \dfrac{v_0^2}{8d}$. (Eq. 2)

Combining Eq. 1 and Eq. 2 gives $\dfrac{\sin\alpha - \mu_k\cos\alpha}{\sin\alpha + \mu_k\cos\alpha} = \dfrac{1}{4}$, from which we get $\mu_k = \dfrac{3}{5}\tan\alpha.$

EVALUATE: We found the $a_{up} > a_{down}$. This is reasonable because on the upward segment both gravity and friction oppose the motion, whereas on the downward segment, friction still opposes the motion but gravity does not.

5.107. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the circular motion of the bead. Also use $a_{rad} = 4\pi^2R/T^2$ to relate a_{rad} to the period of rotation T.

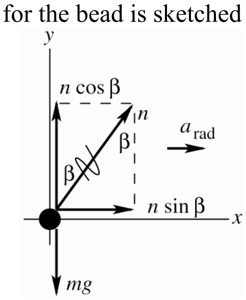
SET UP: The bead and hoop are sketched in Figure 5.107a.



The bead moves in a circle of radius $R = r\sin\beta$. The normal force exerted on the bead by the hoop is radially inward.

Figure 5.107a

The free-body diagram for the bead is sketched in Figure 5.107b.



EXECUTE:

$\Sigma F_y = ma_y$

$n\cos\beta - mg = 0$

$n = mg/\cos\beta$

$\Sigma F_x = ma_x$

$n\sin\beta = ma_{\text{rad}}$

Figure 5.107b

Combine these two equations to eliminate n:

$$\left(\frac{mg}{\cos\beta}\right)\sin\beta = ma_{\text{rad}}$$

$$\frac{\sin\beta}{\cos\beta} = \frac{a_{\text{rad}}}{g}$$

$a_{\text{rad}} = v^2/R$ and $v = 2\pi R/T$, so $a_{\text{rad}} = 4\pi^2 R/T^2$, where T is the time for one revolution.

$R = r\sin\beta$, so $a_{\text{rad}} = \dfrac{4\pi^2 r\sin\beta}{T^2}$

Use this in the above equation: $\dfrac{\sin\beta}{\cos\beta} = \dfrac{4\pi^2 r\sin\beta}{T^2 g}$

This equation is satisfied by $\sin\beta = 0$, so $\beta = 0$, or by $\dfrac{1}{\cos\beta} = \dfrac{4\pi^2 r}{T^2 g}$, which gives $\cos\beta = \dfrac{T^2 g}{4\pi^2 r}$.

(a) 4.00 rev/s implies $T = (1/4.00)\text{ s} = 0.250\text{ s}$

Then $\cos\beta = \dfrac{(0.250\text{ s})^2(9.80\text{ m/s}^2)}{4\pi^2(0.100\text{ m})}$ and $\beta = 81.1°$.

(b) This would mean $\beta = 90°$. But $\cos 90° = 0$, so this requires $T \to 0$. So β approaches $90°$ as the hoop rotates very fast, but $\beta = 90°$ is not possible.

(c) 1.00 rev/s implies $T = 1.00\text{ s}$

The $\cos\beta = \dfrac{T^2 g}{4\pi^2 r}$ equation then says $\cos\beta = \dfrac{(1.00\text{ s})^2(9.80\text{ m/s}^2)}{4\pi^2(0.100\text{ m})} = 2.48,$ which is not possible. The only way to have the $\Sigma\vec{F} = m\vec{a}$ equations satisfied is for $\sin\beta = 0.$ This means $\beta = 0;$ the bead sits at the bottom of the hoop.

EVALUATE: $\beta \rightarrow 90°$ as $T \rightarrow 0$ (hoop moves faster). The largest value T can have is given by $T^2 g/(4\pi^2 r) = 1$ so $T = 2\pi\sqrt{r/g} = 0.635$ s. This corresponds to a rotation rate of $(1/0.635)$ rev/s $= 1.58$ rev/s. For a rotation rate less than 1.58 rev/s, $\beta = 0$ is the only solution and the bead sits at the bottom of the hoop. Part (c) is an example of this.

5.108. IDENTIFY: Apply $\Sigma\vec{F} = m\vec{a}$ to the combined object of motorcycle plus rider.

SET UP: The object has acceleration $a_{\text{rad}} = v^2/r,$ directed toward the center of the circular path.

EXECUTE: **(a)** For the tires not to lose contact, there must be a downward force on the tires. Thus, the (downward) acceleration at the top of the sphere must exceed mg, so $m\dfrac{v^2}{R} > mg,$ and

$v > \sqrt{gR} = \sqrt{(9.80\text{ m/s}^2)(13.0\text{ m})} = 11.3\text{ m/s}.$

(b) The (upward) acceleration will then be $4g$, so the upward normal force must be $5mg = 5(110\text{ kg})(9.80\text{ m/s}^2) = 5390$ N.

EVALUATE: At any nonzero speed the normal force at the bottom of the path exceeds the weight of the object.

5.109. IDENTIFY: The block begins to move when static friction has reached its maximum value. After that, kinetic friction acts and the block accelerates, obeying Newton's second law.

SET UP: $\Sigma F_x = ma_x$ and $f_{s,max} = \mu_s n$, where n is the normal force (the weight of the block in this case).

EXECUTE: **(a) & (b)** $\Sigma F_x = ma_x$ gives $T - \mu_k mg = ma$. The graph with the problem shows the acceleration a of the block versus the tension T in the cord. So we solve the equation from Newton's second law for a versus T, giving $a = (1/m)T - \mu_k g$. Therefore the slope of the graph will be $1/m$ and the intercept with the vertical axis will be $-\mu_k g$. Using the information given in the problem for the best-fit equation, we have $1/m = 0.182\text{ kg}^{-1}$, so $m = 5.4945$ kg and $-\mu_k g = -2.842\text{ m/s}^2,$ so $\mu_k = 0.290$.

When the block is just ready to slip, we have $f_{s,max} = \mu_s n$, which gives $\mu_s = (20.0\text{ N})/[(5.4945\text{ kg})(9.80\text{ m/s}^2)] = 0.371$.

(c) On the Moon, g is less than on earth, but the mass m of the block would be the same as would μ_k. Therefore the slope $(1/m)$ would be the same, but the intercept $(-\mu_k g)$ would be less negative.

EVALUATE: Both coefficients of friction are reasonable for ordinary materials, so our results are believable.

5.110. IDENTIFY: Near the top of the hill the car is traveling in a circular arc, so it has radial acceleration and Newton's second law applies. We have measurements for the force the car exerts on the road at various speeds.

SET UP: The acceleration of the car is $a_{\text{rad}} = v^2/R$ and $\Sigma F_y = ma_y$ applies to the car. Let the $+y$-axis be downward, since that is the direction of the acceleration of the car.

EXECUTE: **(a)** Apply $\Sigma F_y = ma_y$ to the car at the top of the hill: $mg - n = mv^2/R$, where n is the force the road exerts on the car (which is the same as the force the car exerts on the road). Solving for n gives $n = mg - (m/R)v^2$. So if we plot n versus v^2, we should get a straight line having slope equal to $-m/R$ and intercept with the vertical axis at mg. We could make a table of v^2 and n using the given numbers given with the problem, or we could use graphing software. The resulting graph is shown in Figure 5.110.

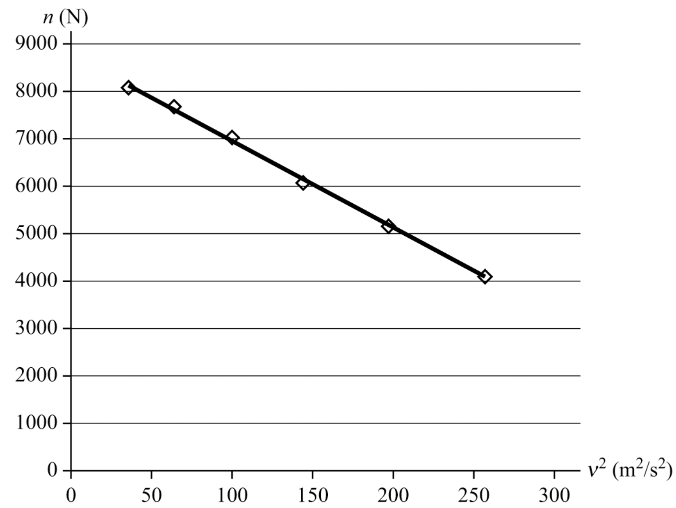


Figure 5.110

(b) The best-fit equation for the graph in Figure 5.110 is $n = [-18.12\text{ N/(m/s)}^2]v^2 + 8794\text{ N}$. Therefore $mg = 8794$ N, which gives $m = (8794\text{ N})/(9.80\text{ m/s}^2) = 897$ kg.
The slope is equal to $-m/R$, so $R = -m/\text{slope} = -(897\text{ kg})/[-18.12\text{ N/(m/s)}^2] = 49.5$ m.

(c) At the maximum speed, $n = 0$. Using $mg - n = mv^2/R$, this gives $v = \sqrt{gR} = \sqrt{(9.80\text{ m/s}^2)(49.5\text{ m})}$ = 22.0 m/s.

EVALUATE: We can double check (c) using our graph. Putting $n = 0$ into the best-fit equation, we get $v = \sqrt{(8794\text{ N})(18.14\text{ N}\cdot\text{s}^2/\text{m}^2)}$ = 22.0 m/s, which checks. Also 22 m/s is about 49 mph, which is not an unreasonabled speed on a hill.

5.111. **IDENTIFY:** A cable pulling parallel to the surface of a ramp accelerates 2170-kg metal blocks up a ramp that rises at 40.0° above the horizontal. Newton's second law applies to the blocks, and the constant-acceleration kinematics formulas can be used.

SET UP: Call the $+x$-axis parallel to the ramp surface pointing upward because that is the direction of the acceleration of the blocks, and let the y-axis be perpendicular to the surface. There is no acceleration in the y-direction. $\Sigma F_x = ma_x$, $f_k = \mu_k n$, and $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$.

EXECUTE: **(a)** First use $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ to find the acceleration of a block. Since $v_{0x} = 0$, we have $a_x = 2(x - x_0)/t^2 = 2(8.00\text{ m})/(4.20\text{ s})^2 = 0.9070\text{ m/s}^2$. The forces in the y-direction balance, so $n = mg\cos(40.0°)$, so $f_k = (0.350)(2170\text{ kg})(9.80\text{ m/s}^2)\cos(40.0°) = 5207$ N. Using $\Sigma F_x = ma_x$, we have $T - mg\sin(40.0°) - f_k = ma$. Solving for T gives $T = (2170\text{ kg})(9.80\text{ m/s}^2)\sin(40.0°) + 5207\text{ N} + (2170\text{ kg})(0.9070\text{ m/s}^2) = 2.13\times 10^4\text{ N} = 21.3$ kN.
From the table shown with the problem, this tension is greater than the safe load of a ½ inch diameter cable (which is 19.0 kN), so we need to use a 5/8-inch cable.

(b) We assume that the safe load (SL) is proportional to the cross-sectional area of the cable, which means that SL $\propto \pi(D/2)^2 \propto (\pi/4)D^2$, where D is the diameter of the cable. Therefore a graph of SL versus D^2 should give a straight line. We could use the data given in the table with the problem to make the graph by hand, or we could use graphing software. The resulting graph is shown in Figure 5.111 (next page). The best-fit line has a slope of 74.09 kN/in.^{2} and a y-intercept of 0.499 kN. For a cable of diameter $D = 9/16$ in., this equation gives SL = (74.09 kN/in.^{2})(9/16 in.)^2 + 0.499 kN = 23.9 kN.

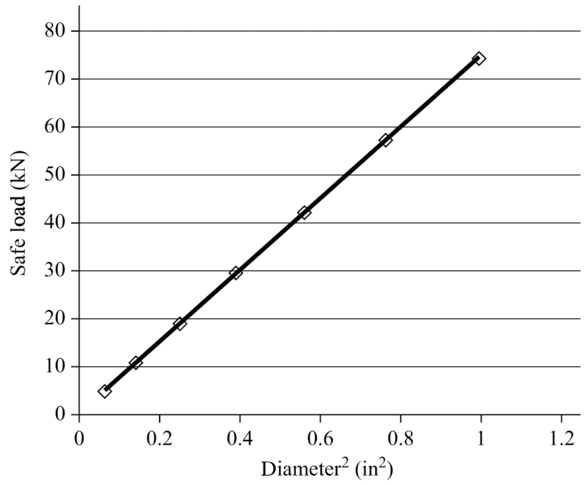

Figure 5.111

(c) The acceleration is now zero, so the forces along the surface balance, giving $T + f_s = mg\sin(40.0°)$. Using the numbers we get $T = 3.57$ kN.
(d) The tension at the top of the cable must accelerate the block and the cable below it, so the tension at the top would be larger. For a 5/8-inch cable, the mass per meter is 0.98 kg/m, so the 9.00-m long cable would have a mass of (0.98 kg/m)(9.00 m) = 8.8 kg. This is only 0.4% of the mass of the block, so neglecting the cable weight has little effect on accuracy.
EVALUATE: It is reasonable that the safe load of a cable is proportional to its cross-sectional area. If we think of the cable as consisting of many tiny strings each pulling, doubling the area would double the number of strings.

5.112. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the block and to the wedge.
SET UP: For both parts, take the x-direction to be horizontal and positive to the right, and the y-direction to be vertical and positive upward. The normal force between the block and the wedge is n; the normal force between the wedge and the horizontal surface will not enter, as the wedge is presumed to have zero vertical acceleration. The horizontal acceleration of the wedge is A, and the components of acceleration of the block are a_x and a_y.
EXECUTE: **(a)** The equations of motion are then $MA = -n\sin\alpha$, $ma_x = n\sin\alpha$ and $ma_y = n\cos\alpha - mg$. Note that the normal force gives the wedge a negative acceleration; the wedge is expected to move to the left. These are three equations in four unknowns, A, a_x, a_y and n. Solution is possible with the imposition of the relation between A, a_x and a_y. An observer on the wedge is not in an inertial frame, and should not apply Newton's laws, but the kinematic relation between the components of acceleration are not so restricted. To such an observer, the vertical acceleration of the block is a_y, but the horizontal acceleration of the block is $a_x - A$. To this observer, the block descends at an angle α, so the relation needed is $\dfrac{a_y}{a_x - A} = -\tan\alpha$. At this point, algebra is unavoidable. A possible approach is to eliminate a_x by noting that $a_x = -\dfrac{M}{m}A$, using this in the kinematic constraint to eliminate a_y and then eliminating n. The results are:

$$A = \frac{-gm}{(M+m)\tan\alpha + (M/\tan\alpha)}$$

$$a_x = \frac{gM}{(M+m)\tan\alpha + (M/\tan\alpha)}$$

$$a_y = \frac{-g(M+m)\tan\alpha}{(M+m)\tan\alpha + (M/\tan\alpha)}$$

(b) When $M \gg m$, $A \to 0$, as expected (the large block won't move). Also,

$a_x \to \dfrac{g}{\tan\alpha + (1/\tan\alpha)} = g\dfrac{\tan\alpha}{\tan^2\alpha + 1} = g\sin\alpha\cos\alpha$ which is the acceleration of the block ($g\sin\alpha$ in this case), with the factor of $\cos\alpha$ giving the horizontal component. Similarly, $a_y \to -g\sin^2\alpha$.

(c) The trajectory is a straight line with slope $-\left(\dfrac{M+m}{M}\right)\tan\alpha$.

EVALUATE: If $m \gg M$, our general results give $a_x = 0$ and $a_y = -g$. The massive block accelerates straight downward, as if it were in free fall.

5.113. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the block and to the wedge.

SET UP: From Problem 5.112, $ma_x = n\sin\alpha$ and $ma_y = n\cos\alpha - mg$ for the block. $a_y = 0$ gives $a_x = g\tan\alpha$.

EXECUTE: If the block is not to move vertically, both the block and the wedge have this horizontal acceleration and the applied force must be $F = (M+m)a = (M+m)g\tan\alpha$.

EVALUATE: $F \to 0$ as $\alpha \to 0$ and $F \to \infty$ as $\alpha \to 90°$.

5.114. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each of the three masses and to the pulley B.

SET UP: Take all accelerations to be positive downward. The equations of motion are straightforward, but the kinematic relations between the accelerations, and the resultant algebra, are not immediately obvious. If the acceleration of pulley B is a_B, then $a_B = -a_3$, and a_B is the average of the accelerations of masses 1 and 2, or $a_1 + a_2 = 2a_B = -2a_3$.

EXECUTE: **(a)** There can be no net force on the massless pulley B, so $T_C = 2T_A$. The five equations to be solved are then $m_1g - T_A = m_1a_1$, $m_2g - T_A = m_2a_2$, $m_3g - T_C = m_3a_3$, $a_1 + a_2 + 2a_3 = 0$ and $2T_A - T_C = 0$. These are five equations in five unknowns, and may be solved by standard means.

The accelerations a_1 and a_2 may be eliminated using $2a_3 = -(a_1 + a_2) = -[2g - T_A((1/m_1) + (1/m_2))]$.

The tension T_A may be eliminated by using $T_A = (1/2)T_C = (1/2)m_3(g - a_3)$.

Combining and solving for a_3 gives $a_3 = g\dfrac{-4m_1m_2 + m_2m_3 + m_1m_3}{4m_1m_2 + m_2m_3 + m_1m_3}$.

(b) The acceleration of the pulley B has the same magnitude as a_3 and is in the opposite direction.

(c) $a_1 = g - \dfrac{T_A}{m_1} = g - \dfrac{T_C}{2m_1} = g - \dfrac{m_3}{2m_1}(g - a_3)$. Substituting the above expression for a_3 gives

$a_1 = g\dfrac{4m_1m_2 - 3m_2m_3 + m_1m_3}{4m_1m_2 + m_2m_3 + m_1m_3}$.

(d) A similar analysis (or, interchanging the labels 1 and 2) gives $a_2 = g\dfrac{4m_1m_2 - 3m_1m_3 + m_2m_3}{4m_1m_2 + m_2m_3 + m_1m_3}$.

(e), **(f)** Once the accelerations are known, the tensions may be found by substitution into the appropriate equation of motion, giving $T_A = g\dfrac{4m_1m_2m_3}{4m_1m_2 + m_2m_3 + m_1m_3}$, $T_C = g\dfrac{8m_1m_2m_3}{4m_1m_2 + m_2m_3 + m_1m_3}$.

(g) If $m_1 = m_2 = m$ and $m_3 = 2m,$ all of the accelerations are zero, $T_C = 2mg$ and $T_A = mg.$ All masses and pulleys are in equilibrium, and the tensions are equal to the weights they support, which is what is expected.

EVALUATE: It is useful to consider special cases. For example, when $m_1 = m_2 \gg m_3$ our general result gives $a_1 = a_2 = +g$ and $a_3 = g.$

5.115. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the ball at each position.

SET UP: When the ball is at rest, $a = 0.$ When the ball is swinging in an arc it has acceleration component $a_{\text{rad}} = \dfrac{v^2}{R},$ directed inward.

EXECUTE: Before the horizontal string is cut, the ball is in equilibrium, and the vertical component of the tension force must balance the weight, so $T_A \cos\beta = w$ or $T_A = w/\cos\beta.$ At point *B*, the ball is not in equilibrium; its speed is instantaneously 0, so there is no radial acceleration, and the tension force must balance the radial component of the weight, so $T_B = w\cos\beta$ and the ratio $(T_B/T_A) = \cos^2\beta.$

EVALUATE: At point *B* the net force on the ball is not zero; the ball has a tangential acceleration.

5.116. **IDENTIFY:** The forces must balance for the person not to slip.

SET UP and EXECUTE: As was done in earlier problems, balancing forces parallel to and perpendicular to the surface of the rock leads to the equation $\mu_s = \tan\theta = 1.2$, so $\theta = 50°$, which is choice (b).

EVALUATE: The condition $\mu_s = \tan\theta$ applies only when the person is just ready to slip, which would be the case at the maximum angle.

5.117. **IDENTIFY:** Friction changes from static friction to kinetic friction.

SET UP and EXECUTE: When she slipped, static friction must have been at its maximum value, and that was enough to support her weight just before she slipped. But the kinetic friction will be less than the maximum static friction, so the kinetic friction force will not be enough to balance her weight down the incline. Therefore she will slide down the surface and continue to accelerate downward, making (b) the correct choice.

EVALUATE: Shoes with a greater coefficient of static friction would enable her to walk more safely.

5.118. **IDENTIFY:** The person pushes off horizontally and acclerates herself, so Newton's second law applies.

SET UP and EXECUTE: She runs horizontally, so her vertical acceleration is zero, which makes the normal force *n* due to the ground equal to her weight *mg*. In the horizontal direction, static friction accelerates her forward, and it must be its maximum value to achieve her maximum acceleration. Therefore $f_s = ma = \mu_s n = \mu_s mg$, which gives $a = \mu_s g = 1.2g$, making (d) the correct choice.

EVALUATE: Shoes with more friction would allow her to accelerate even faster.

6

WORK AND KINETIC ENERGY

VP6.2.1. **IDENTIFY:** This problem requires the calculation of work knowing the components of the force and displacement vectors.

SET UP: $W = \vec{F} \cdot \vec{S}$, which in terms of components is $W = F_x s_x + F_y s_y$.

EXECUTE: **(a)** $W = F_x s_x + F_y s_y = (126 \text{ N})(3.00 \text{ m}) + (168 \text{ N})(-6.50 \text{ m}) = -714 \text{ J}$

(b) The football player's force is equal and opposite to that of the opponent, but his displacement is the same, so the work he does is the negative of the work done by his opponent. $W = -(-714 \text{ J}) = +714 \text{ J}$.

EVALUATE: As we see in this problem, negative work definitely has physical meaning.

VP6.2.2. **IDENTIFY:** This problem requires a calculation using work. We know the work, force, and displacement and want to find the angle between the force and displacement vectors.

SET UP: To find the angle, we write work in the form $W = \vec{F} \cdot \vec{S} = Fs \cos\phi$.

EXECUTE: $W = Fs \cos\phi \quad \rightarrow \quad 1.47 \times 10^3 \text{ J} = (215 \text{ N})(8.40 \text{ m}) \cos\phi \quad \rightarrow \quad \phi = 35.5°$.

EVALUATE: The angle ϕ is less then 90°, so the work should be positive, which it is.

VP6.2.3. **IDENTIFY:** This problem requires the calculation of work for three forces knowing the magnitudes of the forces and displacements and the angles between them. Work is a scalar quantity, so the total work is the algebraic sum of the individual works.

SET UP: Use $W = Fs \cos\phi$ in each case. Then find the sum of the works.

EXECUTE: **(a)** The friction force is along the surface of the ramp but in the opposite direction from the displacement, so $\phi = 180°$. Thus

$W_f = f_k s \cos\phi° = (30.0 \text{ N})(3.00 \text{ m}) \cos 180° = -90.0 \text{ J}$.

(b) Gravity acts downward and the displacement is along the ramp surface, so $\phi = 62.0°$. Thus $W_g = mgs \cos 62.0° = (15.0 \text{ kg})(9.80 \text{ m/s}^2)(3.00 \text{ m}) \cos 62.0° = 207 \text{ J}$.

(c) The normal force is perpendicular to the displacment, so $\phi = 90°$ and $\cos\phi = 0$, so the normal force does no work.

(d) $W_{tot} = W_f + W_g + W_n = -90.0 \text{ J} + 207 \text{ J} + 0 = 117 \text{ J}$.

EVALUATE: The work is positive because the gravitational force along the ramp is greater than the friction, so the net force does positive work and the displacement is down the ramp.

VP6.2.4. **IDENTIFY:** We want to calculate work using the components of the force and displacement.

SET UP: Since we know the components, we use $W = F_x s_x + F_y s_y$.

EXECUTE: **(a)** $W_1 = F_0(2d) = 2F_0 d$, $W_2 = (-3F_0)d = -3F_0 d$, $W_3 = (-4F_0)(2d) + Gd = -8F_0 d + Gd$.

(b) $W_{tot} = 2F_0 d + (-3F_0 d) + (-8F_0 d + Gd) = 0 \quad \rightarrow \quad G = 9F_0$.

EVALUATE: The equation $W = Fs \cos\phi$ is still correct, but it would not allow us to easily calculate the work for these forces.

VP6.4.1. **IDENTIFY:** This problem requires the work-energy theorem. As the cylinder falls, work is done on it by gravity and friction. This work changes its kinetic energy.

SET UP: $W_{\text{tot}} = \Delta K = K_2 - K_1$, where $K = \frac{1}{2}mv^2$. The work is $W = Fs\cos\phi$. Figure VP6.4.1 illustrates the arrangement.

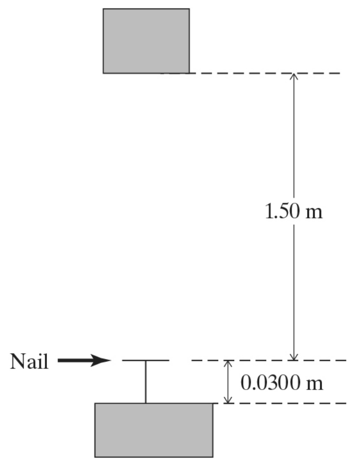

Figure VP6.4.1

EXECUTE: **(a)** Call point 1 where the cylinder is first released, and point 2 where it is just about to hit the nail. $W_g = mgs$ and $W_f = -fs$, so $W_{\text{tot}} = mgs - fs$. $K_1 = 0$ and $K_2 = \frac{1}{2}mv^2$. The work-energy theorem gives $mgs - fs = \frac{1}{2}mv^2$. Using $s = 1.50$ m, $f = 16.0$ N, $m = 20.0$ kg gives $v = 5.20$ m/s.

(b) Now we want to know about the force the cylinder exerts on the nail while hammering it in. Therefore we choose point 1 to be the instant just as the cylinder strikes the nail (that was point 2 in part (a)) and point 2 to be the instant when the nail has first stopped. As the cylinder pushes in the nail, it exerts a force F_N on the nail while pushing 0.0300 m into the block of wood. Likewise the other forces act for the same distance.

$W_{\text{tot}} = W_g + W_f + W_N = mgs - fs - F_N s$, $K_1 = \frac{1}{2}mv^2$ (using $v = 5.20$ m/s), $K_2 = 0$. The work-energy theorem gives $mgs - fs - f_N s = 0 - \frac{1}{2}mv^2$. Putting in the numbers, with $s = 0.0300$ m, gives $F_N = 9180$ N.

EVALUATE: The force in (a) is around a thousand pounds. From experience, we know that it takes a large force to hammer in a nail.

VP6.4.2. **IDENTIFY:** This problem requires the work-energy theorem. Gravity and the tension in the rope do work on the crate.

SET UP: $W_{\text{tot}} = \Delta K = K_2 - K_1$, where $K = \frac{1}{2}mv^2$. The work is $W = Fs\cos\phi$. Call point 1 when you just increase the tension to 175 N and point 2 just after you have lifted it the additional 1.25 m.

EXECUTE: **(a)** $W_T = Ts = (175\text{ N})(1.25\text{ m}) = 219$ J.

(b) $W_g = mgs\cos\phi = (14.5\text{ kg})(9.80\text{ m/s}^2)(1.25\text{ m})\cos 180° = -178$ J

(c) $F_{\text{net}} = T - mg$, so $W_{\text{tot}} = F_{\text{net}}s = (T - mg)s = W_T + W_g = 219\text{ J} - 178\text{ J} = 41$ J.

(d) $W_{tot} = K_2 - K_1 = K_2 - \frac{1}{2}mv_1^2$. Solving for K_2 gives $K_2 = W_{tot} + \frac{1}{2}mv_1^2$, so we get

$K_2 = 41\text{ J} + \frac{1}{2}(14.5\text{ kg})(0.500\text{ m/s})^2 = 43\text{ J} = \frac{1}{2}mv_2^2 = \frac{1}{2}(14.5\text{ kg})\,v_2^2 \rightarrow v_2 = 2.4\text{ m/s}$.

EVALUATE: The tension does positive work and therefore increases the crate's kinetic energy.

VP6.4.3. **IDENTIFY:** This problem requires the work-energy theorem. Gravity and the thrust of the engine do work on the helicopter.

SET UP: $W_{tot} = \Delta K = K_2 - K_1$, where $K = \frac{1}{2}mv^2$. The work is $W = Fs\cos\phi$. Call point 1 when the pilot just increases the thrust and point 2 just as the speed has decreased to 0.450 m/s.

EXECUTE: **(a)** $K_1 = \frac{1}{2}mv_1^2 = \frac{1}{2}(1400\text{ kg})(3.00\text{ m/s})^2 = 6300\text{ J}$.

$K_2 = \frac{1}{2}mv_2^2 = \frac{1}{2}(1400\text{ kg})(0.450\text{ m/s})^2 = 142\text{ J}$.

(b) $W_{tot} = K_2 - K_1 = 142\text{ J} - 6300\text{ J} = -6160\text{ J}$

$W_g = mg\Delta y = (1400\text{ kg})(9.80\text{ m/s}^2)(2.00\text{ m}) = 27{,}400\text{ J}$

$W_{tot} = W_{thrust} + W_g \rightarrow -6160\text{ J} = W_{thrust} + 27{,}400\text{ J} \rightarrow W_{thrust} = -3.36\times10^4\text{ J}$.

(c) $W_{thrust} = F_{thrust}s\cos\phi \rightarrow -3.36\times10^4\text{ J} = F_{thrust}(2.00\text{ m})\cos 180° \rightarrow F_{thrust} = 1.68\times10^4\text{ N}$.

EVALUATE: The magnitude of the thrust force is around ten times as great as the force of gravity, so the net work is negative in order to slow down the helicopter.

VP6.4.4. **IDENTIFY:** This problem requires the work-energy theorem.

SET UP: $W_{tot} = \Delta K = K_2 - K_1$, where $K = \frac{1}{2}mv^2$. The work is $W = Fs\cos\phi$. Call point 1 the point where the block is released and point 2 the bottom of the ramp. Let d be the distance it moves along the surface of the ramp. We also use $\sum F_y = 0$.

EXECUTE: **(a)** See Fig. VP6.4.4. $W_g = mgd\cos\phi = mgd\sin\theta$.

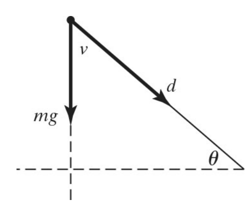

Figure VP6.4.4

(b) $W_f = f_k d\cos 180° = -f_k d = -\mu_k n$. Using $\sum F_y = 0$, where the y-axis is perpendicular to the face of the ramp, gives $n = mg\cos\theta$, so $W_f = -\mu_k mgd\cos\theta$.

(c) $W_{tot} = K_2 - K_1 = W_g + W_f + W_n$. $W_n = 0$ and $K_1 = 0$, so we get

$mgd\sin\theta - \mu_k mgd\cos\theta = \frac{1}{2}mv_2^2 \rightarrow v_2 = \sqrt{2gd(\sin\theta - \mu_k\cos\theta)}$.

EVALUATE: To check our result, let $\mu_k = 0$ for a frictionless surface. In that case, our result reduces to $v = \sqrt{2gd\sin\theta} = \sqrt{2gh}$. From our study of free-fall, we know that an object falling a distance h from rest has speed $v = \sqrt{2gh}$, which agrees with our result in this special case.

VP6.8.1. **IDENTIFY:** This problem requires the work-energy theorem and involves the work done by a spring.

SET UP: $W_{tot} = K_2 - K_1$, where $K = \frac{1}{2}mv^2$. The work is $W = Fs\cos\phi$, and the work done to compress a spring is $W = \frac{1}{2}kx^2$. Call point 1 the point just before the glider hits the spring and point 2 to be at maximum compression of the spring.

EXECUTE: **(a)** $W_{tot} = K_2 - K_1$. The final kinetic energy is zero and the work done by the spring on the glider is $-\frac{1}{2}kd^2$, so we get $-\frac{1}{2}kd^2 = -\frac{1}{2}mv_1^2$, which gives

$(30.0\text{ N/m})d^2 = (0.150\text{ kg})(1.25\text{ m/s})^2 \quad \rightarrow \quad d = 0.0884\text{ m} = 8.84\text{ cm}$.

(b) Both friction and the spring oppose the glider's motion and therefore do negative work on the glider. The work done by the spring is still $-\frac{1}{2}kd^2$, but d is now different. The work done by kinetic friction is $W_f = -f_k d = -\mu_k mgd$. So the work-energy theorem gives

$-\frac{1}{2}kd^2 - \mu_k mgd = 0 - \frac{1}{2}mv_1^2$. Putting in the numbers and simplifying gives

$(30.0\text{ N/m})d^2 + 2(0.320)(0.150\text{ kg})(9.80\text{ m/s}^2)d - (0.150\text{ kg})(1.25\text{ m/s})^2 = 0$. The quadratic formula gives two solutions (one positive and one negative), but we need the positive root, which is $d = 0.0741$ m = 7.41 cm.

EVALUATE: With no friction, the glider traveled 8.84 cm, but with friction it traveled only 7.41 cm. This is reasonable since both friction and the spring slowed down the glider in the case with friction.

VP6.8.2. **IDENTIFY:** This problem requires the work-energy theorem and involves the work done by a spring.

SET UP: $W_{tot} = K_2 - K_1$, where $K = \frac{1}{2}mv^2$. The work is $W = Fs\cos\phi$, and the work done to compress a spring is $W = \frac{1}{2}kx^2$. Call point 1 the point just before the glider hits the spring and point 2 to be at maximum compression of the spring.

EXECUTE: $W_{tot} = K_2 - K_1$. The final kinetic energy is zero and the work done by the spring on the glider is $-\frac{1}{2}kd^2$. The work done by kinetic friction is $W_f = -f_k d = -\mu_k mgd$. So the work-energy theorem gives so the work-energy theorem gives $-\frac{1}{2}kd^2 - \mu_k mgd = 0 - \frac{1}{2}mv_1^2$. Solving for μ_k gives

$\mu_k = \dfrac{mv_1^2 - kd^2}{2mgd}$.

EVALUATE: Checking units shows that $\dfrac{mv_1^2 - kd^2}{2mgd}$ is dimensionless, which is correct for a coefficient of friction.

VP6.8.3. **IDENTIFY:** This problem involves the work done on the bob of a swinging pendulum.

SET UP: $W = Fs\cos\phi$. Let L be the length of the string and θ the angle it makes with the vertical.

EXECUTE: **(a)** $W_g = mg\,\Delta y = mgL(1 - \cos\theta)$

$W_g = (0.500\text{ kg})(9.80\text{ m/s}^2)(0.750\text{ m})(1 - \cos 35.0°) = 0.665$ J.

(b) $W_g = mg\,\Delta y$ where Δy is negative, so $W_g = -0.665$ J.

(c) $W_{tot} = W_{AB} + W_{BC} = 0.665\text{ J} - 0.665\text{ J} = 0$.

EVALUATE: The total work is zero because gravity does positive work as the bob is moving downward and negative work as it is moving upward.

VP6.8.4. **IDENTIFY:** This problem requires application of the work-energy theorem to a pendulum.

SET UP: $W_{tot} = K_2 - K_1$, where $K = \frac{1}{2}mv^2$, and work is $W = Fs\cos\phi$. Call point 1 the highest point in its swing point 2 the lowest point.

EXECUTE: The tension in the silk strand does zero work because the tension is perpendicular to the path of the spider, so only gravity does work. $K_1 = 0$ and $K_2 = \frac{1}{2}mv^2$. Therefore

$$mgL(1 - \cos\theta) = \frac{1}{2}mv^2 \qquad \rightarrow \qquad v = \sqrt{2gL(1-\cos\theta)}.$$

EVALUATE: Using our result, we see that as θ approaches 90°, $\cos\theta$ approaches zero, so v gets larger and larger. This is reasonable because the spider starts swinging from a higher and higher elevation.

6.1. **IDENTIFY** and **SET UP:** For parts (a) through (d), identify the appropriate value of ϕ and use the relation $W = F_P s = (F\cos\phi)s$. In part (e), apply the relation $W_{\text{net}} = W_{\text{student}} + W_{\text{grav}} + W_n + W_f$.

EXECUTE: **(a)** Since you are applying a horizontal force, $\phi = 0°$. Thus,

$W_{\text{student}} = (2.40\text{ N})(\cos 0°)(1.50\text{ m}) = 3.60\text{ J}.$

(b) The friction force acts in the horizontal direction, opposite to the motion, so $\phi = 180°$.

$W_f = (F_f\cos\phi)s = (0.600\text{ N})(\cos 180°)(1.50\text{ m}) = -0.900\text{ J}.$

(c) Since the normal force acts upward and perpendicular to the tabletop, $\phi = 90°$.

$W_n = (n\cos\phi)s = (ns)(\cos 90°) = 0.0\text{ J}.$

(d) Since gravity acts downward and perpendicular to the tabletop, $\phi = 270°$.

$W_{\text{grav}} = (mg\cos\phi)s = (mgs)(\cos 270°) = 0.0\text{ J}.$

(e) $W_{\text{net}} = W_{\text{student}} + W_{\text{grav}} + W_n + W_f = 3.60\text{ J} + 0.0\text{ J} + 0.0\text{ J} - 0.900\text{ J} = 2.70\text{ J}.$

EVALUATE: Whenever a force acts perpendicular to the direction of motion, its contribution to the net work is zero.

6.2. **IDENTIFY:** In each case the forces are constant and the displacement is along a straight line, so $W = Fs\cos\phi$.

SET UP: In part **(a)**, when the cable pulls horizontally $\phi = 0°$ and when it pulls at 35.0° above the horizontal $\phi = 35.0°$. In part **(b)**, if the cable pulls horizontally $\phi = 180°$. If the cable pulls on the car at 35.0° above the horizontal it pulls on the truck at 35.0° below the horizontal and ϕ 145.0°. For the gravity force $\phi = 90°$, since the force is vertical and the displacement is horizontal.

EXECUTE: **(a)** When the cable is horizontal, $W = (1350\text{ N})(5.00\times 10^3\text{ m})\cos 0° = 6.75\times 10^6\text{ J}$. When the cable is 35.0° above the horizontal, $W = (1350\text{ N})(5.00\times 10^3\text{ m})\cos 35.0° = 5.53\times 10^6\text{ J}$.

(b) $\cos 180° = -\cos 0°$ and $\cos 145.0° = -\cos 35.0°$, so the answers are -6.75×10^6 J and -5.53×10^6 J.

(c) Since $\cos\phi = \cos 90° = 0$, $W = 0$ in both cases.

EVALUATE: If the car and truck are taken together as the system, the tension in the cable does no net work.

6.3. **IDENTIFY:** Each force can be used in the relation $W = F_{\parallel}s = (F\cos\phi)s$ for parts (b) through (d). For part (e), apply the net work relation as $W_{\text{net}} = W_{\text{worker}} + W_{\text{grav}} + W_n + W_f$.

SET UP: In order to move the crate at constant velocity, the worker must apply a force that equals the force of friction, $F_{\text{worker}} = f_k = \mu_k n$.

EXECUTE: **(a)** The magnitude of the force the worker must apply is:

$$F_{\text{worker}} = f_k = \mu_k n = \mu_k mg = (0.25)(30.0\text{ kg})(9.80\text{ m/s}^2) = 74\text{ N}$$

(b) Since the force applied by the worker is horizontal and in the direction of the displacement, $\phi = 0°$ and the work is:

$$W_{\text{worker}} = (F_{\text{worker}} \cos\phi)s = [(74 \text{ N})(\cos 0°)](4.5 \text{ m}) = +333 \text{ J}$$

(c) Friction acts in the direction opposite of motion, thus $\phi = 180°$ and the work of friction is:

$$W_f = (f_k \cos\phi)s = [(74 \text{ N})(\cos 180°)](4.5 \text{ m}) = -333 \text{ J}$$

(d) Both gravity and the normal force act perpendicular to the direction of displacement. Thus, neither force does any work on the crate and $W_{\text{grav}} = W_n = 0.0$ J.

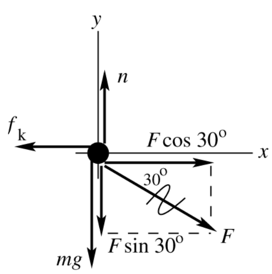
(e) Substituting into the net work relation, the net work done on the crate is:

$$W_{\text{net}} = W_{\text{worker}} + W_{\text{grav}} + W_n + W_f = +333 \text{ J} + 0.0 \text{ J} + 0.0 \text{ J} - 333 \text{ J} = 0.0 \text{ J}$$

EVALUATE: The net work done on the crate is zero because the two contributing forces, F_{worker} and F_f, are equal in magnitude and opposite in direction.

6.4. IDENTIFY: The forces are constant so we can use $W = Fs\cos\phi$ to calculate the work. Constant speed implies $a = 0$. We must use $\Sigma\vec{F} = m\vec{a}$ applied to the crate to find the forces acting on it.

(a) SET UP: The free-body diagram for the crate is given in Figure 6.4.



EXECUTE: $\Sigma F_y = ma_y$

$n - mg - F\sin 30° = 0$

$n = mg + F\sin 30°$

$f_k = \mu_k n = \mu_k mg + F\mu_k \sin 30°$

Figure 6.4

$\Sigma F_x = ma_x$

$F\cos 30° - f_k = 0$

$F\cos 30° - \mu_k mg - \mu_k \sin 30° F = 0$

$$F = \frac{\mu_k mg}{\cos 30° - \mu_k \sin 30°} = \frac{0.25(30.0 \text{ kg})(9.80 \text{ m/s}^2)}{\cos 30° - (0.25)\sin 30°} = 99.2 \text{ N}$$

(b) $W_F = (F\cos\phi)s = (99.2 \text{ N})(\cos 30°)(4.5 \text{ m}) = 387$ J

($F\cos 30°$ is the horizontal component of $\vec{F}$; the work done by $\vec{F}$ is the displacement times the component of $\vec{F}$ in the direction of the displacement.)

(c) We have an expression for f_k from part (a):

$$f_k = \mu_k(mg + F\sin 30°) = (0.250)[(30.0 \text{ kg})(9.80 \text{ m/s}^2) + (99.2 \text{ N})(\sin 30°)] = 85.9 \text{ N}$$

$\phi = 180°$ since f_k is opposite to the displacement. Thus

$W_f = (f_k \cos\phi)s = (85.9 \text{ N})(\cos 180°)(4.5 \text{ m}) = -387$ J.

(d) The normal force is perpendicular to the displacement so $\phi = 90°$ and $W_n = 0$. The gravity force (the weight) is perpendicular to the displacement so $\phi = 90°$ and $W_w = 0$.

(e) $W_{\text{tot}} = W_F + W_f + W_n + W_w = +387 \text{ J} + (-387 \text{ J}) = 0$

EVALUATE: Forces with a component in the direction of the displacement do positive work, forces opposite to the displacement do negative work, and forces perpendicular to the displacement do zero work. The total work, obtained as the sum of the work done by each force, equals the work done by the net force. In this problem, $F_{\text{net}} = 0$ since $a = 0$ and $W_{\text{tot}} = 0,$ which agrees with the sum calculated in part (e).

6.5. **IDENTIFY:** The gravity force is constant and the displacement is along a straight line, so $W = Fs\cos\phi.$

SET UP: The displacement is upward along the ladder and the gravity force is downward, so $\phi = 180.0° - 30.0° = 150.0°.$ $w = mg = 735$ N.

EXECUTE: **(a)** $W = (735\text{ N})(2.75\text{ m})\cos150.0° = -1750$ J.

(b) No, the gravity force is independent of the motion of the painter.

EVALUATE: Gravity is downward and the vertical component of the displacement is upward, so the gravity force does negative work.

6.6. **IDENTIFY** and **SET UP:** $W_F = (F\cos\phi)s,$ since the forces are constant. We can calculate the total work by adding the work done by each force. The forces are sketched in Figure 6.6.

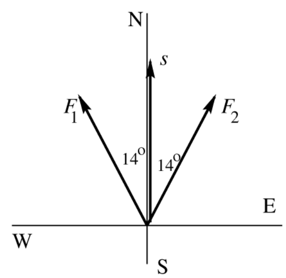


Figure 6.6

EXECUTE: $W_1 = F_1 s\cos\phi_1$

$W_1 = (1.80\times10^6\text{ N})(0.75\times10^3\text{ m})\cos14°$

$W_1 = 1.31\times10^9$ J

$W_2 = F_2 s\cos\phi_2 = W_1$

$W_{\text{tot}} = W_1 + W_2 = 2(1.31\times10^9\text{ J}) = 2.62\times10^9$ J

EVALUATE: Only the component $F\cos\phi$ of force in the direction of the displacement does work. These components are in the direction of $\vec{s}$ so the forces do positive work.

6.7. **IDENTIFY:** All forces are constant and each block moves in a straight line, so $W = Fs\cos\phi.$ The only direction the system can move at constant speed is for the 12.0 N block to descend and the 20.0 N block to move to the right.

SET UP: Since the 12.0 N block moves at constant speed, $a = 0$ for it and the tension T in the string is $T = 12.0$ N. Since the 20.0 N block moves to the right at constant speed, the friction force f_k on it is to the left and $f_k = T = 12.0$ N.

EXECUTE: **(a)** (i) $\phi = 0°$ and $W = (12.0\text{ N})(0.750\text{ m})\cos0° = 9.00$ J. (ii) $\phi = 180°$ and $W = (12.0\text{ N})(0.750\text{ m})\cos180° = -9.00$ J.

(b) (i) $\phi = 90°$ and $W = 0.$ (ii) $\phi = 0°$ and $W = (12.0\text{ N})(0.750\text{ m})\cos0° = 9.00$ J. (iii) $\phi = 180°$ and $W = (12.0\text{ N})(0.750\text{ m})\cos180° = -9.00$ J. (iv) $\phi = 90°$ and $W = 0.$

(c) $W_{\text{tot}} = 0$ for each block.

EVALUATE: For each block there are two forces that do work, and for each block the two forces do work of equal magnitude and opposite sign. When the force and displacement are in opposite directions, the work done is negative.

6.8. **IDENTIFY:** Apply $W = Fs\cos\phi$.

SET UP: $\hat{\boldsymbol{i}}\cdot\hat{\boldsymbol{i}} = \hat{\boldsymbol{j}}\cdot\hat{\boldsymbol{j}} = 1$ and $\hat{\boldsymbol{i}}\cdot\hat{\boldsymbol{j}} = \hat{\boldsymbol{j}}\cdot\hat{\boldsymbol{i}} = 0$

EXECUTE: The work you do is $\vec{F}\cdot\vec{s}=\left[(30\text{ N})\hat{\boldsymbol{i}}-(40\text{ N})\hat{\boldsymbol{j}}\right]\cdot\left[(-9.0\text{ m})\hat{\boldsymbol{i}}-(3.0\text{ m})\hat{\boldsymbol{j}}\right]$

$\vec{F}\cdot\vec{s}=(30\text{ N})(-9.0\text{ m})+(-40\text{ N})(-3.0\text{ m})=-270\text{ N}\cdot\text{m}+120\text{ N}\cdot\text{m}=-150\text{ J}.$

EVALUATE: The x-component of $\vec{F}$ does negative work and the y-component of $\vec{F}$ does positive work. The total work done by $\vec{F}$ is the sum of the work done by each of its components.

6.9. IDENTIFY: We want to compare the work done by friction over two different paths.
SET UP: Work is $W = Fs\cos\phi$. Call A the starting point and C the ending point for the first trip, and call B the end of the first segment of the second trip. On the first trip, $W_{AC} = -4.8$ J. We want to find the work done on the second trip, which is $W_{ABC} = W_{AB} + W_{BC}$. Call f_k the friction force, which is the same on all parts of the trips.
EXECUTE: $W_{AC} = -f_k s_{AC} = -f_k(0.500\text{ m})$. Likewise $W_{ABC} = W_{AB} + W_{BC}$ which gives $W_{ABC} = -f_k(0.300\text{ m}) - f_k(0.400\text{ m}) = -f_k(0.700\text{ m})$. Comparing the work in the two paths gives $\dfrac{W_{ABC}}{W_{AC}}=\dfrac{(-0.700\text{ m})f_k}{(-0.500\text{ m})f_k}=1.40$. So $W_{ABC} = 1.40W_{AC} = (1.40)(-4.8\text{ J}) = -6.7$ J.
EVALUATE: We found that friction does more work during the ABC path than during the AC path. This is reasonable because the force is the same but the distance is greater during the ABC path. Notice that the work done by friction between two points depends on the *path* taken between those points.

6.10. IDENTIFY and SET UP: Use $W = F_p s = (F\cos\phi)s$ to calculate the work done in each of parts (a) through (c). In part (d), the net work consists of the contributions due to all three forces, or $w_{\text{net}} = w_{\text{grav}} + w_{\text{n}} + w_{\text{f}}$.

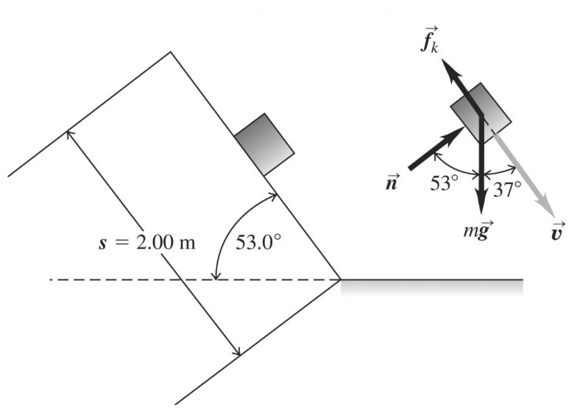

Figure 6.10

EXECUTE: **(a)** As the package slides, work is done by the frictional force which acts at $\phi = 180°$ to the displacement. The normal force is $mg\cos 53.0°$. Thus for $\mu_k = 0.40$,

$W_f = F_p s = (f_k\cos\phi)s = (\mu_k n\cos\phi)s = [\mu_k(mg\cos 53.0°)](\cos 180°)s.$

$W_f = (0.40)[(12.0\text{ kg})(9.80\text{ m/s}^2)(\cos 53.0°)](\cos 180°)(2.00\text{ m}) = -57\text{ J}.$

(b) Work is done by the component of the gravitational force parallel to the displacement. $\phi = 90° - 53° = 37°$ and the work of gravity is

$W_{\text{grav}} = (mg\cos\phi)s = [(12.0\text{ kg})(9.80\text{ m/s}^2)(\cos 37.0°)](2.00\text{ m}) = +188\text{ J}.$

(c) $W_n = 0$ since the normal force is perpendicular to the displacement.

(d) The net work done on the package is $W_{\text{net}} = W_{\text{grav}} + W_n + W_f = 188\text{ J} + 0.0\text{ J} - 57\text{ J} = 131\text{ J}.$

EVALUATE: The net work is positive because gravity does more positive work than the magnitude of the negative work done by friction.

6.11. IDENTIFY: We need to calculate work and use the work-energy theorem.

SET UP: $W = Fs\cos\phi$, $W_{tot} = K_2 - K_1$, $K = \frac{1}{2}mv^2$.

EXECUTE: **(a)** Using $W = Fs\cos\phi$, we see that to double the work for the same force and displacement, the angle $\cos\phi$ must double. Thus $\cos\phi = 2\cos 60° = 1.00$, so $\phi = 0°$. We should pull horizontally.

(b) The block starts from rest so $K_1 = 0$. Using the work-energy theorem tells us that in this case $W_1 = \frac{1}{2}mv^2$. To double v, the work must be $W_2 = \frac{1}{2}m(2v)^2 = 4\left(\frac{1}{2}mv^2\right) = 4K_1 = 4W_1$. Since only the force F varies, F must increase by a factor of 4 to double the speed.

EVALUATE: To double the speed does not take twice as much work; it takes 4 times as much.

6.12. IDENTIFY: Since the speed is constant, the acceleration and the net force on the monitor are zero.

SET UP: Use the fact that the net force on the monitor is zero to develop expressions for the friction force, f_k, and the normal force, n. Then use $W = F_P s = (F\cos\phi)s$ to calculate W.

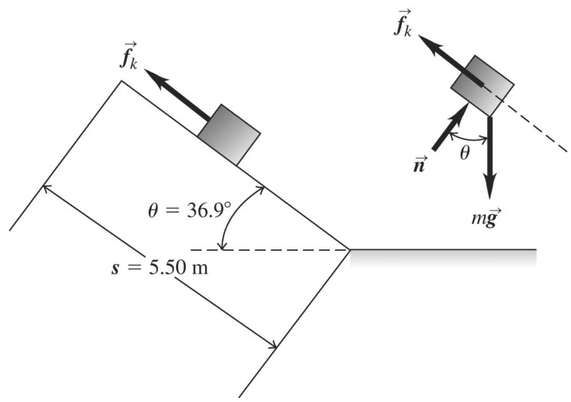

Figure 6.12

EXECUTE: **(a)** Summing forces along the incline, $\Sigma F = ma = 0 = f_k - mg\sin\theta$, giving $f_k = mg\sin\theta$, directed up the incline. Substituting gives $W_f = (f_k\cos\phi)s = [(mg\sin\theta)\cos\phi]s$.

$W_f = [(10.0\text{ kg})(9.80\text{ m/s}^2)(\sin 36.9°)](\cos 0°)(5.50\text{ m}) = +324\text{ J}.$

(b) The gravity force is downward and the displacement is directed up the incline so $\phi = 126.9°$.

$W_{grav} = (10.0\text{ kg})(9.80\text{ m/s}^2)(\cos 126.9°)(5.50\text{ m}) = -324\text{ J}.$

(c) The normal force, n, is perpendicular to the displacement and thus does zero work.

EVALUATE: Friction does positive work and gravity does negative work. The net work done is zero.

6.13. IDENTIFY: We want the work done by a known force acting through a known displacement.

SET UP: $W = Fs\cos\phi$

EXECUTE: $W = (48.0\text{ N})(12.0\text{ m})\cos(173°) = -572\text{ J}.$

EVALUATE: The force has a component opposite to the displacement, so it does negative work.

6.14. IDENTIFY: We want to find the work done by a known force acting through a known displacement.

SET UP: $W = \vec{F}\cdot\vec{s} = F_x s_x + F_y s_y$. We know the components of $\vec{F}$ but need to find the components of the displacement $\vec{s}$.

EXECUTE: Using the magnitude and direction of $\vec{s}$, its components are $x = (48.0\text{ m})\cos 240.0° = -24.0\text{ m}$ and $y = (48.0\text{ m})\sin 240.0° = -41.57\text{ m}$. Therefore,

$\vec{s} = (-24.0\text{ m})\hat{\boldsymbol{i}} + (-41.57\text{ m})\hat{\boldsymbol{j}}$. The definition of work gives

$W = \vec{F}\cdot\vec{s} = (-68.0\text{ N})(-24.0\text{ m}) + (36.0\text{ N})(-41.57\text{ m}) = +1632\text{ J} - 1497\text{ J} = +135\text{ J}.$

EVALUATE: The mass of the car is not needed since it is the given force that is doing the work.

6.15. **IDENTIFY:** We want the work done by the force, and we know the force and the displacement in terms of their components.

SET UP: We can use either $W = \vec{F}\cdot\vec{s} = F_x s_x + F_y s_y$ or $W = Fs\cos\phi$, depending on what we know.

EXECUTE: (a) We know the magnitudes of the two given vectors and the angle between them, so $W = Fs\cos\phi$ = (30.0 N)(5.00 m)(cos37°) = 120 J.

(b) As in (a), we have $W = Fs\cos\phi$ = (30.0 N)(6.00 m)(cos127°) = –108 J.

(c) We know the components of both vectors, so we use $W = \vec{F}\cdot\vec{s} = F_x s_x + F_y s_y$.

$W = \vec{F}\cdot\vec{s} = F_x s_x + F_y s_y$ = (30.0 N)(cos37°)(–2.00 m) + (30.00 N)(sin37°)(4.00 m) = 24.3 J.

EVALUATE: We could check parts (a) and (b) using the method from part (c).

6.16. **IDENTIFY:** The book changes its speed and hence its kinetic energy, so work must have been done on it.

SET UP: Use the work-kinetic energy theorem $W_{\text{net}} = K_{\text{f}} - K_{\text{i}}$, with $K = \frac{1}{2}mv^2$. In part (a) use K_{i} and K_{f} to calculate W. In parts (b) and (c) use K_{i} and W to calculate K_{f}.

EXECUTE: **(a)** Substituting the notation $\text{i} = A$ and $\text{f} = B$,

$W_{\text{net}} = K_B - K_A = \frac{1}{2}(1.50\text{ kg})[(1.25\text{ m/s})^2 - (3.21\text{ m/s})^2] = -6.56\text{ J}.$

(b) Noting $\text{i} = B$ and $\text{f} = C$,

$K_C = K_B + W_{\text{net}} = \frac{1}{2}(1.50\text{ kg})(1.25\text{ m/s})^2 - 0.750\text{ J} = +0.422\text{ J}.$ $K_C = \frac{1}{2}mv_C^2$ so

$v_C = \sqrt{2K_C/m} = 0.750\text{ m/s}.$

(c) Similarly, $K_C = \frac{1}{2}(1.50\text{ kg})(1.25\text{ m/s})^2 + 0.750\text{ J} = 1.922\text{ J}$ and $v_C = 1.60\text{ m/s}.$

EVALUATE: Negative W_{net} corresponds to a decrease in kinetic energy (slowing down) and positive W_{net} corresponds to an increase in kinetic energy (speeding up).

6.17. **IDENTIFY:** Find the kinetic energy of the cheetah knowing its mass and speed.

SET UP: Use $K = \frac{1}{2}mv^2$ to relate v and K.

EXECUTE: **(a)** $K = \dfrac{1}{2}mv^2 = \dfrac{1}{2}(70\text{ kg})(32\text{ m/s})^2 = 3.6\times10^4\text{ J}.$

(b) K is proportional to v^2, so K increases by a factor of 4 when v doubles.

EVALUATE: A running person, even with a mass of 70 kg, would have only 1/100 of the cheetah's kinetic energy since a person's top speed is only about 1/10 that of the cheetah.

6.18. **IDENTIFY:** Apply the work-energy theorem to the ball.

SET UP: $W_{\text{tot}} = K_2 - K_1$, $K = \dfrac{1}{2}mv^2$.

EXECUTE: **(a)** $W_{\text{tot}} = K_2 - K_1 = \dfrac{1}{2}mv_2^2 - 0 = \dfrac{1}{2}(0.145\text{ kg})(30.0\text{ m/s})^2 = 65.3\text{ J}.$

(b) $W_{\text{tot}} = \dfrac{1}{2}mv_2^2 - \dfrac{1}{2}mv_1^2 = \dfrac{1}{2}(0.145\text{ kg})(-30.0\text{ m/s})^2 - \dfrac{1}{2}(0.145\text{ kg})(20.0\text{ m/s})^2 = 36.3\text{ J}.$

(c) The work was greater in part (a) than in part (b) because the change in kinetic energy was greater.

EVALUATE: In part (a) the bat does all positive work on the ball because the force and displacement are in the same direction. In part (b) the bat does negative work to stop the ball and then positive work to increase its speed in the opposite direction. So the *total* work the bat does is less than in part (a).

6.19. **IDENTIFY:** $K = \frac{1}{2}mv^2$. Since the meteor comes to rest the energy it delivers to the ground equals its original kinetic energy.

SET UP: $v = 12 \text{ km/s} = 1.2\times10^4 \text{ m/s}$. A 1.0 megaton bomb releases 4.184×10^{15} J of energy.

EXECUTE: **(a)** $K = \frac{1}{2}(1.4\times10^8 \text{ kg})(1.2\times10^4 \text{ m/s})^2 = 1.0\times10^{16} \text{ J}$.

(b) $\dfrac{1.0\times10^{16} \text{ J}}{4.184\times10^{15} \text{ J}} = 2.4$. The energy is equivalent to 2.4 one-megaton bombs.

EVALUATE: Part of the energy transferred to the ground lifts soil and rocks into the air and creates a large crater.

6.20. **IDENTIFY:** Only gravity does work on the watermelon, so $W_{\text{tot}} = W_{\text{grav}}$. $W_{\text{tot}} = \Delta K$ and $K = \frac{1}{2}mv^2$.

SET UP: Since the watermelon is dropped from rest, $K_1 = 0$.

EXECUTE: **(a)** $W_{\text{grav}} = mgs = (4.80 \text{ kg})(9.80 \text{ m/s}^2)(18.0 \text{ m}) = 847 \text{ J}$.

(b) **(i)** $W_{\text{tot}} = K_2 - K_1$ so $K_2 = 847$ J. **(ii)** $v = \sqrt{\dfrac{2K_2}{m}} = \sqrt{\dfrac{2(847 \text{ J})}{4.80 \text{ kg}}} = 18.8 \text{ m/s}$.

(c) The work done by gravity would be the same. Air resistance would do negative work and W_{tot} would be less than W_{grav}. The answer in (a) would be unchanged and both answers in (b) would decrease.

EVALUATE: The gravity force is downward and the displacement is downward, so gravity does positive work.

6.21. **IDENTIFY:** We need to calculate work.

SET UP: $W = Fs\cos\phi$. Since d and ϕ are the same in both cases, but F is different.

EXECUTE: If the box travels a distance d in time t starting from rest, $x = x_0 + v_{0x}t + \dfrac{1}{2}a_x t^2$ tells us that $d = \dfrac{1}{2}a_1 t^2$. If it travels the same distance in half the time, we have $d = \dfrac{1}{2}a_2\left(\dfrac{t}{2}\right)^2 = \dfrac{1}{2}a_2\dfrac{t^2}{4} = \dfrac{1}{2}\left(\dfrac{a_2}{4}\right)t^2$.

Comparing these two equations for d shows that $a_2/4 = a_1$ so $a_2 = 4a_1$. $\sum F_x = ma_x$ tells us that the force F is 4 times as great, and so the work $W = Fs\cos\phi$ done by the force is 4 times as great. Therefore the work is $4W_1$.

EVALUATE: We must be careful of using ratios when quantities are squared.

6.22. **IDENTIFY:** $W_{\text{tot}} = K_2 - K_1$. In each case calculate W_{tot} from what we know about the force and the displacement.

SET UP: The gravity force is mg, downward. The friction force is $f_k = \mu_k n = \mu_k mg$ and is directed opposite to the displacement. The mass of the object isn't given, so we expect that it will divide out in the calculation.

EXECUTE: **(a)** $K_1 = \frac{1}{2}mv_1^2$. $K_2 = 0$. $W_{\text{tot}} = W_f = -\mu_k mgs$. $-\mu_k mgs = -\frac{1}{2}mv_1^2$.

$$s = \frac{v_1^2}{2\mu_k g} = \frac{(5.00 \text{ m/s})^2}{2(0.220)(9.80 \text{ m/s}^2)} = 5.80 \text{ m}.$$

(b) $K_1 = \frac{1}{2}mv_1^2$. $K_2 = \frac{1}{2}mv_2^2$. $W_{\text{tot}} = W_f = -\mu_k mgs$. $K_2 = W_{\text{tot}} + K_1$. $\frac{1}{2}mv_2^2 = -\mu_k mgs + \frac{1}{2}mv_1^2$.

$$v_2 = \sqrt{v_1^2 - 2\mu_k gs} = \sqrt{(5.00 \text{ m/s})^2 - 2(0.220)(9.80 \text{ m/s}^2)(2.90 \text{ m})} = 3.53 \text{ m/s}.$$

(c) $K_1 = \frac{1}{2}mv_1^2$. $K_2 = 0$. $W_{\text{grav}} = -mgy_2$, where y_2 is the vertical height. $-mgy_2 = -\frac{1}{2}mv_1^2$ and

$$y_2 = \frac{v_1^2}{2g} = \frac{(12.0 \text{ m/s})^2}{2(9.80 \text{ m/s}^2)} = 7.35 \text{ m}.$$

EVALUATE: In parts (a) and (b), friction does negative work and the kinetic energy is reduced. In part (c), gravity does negative work and the speed decreases. The vertical height in part (c) is independent of the slope angle of the hill.

6.23. IDENTIFY and **SET UP:** Apply the work-energy theorem $W_{\text{tot}} = K_2 - K_1$ to the box. Let point 1 be at the bottom of the incline and let point 2 be at the skier. Work is done by gravity and by friction. Solve for K_1 and from that obtain the required initial speed.

EXECUTE: $W_{\text{tot}} = K_2 - K_1$

$K_1 = \frac{1}{2}mv_0^2, \;\; K_2 = 0$

Work is done by gravity and friction, so $W_{\text{tot}} = W_{mg} + W_f$.

$W_{mg} = -mg(y_2 - y_1) = -mgh$

$W_f = -fs$. The normal force is $n = mg\cos\alpha$ and $s = h/\sin\alpha$, where s is the distance the box travels along the incline.

$W_f = -(\mu_k mg\cos\alpha)(h/\sin\alpha) = -\mu_k mgh/\tan\alpha$

Substituting these expressions into the work-energy theorem gives $-mgh - \mu_k mgh/\tan\alpha = -\frac{1}{2}mv_0^2$.

Solving for v_0 then gives $v_0 = \sqrt{2gh(1+\mu_k/\tan\alpha)}$.

EVALUATE: The result is independent of the mass of the box. As $\alpha \to 90°$, $h = s$ and $v_0 = \sqrt{2gh}$, the same as throwing the box straight up into the air. For $\alpha = 90°$ the normal force is zero so there is no friction.

6.24. IDENTIFY: From the work-energy relation, $W = W_{\text{grav}} = \Delta K_{\text{rock}}$.

SET UP: As the rock rises, the gravitational force, $F = mg$, does work on the rock. Since this force acts in the direction opposite to the motion and displacement, s, the work is negative. Let h be the vertical distance the rock travels.

EXECUTE: **(a)** Applying $W_{\text{grav}} = K_2 - K_1$ we obtain $-mgh = \frac{1}{2}mv_2^2 - \frac{1}{2}mv_1^2$. Dividing by m and solving for v_1, $v_1 = \sqrt{v_2^2 + 2gh}$. Substituting $h = 15.0$ m and $v_2 = 25.0$ m/s,

$$v_1 = \sqrt{(25.0 \text{ m/s})^2 + 2(9.80 \text{ m/s}^2)(15.0 \text{ m})} = 30.3 \text{ m/s}$$

(b) Solve the same work-energy relation for h. At the maximum height $v_2 = 0$.

$$-mgh = \tfrac{1}{2}mv_2^2 - \tfrac{1}{2}mv_1^2 \text{ and } h = \frac{v_1^2 - v_2^2}{2g} = \frac{(30.3 \text{ m/s})^2 - (0.0 \text{ m/s})^2}{2(9.80 \text{ m/s}^2)} = 46.8 \text{ m}.$$

EVALUATE: Note that the weight of the rock was never used in the calculations because both gravitational potential and kinetic energy are proportional to mass, m. Thus any object, that attains 25.0 m/s at a height of 15.0 m, must have an initial velocity of 30.3 m/s. As the rock moves upward gravity does negative work and this reduces the kinetic energy of the rock.

6.25. IDENTIFY: Apply $W = Fs\cos\phi$ and $W_{\text{tot}} = K_2 - K_1$.

SET UP: $\phi = 0°$

EXECUTE: Use $W = Fs\cos\phi$, $W_{\text{tot}} = K_2 - K_1$, and $K = \dfrac{1}{2}mv^2$ and solve for F, giving

$$F = \frac{\Delta K}{s} = \frac{\frac{1}{2}m(v_2^2 - v_1^2)}{s} = \frac{\frac{1}{2}(12.0\text{ kg})\left[(6.00\text{ m/s})^2 - (4.00\text{ m/s})^2\right]}{(2.50\text{ m})} = 48.0 \text{ N}$$

EVALUATE: The force is in the direction of the displacement, so the force does positive work and the kinetic energy of the object increases.

6.26. **IDENTIFY** and **SET UP:** Use the work-energy theorem to calculate the work done by the foot on the ball. Then use $W = Fs\cos\phi$ to find the distance over which this force acts.

EXECUTE: $W_{\text{tot}} = K_2 - K_1$

$K_1 = \frac{1}{2}mv_1^2 = \frac{1}{2}(0.420 \text{ kg})(2.00 \text{ m/s})^2 = 0.84 \text{ J}$

$K_2 = \frac{1}{2}mv_2^2 = \frac{1}{2}(0.420 \text{ kg})(6.00 \text{ m/s})^2 = 7.56 \text{ J}$

$W_{\text{tot}} = K_2 - K_1 = 7.56 \text{ J} - 0.84 \text{ J} = 6.72 \text{ J}$

The 40.0 N force is the only force doing work on the ball, so it must do 6.72 J of work. $W_F = (F\cos\phi)s$ gives that $s = \dfrac{W}{F\cos\phi} = \dfrac{6.72 \text{ J}}{(40.0 \text{ N})(\cos 0)} = 0.168 \text{ m}.$

EVALUATE: The force is in the direction of the motion so positive work is done and this is consistent with an increase in kinetic energy.

6.27. **IDENTIFY:** Apply $W_{\text{tot}} = \Delta K.$

SET UP: $v_1 = 0,\ v_2 = v.\ f_k = \mu_k mg$ and f_k does negative work. The force $F = 36.0 \text{ N}$ is in the direction of the motion and does positive work.

EXECUTE: **(a)** If there is no work done by friction, the final kinetic energy is the work done by the applied force, and solving for the speed,

$$v = \sqrt{\frac{2W}{m}} = \sqrt{\frac{2Fs}{m}} = \sqrt{\frac{2(36.0 \text{ N})(1.20 \text{ m})}{(4.30 \text{ kg})}} = 4.48 \text{ m/s}.$$

(b) The net work is $Fs - f_k s = (F - \mu_k mg)s,$ so

$$v = \sqrt{\frac{2(F - \mu_k mg)s}{m}} = \sqrt{\frac{2(36.0 \text{ N} - (0.30)(4.30 \text{ kg})(9.80 \text{ m/s}^2)(1.20 \text{ m})}{(4.30 \text{ kg})}} = 3.61 \text{ m/s}$$

EVALUATE: The total work done is larger in the absence of friction and the final speed is larger in that case.

6.28. **IDENTIFY:** Apply $W_{\text{tot}} = K_2 - K_1.$

SET UP: $K_1 = 0.$ The normal force does no work. The work W done by gravity is $W = mgh,$ where $h = L\sin\theta$ is the vertical distance the block has dropped when it has traveled a distance L down the incline and θ is the angle the plane makes with the horizontal.

EXECUTE: The work-energy theorem gives $v = \sqrt{\dfrac{2K}{m}} = \sqrt{\dfrac{2W}{m}} = \sqrt{2gh} = \sqrt{2gL\sin\theta}.$ Using the given numbers, $v = \sqrt{2(9.80 \text{ m/s}^2)(1.35 \text{ m})\sin 36.9°} = 3.99 \text{ m/s}.$

6.29. **IDENTIFY:** We use the work-energy theorem.

SET UP: $W_{\text{tot}} = K_2 - K_1,\ K = \dfrac{1}{2}mv^2.$

EXECUTE: **(a)** $K_A = \dfrac{1}{2}m_A v_A^2 = 27 \text{ J}$ and $K_B = \dfrac{1}{2}\left(\dfrac{m_A}{4}\right)v_B^2 = 27 \text{ J}.$ Equate both expressions, which gives $\dfrac{1}{2}m_A v_A^2 = = \dfrac{1}{2}\left(\dfrac{m_A}{4}\right)v_B^2.$ Solving for v_B we have $v_B = 2v_A.$ So B is moving faster and its speed is twice that of A.

(b) Apply the work-energy theorem to A. –18 J = K_2 – 27 J, so K_2 = 9 J. Take the ratio of its initial and final kinetic energy, giving $\dfrac{K_2}{K_1} = \dfrac{\frac{1}{2}mv_2^2}{\frac{1}{2}mv_1^2} = \dfrac{9 \text{ J}}{27 \text{ J}} = \dfrac{1}{3} = \dfrac{v_2^2}{v_1^2}.$ Thus $v_2 = \dfrac{v_1}{\sqrt{3}}.$ We will get the same result for B because both objects have the same initial kinetic energy (27 J) and the same amount of work (–18 J) is done on them.

EVALUATE: The result to part (a) is reasonable since a lighter object must move faster to have the same kinetic energy as a heavier object. Part (b) is reasonable because the kinetic energy decreases since the work done on the objects is negative.

6.30. IDENTIFY: We know (or can calculate) the change in the kinetic energy of the crate and want to find the work needed to cause this change, so the work-energy theorem applies.

SET UP: $W_{\text{tot}} = \Delta K = K_{\text{f}} - K_{\text{i}} = \frac{1}{2}mv_{\text{f}}^2 - \frac{1}{2}mv_{\text{i}}^2.$

EXECUTE: $W_{\text{tot}} = K_{\text{f}} - K_{\text{i}} = \frac{1}{2}(30.0\text{ kg})(5.62\text{ m/s})^2 - \frac{1}{2}(30.0\text{ kg})(3.90\text{ m/s})^2.$

$W_{\text{tot}} = 473.8\text{ J} - 228.2\text{ J} = 246\text{ J}.$

EVALUATE: Kinetic energy is a scalar and does not depend on direction, so only the initial and final speeds are relevant.

6.31. IDENTIFY: $W_{\text{tot}} = K_2 - K_1$. Only friction does work.

SET UP: $W_{\text{tot}} = W_{f_{\text{k}}} = -\mu_{\text{k}}mgs.$ $K_2 = 0$ (car stops). $K_1 = \frac{1}{2}mv_0^2.$

EXECUTE: **(a)** $W_{\text{tot}} = K_2 - K_1$ gives $-\mu_{\text{k}}mgs = -\frac{1}{2}mv_0^2.$ $s = \dfrac{v_0^2}{2\mu_{\text{k}}g}.$

(b) (i) $\mu_{\text{k}b} = 2\mu_{\text{k}a}.$ $s\mu_{\text{k}} = \dfrac{v_0^2}{2g} = \text{constant}$ so $s_a\mu_{\text{k}a} = s_b\mu_{\text{k}b}.$ $s_b = \left(\dfrac{\mu_{\text{k}a}}{\mu_{\text{k}b}}\right)s_a = s_a/2.$ The minimum stopping distance would be halved. (ii) $v_{0b} = 2v_{0a}.$ $\dfrac{s}{v_0^2} = \dfrac{1}{2\mu_{\text{k}}g} = \text{constant},$ so $\dfrac{s_a}{v_{0a}^2} = \dfrac{s_b}{v_{0b}^2}.$

$s_b = s_a\left(\dfrac{v_{0b}}{v_{0a}}\right)^2 = 4s_a.$ The stopping distance would become 4 times as great. (iii) $v_{0b} = 2v_{0a},$

$\mu_{\text{k}b} = 2\mu_{\text{k}a}.$ $\dfrac{s\mu_{\text{k}}}{v_0^2} = \dfrac{1}{2g} = \text{constant},$ so $\dfrac{s_a\mu_{\text{k}a}}{v_{0a}^2} = \dfrac{s_b\mu_{\text{k}b}}{v_{0b}^2}.$ $s_b = s_a\left(\dfrac{\mu_{\text{k}a}}{\mu_{\text{k}b}}\right)\left(\dfrac{v_{0b}}{v_{0a}}\right)^2 = s_a\left(\dfrac{1}{2}\right)(2)^2 = 2s_a.$ The stopping distance would double.

EVALUATE: The stopping distance is directly proportional to the square of the initial speed and indirectly proportional to the coefficient of kinetic friction.

6.32. IDENTIFY: The work that must be done to move the end of a spring from x_1 to x_2 is $W = \frac{1}{2}kx_2^2 - \frac{1}{2}kx_1^2.$ The force required to hold the end of the spring at displacement x is $F_x = kx.$

SET UP: When the spring is at its unstretched length, $x = 0.$ When the spring is stretched, $x > 0,$ and when the spring is compressed, $x < 0.$

EXECUTE: **(a)** $x_1 = 0$ and $W = \frac{1}{2}kx_2^2.$ $k = \dfrac{2W}{x_2^2} = \dfrac{2(12.0\text{ J})}{(0.0300\text{ m})^2} = 2.67\times10^4\text{ N/m}.$

(b) $F_x = kx = (2.67\times10^4\text{ N/m})(0.0300\text{ m}) = 801\text{ N}.$

(c) $x_1 = 0,$ $x_2 = -0.0400\text{ m}.$ $W = \frac{1}{2}(2.67\times10^4\text{ N/m})(-0.0400\text{ m})^2 = 21.4\text{ J}.$

$F_x = kx = (2.67\times10^4\text{ N/m})(0.0400\text{ m}) = 1070\text{ N}.$

EVALUATE: When a spring, initially unstretched, is either compressed or stretched, positive work is done by the force that moves the end of the spring.

6.33. IDENTIFY: The springs obey Hooke's law and balance the downward force of gravity.

SET UP: Use coordinates with $+y$ upward. Label the masses 1, 2, and 3, with 1 the top mass and 3 the bottom mass, and call the amounts the springs are stretched $x_1,$ $x_2,$ and $x_3.$ Each spring force is kx.

EXECUTE: **(a)** The three free-body diagrams are shown in Figure 6.33.

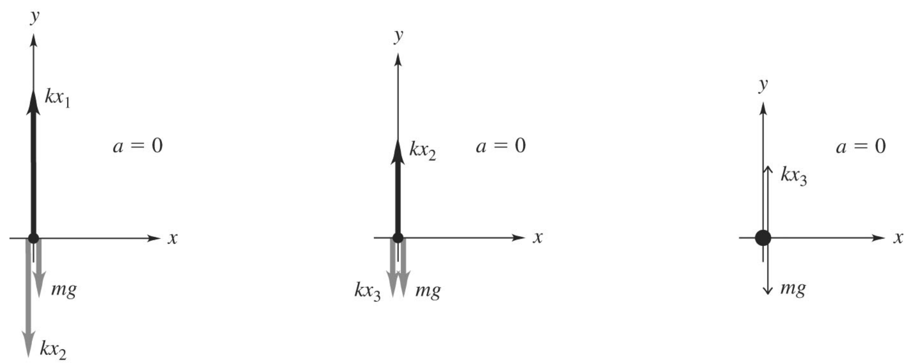

Figure 6.33

(b) Balancing forces on each of the masses and using $F = kx$ gives $kx_3 = mg$ so

$x_3 = \dfrac{mg}{k} = \dfrac{(8.50\text{ kg})(9.80\text{ m/s}^2)}{7.80\times 10^3\text{ N/m}} = 1.068\text{ cm}$. $kx_2 = mg + kx_3 = 2mg$ so $x_2 = 2\left(\dfrac{mg}{k}\right) = 2.136\text{ cm}$.

$kx_1 = mg + kx_2 = 3mg$ so $x_3 = 3\left(\dfrac{mg}{k}\right) = 3.204\text{ cm}$. Adding the original lengths to the distance stretched, the lengths of the springs, starting from the bottom one, are 13.1 cm, 14.1 cm, and 15.2 cm.

N**EVALUATE:** The top spring stretches most because it supports the most weight, while the bottom spring stretches least because it supports the least weight.

6.34. **IDENTIFY:** The magnitude of the work can be found by finding the area under the graph.
SET UP: The area under each triangle is 1/2 base$\times$height. $F_x > 0$, so the work done is positive when x increases during the displacement.
EXECUTE: **(a)** $1/2\ (8\text{ m})(10\text{ N}) = 40\text{ J}$.
(b) $1/2\ (4\text{ m})(10\text{ N}) = 20\text{ J}$.
(c) $1/2\ (12\text{ m})(10\text{ N}) = 60\text{ J}$.
EVALUATE: The sum of the answers to parts (a) and (b) equals the answer to part (c).

6.35. **IDENTIFY:** Use the work-energy theorem and the results of Problem 6.36.
SET UP: For $x = 0$ to $x = 8.0\text{ m}$, $W_{\text{tot}} = 40\text{ J}$. For $x = 0$ to $x = 12.0\text{ m}$, $W_{\text{tot}} = 60\text{ J}$.

EXECUTE: **(a)** $v = \sqrt{\dfrac{(2)(40\text{ J})}{10\text{ kg}}} = 2.83\text{ m/s}$

(b) $v = \sqrt{\dfrac{(2)(60\text{ J})}{10\text{ kg}}} = 3.46\text{ m/s}$.

EVALUATE: $\vec{F}$ is always in the $+x$-direction. For this motion $\vec{F}$ does positive work and the speed continually increases during the motion.

6.36. **IDENTIFY:** The spring obeys Hooke's law.
SET UP: Solve $F = kx$ for x to determine the length of stretch and use $W = +\frac{1}{2}kx^2$ to assess the corresponding work.

EXECUTE: $x = \dfrac{F}{k} = \dfrac{15.0\text{ N}}{300.0\text{ N/m}} = 0.0500\text{ m}$. The new length will be $0.240\text{ m} + 0.0500\text{ m} = 0.290\text{ m}$.

The corresponding work done is $W = \dfrac{1}{2}(300.0\text{ N/m})(0.0500\text{ m})^2 = 0.375\text{ J}$.

EVALUATE: In $F = kx$, F is always the force applied to one end of the spring, thus we did not need to double the 15.0 N force. Consider a free-body diagram of a spring at rest; forces of equal magnitude and opposite direction are always applied to both ends of every section of the spring examined.

6.37. IDENTIFY: Apply the work-energy theorem $W_{\text{tot}} = K_2 - K_1$ to the box.

SET UP: Let point 1 be just before the box reaches the end of the spring and let point 2 be where the spring has maximum compression and the box has momentarily come to rest.

EXECUTE: $W_{\text{tot}} = K_2 - K_1$

$K_1 = \frac{1}{2}mv_0^2,\ \ K_2 = 0$

Work is done by the spring force. $W_{\text{tot}} = -\frac{1}{2}kx_2^2$, where x_2 is the amount the spring is compressed.

$-\frac{1}{2}kx_2^2 = -\frac{1}{2}mv_0^2$ and $x_2 = v_0\sqrt{m/k} = (3.0\text{ m/s})\sqrt{(6.0\text{ kg})/(7500\text{ N/m})} = 8.5\text{ cm}$

EVALUATE: The compression of the spring increases when either v_0 or m increases and decreases when k increases (stiffer spring).

6.38. IDENTIFY: The force applied to the springs is $F_x = kx$. The work done on a spring to move its end from x_1 to x_2 is $W = \frac{1}{2}kx_2^2 - \frac{1}{2}kx_1^2$. Use the information that is given to calculate k.

SET UP: When the springs are compressed 0.200 m from their uncompressed length, $x_1 = 0$ and $x_2 = -0.200\text{ m}$. When the platform is moved 0.200 m farther, x_2 becomes -0.400 m.

EXECUTE: **(a)** $k = \dfrac{2W}{x_2^2 - x_1^2} = \dfrac{2(80.0\text{ J})}{(0.200\text{ m})^2 - 0} = 4000\text{ N/m}$. $F_x = kx = (4000\text{ N/m})(-0.200\text{ m}) = -800\text{ N}$.

The magnitude of force that is required is 800 N.

(b) To compress the springs from $x_1 = 0$ to $x_2 = -0.400\text{ m}$, the work required is

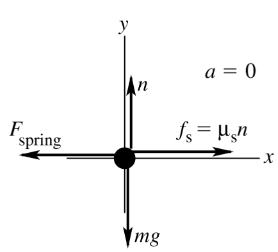
$W = \frac{1}{2}kx_2^2 - \frac{1}{2}kx_1^2 = \frac{1}{2}(4000\text{ N/m})(-0.400\text{ m})^2 = 320\text{ J}$. The additional work required is

$320\text{ J} - 80\text{ J} = 240\text{ J}$. For $x = -0.400\text{ m}$, $F_x = kx = -1600\text{ N}$. The magnitude of force required is 1600 N.

EVALUATE: More work is required to move the end of the spring from $x = -0.200\text{ m}$ to $x = -0.400\text{ m}$ than to move it from $x = 0$ to $x = -0.200\text{ m}$, even though the displacement of the platform is the same in each case. The magnitude of the force increases as the compression of the spring increases.

6.39. IDENTIFY: Apply $\Sigma\vec{F} = m\vec{a}$ to calculate the μ_s required for the static friction force to equal the spring force.

SET UP: **(a)** The free-body diagram for the glider is given in Figure 6.39.



EXECUTE: $\Sigma F_y = ma_y$

$n - mg = 0$

$n = mg$

$f_s = \mu_s mg$

Figure 6.39

$\Sigma F_x = ma_x$

$f_s - F_{\text{spring}} = 0$

$\mu_s mg - kd = 0$

$$\mu_s = \frac{kd}{mg} = \frac{(20.0\text{ N/m})(0.086\text{ m})}{(0.100\text{ kg})(9.80\text{ m/s}^2)} = 1.76$$

(b) IDENTIFY and **SET UP:** Apply $\Sigma\vec{F} = m\vec{a}$ to find the maximum amount the spring can be compressed and still have the spring force balanced by friction. Then use $W_{\text{tot}} = K_2 - K_1$ to find the initial speed that results in this compression of the spring when the glider stops.

EXECUTE: $\mu_s mg = kd$

$$d = \frac{\mu_s mg}{k} = \frac{(0.60)(0.100\text{ kg})(9.80\text{ m/s}^2)}{20.0\text{ N/m}} = 0.0294\text{ m}$$

Now apply the work-energy theorem to the motion of the glider:

$W_{\text{tot}} = K_2 - K_1$

$K_1 = \frac{1}{2}mv_1^2$, $K_2 = 0$ (instantaneously stops)

$W_{\text{tot}} = W_{\text{spring}} + W_{\text{fric}} = -\frac{1}{2}kd^2 - \mu_k mgd$ (as in Example 6.7)

$W_{\text{tot}} = -\frac{1}{2}(20.0\text{ N/m})(0.0294\text{ m})^2 - 0.47(0.100\text{ kg})(9.80\text{ m/s}^2)(0.0294\text{ m}) = -0.02218\text{ J}$

Then $W_{\text{tot}} = K_2 - K_1$ gives $-0.02218\text{ J} = -\frac{1}{2}mv_1^2$.

$$v_1 = \sqrt{\frac{2(0.02218\text{ J})}{0.100\text{ kg}}} = 0.67\text{ m/s}.$$

EVALUATE: In Example 6.7 an initial speed of 1.50 m/s compresses the spring 0.086 m and in part (a) of this problem we found that the glider doesn't stay at rest. In part (b) we found that a smaller displacement of 0.0294 m when the glider stops is required if it is to stay at rest. And we calculate a smaller initial speed (0.67 m/s) to produce this smaller displacement.

6.40. IDENTIFY: For the spring, $W = \frac{1}{2}kx_1^2 - \frac{1}{2}kx_2^2$. Apply $W_{\text{tot}} = K_2 - K_1$.

SET UP: $x_1 = -0.025$ m and $x_2 = 0$.

EXECUTE: **(a)** $W = \frac{1}{2}kx_1^2 = \frac{1}{2}(200\text{ N/m})(-0.025\text{ m})^2 = 0.0625\text{ J}$, which rounds to 0.063 J.

(b) The work-energy theorem gives $v_2 = \sqrt{\frac{2W}{m}} = \sqrt{\frac{2(0.0625\text{ J})}{(4.0\text{ kg})}} = 0.18\text{ m/s}$.

EVALUATE: The block moves in the direction of the spring force, the spring does positive work and the kinetic energy of the block increases.

6.41. IDENTIFY and **SET UP:** The magnitude of the work done by F_x equals the area under the F_x versus x curve. The work is positive when F_x and the displacement are in the same direction; it is negative when they are in opposite directions.

EXECUTE: **(a)** F_x is positive and the displacement Δx is positive, so $W > 0$.

$W = \frac{1}{2}(2.0\text{ N})(2.0\text{ m}) + (2.0\text{ N})(1.0\text{ m}) = +4.0\text{ J}$

(b) During this displacement $F_x = 0$, so $W = 0$.

(c) F_x is negative, Δx is positive, so $W < 0$. $W = -\frac{1}{2}(1.0\text{ N})(2.0\text{ m}) = -1.0\text{ J}$

(d) The work is the sum of the answers to parts (a), (b), and (c), so $W = 4.0\text{ J} + 0 - 1.0\text{ J} = +3.0\text{ J}$.

(e) The work done for $x = 7.0$ m to $x = 3.0$ m is $+1.0$ J. This work is positive since the displacement and the force are both in the $-x$-direction. The magnitude of the work done for $x = 3.0$ m to $x = 2.0$ m is 2.0 J, the area under F_x versus x. This work is negative since the displacement is in the $-x$-direction and the force is in the $+x$-direction. Thus $W = +1.0\text{ J} - 2.0\text{ J} = -1.0\text{ J}$.

EVALUATE: The work done when the car moves from $x = 2.0$ m to $x = 0$ is $-\frac{1}{2}(2.0\text{ N})(2.0\text{ m}) = -2.0$ J. Adding this to the work for $x = 7.0$ m to $x = 2.0$ m gives a total of $W = -3.0$ J for $x = 7.0$ m to $x = 0$. The work for $x = 7.0$ m to $x = 0$ is the negative of the work for $x = 0$ to $x = 7.0$ m.

6.42. **IDENTIFY:** Apply $W_{\text{tot}} = K_2 - K_1$.

SET UP: $K_1 = 0$. From Exercise 6.41, the work for $x = 0$ to $x = 3.0$ m is 4.0 J. W for $x = 0$ to $x = 4.0$ m is also 4.0 J. For $x = 0$ to $x = 7.0$ m, $W = 3.0$ J.

EXECUTE: **(a)** $K = 4.0$ J, so $v = \sqrt{2K/m} = \sqrt{2(4.0\text{ J})/(2.0\text{ kg})} = 2.00$ m/s.

(b) No work is done between $x = 3.0$ m and $x = 4.0$ m, so the speed is the same, 2.00 m/s.

(c) $K = 3.0$ J, so $v = \sqrt{2K/m} = \sqrt{2(3.0\text{ J})/(2.0\text{ kg})} = 1.73$ m/s.

EVALUATE: In each case the work done by F is positive and the car gains kinetic energy.

6.43. **IDENTIFY** and **SET UP:** Apply the work-energy theorem. Let point 1 be where the sled is released and point 2 be at $x = 0$ for part (a) and at $x = -0.200$ m for part (b). Use $W = \dfrac{1}{2}kx^2$ for the work done by the spring and calculate K_2. Then $K_2 = \frac{1}{2}mv_2^2$ gives v_2.

EXECUTE: **(a)** $W_{\text{tot}} = K_2 - K_1$ so $K_2 = K_1 + W_{\text{tot}}$

$K_1 = 0$ (released with no initial velocity), $K_2 = \frac{1}{2}mv_2^2$

The only force doing work is the spring force. $W = \dfrac{1}{2}kx^2$ gives the work done *on* the spring to move its end from x_1 to x_2. The force the spring exerts on an object attached to it is $F = -kx$, so the work the spring does is

$W_{\text{spr}} = -\left(\frac{1}{2}kx_2^2 - \frac{1}{2}kx_1^2\right) = \frac{1}{2}kx_1^2 - \frac{1}{2}kx_2^2$. Here $x_1 = -0.375$ m and $x_2 = 0$. Thus

$W_{\text{spr}} = \frac{1}{2}(4000\text{ N/m})(-0.375\text{ m})^2 - 0 = 281$ J.

$K_2 = K_1 + W_{\text{tot}} = 0 + 281\text{ J} = 281$ J.

Then $K_2 = \frac{1}{2}mv_2^2$ implies $v_2 = \sqrt{\dfrac{2K_2}{m}} = \sqrt{\dfrac{2(281\text{ J})}{70.0\text{ kg}}} = 2.83$ m/s.

(b) $K_2 = K_1 + W_{\text{tot}}$

$K_1 = 0$

$W_{\text{tot}} = W_{\text{spr}} = \frac{1}{2}kx_1^2 - \frac{1}{2}kx_2^2$. Now $x_2 = -0.200$ m, so

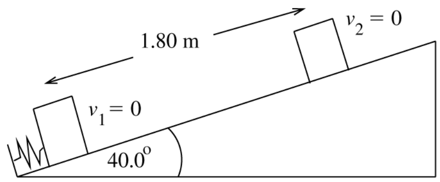
$W_{\text{spr}} = \frac{1}{2}(4000\text{ N/m})(-0.375\text{ m})^2 - \frac{1}{2}(4000\text{ N/m})(-0.200\text{ m})^2 = 281\text{ J} - 80\text{ J} = 201$ J

Thus $K_2 = 0 + 201\text{ J} = 201$ J and $K_2 = \frac{1}{2}mv_2^2$ gives $v_2 = \sqrt{\dfrac{2K_2}{m}} = \sqrt{\dfrac{2(201\text{ J})}{70.0\text{ kg}}} = 2.40$ m/s.

EVALUATE: The spring does positive work and the sled gains speed as it returns to $x = 0$. More work is done during the larger displacement in part (a), so the speed there is larger than in part (b).

6.44. **IDENTIFY** and **SET UP:** Apply the work-energy theorem to the glider. Work is done by the spring and by gravity. Take point 1 to be where the glider is released. In part (a) point 2 is where the glider has traveled 1.80 m and $K_2 = 0$. There are two points shown in Figure 6.44a. In part (b) point 2 is where the glider has traveled 0.80 m.

EXECUTE: (a) $W_{\text{tot}} = K_2 - K_1 = 0$. Solve for x_1, the amount the spring is initially compressed.



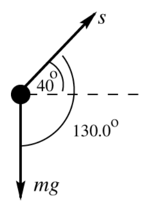
$W_{tot} = W_{spr} + W_w = 0$

So $W_{spr} = -W_w$

(The spring does positive work on the glider since the spring force is directed up the incline, the same as the direction of the displacement.)

Figure 6.44a

The directions of the displacement and of the gravity force are shown in Figure 6.44b.



$W_w = (w\cos\phi)s = (mg\cos 130.0°)s$

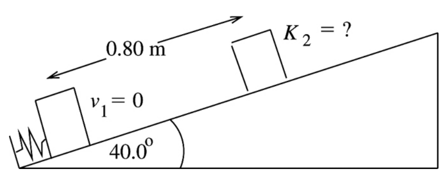
$W_w = (0.0900\text{ kg})(9.80\text{ m/s}^2)(\cos 130.0°)(1.80\text{ m}) = -1.020\text{ J}$ (The component of w parallel to the incline is directed down the incline, opposite to the displacement, so gravity does negative work.)

Figure 6.44b

$W_{spr} = -W_w = +1.020\text{ J}$

$W_{spr} = \frac{1}{2}kx_1^2$ so $x_1 = \sqrt{\dfrac{2W_{spr}}{k}} = \sqrt{\dfrac{2(1.020\text{ J})}{640\text{ N/m}}} = 0.0565\text{ m}$

(b) The spring was compressed only 0.0565 m so at this point in the motion the glider is no longer in contact with the spring. Points 1 and 2 are shown in Figure 6.44c.



$W_{tot} = K_2 - K_1$

$K_2 = K_1 + W_{tot}$

$K_1 = 0$

Figure 6.44c

$W_{tot} = W_{spr} + W_w$

From part (a), $W_{spr} = 1.020\text{ J}$ and

$W_w = (mg\cos 130.0°)s = (0.0900\text{ kg})(9.80\text{ m/s}^2)(\cos 130.0°)(0.80\text{ m}) = -0.454\text{ J}$

Then $K_2 = W_{spr} + W_w = +1.020\text{ J} - 0.454\text{ J} = +0.57\text{ J}.$

EVALUATE: The kinetic energy in part (b) is positive, as it must be. In part (a), $x_2 = 0$ since the spring force is no longer applied past this point. In computing the work done by gravity we use the full 0.80 m the glider moves.

6.45. IDENTIFY: The force does work on the box, which gives it kinetic energy, so the work-energy theorem applies. The force is variable so we must integrate to calculate the work it does on the box.

SET UP: $W_{tot} = \Delta K = K_f - K_i = \frac{1}{2}mv_f^2 - \frac{1}{2}mv_i^2$ and $W_{tot} = \int_{x_1}^{x_2} F(x)dx.$

EXECUTE: $W_{tot} = \int_{x_1}^{x_2} F(x)dx = \int_0^{14.0\text{ m}} [18.0\text{ N} - (0.530\text{ N/m})x]dx$

$W_{\text{tot}} = (18.0\text{ N})(14.0\text{ m}) - (0.265\text{ N/m})(14.0\text{ m})^2 = 252.0\text{ J} - 51.94\text{ J} = 200.1\text{ J}$. The initial kinetic energy is zero, so $W_{\text{tot}} = \Delta K = K_f - K_i = \frac{1}{2}mv_f^2$. Solving for v_f gives $v_f = \sqrt{\frac{2W_{\text{tot}}}{m}} = \sqrt{\frac{2(200.1\text{ J})}{6.00\text{ kg}}} = 8.17\text{ m/s}$.

EVALUATE: We could not readily do this problem by integrating the acceleration over time because we know the force as a function of *x*, not of *t*. The work-energy theorem provides a much simpler method.

6.46. **IDENTIFY:** The force acts through a distance over time, so it does work on the crate and hence supplies power to it. The force exerted by the worker is variable but the acceleration of the cart is constant.

SET UP: Use $P = Fv$ to find the power, and we can use $v = v_0 + at$ to find the instantaneous velocity.

EXECUTE: First find the instantaneous force and velocity: $F = (5.40\text{ N/s})(5.00\text{ s}) = 27.0\text{ N}$ and $v = v_0 + at = (2.80\text{ m/s}^2)(5.00\text{ s}) = 14.0\text{ m/s}$. Now find the power: $P = (27.0\text{ N})(14.0\text{ m/s}) = 378\text{ W}$.

EVALUATE: The instantaneous power will increase as the worker pushes harder and harder.

6.47. **IDENTIFY:** Apply the relation between energy and power.

SET UP: Use $P = \frac{W}{\Delta t}$ to solve for *W*, the energy the bulb uses. Then set this value equal to $\frac{1}{2}mv^2$ and solve for the speed.

EXECUTE: $W = P\Delta t = (100\text{ W})(3600\text{ s}) = 3.6\times10^5\text{ J}$

$K = 3.6\times10^5\text{ J}$ so $v = \sqrt{\frac{2K}{m}} = \sqrt{\frac{2(3.6\times10^5\text{ J})}{70\text{ kg}}} = 100\text{ m/s}$

EVALUATE: Olympic runners achieve speeds up to approximately 10 m/s, or roughly one-tenth the result calculated.

6.48. **IDENTIFY:** Knowing the rate at which energy is consumed, we want to find out the total energy used.

SET UP: Find the elapsed time Δt in each case by dividing the distance by the speed, $\Delta t = d / v$. Then calculate the energy as $W = P\Delta t$.

EXECUTE: Running: $\Delta t = (5.0\text{ km})/(10\text{ km/h}) = 0.50\text{ h} = 1.8\times10^3\text{ s}$. The energy used is

$W = (700\text{ W})(1.8\times10^3\text{ s}) = 1.3\times10^6\text{ J}$.

Walking: $\Delta t = \frac{5.0\text{ km}}{3.0\text{ km/h}}\left(\frac{3600\text{ s}}{\text{h}}\right) = 6.0\times10^3\text{ s}$. The energy used is

$W = (290\text{ W})(6.0\times10^3\text{ s}) = 1.7\times10^6\text{ J}$.

EVALUATE: The less intense exercise lasts longer and therefore burns up more energy than the intense exercise.

6.49. **IDENTIFY:** We want to calculate power.

SET UP: Estimate: 4 bags/min, so 20 bags in 5.0 min. $P_{\text{av}} = W/t$.

EXECUTE: $W = wh = (30\text{ lb})(4.0\text{ ft}) = 120\text{ ft}\cdot\text{lb}$ per bag. The total work is $(120\text{ ft}\cdot\text{lb})(20\text{ bags}) = 2400\text{ ft}\cdot\text{lb}$. The time is 5.0 min =300 s. So the power is

$P_{\text{av}} = \frac{W}{t} = \frac{2400\text{ ft}\cdot\text{lb}}{300\text{ s}} = 8.0\text{ ft}\cdot\text{lb/s}$. Convert to horsepower: $(8.0\text{ ft}\cdot\text{lb/s})\left(\frac{1\text{ hp}}{550\text{ ft}\cdot\text{lb/s}}\right) = 1.5\times10^{-2}\text{ hp}$.

Convert to watts: $\left(1.5\times10^{-2}\text{ hp}\right)\left(\frac{746\text{ W}}{1\text{ hp}}\right) = 11\text{ W}$.

EVALUATE: This college student puts a lot less power than the marathon runner in Example 6.10 in the text!

6.50. **IDENTIFY:** The thermal energy is produced as a result of the force of friction, $F = \mu_k mg$. The average thermal power is thus the average rate of work done by friction or $P = F_{\|}v_{av}$.

SET UP: $v_{av} = \dfrac{v_2 + v_1}{2} = \left(\dfrac{8.00\text{ m/s} + 0}{2}\right) = 4.00\text{ m/s}$

EXECUTE: $P = Fv_{av} = [(0.200)(20.0\text{ kg})(9.80\text{ m/s}^2)](4.00\text{ m/s}) = 157\text{ W}$

EVALUATE: The power could also be determined as the rate of change of kinetic energy, $\Delta K / t$, where the time is calculated from $v_f = v_i + at$ and a is calculated from a force balance, $\Sigma F = ma = \mu_k mg$.

6.51. **IDENTIFY:** We need to use power.
SET UP: Estimates: student weight is 150 lb which is about 667 N. $P_{av} = W/t$.
EXECUTE: Convert units: 50 ft = 15.2 m. The work is $W = wy = (667\text{ N})(15.2\text{ m}) = 10{,}000\text{ J}$. Solve $P_{av} = W/t$ for t: $t = W/P_{av} = (10{,}000\text{ J})/(500\text{ W}) = 20\text{ s}$.
EVALUATE: 20 s seems like a reasonable time to climb three flights of stairs.

6.52. **IDENTIFY** and **SET UP:** Calculate the power used to make the plane climb against gravity. Consider the vertical motion since gravity is vertical.
EXECUTE: The rate at which work is being done against gravity is

$P = Fv = mgv = (700\text{ kg})(9.80\text{ m/s}^2)(2.5\text{ m/s}) = 17.15\text{ kW}$.

This is the part of the engine power that is being used to make the airplane climb. The fraction this is of the total is $17.15\text{ kW}/75\text{ kW} = 0.23$.
EVALUATE: The power we calculate for making the airplane climb is considerably less than the power output of the engine.

6.53. **IDENTIFY:** $P_{av} = \dfrac{\Delta W}{\Delta t}$. The work you do in lifting mass m a height h is mgh.

SET UP: $1\text{ hp} = 746\text{ W}$

EXECUTE: **(a)** The number per minute would be the average power divided by the work (mgh) required to lift one box, $\dfrac{(0.50\text{ hp})(746\text{ W/hp})}{(30\text{ kg})(9.80\text{ m/s}^2)(0.90\text{ m})} = 1.41/\text{s}$, or $84.6/\text{min}$.

(b) Similarly, $\dfrac{(100\text{ W})}{(30\text{ kg})(9.80\text{ m/s}^2)(0.90\text{ m})} = 0.378/\text{s}$, or $22.7/\text{min}$.

EVALUATE: A 30-kg crate weighs about 66 lbs. It is not possible for a person to perform work at this rate.

6.54. **IDENTIFY** and **SET UP:** Use $P_{av} = \dfrac{\Delta W}{\Delta t}$ to relate the power provided and the amount of work done against gravity in 16.0 s. The work done against gravity depends on the total weight which depends on the number of passengers.
EXECUTE: Find the total mass that can be lifted:

$$P_{av} = \frac{\Delta W}{\Delta t} = \frac{mgh}{t}, \text{ so } m = \frac{P_{av}t}{gh}$$

$$P_{av} = (40\text{ hp})\left(\frac{746\text{ W}}{1\text{ hp}}\right) = 2.984\times 10^4\text{ W}$$

$$m = \frac{P_{av}t}{gh} = \frac{(2.984\times 10^4\text{ W})(16.0\text{ s})}{(9.80\text{ m/s}^2)(20.0\text{ m})} = 2.436\times 10^3\text{ kg}$$

This is the total mass of elevator plus passengers. The mass of the passengers is

$2.436\times10^3\ \text{kg} - 600\ \text{kg} = 1.836\times10^3\ \text{kg}.$ The number of passengers is $\dfrac{1.836\times10^3\ \text{kg}}{65.0\ \text{kg}} = 28.2.$ 28

passengers can ride.

EVALUATE: Typical elevator capacities are about half this, in order to have a margin of safety.

6.55. **IDENTIFY:** To lift the skiers, the rope must do positive work to counteract the negative work developed by the component of the gravitational force acting on the total number of skiers, $F_{\text{rope}} = Nmg\sin\alpha.$

SET UP: $P = F_{\|}v = F_{\text{rope}}v$

EXECUTE: $P_{\text{rope}} = F_{\text{rope}}v = [+Nmg(\cos\phi)]v.$

$$P_{\text{rope}} = [(50\ \text{riders})(70.0\ \text{kg})(9.80\ \text{m/s}^2)(\cos 75.0)]\left[(12.0\ \text{km/h})\left(\frac{1\ \text{m/s}}{3.60\ \text{km/h}}\right)\right].$$

$P_{\text{rope}} = 2.96\times10^4\ \text{W} = 29.6\ \text{kW}.$

EVALUATE: Some additional power would be needed to give the riders kinetic energy as they are accelerated from rest.

6.56. **IDENTIFY:** We want to find the power supplied by a known force acting on a crate at a known velocity.

SET UP: We know the vector components, so we use $P = \vec{F}\cdot\vec{v} = F_xv_x + F_yv_y$

EXECUTE: $P = F_xv_x + F_yv_y = (-8.00\ \text{N})(3.20\ \text{m/s}) + (3.00\ \text{N})(2.20\ \text{m/s}) = -19.0\ \text{W}.$

EVALUATE: The power is negative because the x-component of the force is opposite to the x-component of the velocity and hence opposes the motion of the crate.

6.57. **IDENTIFY:** Relate power, work, and time.

SET UP: Work done in each stroke is $W = Fs$ and $P_{\text{av}} = W/t.$

EXECUTE: 100 strokes per second means $P_{\text{av}} = 100Fs/t$ with $t = 1.00$ s, $F = 2mg$ and $s = 0.010$ m.

$P_{\text{av}} = 0.20$ W.

EVALUATE: For a 70-kg person to apply a force of twice his weight through a distance of 0.50 m for 100 times per second, the average power output would be 7.0×10^4 W. This power output is very far beyond the capability of a person.

6.58. **IDENTIFY:** The force has only an x-component and the motion is along the x-direction, so $W = \int_{x_1}^{x_2} F_x dx.$

SET UP: $x_1 = 0$ and $x_2 = 6.9$ m.

EXECUTE: The work you do with your changing force is

$$W = \int_{x_1}^{x_2} F(x)dx = \int_{x_1}^{x_2}(-20.0\ \text{N})dx - \int_{x_1}^{x_2}(3.0\ \text{N/m})x dx = (-20.0\ \text{N})x\,|_{x_1}^{x_2} - (3.0\ \text{N/m})(x^2/2)\,|_{x_1}^{x_2}$$

$W = -138\ \text{N}\cdot\text{m} - 71.4\ \text{N}\cdot\text{m} = -209\ \text{J}.$

EVALUATE: The work is negative because the cow continues to move forward (in the $+x$-direction) as you vainly attempt to push her backward.

6.59. **IDENTIFY** and **SET UP:** Since the forces are constant, $W_F = (F\cos\phi)s$ can be used to calculate the work done by each force. The forces on the suitcase are shown in Figure 6.59a.

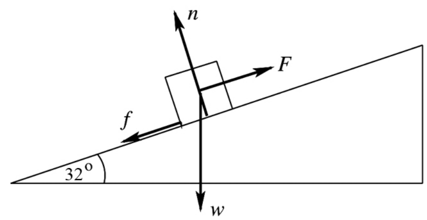


Figure 6.59a

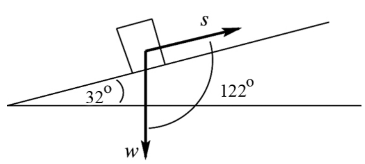
In part (f), the work-energy theorem is used to relate the total work to the initial and final kinetic energy.

EXECUTE: **(a)** $W_F = (F\cos\phi)s$

Both $\vec{F}$ and $\vec{s}$ are parallel to the incline and in the same direction, so $\phi = 90°$ and $W_F = Fs = (160\text{ N})(3.80\text{ m}) = 608\text{ J}.$

(b) The directions of the displacement and of the gravity force are shown in Figure 6.59b.



$W_w = (w\cos\phi)s$

$\phi = 122°,$ so

$W_w = (196\text{ N})(\cos 122°)(3.80\text{ m})$

$W_w = -395\text{ J}$

Figure 6.59b

Alternatively, the component of w parallel to the incline is $w\sin 32°$. This component is down the incline so its angle with $\vec{s}$ is $\phi = 180°$. $W_{w\sin 32°} = (196\text{ N}\sin 32°)(\cos 180°)(3.80\text{ m}) = -395\text{ J}$. The other component of w, $w\cos 32°$, is perpendicular to $\vec{s}$ and hence does no work. Thus $W_w = W_{w\sin 25°} = -315\text{ J},$ which agrees with the above.

(c) The normal force is perpendicular to the displacement $(\phi = 90°)$, so $W_n = 0$.

(d) $n = w\cos 32°$ so $f_k = \mu_k n = \mu_k w\cos 32° = (0.30)(196\text{ N})\cos 32° = 49.87\text{ N}$

$W_f = (f_k\cos\phi)x = (49.87\text{ N})(\cos 180°)(3.80\text{ m}) = -189\text{ J}.$

(e) $W_{\text{tot}} = W_F + W_w + W_n + W_f = +608\text{ J} - 395\text{ J} + 0 - 189\text{ J} = 24\text{ J}.$

(f) $W_{\text{tot}} = K_2 - K_1,\ K_1 = 0,$ so $K_2 = W_{\text{tot}}$

$\tfrac{1}{2}mv_2^2 = W_{\text{tot}}$ so $v_2 = \sqrt{\dfrac{2W_{\text{tot}}}{m}} = \sqrt{\dfrac{2(24\text{ J})}{20.0\text{ kg}}} = 1.5\text{ m/s}.$

EVALUATE: The total work done is positive and the kinetic energy of the suitcase increases as it moves up the incline.

6.60. **IDENTIFY:** We need to use projectile motion and the work-energy theorem.

SET UP: $W_{\text{tot}} = K_2 - K_1$, $K = \dfrac{1}{2}mv^2$. First use projectile motion to find the initial velocity, and then use the work-energy theorem to find the work.

EXECUTE: **(a)** When the can returns to the ground, $y = 0$, so $y = (v_0\sin\alpha_0)t - \dfrac{1}{2}gt^2$ gives us $0 = v_0\sin\alpha_0 T - \dfrac{1}{2}gT^2$, so $T = \dfrac{2v_0\sin\alpha_0}{g}$, which is the time in the air, and $v_0 = \dfrac{gT}{2\sin\alpha_0}$. Now use $W_{\text{tot}} = K_2 - K_1$ with $K_1 = 0$ to find the work. $W = \dfrac{1}{2}Mv_0^2 = \dfrac{1}{2}M\left(\dfrac{gT}{2\sin\alpha_0}\right)^2 = \dfrac{M}{8}\left(\dfrac{gT}{\sin}\alpha_0\right)^2.$

(b) If it is in the air twice as long, T is doubled. Using our result from part (a), we see that T is *squared*, so $(2T)^2$ would become $4T$. Therefore the work would become $W = \frac{M}{8}\left(\frac{g2T}{\sin}\alpha_0\right)^2 = \frac{M}{2}\left(\frac{gT}{\sin}\alpha_0\right)^2$, which is 4 times as much as in part (a).

EVALUATE: Another approach is to use $T = \frac{2v_0 \sin\alpha_0}{g}$ to see that if T is doubled, so is v_0. Therefore the kinetic energy $\frac{1}{2}mv^2$ is 4 times as large, so the work must have 4 times as much.

6.61. IDENTIFY: This problem requires use of the work-energy theorem. Both friction and gravity do work on the block as it slides down the ramp, but the normal force does no work.

SET UP: $W_{\text{tot}} = K_2 - K_1$, $W = Fs\cos\phi$, $K = \frac{1}{2}mv^2$, $K_1 = 0$ when the block is released. Fig. 6.61 shows the information in the problem.

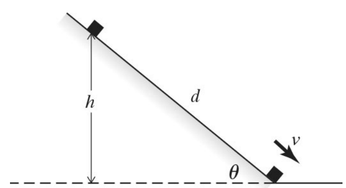


Figure 6.61

EXECUTE: **(a)** We want the work done by friction. $W_{\text{tot}} = K_2 - K_1$, where $K_1 = 0$, $K_2 = \frac{1}{2}mv^2$, $W_{\text{tot}} = W_f + W_g$. So $W_f = K_2 - W_g = \frac{1}{2}mv^2 - mgh$.

$W_f = \frac{1}{2}(5.00\text{ kg})(5.00\text{ m/s})^2 - (5.00\text{ kg})(9.80\text{ m/s}^2)(2.00\text{ m}) = -35.5\text{ J}$.

(b) Now the ramp is lowered to 50.0° and the block is released from higher up but still 2.00 m above the bottom. Using $W = Fs\cos\phi$, we have $W_f = -f_k d = -\mu_k nd$. Using $\sum F_y = 0$ perpendicular to the surface of the ramp tells us that $n = mg\cos\theta$, and Fig. 6.61 shows that $d = \frac{h}{\sin\theta}$, so

$W_f = -\mu_k mg\cos\theta\left(\frac{h}{\sin\theta}\right) = -\frac{\mu_k mgh}{\tan\theta}$. From this result we see that as θ decreases, $\tan\theta$ decreases, so $1/\tan\theta$ increases. Therefore the magnitude of the work done by friction *increases* as θ decreases providing that h remains the same.

(c) Take the ratio of the works to find $W_{50°}$. $\frac{W_{50°}}{W_{60°}} = \frac{-\frac{\mu_k mgh}{\tan 50.0°}}{-\frac{\mu_k mgh}{\tan 60.0°}} = \frac{\tan 60.0°}{\tan 50.0°} = 1.45$, which gives $W_{50°} = (1.45)W_{60°} = (1.45)(-35.5\text{ J}) = -51.6\text{ J}$.

EVALUATE: As the slope angle θ decreases, the normal force increases so friction increases, and the distance d that the block slides also increases. So the magnitude of the work $W_f = f_k d$ increases, which agrees with our result.

6.62. **IDENTIFY:** We want to calculate the work that friction does on a block as it slides down an incline.

SET UP: $W = Fs\cos\phi$

EXECUTE: In this case, F is the friction force f, s is the distance that the block slides along the surface of the incline, and ϕ is the angle between the friction force and the displacement of the block, which is 180°. $W_f = fs \cos 180° = -fs$. In terms of h, $s = h/\sin\alpha$, and $f = \mu_k n$. $\sum F_y = 0$ perpendicular to the surface of the incline tells us that $n = mg\cos\alpha$, so $f = \mu_k mg\cos\alpha$. Combining these relations gives $W_f = -\mu_k mg\cos\alpha\left(\dfrac{h}{\sin\alpha}\right) = -\dfrac{\mu_k mgh}{\tan\alpha}$.

EVALUATE: As α is decreased, $\tan\alpha$ decreases, so W_f increases in magnitude.

6.63. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to each block to find the tension in the string. Each force is constant and $W = Fs\cos\phi$.

SET UP: The free-body diagram for each block is shown in Figure 6.63. $m_A = \dfrac{20.0\text{ N}}{g} = 2.04\text{ kg}$ and $m_B = \dfrac{12.0\text{ N}}{g} = 1.22\text{ kg}$.

EXECUTE: $T - f_k = m_A a$. $w_B - T = m_B a$. $w_B - f_k = (m_A + m_B)a$.

(a) $f_k = 0$. $a = \left(\dfrac{w_B}{m_A + m_B}\right)$ and $T = w_B\left(\dfrac{m_A}{m_A + m_B}\right) = w_B\left(\dfrac{w_A}{w_A + w_B}\right) = 7.50\text{ N}$.

20.0 N block: $W_{tot} = Ts = (7.50\text{ N})(0.750\text{ m}) = 5.62\text{ J}$.

12.0 N block: $W_{tot} = (w_B - T)s = (12.0\text{ N} - 7.50\text{ N})(0.750\text{ m}) = 3.38\text{ J}$.

(b) $f_k = \mu_k w_A = 6.50\text{ N}$. $a = \dfrac{w_B - \mu_k w_A}{m_A + m_B}$.

$$T = f_k + (w_B - \mu_k w_A)\left(\frac{m_A}{m_A + m_B}\right) = \mu_k w_A + (w_B - \mu_k w_A)\left(\frac{w_A}{w_A + w_B}\right).$$

$T = 6.50\text{ N} + (5.50\text{ N})(0.625) = 9.94\text{ N}$.

20.0 N block: $W_{tot} = (T - f_k)s = (9.94\text{ N} - 6.50\text{ N})(0.750\text{ m}) = 2.58\text{ J}$.

12.0 N block: $W_{tot} = (w_B - T)s = (12.0\text{ N} - 9.94\text{ N})(0.750\text{ m}) = 1.54\text{ J}$.

EVALUATE: Since the two blocks move with equal speeds, for each block $W_{tot} = K_2 - K_1$ is proportional to the mass (or weight) of that block. With friction the gain in kinetic energy is less, so the total work on each block is less.

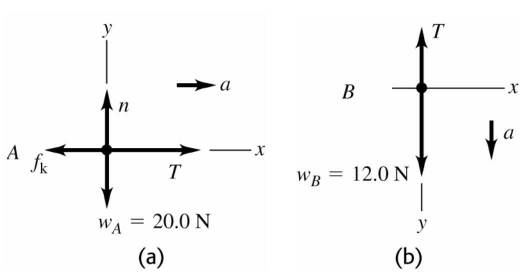

Figure 6.63

6.64. **IDENTIFY:** $W = Fs\cos\phi$ and $W_{tot} = K_2 - K_1$.

SET UP: $f_k = \mu_k n$. The normal force is $n = mg\cos\theta$, with $\theta = 24.0°$. The component of the weight parallel to the incline is $mg\sin\theta$.

EXECUTE: **(a)** $\phi = 180°$ and

$W_f = -f_k s = -(\mu_k mg\cos\theta)s = -(0.31)(5.00\text{ kg})(9.80\text{ m/s}^2)(\cos 24.0°)(2.80\text{ m}) = -38.9\text{ J}.$

(b) $(5.00\text{ kg})(9.80\text{ m/s}^2)(\sin 24.0°)(2.80\text{ m}) = 55.8\text{ J}.$

(c) The normal force does no work.

(d) $W_{\text{tot}} = 55.8\text{ J} - 38.9\text{ J} = +16.9\text{ J}.$

(e) $K_2 = K_1 + W_{\text{tot}} = (1/2)(5.00\text{ kg})(2.20\text{ m/s})^2 + 16.9\text{ J} = 29.0\text{ J},$ and so

$v_2 = \sqrt{2(29.0\text{ J})/(5.00\text{ kg})} = 3.41\text{ m/s}.$

EVALUATE: Friction does negative work and gravity does positive work. The net work is positive and the kinetic energy of the object increases.

6.65. **IDENTIFY:** The initial kinetic energy of the head is absorbed by the neck bones during a sudden stop. Newton's second law applies to the passengers as well as to their heads.

SET UP: In part (a), the initial kinetic energy of the head is absorbed by the neck bones, so $\frac{1}{2}mv_{\text{max}}^2 = 8.0\text{ J}.$ For part (b), assume constant acceleration and use $v_\text{f} = v_\text{i} + at$ with $v_\text{i} = 0,$ to calculate a; then apply $F_{\text{net}} = ma$ to find the net accelerating force.

Solve: (a) $v_{\text{max}} = \sqrt{\dfrac{2(8.0\text{ J})}{5.0\text{ kg}}} = 1.8\text{ m/s} = 4.0\text{ mph}.$

(b) $a = \dfrac{v_\text{f} - v_\text{i}}{t} = \dfrac{1.8\text{ m/s} - 0}{10.0\times 10^{-3}\text{ s}} = 180\text{ m/s}^2 \approx 18g,$ and $F_{\text{net}} = ma = (5.0\text{ kg})(180\text{ m/s}^2) = 900\text{ N}.$

EVALUATE: The acceleration is very large, but if it lasts for only 10 ms it does not do much damage.

6.66. **IDENTIFY:** The force does work on the object, which changes its kinetic energy, so the work-energy theorem applies. The force is variable so we must integrate to calculate the work it does on the object.

SET UP: $W_{\text{tot}} = \Delta K = K_\text{f} - K_\text{i} = \frac{1}{2}mv_\text{f}^2 - \frac{1}{2}mv_\text{i}^2$ and $W_{\text{tot}} = \int_{x_1}^{x_2} F(x)dx.$

EXECUTE: $W_{\text{tot}} = \int_{x_1}^{x_2} F(x)dx = \int_0^{5.00\text{ m}} [-12.0\text{ N} + (0.300\text{ N/m}^2)x^2]dx.$

$W_{\text{tot}} = -(12.0\text{ N})(5.00\text{ m}) + (0.100\text{ N/m}^2)(5.00\text{ m})^3 = -60.0\text{ J} + 12.5\text{ J} = -47.5\text{ J}.$

$W_{\text{tot}} = \frac{1}{2}mv_\text{f}^2 - \frac{1}{2}mv_\text{i}^2 = -47.5\text{ J},$ so the final velocity is

$v_\text{f} = \sqrt{v_\text{i}^2 - \dfrac{2(47.5\text{ J})}{m}} = \sqrt{(6.00\text{ m/s})^2 - \dfrac{2(47.5\text{ J})}{5.00\text{ kg}}} = 4.12\text{ m/s}.$

EVALUATE: We could not readily do this problem by integrating the acceleration over time because we know the force as a function of x, not of t. The work-energy theorem provides a much simpler method.

6.67. **IDENTIFY:** Calculate the work done by friction and apply $W_{\text{tot}} = K_2 - K_1.$ Since the friction force is not constant, use $W = \int F_x dx$ to calculate the work.

SET UP: Let x be the distance past P. Since μ_k increases linearly with x, $\mu_k = 0.100 + Ax.$ When $x = 12.5\text{ m},$ $\mu_k = 0.600,$ so $A = 0.500/(12.5\text{ m}) = 0.0400/\text{m}.$

EXECUTE: **(a)** $W_{\text{tot}} = \Delta K = K_2 - K_1$ gives $-\int \mu_k mg dx = 0 - \dfrac{1}{2}mv_1^2.$ Using the above expression for μ_k, $g\int_0^{x_2}(0.100 + Ax)dx = \dfrac{1}{2}v_1^2$ and $g\left[(0.100)x_2 + A\dfrac{x_2^2}{2}\right] = \dfrac{1}{2}v_1^2.$

$(9.80\text{ m/s}^2)\left[(0.100)x_2 + (0.0400/\text{m})\dfrac{x_2^2}{2}\right] = \dfrac{1}{2}(4.50\text{ m/s})^2.$ Solving for x_2 gives $x_2 = 5.11\text{ m}.$

(b) $\mu_k = 0.100 + (0.0400/\text{m})(5.11\text{ m}) = 0.304$

(c) $W_{tot} = K_2 - K_1$ gives $-\mu_k mgx_2 = 0 - \frac{1}{2}mv_1^2$. $x_2 = \frac{v_1^2}{2\mu_k g} = \frac{(4.50\text{ m/s})^2}{2(0.100)(9.80\text{ m/s}^2)} = 10.3\text{ m}$.

EVALUATE: The box goes farther when the friction coefficient doesn't increase.

6.68. **IDENTIFY:** Use $W = \int F_x dx$ to calculate W.

SET UP: $x_1 = 0$. In part (a), $x_2 = 0.050\text{ m}$. In part (b), $x_2 = -0.050\text{ m}$.

EXECUTE: **(a)** $W = \int_0^{x_2} F_x dx = \int_0^{x_2} (kx - bx^2 + cx^3)\, dx = \frac{k}{2}x_2^2 - \frac{b}{3}x_2^3 + \frac{c}{4}x_2^4$.

$W = (50.0\text{ N/m})\, x_2^2 - (233\text{ N/m}^2)\, x_2^3 + (3000\text{ N/m}^3)\, x_2^4$. When $x_2 = 0.050\text{ m}$, $W = 0.12\text{ J}$.

(b) When $x_2 = -0.050\text{ m}$, $W = 0.17\text{ J}$.

(c) It's easier to stretch the spring; the quadratic $-bx^2$ term is always in the –x-direction, and so the needed force, and hence the needed work, will be less when $x_2 > 0$.

EVALUATE: When $x = 0.050\text{ m}$, $F_x = 4.75\text{ N}$. When $x = -0.050\text{ m}$, $F_x = -8.25\text{ N}$.

6.69. **IDENTIFY:** Use the work-energy theorem.

SET UP: $W_{tot} = K_2 - K_1$, $K = \frac{1}{2}mv^2$. When a force does work W_D on the box, its speed is V starting from rest, so $W_D = \frac{1}{2}mV^2$.

EXECUTE: **(a)** We want to find the speed v of the box when half the total work has been done on it. Using $W_{tot} = K_2 - K_1$, we have $\frac{1}{2}W_D = \frac{1}{2}mv^2$. But as we saw above, $W_D = \frac{1}{2}mV^2$. So $\frac{1}{2}\left(\frac{1}{2}mV^2\right) = \frac{1}{2}mv^2$ which gives $v = \frac{V}{\sqrt{2}}$. Since $v \approx 0.707V$, $v > V/2$.

(b) Now we want to find how much work has been done on the box to reach half of its maximum speed, which is $\frac{1}{2}V$. The work-energy theorem gives $W = \frac{1}{2}m\left(\frac{V}{2}\right)^2 = \frac{1}{4}\left(\frac{1}{2}mV^2\right)$. From above, we know that $W_D = \frac{1}{2}mV^2$, so $W = \frac{1}{4}W_D$, which is *less than* $\frac{1}{2}W_D$.

EVALUATE: It takes $\frac{1}{4}$ of the total work to get the box to half its maximum velocity, and $\frac{3}{4}$ of the total work to get the box from $V/2$ to V.

6.70. **IDENTIFY:** We are dealing with Hooke's law and the work to compress a spring.

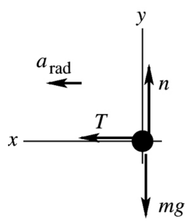
SET UP: Hooke's law: The force to stretch a spring a distance x is $F = kx$. The work to compress a spring a distance x from its equilibrium position is $W = \frac{1}{2}kx^2$.

EXECUTE: First find the force constant k. With you alone on the spring at maximum compression, $kx_1 = mg$, so $k = mg/x_1 = (530\text{ N})/(0.0180\text{ m}) = 2.94\times 10^4\text{ N/m}$. The spring compression with you and the dog is given by $kx_2 = w_{you} + w_{dog}$, so $x_2 = (710\text{ N})/(2.94\times 10^4\text{ N/m}) = 2.411\times 10^{-2}\text{ m} = 0.02411\text{ m}$. The work to compress the spring from x_1 to x_2 is $W_{1\to 2} = \frac{1}{2}kx_2^2 - \frac{1}{2}kx_1^2$. Using $x_1 = 0.0180\text{ m}$, $x_2 = 0.02411\text{ m}$, and $k = 2.94\times 10^4\text{ N/m}$, we get $W_{1\to 2} = 3.79\text{ J}$.

EVALUATE: The work to bring you to rest without your dog is $\frac{1}{2}kx_1^2 = \frac{1}{2}(2.944\times10^4 \text{ N/m})(0.0180 \text{ m})^2$ $= 4.77$ J. This is greater than the work to compress the spring with you and your dog because the amount of compression was less. You alone compressed the spring by 1.80 cm, but you with your dog compressed it only an additional 0.61 cm.

6.71. IDENTIFY and **SET UP:** Use $\Sigma\vec{F} = m\vec{a}$ to find the tension force T. The block moves in uniform circular motion and $\vec{a} = \vec{a}_{\text{rad}}$.

(a) The free-body diagram for the block is given in Figure 6.71.



EXECUTE: $\Sigma F_x = ma_x$

$$T = m\frac{v^2}{R}$$

$$T = (0.0600 \text{ kg})\frac{(0.70 \text{ m/s})^2}{0.40 \text{ m}} = 0.074 \text{ N}.$$

Figure 6.71

(b) $T = m\frac{v^2}{R} = (0.0600 \text{ kg})\frac{(2.80 \text{ m/s})^2}{0.10 \text{ m}} = 4.7 \text{ N}.$

(c) SET UP: The tension changes as the distance of the block from the hole changes. We could use $W = \int_{x_1}^{x_2} F_x\, dx$ to calculate the work. But a much simpler approach is to use $W_{\text{tot}} = K_2 - K_1$.

EXECUTE: The only force doing work on the block is the tension in the cord, so $W_{\text{tot}} = W_T$.

$K_1 = \frac{1}{2}mv_1^2 = \frac{1}{2}(0.0600 \text{ kg})(0.70 \text{ m/s})^2 = 0.01470 \text{ J}$, $K_2 = \frac{1}{2}mv_2^2 = \frac{1}{2}(0.0600 \text{ kg})(2.80 \text{ m/s})^2 = 0.2352 \text{ J}$, so $W_{\text{tot}} = K_2 - K_1 = 0.2352 \text{ J} - 0.01470 \text{ J} = 0.22 \text{ J}$. This is the amount of work done by the person who pulled the cord.

EVALUATE: The block moves inward, in the direction of the tension, so T does positive work and the kinetic energy increases.

6.72. IDENTIFY: Use $W = \int F_x dx$ to find the work done by F. Then apply $W_{\text{tot}} = K_2 - K_1$.

SET UP: $\int \frac{dx}{x^2} = -\frac{1}{x}$.

EXECUTE: $W = \int_{x_1}^{x_2} \frac{\alpha}{x^2}\, dx = \alpha\left(\frac{1}{x_1} - \frac{1}{x_2}\right)$.

$W = (2.12\times10^{-26} \text{ N}\cdot\text{m}^2)\left[(0.200 \text{ m}^{-1}) - (1.25\times10^9 \text{ m}^{-1})\right] = -2.65\times10^{-17} \text{ J}.$

Note that x_1 is so large compared to x_2 that the term $1/x_1$ is negligible. Then, using the work-energy theorem and solving for v_2,

$$v_2 = \sqrt{v_1^2 + \frac{2W}{m}} = \sqrt{(3.00\times10^5 \text{ m/s})^2 + \frac{2(-2.65\times10^{-17} \text{ J})}{(1.67\times10^{-27} \text{ kg})}} = 2.41\times10^5 \text{ m/s}.$$

(b) With $K_2 = 0, W = -K_1$. Using $W = -\frac{\alpha}{x_2}$,

$$x_2 = \frac{\alpha}{K_1} = \frac{2\alpha}{mv_1^2} = \frac{2(2.12\times10^{-26} \text{ N}\cdot\text{m}^2)}{(1.67\times10^{-27} \text{ kg})(3.00\times10^5 \text{ m/s})^2} = 2.82\times10^{-10} \text{ m}.$$

(c) The repulsive force has done no net work, so the kinetic energy and hence the speed of the proton have their original values, and the speed is 3.00×10^5 m/s.

EVALUATE: As the proton moves toward the uranium nucleus the repulsive force does negative work and the kinetic energy of the proton decreases. As the proton moves away from the uranium nucleus the repulsive force does positive work and the kinetic energy of the proton increases.

6.73. IDENTIFY: The negative work done by the spring equals the change in kinetic energy of the car.

SET UP: The work done by a spring when it is compressed a distance x from equilibrium is $-\frac{1}{2}kx^2$. $K_2 = 0$.

EXECUTE: $-\frac{1}{2}kx^2 = K_2 - K_1$ gives $\frac{1}{2}kx^2 = \frac{1}{2}mv_1^2$ and

$k = (mv_1^2)/x^2 = [(1200\text{ kg})(0.65\text{ m/s})^2]/(0.090\text{ m})^2 = 6.3\times 10^4$ N/m.

EVALUATE: When the spring is compressed, the spring force is directed opposite to the displacement of the object and the work done by the spring is negative.

6.74. IDENTIFY and SET UP: Use the work-energy theorem $W_{\text{tot}} = K_2 - K_1$. You do positive work and gravity does negative work. Let point 1 be at the base of the bridge and point 2 be at the top of the bridge.

EXECUTE: **(a)** $W_{\text{tot}} = K_2 - K_1$

$K_1 = \frac{1}{2}mv_1^2 = \frac{1}{2}(80.0\text{ kg})(5.00\text{ m/s})^2 = 1000\text{ J}$

$K_2 = \frac{1}{2}mv_2^2 = \frac{1}{2}(80.0\text{ kg})(1.50\text{ m/s})^2 = 90\text{ J}$

$W_{\text{tot}} = 90\text{ J} - 1000\text{ J} = -910\text{ J}$

(b) Neglecting friction, work is done by you (with the force you apply to the pedals) and by gravity: $W_{\text{tot}} = W_{\text{you}} + W_{\text{gravity}}$. The gravity force is $w = mg = (80.0\text{ kg})(9.80\text{ m/s}^2) = 784\text{ N}$, downward. The displacement is 5.20 m, upward. Thus $\phi = 180°$ and

$$W_{\text{gravity}} = (F\cos\phi)s = (784\text{ N})(5.20\text{ m})\cos 180° = -4077\text{ J}$$

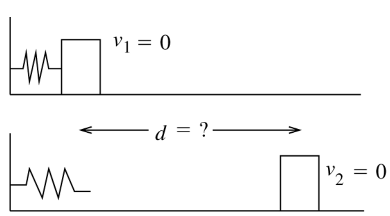
Then $W_{\text{tot}} = W_{\text{you}} + W_{\text{gravity}}$ gives

$$W_{\text{you}} = W_{\text{tot}} - W_{\text{gravity}} = -910\text{ J} - (-4077\text{ J}) = +3170\text{ J}$$

EVALUATE: The total work done is negative and you lose kinetic energy.

6.75. IDENTIFY and SET UP: Use the work-energy theorem $W_{\text{tot}} = K_2 - K_1$. Work is done by the spring and by gravity. Let point 1 be where the textbook is released and point 2 be where it stops sliding. $x_2 = 0$ since at point 2 the spring is neither stretched nor compressed. The situation is sketched in Figure 6.75.

EXECUTE:



$W_{\text{tot}} = K_2 - K_1$

$K_1 = 0,\ \ K_2 = 0$

$W_{\text{tot}} = W_{\text{fric}} + W_{\text{spr}}$

Figure 6.75

$W_{\text{spr}} = \frac{1}{2}kx_1^2$, where $x_1 = 0.250$ m (the spring force is in direction of motion of block so it does positive work).

$W_{\text{fric}} = -\mu_k mgd$

Then $W_{\text{tot}} = K_2 - K_1$ gives $\frac{1}{2}kx_1^2 - \mu_k mgd = 0$

$$d = \frac{kx_1^2}{2\mu_k mg} = \frac{(250\text{ N/m})(0.250\text{ m})^2}{2(0.30)(2.50\text{ kg})(9.80\text{ m/s}^2)} = 1.1\text{ m},$$ measured from the point where the block was released.

EVALUATE: The positive work done by the spring equals the magnitude of the negative work done by friction. The total work done during the motion between points 1 and 2 is zero, and the textbook starts and ends with zero kinetic energy.

6.76. **IDENTIFY:** Apply $W_{\text{tot}} = K_2 - K_1$.

SET UP: Let x_0 be the initial distance the spring is compressed. The work done by the spring is $\frac{1}{2}kx_0^2 - \frac{1}{2}kx^2$, where x is the final distance the spring is compressed.

EXECUTE: **(a)** Equating the work done by the spring to the gain in kinetic energy, $\frac{1}{2}kx_0^2 = \frac{1}{2}mv^2$, so

$$v = \sqrt{\frac{k}{m}}x_0 = \sqrt{\frac{400\text{ N/m}}{0.0300\text{ kg}}}(0.060\text{ m}) = 6.93\text{ m/s}.$$

(b) W_{tot} must now include friction, so $\frac{1}{2}mv^2 = W_{\text{tot}} = \frac{1}{2}kx_0^2 - fx_0$, where f is the magnitude of the friction force. Then,

$$v = \sqrt{\frac{k}{m}x_0^2 - \frac{2f}{m}x_0} = \sqrt{\frac{400\text{ N/m}}{0.0300\text{ kg}}(0.060\text{ m})^2 - \frac{2(6.00\text{ N})}{(0.0300\text{ kg})}(0.060\text{ m})} = 4.90\text{ m/s}.$$

(c) The greatest speed occurs when the acceleration (and the net force) are zero. Let x be the amount the spring is still compressed, so the distance the ball has moved is $x_0 - x$. $kx = f$, $x = \frac{f}{k} = \frac{6.00\text{ N}}{400\text{ N/m}} =$ 0.0150 m.

The ball is 0.0150 m from the end of the barrel, or 0.0450 m from its initial position.

To find the speed, the net work is $W_{\text{tot}} = \frac{1}{2}k(x_0^2 - x^2) - f(x_0 - x)$, so the maximum speed is

$$v_{\max} = \sqrt{\frac{k}{m}(x_0^2 - x^2) - \frac{2f}{m}(x_0 - x)}.$$

$$v_{\max} = \sqrt{\frac{400\text{ N/m}}{(0.0300\text{ kg})}\left[(0.060\text{ m})^2 - (0.0150\text{ m})^2\right] - \frac{2(6.00\text{ N})}{(0.0300\text{ kg})}(0.060\text{ m} - 0.0150\text{ m})} = 5.20\text{ m/s}$$

EVALUATE: The maximum speed with friction present (part (c)) is larger than the result of part (b) but smaller than the result of part (a).

6.77. **IDENTIFY:** A constant horizontal force pushes a block against a spring on a rough floor. The work-energy theorem and Newton's second law both apply.

SET UP: In part (a), we apply the work-energy theorem $W_{\text{tot}} = K_2 - K_1$ to the block. $f_k = \mu_k n$ and $W_{\text{spring}} = -\frac{1}{2} kx^2$. In part (b), we apply Newton's second law to the block.

EXECUTE: **(a)** $W_F + W_{\text{spring}} + W_f = K_2 - K_1$. $Fx - \frac{1}{2} kx^2 - \mu_k mgx = \frac{1}{2} mv^2 - 0$. Putting in the numbers from the problem gives (82.0 N)(0.800 m) – (130.0 N/m)(0.800 m)^2/2 – (0.400)(4.00 kg)(9.80 m/s^2)(0.800 m) = (4.00 kg)v^2/2, v = 2.39 m/s.

(b) Looking at quantities parallel to the floor, with the positive direction toward the wall, Newton's second law gives $F - f_k - F_{\text{spring}} = ma$.

$F - \mu_k mg - kx = ma$: 82.0 N – (0.400)(4.00 kg)(9.80 m/s^2) – (130.0 N/m)(0.800 m) = (4.00 kg)a

a = –9.42 m/s^2. The minus sign means that the acceleration is away from the wall.

EVALUATE: The force you apply is toward the wall but the block is accelerating away from the wall.

6.78. **IDENTIFY:** A constant horizontal force pushes a frictionless block of ice against a spring on the floor. The work-energy theorem and Newton's second law both apply.

SET UP: In part (a), we apply the work-energy theorem $W_{\text{tot}} = K_2 - K_1$ to the ice. $W_{\text{spring}} = -\frac{1}{2}kx^2$. In part (b), we apply Newton's second law to the ice.

EXECUTE: **(a)** $W_F + W_{\text{spring}} = K_2 - K_1$. $Fx - \frac{1}{2}kx^2 = \frac{1}{2}mv^2 - 0$. Putting in the numbers from the problem gives $(54.0\text{ N})(0.400\text{ m}) - (76.0\text{ N/m})(0.400\text{ m})^2/2 = (2.00\text{ kg})v^2/2$, $v = 3.94$ m/s.

(b) Looking at quantities parallel to the floor, with the positive direction away from the post, Newton's second law gives $F - F_{\text{spring}} = ma$, so $F - kx = ma$.

54.0 N – (76.0 N/m)(0.400 m) = (2.00 kg)a, which gives $a = 11.8\text{ m/s}^2$. The acceleration is positive, so the block is accelerating away from the post.

EVALUATE: The given force must be greater than the spring force since the ice is accelerating away from the post.

6.79. **IDENTIFY:** Apply $W_{\text{tot}} = K_2 - K_1$ to the blocks.

SET UP: If X is the distance the spring is compressed, the work done by the spring is $-\frac{1}{2}kX^2$. At maximum compression, the spring (and hence the block) is not moving, so the block has no kinetic energy.

EXECUTE: **(a)** The work done *by* the block is equal to its initial kinetic energy, and the maximum compression is found from $\frac{1}{2}kX^2 = \frac{1}{2}mv_0^2$ and $X = \sqrt{\frac{m}{k}}v_0 = \sqrt{\frac{5.00\text{ kg}}{500\text{ N/m}}}(6.00\text{ m/s}) = 0.600\text{ m}.$

(b) Solving for v_0 in terms of a known X, $v_0 = \sqrt{\frac{k}{m}}X = \sqrt{\frac{500\text{ N/m}}{5.00\text{ kg}}}(0.150\text{ m}) = 1.50\text{ m/s}.$

EVALUATE: The negative work done by the spring removes the kinetic energy of the block.

6.80. **IDENTIFY:** Apply $W_{\text{tot}} = K_2 - K_1$. $W = Fs\cos\phi$.

SET UP: The students do positive work, and the force that they exert makes an angle of $30.0°$ with the direction of motion. Gravity does negative work, and is at an angle of $120.0°$ with the chair's motion.

EXECUTE: The total work done is $W_{\text{tot}} =$
$\left[(600\text{ N})\cos 30.0° + (85.0\text{ kg})(9.80\text{ m/s}^2)\cos 120.0°\right](2.50\text{ m}) = 257.8\text{ J}$, and so the speed at the top of the ramp is $v_2 = \sqrt{v_1^2 + \frac{2W_{\text{tot}}}{m}} = \sqrt{(2.00\text{ m/s})^2 + \frac{2(257.8\text{ J})}{(85.0\text{ kg})}} = 3.17\text{ m/s}.$

EVALUATE: The component of gravity down the incline is $mg\sin 30° = 417\text{ N}$ and the component of the push up the incline is $(600\text{ N})\cos 30° = 520\text{ N}$. The force component up the incline is greater than the force component down the incline; the net work done is positive and the speed increases.

6.81. **IDENTIFY** and **SET UP:** Apply $W_{\text{tot}} = K_2 - K_1$ to the system consisting of both blocks. Since they are connected by the cord, both blocks have the same speed at every point in the motion. Also, when the 6.00-kg block has moved downward 1.50 m, the 8.00-kg block has moved 1.50 m to the right. The target variable, μ_k, will be a factor in the work done by friction. The forces on each block are shown in Figure 6.81.

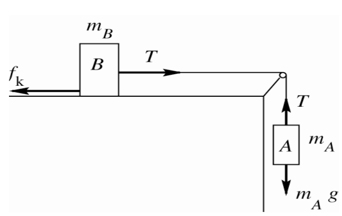


Figure 6.81

EXECUTE: $K_1 = \frac{1}{2}m_A v_1^2 + \frac{1}{2}m_B v_1^2 = \frac{1}{2}(m_A + m_B)v_1^2$

$K_2 = 0$

The tension T in the rope does positive work on block B and the same magnitude of negative work on block A, so T does no net work on the system. Gravity does work $W_{mg} = m_A gd$ on block A, where $d = 2.00$ m. (Block B moves horizontally, so no work is done on it by gravity.) Friction does work $W_{\text{fric}} = -\mu_k m_B gd$ on block B. Thus $W_{\text{tot}} = W_{mg} + W_{\text{fric}} = m_A gd - \mu_k m_B gd$. Then $W_{\text{tot}} = K_2 - K_1$ gives $m_A gd - \mu_k m_B gd = -\frac{1}{2}(m_A + m_B)v_1^2$ and

$$\mu_k = \frac{m_A}{m_B} + \frac{\frac{1}{2}(m_A + m_B)v_1^2}{m_B gd} = \frac{6.00\text{ kg}}{8.00\text{ kg}} + \frac{(6.00\text{ kg} + 8.00\text{ kg})(0.900\text{ m/s})^2}{2(8.00\text{ kg})(9.80\text{ m/s}^2)(2.00\text{ m})} = 0.786$$

EVALUATE: The weight of block A does positive work and the friction force on block B does negative work, so the net work is positive and the kinetic energy of the blocks increases as block A descends. Note that K_1 includes the kinetic energy of both blocks. We could have applied the work-energy theorem to block A alone, but then W_{tot} includes the work done on block A by the tension force.

6.82. IDENTIFY: Apply $W_{\text{tot}} = K_2 - K_1$ to the system of the two blocks. The total work done is the sum of that done by gravity (on the hanging block) and that done by friction (on the block on the table).

SET UP: Let h be the distance the 6.00 kg block descends. The work done by gravity is (6.00 kg)gh and the work done by friction is $-\mu_k(8.00\text{ kg})gh$.

EXECUTE: $W_{\text{tot}} = (6.00\text{ kg} - (0.25)(8.00\text{ kg}))(9.80\text{ m/s}^2)(1.50\text{ m}) = 58.8\text{ J}$. This work increases the kinetic energy of both blocks: $W_{\text{tot}} = \frac{1}{2}(m_1 + m_2)v^2$, so $v = \sqrt{\dfrac{2(58.8\text{ J})}{(14.00\text{ kg})}} = 2.90\text{ m/s}$.

EVALUATE: Since the two blocks are connected by the rope, they move the same distance h and have the same speed v.

6.83. IDENTIFY: Apply the work-energy theorem $W_{\text{tot}} = K_2 - K_1$ to the skater.

SET UP: Let point 1 be just before she reaches the rough patch and let point 2 be where she exits from the patch. Work is done by friction. We don't know the skater's mass so can't calculate either friction or the initial kinetic energy. Leave her mass m as a variable and expect that it will divide out of the final equation.

EXECUTE: $f_k = 0.25mg$ so $W_f = W_{\text{tot}} = -(0.25mg)s$, where s is the length of the rough patch.

$W_{\text{tot}} = K_2 - K_1$

$K_1 = \frac{1}{2}mv_0^2$, $K_2 = \frac{1}{2}mv_2^2 = \frac{1}{2}m(0.55v_0)^2 = 0.3025\left(\frac{1}{2}mv_0^2\right)$

The work-energy relation gives $-(0.25mg)s = (0.3025 - 1)\frac{1}{2}mv_0^2$.

The mass divides out, and solving gives $s = 1.3$ m.

EVALUATE: Friction does negative work and this reduces her kinetic energy.

6.84. IDENTIFY and **SET UP:** $W = Pt$

EXECUTE: **(a)** The hummingbird produces energy at a rate of 0.7 J/s to 1.75 J/s. At 10 beats/s, the bird must expend between 0.07 J/beat and 0.175 J/beat.

(b) The steady output of the athlete is (500 W)/(70 kg) = 7 W/kg, which is below the 10 W/kg necessary to stay aloft. Though the athlete can expend 1400 W/70 kg = 20 W/kg for short periods of time, no human-powered aircraft could stay aloft for very long.

EVALUATE: Movies of early attempts at human-powered flight bear out our results.

6.85. IDENTIFY: To lift a mass m a height h requires work $W = mgh$. To accelerate mass m from rest to speed v requires $W = K_2 - K_1 = \frac{1}{2}mv^2$. $P_{\text{av}} = \dfrac{\Delta W}{\Delta t}$.

SET UP: $t = 60$ s

EXECUTE: **(a)** $(800\text{ kg})(9.80\text{ m/s}^2)(14.0\text{ m}) = 1.10\times 10^5\text{ J}.$

(b) $(1/2)(800\text{ kg})(18.0\text{ m/s}^2) = 1.30\times 10^5\text{ J}.$

(c) $\dfrac{1.10\times 10^5\text{ J} + 1.30\times 10^5\text{ J}}{60\text{ s}} = 3.99\text{ kW}.$

EVALUATE: Approximately the same amount of work is required to lift the water against gravity as to accelerate it to its final speed.

6.86. **IDENTIFY:** This problem requires the work-energy theorem. Gravity and the force $\vec{F}$ do work on the steel ball, the tension in the rope does none since it is perpendicular to the displacement.

SET UP: $W_{\text{tot}} = K_2 - K_1$, $K = \frac{1}{2}mv^2$, $W = Fs\cos\phi$. The work done by gravity is $-mgL(1-\cos\alpha)$ and $K_1 = 0$. The work done by $\vec{F}$ is Fs, where s is the arc length subtended by α. So $s = L\alpha$, but α must be in radians. Converting gives $\alpha = 37.0° = 0.6458$ rad.

EXECUTE: Applying $W_{\text{tot}} = K_2 - K_1$ we have $W_F + W_g = \frac{1}{2}mv^2$, which gives

$FL\alpha(\text{rad}) - mgL(1-\cos\alpha) = \frac{1}{2}mv^2.$ Putting in the numbers gives us

$(0.760\text{ N})(0.600\text{ m})(0.6458\text{ rad}) - (0.200\text{ kg})(9.80\text{ m/s}^2)(0.600\text{ m})(1 - \cos 37.0°) = \frac{1}{2}(0.200\text{ kg})v^2$

which gives $v = 0.759$ m/s.

EVALUATE: Note that we used $\alpha = 0.6458$ rad for the arc length but $\alpha = 37.0°$ for $\cos\alpha$. We could have used $\alpha = 0.6458$ rad in $\cos\alpha$, but we would have had to put our calculator in the radian mode for angles, and most people would forget to do this!

6.87. **IDENTIFY:** This problem requires the work-energy theorem. Gravity does work on the system, the tension in the rope does work on both of the blocks, and friction does work on the 8.00-kg block.

SET UP: $W_{\text{tot}} = K_2 - K_1$, $K = \frac{1}{2}mv^2$, $W = Fs\cos\phi$, and $K_1 = 0$. The blocks move together and therefore have the same speed.

EXECUTE: **(a)** $W_g = mgs = (6.00\text{ kg})(9.80\text{ m/s}^2)(0.800\text{ m}) = 47.0$ J.

$W_T = -Ts = -(37.0\text{ N})(0.800\text{ m}) = -29.6$ J.

$W_{\text{tot}} = K_2 - K_1$, where $W_{\text{tot}} = 47.0\text{ J} - 29.6\text{ J} = 17.4$ J. So $17.4\text{ J} = \frac{1}{2}mv^2 = \frac{1}{2}(6.00\text{ kg})v^2$, which gives $v = 2.41$ m/s.

(b) $W_{\text{tot}} = \frac{1}{2}mv^2 = \frac{1}{2}(8.00\text{ kg})(2.41\text{ m/s})^2 = 23.2$ J.

$W_T = Ts = (37.0\text{ N})(0.800\text{ m}) = 29.6$ J.

$W_{\text{tot}} = W_T + W_f \rightarrow \quad 23.2\text{ J} = 29.6\text{ J} + W_f \quad \rightarrow \quad W_f = -6.4$ J.

(c) $W_{\text{tot}} = \frac{1}{2}mv^2 = \frac{1}{2}(14.0\text{ kg})(2.41\text{ m/s})^2 = 40.6$ J.

$W_g = 47.0$ J (from part (a)).

$W_f = -6.4$ J (from part (b)).

$W_{\text{tot}} = 0$ since the tension is internal. Another way to see this is that the tension does positive work on the 8.00-kg block and an equal amount of negative work on the 6.00-kg block, so its total work is zero.

EVALUATE: In part (c), the total work on the system is 47.0 J – 6.4 J = 40.6 J, which agrees from our result using the work-energy theorem.

6.88. **IDENTIFY:** $W = \int_{x_1}^{x_2} F_x dx$, and F_x depends on both x and y.

SET UP: In each case, use the value of y that applies to the specified path. $\int x dx = \frac{1}{2}x^2$. $\int x^2 dx = \frac{1}{3}x^3$.

EXECUTE: **(a)** Along this path, y is constant, with the value $y = 3.00$ m.

$$W = \alpha y \int_{x_1}^{x_2} x dx = (2.50\ \text{N/m}^2)(3.00\ \text{m})\frac{(2.00\ \text{m})^2}{2} = 15.0\ \text{J},\ \text{since}\ x_1 = 0\ \text{and}\ x_2 = 2.00\ \text{m}.$$

(b) Since the force has no y-component, no work is done moving in the y-direction.

(c) Along this path, y varies with position along the path, given by $y = 1.5x$, so $F_x = \alpha(1.5x)x = 1.5\alpha x^2$, and

$$W = \int_{x_1}^{x_2} F dx = 1.5\alpha \int_{x_1}^{x_2} x^2 dx = 1.5(2.50\ \text{N/m}^2)\frac{(2.00\ \text{m})^3}{3} = 10.0\ \text{J}.$$

EVALUATE: The force depends on the position of the object along its path.

6.89. **IDENTIFY** and **SET UP:** For part (a) calculate m from the volume of blood pumped by the heart in one day. For part (b) use W calculated in part (a) in $P_{\text{av}} = \dfrac{\Delta W}{\Delta t}$.

EXECUTE: (a) The work to life the blood is $W = mgh$. We need the mass of blood lifted; we are given the volume $V = (7500\ \text{L})\left(\dfrac{1\times10^{-3}\ \text{m}^3}{1\ \text{L}}\right) = 7.50\ \text{m}^3$.

$$m = \text{density}\times\text{volume} = (1.05\times10^3\ \text{kg/m}^3)(7.50\ \text{m}^3) = 7.875\times10^3\ \text{kg}$$

Then $W = mgh = (7.875\times10^3\ \text{kg})(9.80\ \text{m/s}^2)(1.63\ \text{m}) = 1.26\times10^5\ \text{J}$.

(b) $P_{\text{av}} = \dfrac{\Delta W}{\Delta t} = \dfrac{1.26\times10^5\ \text{J}}{(24\ \text{h})(3600\ \text{s/h})} = 1.46\ \text{W}.$

EVALUATE: Compared to light bulbs or common electrical devices, the power output of the heart is rather small.

6.90. **IDENTIFY:** We know information about the force exerted by a stretched rubber band and want to know if it obeys Hooke's law.

SET UP: Hooke's law is $F = kx$. The graph fits the equation $F = 33.55x^{0.4871}$, with F in newtons and x in meters.

EXECUTE: **(a)** For Hooke's law, a graph of F versus x is a straight line through the origin. This graph is not a straight line, so the rubber band does not obey Hooke's law.

(b) $k_{\text{eff}} = \dfrac{dF}{dx} = \dfrac{d}{dx}(33.55x^{0.4871}) = 16.34x^{-0.5129}$. Because of the negative exponent for x, as x increases, k_{eff} decreases.

(c) The definition of work gives $W = \int_a^b F_x dx = \int_0^{0.0400\ \text{m}} 0.3355x^{0.4871} dx = (33.55/1.4871)\ 0.0400^{1.4871}$

$W = 0.188$ J. From 0.0400 m to 0.0800 m, we follow the same procedure but with different limits of integration. The result is $W = (33.55/1.4871)\ (0.0800^{1.4871} - 0.0400^{1.4871}) = 0.339$ J.

(d) $W = K_2 - K_1 = ½\ mv^2 - 0$, which gives 0.339 J = (0.300 kg)$v^2/2$, $v = 1.50$ m/s.

EVALUATE: The rubber band does not obey Hooke's law, but it does obey the work-energy theorem.

6.91. **IDENTIFY:** We know a spring obeys Hooke's law, and we want to use observations of the motion of a block attached to this spring to determine its force constant and the coefficient of friction between the block and the surface on which it is sliding. The work-energy theorem applies.

SET UP: $W_{\text{tot}} = K_2 - K_1$, $W_{\text{spring}} = ½\ kx^2$.

EXECUTE: **(a)** The spring force is initially greater than friction, so the block accelerates forward. But eventually the spring force decreases enough so that it is less than the force of friction, and the block then slows down (decelerates).

(b) The spring is initially compressed a distance x_0, and after the block has moved a distance d, the spring is compressed a distance $x = x_0 - d$. Therefore the work done by the spring is

$W_{\text{spring}} = \frac{1}{2}kx_0^2 - \frac{1}{2}k(x_0 - d)^2$. The work done by friction is $W_f = -\mu_k mgd$.

The work-energy theorem gives $W_{\text{spring}} + W_f = K_2 - K_1 = \frac{1}{2}mv^2$. Using our previous results, we get $\frac{1}{2}kx_0^2 - \frac{1}{2}k(x_0 - d)^2 - \mu_k mgd = \frac{1}{2}mv^2$. Solving for v^2 gives $v^2 = -\frac{k}{m}d^2 + 2d\left(\frac{k}{m}x_0 - \mu_k g\right)$, where $x_0 =$ 0.400 m.

(c) Figure 6.91 shows the resulting graph of v^2 versus d. Using a graphing program and a quadratic fit gives $v^2 = -39.96d^2 + 16.31d$. The maximum speed occurs when $dv^2/dd = 0$, which gives $(-39.96)(2d) + 16.31 = 0$, so $d = 0.204$ m. For this value of d, we have $v^2 = (-39.96)(0.204\text{ m})^2 + (16.31)(0.204\text{ m})$, giving $v = 1.29$ m/s.

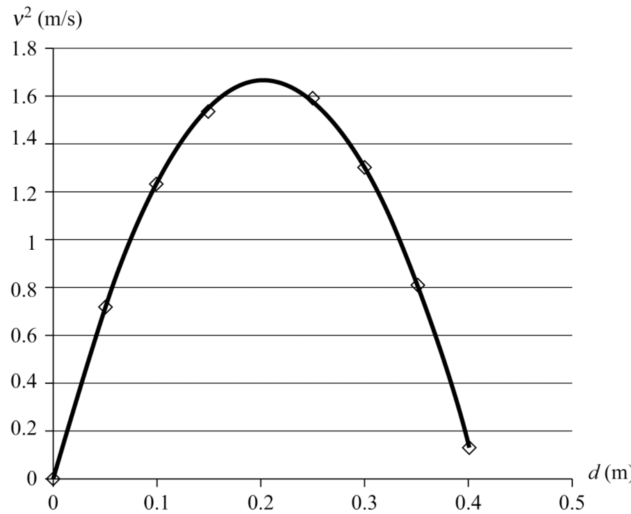

Figure 6.91

(d) From our work in (b) and (c), we know that $-k/m$ is the coefficient of d^2, so $-k/m = -39.96$, which gives $k = (39.96)(0.300\text{ kg}) = 12.0$ N/m. We also know that $2(kx_0/m - \mu_k g)$ is the coefficient of d. Solving for μ_k and putting in the numbers gives $\mu_k = 0.800$.

EVALUATE: The graphing program makes analysis of complicated behavior relatively easy.

6.92. **IDENTIFY:** The power output of the runners is the work they do in running from the basement to the top floor divided by the time it takes to make this run.

SET UP: $P = W/t$ and $W = mgh$.

EXECUTE: **(a)** For each runner, $P = mgh/t$. We must read the time of each runner from the figure shown with the problem. For example, for Tatiana we have $P = (50.2\text{ kg})(9.80\text{ m/s}^2)(16.0\text{ m})/32\text{ s} =$ 246.0 W, which we must round to 2 significant figures because we cannot read the times any more accurate than that using the figure in the text. Carrying out these calculations for all the runners, we get the following results.

Tatiana: 250 W, Bill: 210 W, Ricardo: 290 W, Melanie: 170 W. Ricardo had the greatest power output, and Melanie had the least.

(b) Solving $P = mgh/t$ for t gives $t = mgh/P = (62.3\text{ kg})(9.80\text{ m/s}^2)(16.0\text{ m})/(746\text{ W}) = 13.1\text{ s}$, where we have used the fact that 1 hp = 746 W.

EVALUATE: Even though Tatiana had the shortest time, her power output was less than Ricardo's because she weighs less than he does.

6.93. **IDENTIFY:** In part (a) follow the steps outlined in the problem. For parts (b), (c), and (d) apply the work-energy theorem.

SET UP: $\int x^2 dx = \frac{1}{3}x^3$

EXECUTE: **(a)** Denote the position of a piece of the spring by l; $l = 0$ is the fixed point and $l = L$ is the moving end of the spring. Then the velocity of the point corresponding to l, denoted u, is $u(l) = v(l/L)$ (when the spring is moving, l will be a function of time, and so u is an implicit function of time). The mass of a piece of length dl is $dm = (M/L)dl$, and so $dK = \frac{1}{2}(dm)u^2 = \frac{1}{2}\frac{Mv^2}{L^3}l^2 dl$, and

$$K = \int dK = \frac{Mv^2}{2L^3}\int_0^L l^2 dl = \frac{Mv^2}{6}.$$

(b) $\frac{1}{2}kx^2 = \frac{1}{2}mv^2$, so $v = \sqrt{(k/m)x} = \sqrt{(3200\text{ N/m})/(0.053\text{ kg})}\,(2.50\times 10^{-2}\text{ m}) = 6.1\text{ m/s}$.

(c) With the mass of the spring included, the work that the spring does goes into the kinetic energies of both the ball and the spring, so $\frac{1}{2}kx^2 = \frac{1}{2}mv^2 + \frac{1}{6}Mv^2$. Solving for v,

$$v = \sqrt{\frac{k}{m + M/3}}\,x = \sqrt{\frac{(3200\text{ N/m})}{(0.053\text{ kg}) + (0.243\text{ kg})/3}}(2.50\times 10^{-2}\text{ m}) = 3.9\text{ m/s}.$$

(d) Algebraically, $\frac{1}{2}mv^2 = \frac{(1/2)kx^2}{(1 + M/3m)} = 0.40\text{ J}$ and $\frac{1}{6}Mv^2 = \frac{(1/2)kx^2}{(1 + 3m/M)} = 0.60\text{ J}$.

EVALUATE: For this ball and spring, $\frac{K_{\text{ball}}}{K_{\text{spring}}} = \frac{3m}{M} = 3\left(\frac{0.053\text{ kg}}{0.243\text{ kg}}\right) = 0.65$. The percentage of the final kinetic energy that ends up with each object depends on the ratio of the masses of the two objects. As expected, when the mass of the spring is a small fraction of the mass of the ball, the fraction of the kinetic energy that ends up in the spring is small.

6.94. **IDENTIFY:** In both cases, a given amount of fuel represents a given amount of work W_0 that the engine does in moving the plane forward against the resisting force. Write W_0 in terms of the range R and speed v and in terms of the time of flight T and v.

SET UP: In both cases assume v is constant, so $W_0 = RF$ and $R = vT$.

EXECUTE: In terms of the range R and the constant speed v, $W_0 = RF = R\left(\alpha v^2 + \frac{\beta}{v^2}\right)$.

In terms of the time of flight $T, R = vt$, so $W_0 = vTF = T\left(\alpha v^3 + \frac{\beta}{v}\right)$.

(a) Rather than solve for R as a function of v, differentiate the first of these relations with respect to v, setting $\frac{dW_0}{dv} = 0$ to obtain $\frac{dR}{dv}F + R\frac{dF}{dv} = 0$. For the maximum range, $\frac{dR}{dv} = 0$, so $\frac{dF}{dv} = 0$. Performing the differentiation, $\frac{dF}{dv} = 2\alpha v - 2\beta/v^3 = 0$, which is solved for

$$v = \left(\frac{\beta}{\alpha}\right)^{1/4} = \left(\frac{3.5\times 10^5\text{ N}\cdot\text{m}^2/\text{s}^2}{0.30\text{ N}\cdot\text{s}^2/\text{m}^2}\right)^{1/4} = 32.9\text{ m/s} = 118\text{ km/h}.$$

(b) Similarly, the maximum time is found by setting $\frac{d}{dv}(Fv)=0;$ performing the differentiation,

$3\alpha v^2-\beta/v^2=0.$ $v=\left(\frac{\beta}{3\alpha}\right)^{1/4}=\left(\frac{3.5\times10^5\ \text{N}\cdot\text{m}^2/\text{s}^2}{3(0.30\ \text{N}\cdot\text{s}^2/\text{m}^2)}\right)^{1/4}=25\ \text{m/s}=90\ \text{km/h}.$

EVALUATE: When $v=(\beta/\alpha)^{1/4}$, F_{air} has its minimum value $F_{\text{air}}=2\sqrt{\alpha\beta}$. For this v, $R_1=(0.50)\frac{W_0}{\sqrt{\alpha\beta}}$ and $T_1=(0.50)\alpha^{-1/4}\beta^{-3/4}$. When $v=(\beta/3\alpha)^{1/4}$, $F_{\text{air}}=2.3\sqrt{\alpha\beta}$. For this v, $R_2=(0.43)\frac{W_0}{\sqrt{\alpha\beta}}$ and $T_2=(0.57)\alpha^{-1/4}\beta^{-3/4}$. $R_1>R_2$ and $T_2>T_1$, as they should be.

6.95. **IDENTIFY:** Using 300 W of metabolic power, the person travels 3 times as fast when biking than when walking.
SET UP: $P = W/t$, so $W = Pt$.
EXECUTE: When biking, the person travels 3 times as fast as when walking, so the bike trip takes 1/3 the time. Since $W = Pt$ and the power is the same, the energy when biking will be 1/3 of the energy when walking, which makes choice (a) the correct one.
EVALUATE: Walking is obviously a better way to burn calories than biking.

6.96. **IDENTIFY:** When walking on a grade, metabolic power is required for walking horizontally as well as the vertical climb.
SET UP: $P = W/t$, $W = mgh$.
EXECUTE: $P_{\text{tot}} = P_{\text{horiz}} + P_{\text{vert}} = P_{\text{horiz}} + mgh/t = P_{\text{horiz}} + mg(v_{\text{vert}})$. The slope is a 5% grade, so $v_{\text{vert}} = 0.05v_{\text{horiz}}$. Therefore $P_{\text{tot}} = 300\ \text{W} + (70\ \text{kg})(9.80\ \text{m/s}^2)(0.05)(1.4\ \text{m/s}) = 348\ \text{W} \approx 350\ \text{W}$, which makes choice (c) correct.
EVALUATE: Even a small grade of only 5% makes a difference of about 17% in power output.

6.97. **IDENTIFY:** Using 300 W of metabolic power, the person travels 3 times as fast when biking than when walking.
SET UP: $K = \frac{1}{2} mv^2$.
EXECUTE: The speed when biking is 3 times the speed when walking. Since the kinetic energy is proportional to the square of the speed, the kinetic energy will be $3^2 = 9$ times as great when biking, making choice (d) correct.
EVALUATE: Even a small increase in speed gives a considerable increase in kinetic energy due to the factor of v^2 in the kinetic energy.

7

POTENTIAL ENERGY AND ENERGY CONSERVATION

VP7.2.1. **IDENTIFY:** We use energy conservation. The ball has kinetic energy and gravitational potential energy.

SET UP: $K = \frac{1}{2}mv^2$ and $U_g = mgy$. $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$ Call point 1 the place where the ball leaves your hand and point 2 the height where it has the desired speed. In this case, $W_{\text{other}} = 0$.

EXECUTE: **(a)** In this case, $v_2 = v_1/2$ and $U_1 = 0$. $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$ gives

$0 + \frac{1}{2}mv_1^2 + 0 = mgy_2 + \frac{1}{2}mv_2^2 = mgy_2 + \frac{1}{2}m\left(\frac{v_1}{2}\right)^2$. Solve for y_2 gives $y_2 = \frac{3v_1^2}{8g} = \frac{3(12.0\text{ m/s})^2}{8(9.80\text{ m/s}^2)} = 5.51$ m.

(b) In this case, $K_2 = K_1/2$ and $U_1 = 0$, so $0 + K_1 + 0 = mgy_2 + K_1/2$. Solving for y_2 gives

$y_2 = \frac{K_1}{2mg} = \frac{\frac{1}{2}mv_1^2}{2mg} = \frac{v_1^2}{4g} = \frac{(12.0\text{ m/s})^2}{4(9.80\text{ m/s}^2)} = 3.67$ m.

EVALUATE: Notice that the ball does *not* have half of its initial kinetic energy when it is half-way to the top. Likewise when it has half of its initial kinetic energy, it is *not* half-way to the top.

VP7.2.2. **IDENTIFY:** We use energy conservation. The rock has kinetic energy and gravitational potential energy.

SET UP: $K = \frac{1}{2}mv^2$ and $U_g = mgy$. $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$ .Call point 1 the place where the rock leaves your hand and point 2 the height where it has the desired height. In this case, $W_{\text{other}} = 0$ and $U_1 =$ 0.

EXECUTE: First find the initial speed in terms of h. $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$ gives

$K_1 = U_2 + K_2 \quad \rightarrow \quad \frac{1}{2}mv_1^2 = mgh \quad \rightarrow \quad v_1^2 = 2gh$.

(a) In this case, $y_2 = h/4$ and we use , so $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$ gives

$\frac{1}{2}mv_1^2 = mg(h/4) + \frac{1}{2}mv_2^2 \quad \rightarrow \quad 2(2gh) - gh = 2v_2^2 \quad \rightarrow \quad v_2 = \sqrt{\frac{3gh}{2}}$.

(b) Follow the same procedure as in (a) *except* that $y_2 = 3h/4$. Energy conservation gives

$\frac{1}{2}mv_1^2 = mg(3h/4) + \frac{1}{2}mv_2^2$. Using $v_1^2 = 2gh$ gives $v_2 = \sqrt{\frac{gh}{2}}$.

EVALUATE: Our result says that the speed when $y = 3h/4$ is less than when $y_2 = h/4$, which is reasonable because the rock is slowing down as it rises.

VP7.2.3. **IDENTIFY:** We use energy conservation. The ball has kinetic energy and gravitational potential energy.

SET UP: $K = \frac{1}{2}mv^2$ and $U_g = mgy$. $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$. Call point 1 the place where the ball leaves your hand and point 2 the height where it reaches its maximum height, so $U_1 = 0$ and $K_2 = 0$. Call E the total mechanical energy of the ball, and use $W = Fs\cos\phi$.

EXECUTE: **(a)** $E_1 = K_1 = \frac{1}{2}mv_1^2 = \frac{1}{2}(0.0570 \text{ kg})(15.0 \text{ m/s})^2 = 6.4125 \text{ J}$.

$E_2 = U_2 = mgy_2 = (0.0570 \text{ kg})(9.80 \text{ m/s}^2)(8.00 \text{ m}) = 4.4688 \text{ J}$.

$\Delta E = E_2 - E_1 = 4.4688 \text{ J} - 6.4125 \text{ J} = -1.94 \text{ J}$, so the total mechanical energy has *decreased* by 1.94 J.

(b) The loss of mechanical energy is equal to the work done by the friction of air resistance.

$Fs\cos\phi = \Delta E \quad \to \quad F(8.00 \text{ m})\cos 180° = -1.94 \text{ J} \quad \to \quad F = 0.243 \text{ N}$.

EVALUATE: From our results, we have $E_2/E_1 = (4.4688 \text{ J})/(6.4125 \text{ J}) = 0.700$. We can also calculate this ratio as $E_2/E_1 = \frac{U_2}{U_1} = \frac{mgh}{\frac{1}{2}mv_1^2} = \frac{2gh}{v_1^2} = \frac{2(9.80 \text{ m/s}^2)}{(15.0 \text{ m/s})^2} = 0.700$, so $E_2 = 0.700E_1$. The mechanical energy has decreased by 30%.

VP7.2.4. **IDENTIFY:** We use energy conservation. The ball has kinetic energy and gravitational potential energy.

SET UP: $K = \frac{1}{2}mv^2$ and $U_g = mgy$. $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$. Call point 1 the place where you catch the ball and point 2 the place where the ball stops, so $U_1 = 0$, $y_2 = -0.150$ m, and $K_2 = 0$. Use $W = Fs\cos\phi$. W_{other} is the work done by your hands in stopping the ball.

EXECUTE: **(a)** Using $U_1 = 0$, $K_2 = 0$, $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$ becomes

$\frac{1}{2}mv_1^2 + W_{\text{hands}} = mgy_2$

$W_{\text{hands}} = m\left(gy_2 - \frac{v_1^2}{2}\right) = (0.270 \text{ kg})\left[(9.80 \text{ m/s}^2)(-0.150 \text{ m}) - \frac{(7.50 \text{ m/s})^2}{2}\right] = -7.99 \text{ J}$.

(b) $W = Fs\cos\phi \quad \to \quad -7.99 \text{ J} = F(0.150 \text{ m})\cos 180° \quad \to \quad F = 53.3 \text{ N}$.

EVALUATE: The work done by gravity is $W_g = mgy = (0.270 \text{ kg})(9.80 \text{ m/s}^2)(0.150 \text{ m}) = 39.7 \text{ J}$, which is much more than the magnitude of the work your hands do. This is reasonable because your hands also reduce (to zero) the ball's initial kinetic energy.

VP7.5.1. **IDENTIFY** We use energy conservation. The butter has kinetic energy and gravitational potential energy. Use Newton's second law for circular motion.

SET UP: $K = \frac{1}{2}mv^2$ and $U_g = mgy$. $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$. Call point 1 the place at the rim of the bowl and point 2 the bottom of the bowl, so $K_1 = 0$, $y_2 = 0$, and $W_{\text{other}} = 0$. Use $\sum F_y = ma_y$ at the bottom of the bowl, where $a_y = \frac{v^2}{R}$. At the top of the bowl, $y_1 = R$ (the radius of the bowl).

EXECUTE: **(a)** Using $K_1 = 0$, $U_2 = 0$, and $W_{\text{other}} = 0$, $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$ becomes

$mgR = \frac{1}{2}mv_2^2 \quad \to \quad v_2 = \sqrt{2Rg} = \sqrt{2(0.150 \text{ m})(9.80 \text{ m/s}^2)} = 1.71 \text{ m/s}$.

(b) At the bottom of the bowl, apply Newton's second law for circular motion.

$\sum F_y = ma_y = \frac{v^2}{R} \quad \to \quad F_{\text{bowl}} - mg = mv^2/R \quad \to \quad F_{\text{bowl}} = m(g + v^2/R)$

For the numbers here we get

$F_{\text{bowl}} = (5.00 \times 10^{-3} \text{ kg})[9.80 \text{ m/s}^2 + (1.71 \text{ m/s})^2/(0.150 \text{ m})] = 0.147 \text{ N}$.

$w = mg = (5.00 \times 10^{-3} \text{ kg})(9.80 \text{ m/s}^2) = 0.0490 \text{ N}$.

F_{bowl}/w = (0.147 N)/(0.0490 N) = 3.00, so the force due to the bowl is 3 times the weight of the butter.
EVALUATE: The ratio F_{bowl}/w is $m(g + v^2/R)/mg = g + v^2/R$, which is independent of the butter's mass. Therefore *any* object sliding down this bowl under the same conditions would experience a force from the bowl equal to 3 times the weight of the object.

VP7.5.2. **IDENTIFY:** We use energy conservation. The snowboarder has kinetic energy and gravitational potential energy.

SET UP: $K = \frac{1}{2}mv^2$ and $U_g = mgy$. $U_1 + K_1 + W_{other} = U_2 + K_2$. Call point 1 the bottom of the ditch and point 2 the highest point she reaches, so $K_2 = 0$, $U_1 = 0$.
EXECUTE: **(a)** If there is no friction, $W_{other} = 0$, so $U_1 + K_1 + W_{other} = U_2 + K_2$ becomes $K_1 = U_2$ → $\frac{1}{2}mv^2 = mgh$ → $h = v^2/2g$ = (9.30 m/s²)/[2(9.80 m/s²)] = 4.41 m. This answer does not depend on the shape of the ditch since there is no friction.
(b) The work done by friction is equal to the loss of mechanical energy, so $W_f = U_2 - K_1$.
$W_f = mgh - \frac{1}{2}mv^2 = m(gh - v^2/2)$ = (40.0 kg)[(9.80 m/s²)(3.50 m) – (9.30 m/s)²/2] = –358 J.

EVALUATE: The work done by friction is negative because the friction force is opposite to the displacement of the snowboard, which agrees with our result.

VP7.5.3. **IDENTIFY:** We apply energy conservation and Newton's second law to a swinging pendulum. The small sphere (the bob) has kinetic energy and potential energy. Use Newton's second law for circular motion.

SET UP: $K = \frac{1}{2}mv^2$ and $U_g = mgy$. $U_1 + K_1 + W_{other} = U_2 + K_2$. Call point 1 the high point of the swing and point 2 its low point, so $K_1 = 0$, $U_2 = 0$, and $W_{other} = 0$. Use $\sum F_y = ma_y$ at the bottom of the swing, where $a_y = \frac{v^2}{R}$. At the top of the swing, $h = L(1 - \cos\theta)$, where L is the length of the string and θ is the largest angle it makes with the vertical.
EXECUTE: **(a)** For conditions here, we find that $U_1 = K_2 = mgh = mgL(1 - \cos\theta)$, so
K_2 = (0.250 kg)(9.80 m/s²)(1.20 m)(1 – cos 34.0°) = 0.503 J.
(b) Apply $\sum F_y = ma_y = \frac{v^2}{R}$ at the bottom of the swing: $T - mg = \frac{mv^2}{L} = \frac{2}{L}\left(\frac{1}{2}mv^2\right) = \frac{2K}{L}$.
$T = mg + 2K/L$ = (0.250 kg)(9.80 m/s²) + 2(0.503 J)/(1.20 m) = 3.29 m.
EVALUATE: As a check, find v^2 from the known kinetic energy, giving v^2 = 4.021 m²/s². Then use $T - mg = mv^2/L$ to find T. The result is the same as we found in (b).

VP7.5.4. **IDENTIFY:** We use energy conservation. The car has kinetic energy and gravitational potential energy.

SET UP: $K = \frac{1}{2}mv^2$ and $U_g = mgy$. $U_1 + K_1 + W_{other} = U_2 + K_2$. Call A point 1 and B point 2, so U_1 = 0. In this case, $K_A = K_i$, $K_B = K_i/4$, $U_B = K_i/2$, and $y_B = 2R$.

EXECUTE: **(a)** $\Delta U_{AB} = mg(2R) = \frac{1}{2}K_i = \frac{1}{2}\left(\frac{1}{2}mv_A^2\right)$ → $v_A = \sqrt{8gR}$.

(b) Energy conservation gives $K_A + W_{other} = K_B + (U_B - U_B)$. Since W_{other} is due to friction, this becomes $K_i + W_f = \frac{1}{4}K_i + \frac{1}{2}K_i = \frac{3}{4}K_i$. Solving for W_f gives
$W_f = -\frac{1}{4}K_i = -\frac{1}{4}\left(\frac{1}{2}mv_A^2\right) = -\frac{1}{8}m(8gR) = -mgR$.

(c) Using $W_f = fs\cos\phi$ and the result from (b) gives $-mgR = f(\pi R)\cos 180° = -\pi Rf$

$f = mg/\pi$.

EVALUATE: From (c) we see that the heavier the roller coaster, the greater the friction force, which is reasonable since friction depends on the normal force at the surface of contact.

VP7.9.1. **IDENTIFY:** We use energy conservation. The system has kinetic energy and elastic potential energy in the spring.

SET UP: $K = \frac{1}{2}mv^2$ and $U = \frac{1}{2}kx^2$. The mechanical energy is the kinetic energy plus the potential energy: $E = K + U$.

EXECUTE: **(a)** $E = K + U = \frac{1}{2}mv_1^2 + \frac{1}{2}kx_1^2$

$E = \frac{1}{2}(0.240\text{ kg})(0.400\text{ m/s})^2 + \frac{1}{2}(6.00\text{ N/m})(0.100\text{ m})^2 = 0.0492\text{ J}.$

(b) There is no friction, so E is constant. So when the glider stops, $U = 0.0492$ J. Therefore

$\frac{1}{2}kx_1^2 = 0.0492\text{ J} \quad\rightarrow\quad \frac{1}{2}(6.00\text{ N/m})\,x^2 = 0.0492\text{ J} \quad\rightarrow\quad x = 0.128\text{ m}.$

EVALUATE: During most of the motion, the glider has kinetic energy and potential energy, but the sum of the two is always equal to 0.0492 J.

VP7.9.2. **IDENTIFY:** We use energy conservation. The system has kinetic energy and elastic potential energy in the spring and there is friction.

SET UP: $K = \frac{1}{2}mv^2$ and $U = \frac{1}{2}kx^2$. $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$. $W = Fs\cos\phi$. Call position 1 when the spring is stretched by 0.100 m and position 2 when the glider has instantaneously stopped, so $K_2 = 0$.

EXECUTE: **(a)** $U_1 + K_1 + W_f = U_2 + K_2$ gives $\frac{1}{2}kx_1^2 + \frac{1}{2}mv_1^2 + W_f = \frac{1}{2}kx_2^2$. Using $k = 6.00$ N/m, $m =$ 0.240 kg, $x_1 = 0.100$ m, $x_2 = 0.112$ m, and $v_1 = 0.400$ m/s gives $W_f = -0.0116$ J.

(b) $W_f = fs\cos\phi = \mu_k n(x_2 - x_1)\cos 180° = -\mu_k mg(x_2 - x_1)$. Use the result from (a) for W_f.

$-\mu_k(0.240\text{ kg})(9.80\text{ m/s}^2)(0.112\text{ m} - 0.100\text{ m}) = -0.0116\text{ J} \quad\rightarrow\quad \mu_k = 0.410.$

EVALUATE: From Table 5.1 we see that our result is very reasonable for metal-on-metal coefficients of kinetic friction. For example, $\mu_k = 0.47$ for aluminum on steel.

VP7.9.3. **IDENTIFY:** We use energy conservation. The system has kinetic energy, gravitational potential energy, and elastic potential energy, but there is no friction.

SET UP: $K = \frac{1}{2}mv^2$ and $U = \frac{1}{2}kx^2$. $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$, and $W_{\text{other}} = 0$.

EXECUTE: **(a)** Take point 1 to be the the instant the compressed spring is released and point 2 to be just when the block loses contact with the spring, so $K_1 = 0$ and $U_2 = 0$. This gives

$U_{\text{spring}} + U_g = K_2 \quad\rightarrow\quad \frac{1}{2}kd^2 - mgd = \frac{1}{2}mv_2^2 \quad\rightarrow\quad v_2 = \sqrt{\frac{kd^2}{m} - 2gd}.$

(b) After the block clears the spring, we reapply $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$. Now call point 1 to be the instant it has left the spring and point 2 to be its maximum height. The v_1 in this part is the v_2 we found in part (a). Let maximum height be h.

$\frac{1}{2}mv_1^2 = mgh \quad \rightarrow \qquad h = \frac{v_1^2}{2g}$ The *total* vertical distance the block travels is $D = d + h$, so

$D = d + \frac{v_1^2}{2g}$. Using the value of v_2 (which is v_1 for this part) gives

$$D = d + \frac{\frac{kd^2}{m} - 2gd}{2g} = d + \frac{kd^2}{2mg} - d = \frac{kd^2}{2mg}.$$

EVALUATE: Check units to be sure that both answers have the proper dimensions of length.

VP7.9.4. **IDENTIFY:** We use energy conservation. The system has kinetic energy, gravitational potential energy, and elastic potential energy, but there is no friction.

SET UP: $K = \frac{1}{2}mv^2$ and $U = \frac{1}{2}kx^2$. $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$, and $W_{\text{other}} = W_{\text{f}}$. Call point 1 to be at the place where the cylinder is released with the spring relaxed, and point 2 to be at the maximum elongation of the spring, so $K_1 = 0$, $U_1 = 0$, and $K_2 = 0$. Call x the maximum elongation of the spring. The friction force and gravity both act through a distance x, so $W_{\text{f}} = -fx$ and $U_{2\text{-grav}} = -mgx$. This energy is negative because the cylinder is *below* point 1.

EXECUTE: $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$ gives $-fx = \frac{1}{2}kx^2 - mgx$. Solving for x gives $x = 2(mg - f)/k$.

EVALUATE: Check units to be sure that the answer has the proper dimensions of length.

7.1. **IDENTIFY:** $U_{\text{grav}} = mgy$ so $\Delta U_{\text{grav}} = mg(y_2 - y_1)$

SET UP: $+y$ is upward.

EXECUTE: **(a)** $\Delta U = (75 \text{ kg})(9.80 \text{ m/s}^2)(2400 \text{ m} - 1500 \text{ m}) = +6.6\times10^5 \text{ J}$

(b) $\Delta U = (75 \text{ kg})(9.80 \text{ m/s}^2)(1350 \text{ m} - 2400 \text{ m}) = -7.7\times10^5 \text{ J}$

EVALUATE: U_{grav} increases when the altitude of the object increases.

7.2. **IDENTIFY:** The change in height of a jumper causes a change in their potential energy.
SET UP: Use $\Delta U_{\text{grav}} = mg(y_2 - y_1)$.

EXECUTE: $\Delta U_{\text{grav}} = (72 \text{ kg})(9.80 \text{ m/s}^2)(0.60 \text{ m}) = 420 \text{ J}$.

EVALUATE: This gravitational potential energy comes from elastic potential energy stored in the jumper's tensed muscles.

7.3. **IDENTIFY:** Use the free-body diagram for the bag and Newton's first law to find the force the worker applies. Since the bag starts and ends at rest, $K_2 - K_1 = 0$ and $W_{\text{tot}} = 0$.

SET UP: A sketch showing the initial and final positions of the bag is given in Figure 7.3a. $\sin\phi = \frac{2.0 \text{ m}}{3.5 \text{ m}}$ and $\phi = 34.85°$. The free-body diagram is given in Figure 7.3b. $\vec{F}$ is the horizontal force applied by the worker. In the calculation of U_{grav} take $+y$ upward and $y = 0$ at the initial position of the bag.

EXECUTE: **(a)** $\Sigma F_y = 0$ gives $T\cos\phi = mg$ and $\Sigma F_x = 0$ gives $F = T\sin\phi$. Combining these equations to eliminate T gives $F = mg\tan\phi = (90.0 \text{ kg})(9.80 \text{ m/s}^2)\tan 34.85° = 610 \text{ N}$.

(b) (i) The tension in the rope is radial and the displacement is tangential so there is no component of T in the direction of the displacement during the motion and the tension in the rope does no work.
(ii) $W_{\text{tot}} = 0$ so

$$W_{\text{worker}} = -W_{\text{grav}} = U_{\text{grav,2}} - U_{\text{grav,1}} = mg(y_2 - y_1) = (90.0 \text{ kg})(9.80 \text{ m/s}^2)(0.6277 \text{ m}) = 550 \text{ J}.$$

EVALUATE: The force applied by the worker varies during the motion of the bag and it would be difficult to calculate W_{worker} directly.

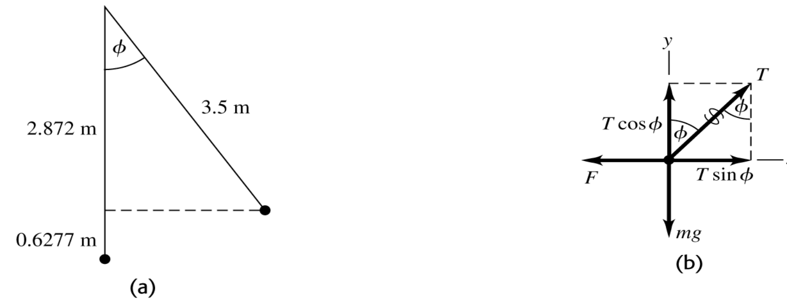

Figure 7.3

7.4. IDENTIFY: The energy from the food goes into the increased gravitational potential energy of the hiker. We must convert food calories to joules.

SET UP: The change in gravitational potential energy is $\Delta U_{\text{grav}} = mg\,(y_f - y_i)$, while the increase in kinetic energy is negligible. Set the food energy, expressed in joules, equal to the mechanical energy developed.

EXECUTE: **(a)** The food energy equals $mg(y_2 - y_1)$, so

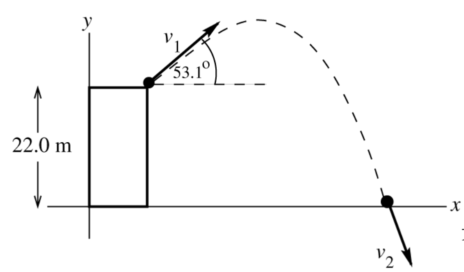
$$y_2 - y_1 = \frac{(140\text{ food calories})(4186\text{ J/1 food calorie})}{(65\text{ kg})(9.80\text{ m/s}^2)} = 920\text{ m}.$$

(b) The mechanical energy would be 20% of the results of part (a), so $\Delta y = (0.20)(920\text{ m}) = 180\text{ m}$.

EVALUATE: Since only 20% of the food calories go into mechanical energy, the hiker needs much less of a climb to turn off the calories in the bar.

7.5. IDENTIFY and SET UP: Use $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$. Points 1 and 2 are shown in Figure 7.5.

(a) $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$. Solve for K_2 and then use $K_2 = \frac{1}{2}mv_2^2$ to obtain v_2.



$W_{\text{other}} = 0$ (The only force on the ball while it is in the air is gravity.)

$K_1 = \frac{1}{2}mv_1^2$; $K_2 = \frac{1}{2}mv_2^2$

$U_1 = mgy_1$, $y_1 = 22.0\text{ m}$

$U_2 = mgy_2 = 0$, since $y_2 = 0$ for our choice of coordinates.

Figure 7.5

EXECUTE: $\frac{1}{2}mv_1^2 + mgy_1 = \frac{1}{2}mv_2^2$

$$v_2 = \sqrt{v_1^2 + 2gy_1} = \sqrt{(12.0\text{ m/s})^2 + 2(9.80\text{ m/s}^2)(22.0\text{ m})} = 24.0\text{ m/s}$$

EVALUATE: The projection angle of 53.1° doesn't enter into the calculation. The kinetic energy depends only on the magnitude of the velocity; it is independent of the direction of the velocity.

(b) Nothing changes in the calculation. The expression derived in part (a) for v_2 is independent of the angle, so $v_2 = 24.0\text{ m/s}$, the same as in part (a).

(c) The ball travels a shorter distance in part (b), so in that case air resistance will have less effect.

7.6. IDENTIFY: The normal force does no work, so only gravity does work and $K_1 + U_1 = K_2 + U_2$ applies.

SET UP: $K_1 = 0$. The crate's initial point is at a vertical height of $d\sin\alpha$ above the bottom of the ramp.

EXECUTE: **(a)** $y_2 = 0$, $y_1 = d\sin\alpha$. $K_1 + U_{\text{grav},1} = K_2 + U_{\text{grav},2}$ gives $U_{\text{grav},1} = K_2$. $mgd\sin\alpha = \frac{1}{2}mv_2^2$ and $v_2 = \sqrt{2gd\sin\alpha}$.

(b) $y_1 = 0$, $y_2 = -d\sin\alpha$. $K_1 + U_{\text{grav},1} = K_2 + U_{\text{grav},2}$ gives $0 = K_2 + U_{\text{grav},2}$. $0 = \frac{1}{2}mv_2^2 + (-mgd\sin\alpha)$ and $v_2 = \sqrt{2gd\sin\alpha}$, the same as in part (a).

(c) The normal force is perpendicular to the displacement and does no work.

EVALUATE: When we use $U_{\text{grav}} = mgy$ we can take any point as $y = 0$ but we must take $+y$ to be upward.

7.7. IDENTIFY: The take-off kinetic energy of the flea goes into gravitational potential energy.

SET UP: Use $K_1 + U_1 = K_2 + U_2$. Let $y_1 = 0$ and $y_2 = h$ and note that $U_1 = 0$ while $K_2 = 0$ at the maximum height. Consequently, conservation of energy becomes $mgh = \frac{1}{2}mv_1^2$.

EXECUTE: **(a)** $v_1 = \sqrt{2gh} = \sqrt{2(9.80\text{ m/s}^2)(0.20\text{ m})} = 2.0\text{ m/s}$.

(b) $K_1 = mgh = (0.50\times10^{-6}\text{ kg})(9.80\text{ m/s}^2)(0.20\text{ m}) = 9.8\times10^{-7}\text{ J}$. The kinetic energy per kilogram is

$$\frac{K_1}{m} = \frac{9.8\times10^{-7}\text{ J}}{0.50\times10^{-6}\text{ kg}} = 2.0\text{ J/kg}.$$

(c) The human can jump to a height of $h_{\text{h}} = h_{\text{f}}\left(\frac{l_{\text{h}}}{l_{\text{f}}}\right) = (0.20\text{ m})\left(\frac{2.0\text{ m}}{2.0\times10^{-3}\text{ m}}\right) = 200\text{ m}$. To attain this height, he would require a takeoff speed of: $v_1 = \sqrt{2gh} = \sqrt{2(9.80\text{ m/s}^2)(200\text{ m})} = 63\text{ m/s}$.

(d) The human's kinetic energy per kilogram is $\frac{K_1}{m} = gh = (9.80\text{ m/s}^2)(0.60\text{ m}) = 5.9\text{ J/kg}$.

(e) EVALUATE: The flea stores the energy in its tensed legs.

7.8. IDENTIFY: This problem involves kinetic energy and gravitational potential energy.

SET UP: Estimates: maximum speed is 2.5 m/s, mass is 70 kg. $U_g = mgh$, $K = \frac{1}{2}mv^2$.

EXECUTE: **(a)** $K = \frac{1}{2}mv^2 = \frac{1}{2}(70\text{ kg})(2.5\text{ m/s})^2 = 220\text{ J}$.

(b) $U_g = mgh$, so $h = U_g/mg = (220\text{ J})/[(70\text{ kg})(9.8\text{ m/s}^2)] = 0.32\text{ m}$.

EVALUATE: These are reasonable values since we put in reasonable estimates.

7.9. IDENTIFY: $W_{\text{tot}} = K_B - K_A$. The forces on the rock are gravity, the normal force and friction.

SET UP: Let $y = 0$ at point B and let $+y$ be upward. $y_A = R = 0.50\text{ m}$. The work done by friction is negative; $W_f = -0.22\text{ J}$. $K_A = 0$. The free-body diagram for the rock at point B is given in Figure 7.9. The acceleration of the rock at this point is $a_{\text{rad}} = v^2/R$, upward.

EXECUTE: **(a)** (i) The normal force is perpendicular to the displacement and does zero work.

(ii) $W_{\text{grav}} = U_{\text{grav},A} - U_{\text{grav},B} = mgy_A = (0.20\text{ kg})(9.80\text{ m/s}^2)(0.50\text{ m}) = 0.98\text{ J}$.

(b) $W_{\text{tot}} = W_n + W_f + W_{\text{grav}} = 0 + (-0.22\text{ J}) + 0.98\text{ J} = 0.76\text{ J}$. $W_{\text{tot}} = K_B - K_A$ gives $\frac{1}{2}mv_B^2 = W_{\text{tot}}$.

$$v_B = \sqrt{\frac{2W_{\text{tot}}}{m}} = \sqrt{\frac{2(0.76\text{ J})}{0.20\text{ kg}}} = 2.8\text{ m/s}.$$

(c) Gravity is constant and equal to mg. n is not constant; it is zero at A and not zero at B. Therefore, $f_{\text{k}} = \mu_{\text{k}}n$ is also not constant.

(d) $\Sigma F_y = ma_y$ applied to Figure 7.9 gives $n - mg = ma_{\text{rad}}$.

$$n = m\left(g + \frac{v^2}{R}\right) = (0.20\text{ kg})\left(9.80\text{ m/s}^2 + \frac{[2.8\text{ m/s}]^2}{0.50\text{ m}}\right) = 5.1\text{ N}.$$

EVALUATE: In the absence of friction, the speed of the rock at point *B* would be $\sqrt{2gR} = 3.1$ m/s. As the rock slides through point *B*, the normal force is greater than the weight $mg = 2.0$ N of the rock.

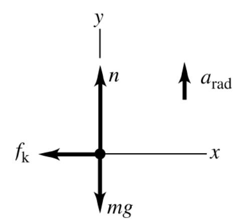


Figure 7.9

7.10. IDENTIFY: The child's energy is transformed from gravitational potential energy to kinetic energy as she swings downward.

SET UP: Let $y_2 = 0$. For part (a), $U_1 = mgy_1$. For part (b) use $K_2 + U_2 = K_1 + U_1$ with $U_2 = K_1 = 0$ and $K_2 = \frac{1}{2}mv_2{}^2$; the result is $\frac{1}{2}mv_2{}^2 = mgy_1$.

EXECUTE: **(a)** Figure 7.10 shows that the difference in potential energy at the top of the swing is proportional to the height difference, $y_1 = (2.20\text{ m})(1 - \cos 42°) = 0.56$ m. The difference in potential energy is thus $U_1 = mgy_1 = (25\text{ kg})(9.80\text{ m/s}^2)(0.56\text{ m}) = 140$ J.

(b) $v_2 = \sqrt{2gy_1} = \sqrt{2(9.80\text{ m/s}^2)(0.56\text{ m})} = 3.3$ m/s.

EVALUATE: (c) The tension is radial while the displacement is tangent to the circular path; thus there is no component of the tension along the direction of the displacement and the tension in the ropes does no work on the child.

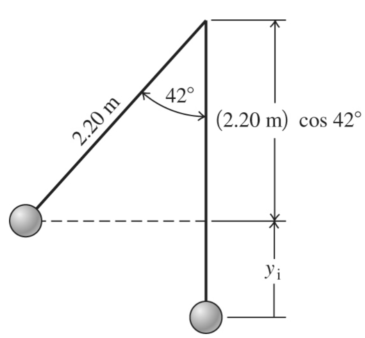

Figure 7.10

7.11. IDENTIFY: Apply $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ to the motion of the car.

SET UP: Take $y = 0$ at point *A*. Let point 1 be *A* and point 2 be *B*.

EXECUTE: $U_1 = 0$, $U_2 = mg(2R) = 28{,}224$ J, $W_{\text{other}} = W_f$

$K_1 = \frac{1}{2}mv_1^2 = 37{,}500$ J, $K_2 = \frac{1}{2}mv_2^2 = 3840$ J

The work-energy relation then gives $W_f = K_2 + U_2 - K_1 = -5400$ J.

EVALUATE: Friction does negative work. The final mechanical energy $(K_2 + U_2 = 32{,}064\ \text{J})$ is less than the initial mechanical energy $(K_1 + U_1 = 37{,}500\ \text{J})$ because of the energy removed by friction work.

7.12. IDENTIFY: Only gravity does work, so apply $K_1 + U_1 = K_2 + U_2$.

SET UP: $v_1 = 0$, so $\frac{1}{2}mv_2^2 = mg(y_1 - y_2)$.

EXECUTE: Tarzan is lower than his original height by a distance $y_1 - y_2 = l(\cos 30° - \cos 45°)$ so his speed is $v = \sqrt{2gl(\cos 30° - \cos 45°)} = 7.9$ m/s, a bit quick for conversation.

EVALUATE: The result is independent of Tarzan's mass.

7.13. IDENTIFY: This problem involves kinetic energy, gravitational potential energy, and energy conservation.

SET UP: $U_g = mgh$, $K = \dfrac{1}{2}mv^2$, $U_1 + K_1 = U_2 + K_2$.

EXECUTE: (a) $\Delta U_6 = m_6 g \Delta y$ = (6.00 kg)(9.80 /s^2)(0.200 m) = 11.8 J

$\Delta U_8 = m_8 g \Delta y$ = (8.00 kg)(9.80 m/s^2)(–0.200 m) = –15.7 J.

(b) $W_6 = T\Delta y$ = (0.200 m)T and $W_8 = T\Delta y$ = (–0.200 m)T.

(c) From part (b), we have W_T = (0.200 m)T + (–0.200 m)T = 0.

$\Delta U_g = \Delta U_6 + \Delta U_8$ = 11.8 J – 15.7 J = –3.9 J, and K_1 = 0.

$U_1 + K_1 = U_2 + K_2$ gives $K_2 = U_1 - U_2 = -(U_2 - U_1) = -\Delta U$ = –(–3.9 J) = 3.9 J.

$$K_2 = \frac{1}{2}mv_2^2 = -\Delta U \quad \rightarrow \quad v_2 = \sqrt{\frac{-2\Delta U}{m}} = \sqrt{\frac{-2(-3.9\ \text{J})}{14\ \text{kg}}} = 0.75\ \text{m/s}.$$

EVALUATE: To check, we could find v_2 using Newton's second law. Treating the two masses as a single system gives $m_8 g - m_6 g = (m_8 + m_6)a$. Kinematics gives $a = \dfrac{v_2^2}{2\Delta y}$. Combining these equations and putting in the numbers gives v_2 = 0.75 m/s.

7.14. IDENTIFY: Use the information given in the problem with $F = kx$ to find k. Then $U_{\text{el}} = \frac{1}{2}kx^2$.

SET UP: x is the amount the spring is stretched. When the weight is hung from the spring, $F = mg$.

EXECUTE: $k = \dfrac{F}{x} = \dfrac{mg}{x} = \dfrac{(3.15\ \text{kg})(9.80\ \text{m/s}^2)}{0.1340\ \text{m} - 0.1200\ \text{m}} = 2205\ \text{N/m}.$

$x = \pm\sqrt{\dfrac{2U_{\text{el}}}{k}} = \pm\sqrt{\dfrac{2(10.0\ \text{J})}{2205\ \text{N/m}}} = \pm 0.0952\ \text{m} = \pm 9.52\ \text{cm}.$ The spring could be either stretched 9.52 cm or compressed 9.52 cm. If it were stretched, the total length of the spring would be $12.00\ \text{cm} + 9.52\ \text{cm} = 21.52\ \text{cm}.$ If it were compressed, the total length of the spring would be $12.00\ \text{cm} - 9.52\ \text{cm} = 2.48\ \text{cm}.$

EVALUATE: To stretch or compress the spring 9.52 cm requires a force $F = kx = 210$ N.

7.15. IDENTIFY: Apply $U_{\text{el}} = \frac{1}{2}kx^2$.

SET UP: $kx = F$, so $U_{\text{el}} = \frac{1}{2}Fx$, where F is the magnitude of force required to stretch or compress the spring a distance x.

EXECUTE: **(a)** $(1/2)(520\ \text{N})(0.200\ \text{m}) = 52.0\ \text{J}.$

(b) The potential energy is proportional to the square of the compression or extension;

$(52.0\ \text{J})\,(0.050\ \text{m}/0.200\ \text{m})^2 = 3.25\ \text{J}.$

EVALUATE: We could have calculated $k = \dfrac{F}{x} = \dfrac{520\text{ N}}{0.200\text{ m}} = 2600\text{ N/m}$ and then used $U_{el} = \frac{1}{2}kx^2$ directly.

7.16. IDENTIFY: We treat the tendon like a spring and apply Hooke's law to it. Knowing the force stretching the tendon and how much it stretched, we can find its force constant.

SET UP: Use $F_{\text{on tendon}} = kx$. In part (a), $F_{\text{on tendon}}$ equals mg, the weight of the object suspended from it. In part (b), also apply $U_{el} = \frac{1}{2}kx^2$ to calculate the stored energy.

EXECUTE: **(a)** $k = \dfrac{F_{\text{on tendon}}}{x} = \dfrac{(0.250\text{ kg})(9.80\text{ m/s}^2)}{0.0123\text{ m}} = 199\text{ N/m}.$

(b) $x = \dfrac{F_{\text{on tendon}}}{k} = \dfrac{138\text{ N}}{199\text{ N/m}} = 0.693\text{m} = 69.3\text{ cm};\ U_{el} = \frac{1}{2}(199\text{ N/m})(0.693\text{ m})^2 = 47.8\text{ J}.$

EVALUATE: The 250 g object has a weight of 2.45 N. The 138 N force is much larger than this and stretches the tendon a much greater distance.

7.17. IDENTIFY: Apply $U_{el} = \frac{1}{2}kx^2$.

SET UP: $U_0 = \frac{1}{2}kx_0^2$. x is the distance the spring is stretched or compressed.

EXECUTE: **(a)** (i) $x = 2x_0$ gives $U_{el} = \frac{1}{2}k(2x_0)^2 = 4(\frac{1}{2}kx_0^2) = 4U_0$. (ii) $x = x_0/2$ gives $U_{el} = \frac{1}{2}k(x_0/2)^2 = \frac{1}{4}(\frac{1}{2}kx_0^2) = U_0/4$.

(b) (i) $U = 2U_0$ gives $\dfrac{1}{2}kx^2 = 2(\dfrac{1}{2}kx_0^2)$ and $x = x_0\sqrt{2}$. (ii) $U = U_0/2$ gives $\frac{1}{2}kx^2 = \frac{1}{2}(\frac{1}{2}kx_0^2)$ and $x = x_0/\sqrt{2}$.

EVALUATE: U is proportional to x^2 and x is proportional to $\sqrt{U}$.

7.18. IDENTIFY: This problem involves energy conservation, elastic potential energy, and kinetic energy.

SET UP: $K = \dfrac{1}{2}mv^2$ and $U_{\text{spring}} = \dfrac{1}{2}kx^2$. The elastic potential energy in the spring is transferred to the block as kinetic energy.

EXECUTE: $\dfrac{1}{2}mv^2 = \dfrac{1}{2}kx^2 \quad \rightarrow \quad v = x\sqrt{k/m} = d\sqrt{k/m}.$

EVALUATE: Our result says that for a given mass and compression distance, the larger that k is the greater that v will be. A large k means a stiff spring, so our result is reasonable.

7.19. IDENTIFY and SET UP: Use energy methods. There are changes in both elastic and gravitational potential energy; elastic; $U = \frac{1}{2}kx^2$, gravitational: $kx - mg = ma$,

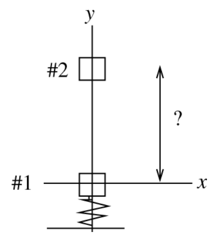
EXECUTE: **(a)** $U_{el} = \frac{1}{2}kx^2$ so $x = \sqrt{\dfrac{2U_{el}}{k}} = \sqrt{\dfrac{2(1.20\text{ J})}{800\text{ N/m}}} = 0.0548\text{ m} = 5.48\text{ cm}.$

(b) The work done by gravity is equal to the gain in elastic potential energy: $W_{grav} = U_{el}$.
$mgx = ½ kx^2$, so $x = 2mg/k = 2(1.60\text{ kg})(9.80\text{ m/s}^2)/(800\text{ N/m}) = 0.0392\text{ m} = 3.92\text{ cm}$.

EVALUATE: When the spring is compressed 3.92 cm, it exerts an upward force of 31.4 N on the book, which is greater than the weight of the book (15.6 N). The book will be accelerated upward from this position.

7.20. IDENTIFY: Use energy methods. There are changes in both elastic and gravitational potential energy.

SET UP: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$. Points 1 and 2 in the motion are sketched in Figure 7.20.



The spring force and gravity are the only forces doing work on the cheese, so $W_{\text{other}} = 0$ and $U = U_{\text{grav}} + U_{\text{el}}$.

Figure 7.20

EXECUTE: Cheese released from rest implies $K_1 = 0$.
At the maximum height $v_2 = 0$ so $K_2 = 0$. $U_1 = U_{1,\text{el}} + U_{1,\text{grav}}$
$y_1 = 0$ implies $U_{1,\text{grav}} = 0$
$U_{1,\text{el}} = \frac{1}{2}kx_1^2 = \frac{1}{2}(1800\text{ N/m})(0.15\text{ m})^2 = 20.25\text{ J}$
(Here x_1 refers to the amount the spring is stretched or compressed when the cheese is at position 1; it is *not* the *x*-coordinate of the cheese in the coordinate system shown in the sketch.)
$U_2 = U_{2,\text{el}} + U_{2,\text{grav}}$ $U_{2,\text{grav}} = mgy_2$, where y_2 is the height we are solving for. $U_{2,\text{el}} = 0$ since now the spring is no longer compressed. Putting all this into $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ gives $U_{1,\text{el}} = U_{2,\text{grav}}$

$$y_2 = \frac{20.25\text{ J}}{mg} = \frac{20.25\text{ J}}{(1.20\text{ kg})(9.80\text{ m/s}^2)} = 1.72\text{ m}$$

EVALUATE: The description in terms of energy is very simple; the elastic potential energy originally stored in the spring is converted into gravitational potential energy of the system.

7.21. IDENTIFY: The energy of the book-spring system is conserved. There are changes in both elastic and gravitational potential energy.
SET UP: $U_{\text{el}} = \frac{1}{2}kx^2$, $U_{\text{grav}} = mgy$, $W_{\text{other}} = 0$.

EXECUTE: **(a)** $U = \frac{1}{2}kx^2$ so $x = \sqrt{\frac{2U}{k}} = \sqrt{\frac{2(3.20\text{ J})}{1600\text{ N/m}}} = 0.0632\text{ m} = 6.32\text{ cm}$

(b) Points 1 and 2 in the motion are sketched in Figure 7.21. We have $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$, where $W_{\text{other}} = 0$ (only work is that done by gravity and spring force), $K_1 = 0$, $K_2 = 0$, and $y = 0$ at final position of book. Using $U_1 = mg(h+d)$ and $U_2 = \frac{1}{2}kd^2$ we obtain $0 + mg(h+d) + 0 = \frac{1}{2}kd^2$. The original gravitational potential energy of the system is converted into potential energy of the compressed spring. Finally, we use the quadratic formula to solve for *d*: $\frac{1}{2}kd^2 - mgd - mgh = 0$, which gives

$d = \frac{1}{k}\left(mg \pm \sqrt{(mg)^2 + 4\left(\frac{1}{2}k\right)(mgh)}\right)$. In our analysis we have assumed that *d* is positive, so we get

$$d = \frac{(1.20\text{ kg})(9.80\text{ m/s}^2) + \sqrt{\left[(1.20\text{ kg})(9.80\text{ m/s}^2)\right]^2 + 2(1600\text{ N/m})(1.20\text{ kg})(9.80\text{ m/s}^2)(0.80\text{ m})}}{1600\text{ N/m}},$$

which gives *d* = 0.12 m = 12 cm.
EVALUATE: It was important to recognize that the total displacement was *h* + *d*; gravity continues to do work as the book moves against the spring. Also note that with the spring compressed 0.12 m it exerts an upward force (192 N) greater than the weight of the book (11.8 N). The book will be accelerated upward from this position.

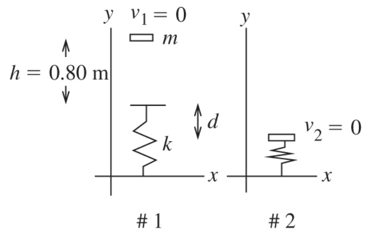


Figure 7.21

7.22. **(a) IDENTIFY** and **SET UP:** Use energy methods. Both elastic and gravitational potential energy changes. Work is done by friction.

Choose point 1 and let that be the origin, so $y_1 = 0$. Let point 2 be 1.00 m below point 1, so $y_2 = -1.00$ m.

EXECUTE: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$

$K_1 = \frac{1}{2}mv_1^2 = \frac{1}{2}(2000 \text{ kg})(4.0 \text{ m/s})^2 = 16{,}000 \text{ J},\ U_1 = 0$

$W_{\text{other}} = -f|y_2| = -(17{,}000 \text{ N})(1.00 \text{ m}) = -17{,}000 \text{ J}$

$K_2 = \frac{1}{2}mv_2^2$

$U_2 = U_{2,\text{grav}} + U_{2,\text{el}} = mgy_2 + \frac{1}{2}ky_2^2$

$U_2 = (2000 \text{ kg})(9.80 \text{ m/s}^2)(-1.00 \text{ m}) + \frac{1}{2}(1.06\times10^4 \text{ N/m})(1.00 \text{ m})^2$

$U_2 = -19{,}600 \text{ J} + 5300 \text{ J} = -14{,}300 \text{ J}$

Thus $16{,}000 \text{ J} - 17{,}000 \text{ J} = \frac{1}{2}mv_2^2 - 14{,}300 \text{ J}$

$\frac{1}{2}mv_2^2 = 13{,}300 \text{ J}$

$$v_2 = \sqrt{\frac{2(13{,}300 \text{ J})}{2000 \text{ kg}}} = 3.65 \text{ m/s}$$

EVALUATE: The elevator stops after descending 3.00 m. After descending 1.00 m it is still moving but has slowed down.

(b) IDENTIFY: Apply $\Sigma\vec{F} = m\vec{a}$ to the elevator. We know the forces and can solve for $\vec{a}$.

SET UP: The free-body diagram for the elevator is given in Figure 7.22.

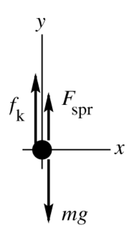

Figure 7.22

EXECUTE: $F_{\text{spr}} = kd$, where d is the distance the spring is compressed

$\Sigma F_y = ma_y$

$f_k + F_{\text{spr}} - mg = ma$

$f_k + kd - mg = ma$

$$a = \frac{f_k + kd - mg}{m} = \frac{17{,}000 \text{ N} + (1.06\times10^4 \text{ N/m})(1.00 \text{ m}) - (2000 \text{ kg})(9.80 \text{ m/s}^2)}{2000 \text{ kg}} = 4.00 \text{ m/s}^2$$

We calculate that a is positive, so the acceleration is upward.

EVALUATE: The velocity is downward and the acceleration is upward, so the elevator is slowing down at this point.

7.23. **IDENTIFY:** Only the spring does work and $K_1 + U_1 = K_2 + U_2$ applies. $a = \frac{F}{m} = \frac{-kx}{m}$, where F is the force the spring exerts on the mass.

SET UP: Let point 1 be the initial position of the mass against the compressed spring, so $K_1 = 0$ and $U_1 = 11.5$ J. Let point 2 be where the mass leaves the spring, so $U_{\text{el},2} = 0$.

EXECUTE: **(a)** $K_1 + U_{\text{el},1} = K_2 + U_{\text{el},2}$ gives $U_{\text{el},1} = K_2$. $\frac{1}{2}mv_2^2 = U_{\text{el},1}$ and

$$v_2 = \sqrt{\frac{2U_{\text{el},1}}{m}} = \sqrt{\frac{2(11.5 \text{ J})}{2.50 \text{ kg}}} = 3.03 \text{ m/s}.$$

K is largest when U_{el} is least and this is when the mass leaves the spring. The mass achieves its maximum speed of 3.03 m/s as it leaves the spring and then slides along the surface with constant speed.

(b) The acceleration is greatest when the force on the mass is the greatest, and this is when the spring has its maximum compression. $U_{\text{el}} = \frac{1}{2}kx^2$ so $x = -\sqrt{\frac{2U_{\text{el}}}{k}} = -\sqrt{\frac{2(11.5 \text{ J})}{2500 \text{ N/m}}} = -0.0959$ m. The minus sign indicates compression. $F = -kx = ma_x$ and $a_x = -\frac{kx}{m} = -\frac{(2500 \text{ N/m})(-0.0959 \text{ m})}{2.50 \text{ kg}} = 95.9 \text{ m/s}^2$.

EVALUATE: If the end of the spring is displaced to the left when the spring is compressed, then a_x in part (b) is to the right, and vice versa.

7.24. **IDENTIFY:** The spring force is conservative but the force of friction is nonconservative. Energy is conserved during the process. Initially all the energy is stored in the spring, but part of this goes to kinetic energy, part remains as elastic potential energy, and the rest does work against friction.

SET UP: Energy conservation: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$, the elastic energy in the spring is $U = \frac{1}{2}kx^2$, and the work done by friction is $W_f = -f_{\text{k}}s = -\mu_{\text{k}}mgs$.

EXECUTE: The initial and final elastic potential energies are

$U_1 = \frac{1}{2}kx_1^2 = \frac{1}{2}(840 \text{ N/m})(0.0300 \text{ m})^2 = 0.378$ J and $U_2 = \frac{1}{2}kx_2^2 = \frac{1}{2}(840 \text{ N/m})(0.0100 \text{ m})^2 = 0.0420$ J.

The initial and final kinetic energies are $K_1 = 0$ and $K_2 = \frac{1}{2}mv_2^2$. The work done by friction is

$W_{\text{other}} = W_{f_{\text{k}}} = -f_{\text{k}}s = -\mu_{\text{k}}mgs = -(0.40)(2.50 \text{ kg})(9.8 \text{ m/s}^2)(0.0200 \text{ m}) = -0.196$ J. Energy conservation gives $K_2 = \frac{1}{2}mv_2^2 = K_1 + U_1 + W_{\text{other}} - U_2 = 0.378 \text{ J} + (-0.196 \text{ J}) - 0.0420 \text{ J} = 0.140$ J. Solving for v_2 gives $v_2 = \sqrt{\frac{2K_2}{m}} = \sqrt{\frac{2(0.140 \text{ J})}{2.50 \text{ kg}}} = 0.335$ m/s.

EVALUATE: Mechanical energy is not conserved due to friction.

7.25. **IDENTIFY:** Apply $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ and $F = ma$.

SET UP: $W_{\text{other}} = 0$. There is no change in U_{grav}. $K_1 = 0$, $U_2 = 0$.

EXECUTE: $\frac{1}{2}kx^2 = \frac{1}{2}mv_x^2$. The relations for m, v_x, k and x are $kx^2 = mv_x^2$ and $kx = 5mg$.

Dividing the first equation by the second gives $x = \frac{v_x^2}{5g}$, and substituting this into the second gives

$$k = 25\frac{mg^2}{v_x^2}.$$

(a) $k = 25\frac{(1160 \text{ kg})(9.80 \text{ m/s}^2)^2}{(2.50 \text{ m/s})^2} = 4.46 \times 10^5$ N/m

(b) $x = \frac{(2.50 \text{ m/s})^2}{5(9.80 \text{ m/s}^2)} = 0.128$ m

EVALUATE: Our results for k and x do give the required values for a_x and v_x:

$$a_x = \frac{kx}{m} = \frac{(4.46\times10^5\ \text{N/m})(0.128\ \text{m})}{1160\ \text{kg}} = 49.2\ \text{m/s}^2 = 5.0g \ \text{ and } \ v_x = x\sqrt{\frac{k}{m}} = 2.5\ \text{m/s}.$$

7.26. IDENTIFY: This problem involves the work to stretch a spring and the energy stored in the spring.

SET UP: $U_{\text{spring}} = \frac{1}{2}kx^2$ and $F = kx$ (Hooke's law).

EXECUTE: **(a)** At a 2.00-cm stretch: $F = kx$ becomes $5.00\ \text{N} = k(2.00\ \text{cm})$. At the additional stretch, the spring is now stretched 6.00 cm, so $F = k(6.00\ \text{cm})$. This gives $\frac{F}{5.00\ \text{N}} = \frac{k(6.00\ \text{cm})}{k(2.00\ \text{cm})}$, which gives $F = 15.0$ N.

(b) At 2.00-cm stretch, $U_2 = \frac{1}{2}kx^2 = \frac{1}{2}k(2.00\ \text{cm})^2$ and $U_6 = \frac{1}{2}k(6.00\ \text{cm})^2$. Therefore

$$\frac{U_6}{U_2} = \frac{\frac{1}{2}k(6.00\ \text{cm})^2}{\frac{1}{2}k(2.00\ \text{cm})^2} = 9.00.$$

EVALUATE: The force increases by a factor of 3 but the stored energy increases by a factor of 9 because the energy is proportional to the *square* of x while the force is only proportional to x. We could have solved this problem by first finding k and then using the force and energy formulas. However by taking ratios we never needed to know k and we did not have to convert any units.

7.27. IDENTIFY: Since the force is constant, use $W = Fs\cos\phi$.

SET UP: For both displacements, the direction of the friction force is opposite to the displacement and $\phi = 180°$.

EXECUTE: **(a)** When the book moves to the left, the friction force is to the right, and the work is $-(1.8\ \text{N})(3.0\ \text{m}) = -5.4\ \text{J}$.

(b) The friction force is now to the left, and the work is again -5.4 J.

(c) The total work is sum of the work in both directions, which is –10.8 J.

(d) The net work done by friction for the round trip is not zero, so friction is not a conservative force.

EVALUATE: The direction of the friction force depends on the motion of the object. For the gravity force, which is conservative, the force does not depend on the motion of the object.

7.28. IDENTIFY and SET UP: The force is not constant so we must integrate to calculate the work. $W = \int_1^2 \vec{F}\cdot d\vec{l}$, $\vec{F} = -\alpha x^2\hat{i}$.

EXECUTE: **(a)** $d\vec{l} = dy\hat{j}$ (x is constant; the displacement is in the $+y$-direction)

$\vec{F}\cdot d\vec{l} = 0$ (since $\hat{i}\cdot\hat{j} = 0$) and thus $W = 0$.

(b) $d\vec{l} = dx\hat{i}$

$\vec{F}\cdot d\vec{l} = (-\alpha x^2\hat{i})\cdot(dx\hat{i}) = -\alpha x^2\,dx$

$$W = \int_{x_1}^{x_2}(-\alpha x^2)\,dx = -\tfrac{1}{3}\alpha x^3\Big|_{x_1}^{x_2} = -\tfrac{1}{3}\alpha\,(x_2^3 - x_1^3) = -\frac{12\ \text{N/m}^2}{3}\left[(0.300\ \text{m})^3 - (0.10\ \text{m})^3\right] = -0.10\ \text{J}$$

(c) $d\vec{l} = dx\hat{i}$ as in part (b), but now $x_1 = 0.30$ m and $x_2 = 0.10$ m, so $W = -\tfrac{1}{3}\alpha(x_2^3 - x_1^3) = +0.10$ J.

(d) EVALUATE: The total work for the displacement along the x-axis from 0.10 m to 0.30 m and then back to 0.10 m is the sum of the results of parts (b) and (c), which is zero. The total work is zero when the starting and ending points are the same, so the force is conservative.

EXECUTE: $W_{x_1 \to x_2} = -\frac{1}{3}\alpha(x_2^3 - x_1^3) = \frac{1}{3}\alpha x_1^3 - \frac{1}{3}\alpha x_2^3$

The definition of the potential energy function is $W_{x_1 \to x_2} = U_1 - U_2$. Comparison of the two expressions for *W* gives $U = \frac{1}{3}\alpha x^3$. This does correspond to $U = 0$ when $x = 0$.

EVALUATE: In part (a) the work done is zero because the force and displacement are perpendicular. In part (b) the force is directed opposite to the displacement and the work done is negative. In part (c) the force and displacement are in the same direction and the work done is positive.

7.29. **IDENTIFY:** Some of the mechanical energy of the skier is converted to internal energy by the nonconservative force of friction on the rough patch. Use $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$.

SET UP: For part (a) use $E_{\text{mech, 2}} = E_{\text{mech, 1}} - f_k s$ where $f_k = \mu_k mg$. Let $y_2 = 0$ at the bottom of the hill; then $y_1 = 2.50\text{ m}$ along the rough patch. The energy equation is $\frac{1}{2}mv_2^2 = \frac{1}{2}mv_1^2 + mgy_1 - \mu_k mgs$. Solving for her final speed gives $v_2 = \sqrt{v_1^2 + 2gy_1 - 2\mu_k gs}$. For part (b), the internal energy is calculated as the negative of the work done by friction: $-W_f = +f_k s = +\mu_k mgs$.

EXECUTE: **(a)** $v_2 = \sqrt{(6.50\text{ m/s})^2 + 2(9.80\text{ m/s}^2)(2.50\text{ m}) - 2(0.300)(9.80\text{ m/s}^2)(4.20\text{ m})} = 8.16\text{ m/s}$.

(b) Internal energy $= \mu_k mgs = (0.300)(62.0\text{ kg})(9.80\text{ m/s}^2)(4.20\text{ m}) = 766\text{ J}$.

EVALUATE: Without friction the skier would be moving faster at the bottom of the hill than at the top, but in this case she is moving *slower* because friction converted some of her initial kinetic energy into internal energy.

7.30. **IDENTIFY:** Some of the initial gravitational potential energy is converted to kinetic energy, but some of it is lost due to work by the nonconservative friction force.

SET UP: The energy of the box at the edge of the roof is given by: $E_{\text{mech, f}} = E_{\text{mech, i}} - f_k s$. Setting $y_f = 0$ at this point, $y_i = (4.25\text{ m})\sin 36° = 2.50\text{ m}$. Furthermore, by substituting $K_i = 0$ and $K_f = \frac{1}{2}mv_f^2$ into the conservation equation, $\frac{1}{2}mv_f^2 = mgy_i - f_k s$ or $v_f = \sqrt{2gy_i - 2f_k sg/w} = \sqrt{2g(y_i - f_k s/w)}$.

EXECUTE: $v_f = \sqrt{2(9.80\text{ m/s}^2)[(2.50\text{ m}) - (22.0\text{ N})(4.25\text{ m})/(85.0\text{ N})]} = 5.24\text{ m/s}$.

EVALUATE: Friction does negative work and removes mechanical energy from the system. In the absence of friction the final speed of the toolbox would be 7.00 m/s.

7.31. **IDENTIFY:** We know the potential energy function and want to find the force causing this energy.

SET UP: $F_x = -\dfrac{dU}{dx}$. The sign of F_x indicates its direction.

EXECUTE: $F_x = -\dfrac{dU}{dx} = -4\alpha x^3 = -4(0.630\text{ J/m}^4)x^3$.

$F_x(-0.800\text{ m}) = -4(0.630\text{ J/m}^4)(-0.80\text{ m})^3 = 1.29\text{ N}$. The force is in the $+x$-direction.

EVALUATE: $F_x > 0$ when $x < 0$ and $F_x < 0$ when $x > 0$, so the force is always directed toward the origin.

7.32. **IDENTIFY** and **SET UP:** Use $F_x = -\dfrac{dU}{dx}$ to calculate the force from $U(x)$. Use coordinates where the origin is at one atom. The other atom then has coordinate *x*.

EXECUTE:

$$F_x = -\frac{dU}{dx} = -\frac{d}{dx}\left(-\frac{C_6}{x^6}\right) = +C_6\frac{d}{dx}\left(\frac{1}{x^6}\right) = -\frac{6C_6}{x^7}$$

The minus sign means that F_x is directed in the $-x$-direction, toward the origin. The force has magnitude $6C_6/x^7$ and is attractive.

EVALUATE: U depends only on x so $\vec{F}$ is along the x-axis; it has no y- or z-components.

7.33. **IDENTIFY:** From the potential energy function of the block, we can find the force on it, and from the force we can use Newton's second law to find its acceleration.

SET UP: The force components are $F_x = -\dfrac{\partial U}{\partial x}$ and $F_y = -\dfrac{\partial U}{\partial y}$. The acceleration components are $a_x = F_x/m$ and $a_y = F_y/m$. The magnitude of the acceleration is $a = \sqrt{a_x^2 + a_y^2}$ and we can find its angle with the $+x$ axis using $\tan\theta = a_y/a_x$.

EXECUTE: $F_x = -\dfrac{\partial U}{\partial x} = -(11.6\text{ J/m}^2)x$ and $F_y = -\dfrac{\partial U}{\partial y} = (10.8\text{ J/m}^3)y^2$. At the point ($x = 0.300$ m, $y = 0.600$ m), $F_x = -(11.6\text{ J/m}^2)(0.300\text{ m}) = -3.48$ N and $F_y = (10.8\text{ J/m}^3)(0.600\text{ m})^2 = 3.89$ N. Therefore $a_x = \dfrac{F_x}{m} = -87.0\text{ m/s}^2$ and $a_y = \dfrac{F_y}{m} = 97.2\text{ m/s}^2$, giving $a = \sqrt{a_x^2 + a_y^2} = 130\text{ m/s}^2$ and $\tan\theta = \dfrac{97.2}{87.0}$, so $\theta = 48.2°$. The direction is $132°$ counterclockwise from the $+x$-axis.

EVALUATE: The force is not constant, so the acceleration will not be the same at other points.

7.34. **IDENTIFY:** Apply $\vec{F} = -\dfrac{\partial U}{\partial x}\hat{\boldsymbol{i}} - \dfrac{\partial U}{\partial y}\hat{\boldsymbol{j}}$.

SET UP: $\dfrac{d}{dx}\left(\dfrac{1}{x^2}\right) = -\dfrac{2}{x^3}$ and $\dfrac{d}{dy}\left(\dfrac{1}{y^2}\right) = -\dfrac{2}{y^3}$.

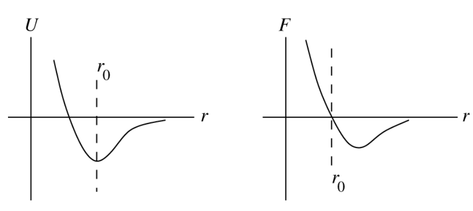
EXECUTE: $\vec{F} = -\dfrac{\partial U}{\partial x}\hat{\boldsymbol{i}} - \dfrac{\partial U}{\partial y}\hat{\boldsymbol{j}}$ since U has no z-dependence. $\dfrac{\partial U}{\partial x} = \dfrac{-2\alpha}{x^3}$ and $\dfrac{\partial U}{\partial y} = \dfrac{-2\alpha}{y^3}$, so

$$\vec{F} = -\alpha\left(\frac{-2}{x^3}\hat{\boldsymbol{i}} + \frac{-2}{y^3}\hat{\boldsymbol{j}}\right) = 2\alpha\left(\frac{\vec{\boldsymbol{i}}}{x^3} + \frac{\vec{\boldsymbol{j}}}{y^3}\right).$$

EVALUATE: F_x and x have the same sign and F_y and y have the same sign. When $x > 0$, F_x is in the $+x$-direction, and so forth.

7.35. **IDENTIFY** and **SET UP:** Use $F = -dU/dr$ to calculate the force from U. At equilibrium $F = 0$.

(a) EXECUTE: The graphs are sketched in Figure 7.35.



$$U = \frac{a}{r^{12}} - \frac{b}{r^6}$$

$$F = -\frac{dU}{dr} = +\frac{12a}{r^{13}} - \frac{6b}{r^7}$$

Figure 7.35

(b) At equilibrium $F = 0$, so $\dfrac{dU}{dr} = 0$

$$F = 0 \text{ implies } \frac{+12a}{r^{13}} - \frac{6b}{r^7} = 0$$

$6br^6 = 12a$; solution is the equilibrium distance $r_0 = (2a/b)^{1/6}$

U is a minimum at this r; the equilibrium is stable.

(c) At $r = (2a/b)^{1/6}$, $U = a/r^{12} - b/r^6 = a(b/2a)^2 - b(b/2a) = -b^2/4a$.

At $r \to \infty$, $U = 0$. The energy that must be added is $-\Delta U = b^2/4a$.

(d) $r_0 = (2a/b)^{1/6} = 1.13\times10^{-10}$ m gives that

$2a/b = 2.082\times10^{-60}\ \text{m}^6$ and $b/4a = 2.402\times10^{59}\ \text{m}^{-6}$

$b^2/4a = b(b/4a) = 1.54\times10^{-18}$ J

$b(2.402\times10^{59}\ \text{m}^{-6}) = 1.54\times10^{-18}$ J and $b = 6.41\times10^{-78}\ \text{J}\cdot\text{m}^6$.

Then $2a/b = 2.082\times10^{-60}\ \text{m}^6$ gives $a = (b/2)(2.082\times10^{-60}\ \text{m}^6) =$

$\frac{1}{2}(6.41\times10^{-78}\ \text{J}\cdot\text{m}^6)\ (2.082\times10^{-60}\ \text{m}^6)\ = 6.67\times10^{-138}\ \text{J}\cdot\text{m}^{12}$

EVALUATE: As the graphs in part (a) show, $F(r)$ is the slope of $U(r)$ at each r. $U(r)$ has a minimum where $F = 0$.

7.36. **IDENTIFY:** Apply $F_x = -\dfrac{dU}{dx}$.

SET UP: $\dfrac{dU}{dx}$ is the slope of the U versus x graph.

EXECUTE: **(a)** Considering only forces in the x-direction, $F_x = -\dfrac{dU}{dx}$ and so the force is zero when the slope of the U *vs* x graph is zero, at points b and d.

(b) Point b is at a potential minimum; to move it away from b would require an input of energy, so this point is stable.

(c) Moving away from point d involves a decrease of potential energy, hence an increase in kinetic energy, and the marble tends to move further away, and so d is an unstable point.

EVALUATE: At point b, F_x is negative when the marble is displaced slightly to the right and F_x is positive when the marble is displaced slightly to the left, the force is a restoring force, and the equilibrium is stable. At point d, a small displacement in either direction produces a force directed away from d and the equilibrium is unstable.

7.37. **IDENTIFY:** Apply $\Sigma\vec{F} = m\vec{a}$ to the bag and to the box. Apply $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ to the motion of the system of the box and bucket after the bag is removed.

SET UP: Let $y = 0$ at the final height of the bucket, so $y_1 = 2.00$ m and $y_2 = 0$. $K_1 = 0$. The box and the bucket move with the same speed v, so $K_2 = \frac{1}{2}(m_{\text{box}} + m_{\text{bucket}})v^2$. $W_{\text{other}} = -f_k d$, with $d = 2.00$ m and $f_k = \mu_k m_{\text{box}} g$. Before the bag is removed, the maximum possible friction force the roof can exert on the box is $(0.700)(80.0\ \text{kg} + 50.0\ \text{kg})(9.80\ \text{m/s}^2) = 892$ N. This is larger than the weight of the bucket (637 N), so before the bag is removed the system is at rest.

EXECUTE: **(a)** The friction force on the bag of gravel is zero, since there is no other horizontal force on the bag for friction to oppose. The static friction force on the box equals the weight of the bucket, 637 N.

(b) Applying $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ gives $m_{\text{bucket}} g y_1 - f_k d = \frac{1}{2} m_{\text{tot}} v^2$, with $m_{\text{tot}} = 145.0$ kg.

$$v = \sqrt{\frac{2}{m_{\text{tot}}}(m_{\text{bucket}} g y_1 - \mu_k m_{\text{box}} g d)}.$$

$$v = \sqrt{\frac{2}{145.0\ \text{kg}}\left[(65.0\ \text{kg})(9.80\ \text{m/s}^2)(2.00\ \text{m}) - (0.400)(80.0\ \text{kg})(9.80\ \text{m/s}^2)(2.00\ \text{m})\right]} = 2.99\ \text{m/s}.$$

EVALUATE: If we apply $\Sigma\vec{F} = m\vec{a}$ to the box and to the bucket we can calculate their common acceleration a. Then a constant acceleration equation applied to either object gives $v = 2.99$ m/s, in agreement with our result obtained using energy methods.

7.38. IDENTIFY: This problem involves projectile motion and energy conservation.

SET UP: Estimate: horizontal range is about 75 ft, which is about 25 m. The range of a projectile is $R = \dfrac{v_0^2}{g}\sin 2\alpha_0$, energy conservation says $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$, $K = \dfrac{1}{2}mv^2$, $U_g = mgy$.

EXECUTE: **(a)** Use range formula to find v_0. At 45° $R = \dfrac{v_0^2}{g}\sin 2\alpha_0$ gives $v_0 = \sqrt{Rg} = \sqrt{(25\text{ m})(9.80\text{ m/s}^2)}$ = 15.65 m/s. $K = \dfrac{1}{2}mv^2 = \dfrac{1}{2}(0.145\text{ kg})(15.65\text{ m/s})^2 = 18$ J.

(b) At the highest point, $v = v_x = v_0\cos\alpha_0$ = (15.65 m/s) cos 45° = 11.1 m/s, so $\dfrac{1}{2}(0.145\text{ kg})(11.1\text{ m/s})^2 = 8.88$ J. At the maximum height, $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $0 = (v_0\sin\alpha_0)^2 - 2gh$. This gives $h = \dfrac{(v_0\sin\alpha_0)^2}{2g}$ = 6.248 m. The gravitational potential energy is $U_g = mgh$ = (0.145 kg)(9.80 m/s^2)(6.248 m) = 8.88 J. As we have just found, at the maximum height $U_g = K$ = 8.88 J. So with α_0 = 45°, half of the mechanical energy is kinetic energy and half is potential energy.

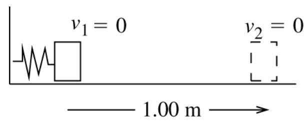
(c) At the highest point $K = \dfrac{1}{2}mv_x^2 = \dfrac{1}{2}m(v_0\cos\alpha_0)^2 = \dfrac{1}{2}mv_0^2\cos^2\alpha_0$. In part (b) we saw that the maximum height is $h = \dfrac{(v_0\sin\alpha_0)^2}{2g}$, so $U_g = mgh = mg\dfrac{(v_0\sin\alpha_0)^2}{2g} = \dfrac{1}{2}mv_0^2\sin^2\alpha_0$. The total energy is $E = K + U_g = \dfrac{1}{2}mv_0^2\cos^2\alpha_0 + \dfrac{1}{2}mv_0^2\sin^2\alpha_0 = \dfrac{1}{2}mv_0^2$. The fraction that is kinetic energy is $\dfrac{K}{E} = \dfrac{\frac{1}{2}mv_0^2\cos^2\alpha_0}{\frac{1}{2}mv_0^2} = \cos^2\alpha_0 = \cos^2 60° = \dfrac{1}{4}$. The fraction of the total energy that is potential energy is $\dfrac{U_g}{E} = \dfrac{\frac{1}{2}mv_0^2\sin^2\alpha_0}{\frac{1}{2}mv_0^2} = \sin^2\alpha_0 = \sin^2 60° = \dfrac{3}{4}$. So ¼ of the energy is kinetic energy and ¾ of the energy is potential energy.

EVALUATE: **(d)** If α_0 = 0: The ball is thrown horizontally. In this case, $K/E = \cos^2 0° = 1$ and $U_g/E = \sin^2 0° = 0$. All of the energy is kinetic and none is potential. This is reasonable because the ball never leaves the ground. If α_0 = 90°: The ball is thrown vertically upward. In this case, $K/E = \cos^2 90° = 0$ and $U_g/E = \sin^2 90° = 1$. All of the energy is potential and none is kinetic. This is reasonable because at its highest point the ball has stopped moving vertically and has no horizontal velocity, so its kinetic energy is zero.

7.39. IDENTIFY: Use $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$. The target variable μ_k will be a factor in the work done by friction.

SET UP: Let point 1 be where the block is released and let point 2 be where the block stops, as shown in Figure 7.39.

$K_1 + U_1 + W_{\text{other}} = K_2 + U_2$



Work is done on the block by the spring and by friction, so $W_{\text{other}} = W_f$ and $U = U_{\text{el}}$.

Figure 7.39

EXECUTE: $K_1 = K_2 = 0$

$U_1 = U_{1,\text{el}} = \frac{1}{2}kx_1^2 = \frac{1}{2}(100\ \text{N/m})(0.200\ \text{m})^2 = 2.00\ \text{J}$

$U_2 = U_{2,\text{el}} = 0,$ since after the block leaves the spring has given up all its stored energy

$W_{\text{other}} = W_f = (f_k \cos\phi)s = \mu_k mg(\cos\phi)s = -\mu_k mgs,$ since $\phi = 180°$ (The friction force is directed opposite to the displacement and does negative work.)

Putting all this into $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ gives

$U_{1,\text{el}} + W_f = 0$

$\mu_k mgs = U_{1,\text{el}}$

$$\mu_k = \frac{U_{1,\text{el}}}{mgs} = \frac{2.00\ \text{J}}{(0.50\ \text{kg})(9.80\ \text{m/s}^2)(1.00\ \text{m})} = 0.41.$$

EVALUATE: $U_{1,\text{el}} + W_f = 0$ says that the potential energy originally stored in the spring is taken out of the system by the negative work done by friction.

7.40. **IDENTIFY:** Apply $K_1 + U_1 + W_{\text{other}} = K_2 + U_2.$

SET UP: Only the spring force and gravity do work, so $W_{\text{other}} = 0.$ Let $y = 0$ at the horizontal surface.

EXECUTE: **(a)** Equating the potential energy stored in the spring to the block's kinetic energy,

$\frac{1}{2}kx^2 = \frac{1}{2}mv^2,$ or $v = \sqrt{\frac{k}{m}}x = \sqrt{\frac{400\ \text{N/m}}{2.00\ \text{kg}}}(0.220\ \text{m}) = 3.11\ \text{m/s}.$

(b) Using energy methods directly, the initial potential energy of the spring equals the final gravitational potential energy, $\frac{1}{2}kx^2 = mgL\sin\theta,$ or $L = \frac{\frac{1}{2}kx^2}{mg\sin\theta} = \frac{\frac{1}{2}(400\ \text{N/m})(0.220\ \text{m})^2}{(2.00\ \text{kg})(9.80\ \text{m/s}^2)\sin 37.0°} = 0.821\ \text{m}.$

EVALUATE: The total energy of the system is constant. Initially it is all elastic potential energy stored in the spring, then it is all kinetic energy and finally it is all gravitational potential energy.

7.41. **IDENTIFY:** The mechanical energy of the roller coaster is conserved since there is no friction with the track. We must also apply Newton's second law for the circular motion.

SET UP: For part (a), apply conservation of energy to the motion from point *A* to point *B*: $K_B + U_{\text{grav},B} = K_A + U_{\text{grav},A}$ with $K_A = 0.$ Defining $y_B = 0$ and $y_A = 13.0\ \text{m},$ conservation of energy becomes $\frac{1}{2}mv_B^2 = mgy_A$ or $v_B = \sqrt{2gy_A}.$ In part (b), the free-body diagram for the roller coaster car at point *B* is shown in Figure 7.41. $\Sigma F_y = ma_y$ gives $mg + n = ma_{\text{rad}},$ where $a_{\text{rad}} = v^2/r.$ Solving for the normal force gives $n = m\left(\frac{v^2}{r} - g\right).$

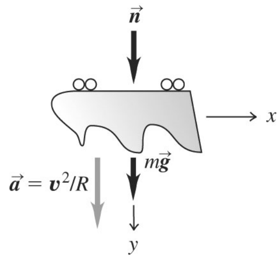


Figure 7.41

EXECUTE: **(a)** $v_B = \sqrt{2(9.80\ \text{m/s}^2)(13.0\ \text{m})} = 16.0\ \text{m/s}.$

(b) $n = (350\ \text{kg})\left[\dfrac{(16.0\ \text{m/s})^2}{6.0\ \text{m}} - 9.80\ \text{m/s}^2\right] = 1.15\times 10^4\ \text{N}.$

EVALUATE: The normal force n is the force that the tracks exert on the roller coaster car. The car exerts a force of equal magnitude and opposite direction on the tracks.

7.42. **IDENTIFY:** In this problem, we need to use Newton's second law and energy conservation.

SET UP: $\sum F = m\dfrac{v^2}{R}$ and $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$, where W_{other} is the work done by friction. At the bottom of the bowl, the normal force on the rock is equal to twice its weight, so $n = 2mg$.

EXECUTE: First use $\sum F = m\dfrac{v^2}{R}$ to find the speed at B. $n - mg = m\dfrac{v_B^2}{R} \rightarrow 2mg - mg = m\dfrac{v_B^2}{R}$, which gives $v_B^2 = Rg$. Now use energy conservation. $U_A + K_A + W_\text{f} = U_B + K_B$ gives us $W_\text{f} = -(U_A - U_B) + K_B = -mgR + \dfrac{1}{2}mRg = -\dfrac{mgR}{2}.$

EVALUATE: If there were no friction, energy conservation gives $mgR = \dfrac{1}{2}mv_B^2$, so $v_B^2 = 2Rg$. Newton's second law gives $n - mg = m\dfrac{v_B^2}{R} = m\left(\dfrac{2Rg}{R}\right)$, so $n = 3mg$. With friction the normal force was $2mg$, which is reasonable because friction slowed down the rock.

7.43. **(a) IDENTIFY:** Use $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ to find the kinetic energy of the wood as it enters the rough bottom.

SET UP: Let point 1 be where the piece of wood is released and point 2 be just before it enters the rough bottom. Let $y = 0$ be at point 2.

EXECUTE: $U_1 = K_2$ gives $K_2 = mgy_1 = 78.4\ \text{J}$.

IDENTIFY: Now apply $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ to the motion along the rough bottom.

SET UP: Let point 1 be where it enters the rough bottom and point 2 be where it stops.
$K_1 + U_1 + W_{\text{other}} = K_2 + U_2.$

EXECUTE: $W_{\text{other}} = W_f = -\mu_\text{k} mgs,\ \ K_2 = U_1 = U_2 = 0;\ \ K_1 = 78.4\ \text{J}$

$78.4\ \text{J} - \mu_\text{k} mgs = 0;$ solving for s gives $s = 20.0\ \text{m}$.

The wood stops after traveling 20.0 m along the rough bottom.

(b) Friction does $-78.4\ \text{J}$ of work.

EVALUATE: The piece of wood stops before it makes one trip across the rough bottom. The final mechanical energy is zero. The negative friction work takes away all the mechanical energy initially in the system.

7.44. IDENTIFY: In this problem, we need to use Newton's second law and energy conservation.

SET UP: $\sum F = m\dfrac{v^2}{R}$ and $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$, where $W_{\text{other}} = 0$. In order that the block will not fall off the track at the top, it must be moving; otherwise it would simply drop down. First find the minimum speed at the top and then use that result to find the speed at the bottom.

EXECUTE: At the top n and mg are both downward, so $\sum F = m\dfrac{v^2}{R}$ gives $n + mg = m\dfrac{v^2}{R}$. The smallest that n can be is zero, so the minimum speed at the top is $v_{\text{min}}^2 = Rg$. Now use energy conservation to find the speed v_B at the bottom. $U_T + K_T = U_B + K_B a$ gives $\dfrac{1}{2}mv_B^2 = \dfrac{1}{2}mv_T^2 + 2mgR$, which gives $v_B = \sqrt{v_T^2 + 4Rg} = \sqrt{Rg + 4Rg} = \sqrt{5Rg}$.

EVALUATE: The larger R, the greater the speed at the bottom.

7.45. IDENTIFY: Apply $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ to the motion of the stone.

SET UP: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$. Let point 1 be point A and point 2 be point B. Take $y = 0$ at B.

EXECUTE: $mgy_1 + \frac{1}{2}mv_1^2 = \frac{1}{2}mv_2^2$, with $h = 20.0\text{ m}$ and $v_1 = 10.0\text{ m/s}$, so $v_2 = \sqrt{v_1^2 + 2gh} = 22.2\text{ m/s}$.

EVALUATE: The loss of gravitational potential energy equals the gain of kinetic energy.

(b) IDENTIFY: Apply $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ to the motion of the stone from point B to where it comes to rest against the spring.

SET UP: Use $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$, with point 1 at B and point 2 where the spring has its maximum compression x.

EXECUTE: $U_1 = U_2 = K_2 = 0$; $K_1 = \frac{1}{2}mv_1^2$ with $v_1 = 22.2\text{ m/s}$. $W_{\text{other}} = W_f + W_{\text{el}} = -\mu_k mgs - \frac{1}{2}kx^2$, with $s = 100\text{ m} + x$. The work-energy relation gives $K_1 + W_{\text{other}} = 0$. $\frac{1}{2}mv_1^2 - \mu_k mgs - \frac{1}{2}kx^2 = 0$.

Putting in the numerical values gives $x^2 + 29.4x - 750 = 0$. The positive root to this equation is $x = 16.4\text{ m}$.

EVALUATE: Part of the initial mechanical (kinetic) energy is removed by friction work and the rest goes into the potential energy stored in the spring.

(c) IDENTIFY and **SET UP:** Consider the forces.

EXECUTE: When the spring is compressed $x = 16.4\text{ m}$ the force it exerts on the stone is $F_{\text{el}} = kx = 32.8\text{ N}$. The maximum possible static friction force is

$\max f_s = \mu_s mg = (0.80)(15.0\text{ kg})(9.80\text{ m/s}^2) = 118\text{ N}$.

EVALUATE: The spring force is less than the maximum possible static friction force so the stone remains at rest.

7.46. IDENTIFY: Once the block leaves the top of the hill it moves in projectile motion. Use $K_1 + U_1 = K_2 + U_2$ to relate the speed v_{B} at the bottom of the hill to the speed v_{Top} at the top and the 70 m height of the hill.

SET UP: For the projectile motion, take $+y$ to be downward. $a_x = 0$, $a_y = g$. $v_{0x} = v_{\text{Top}}$, $v_{0y} = 0$. For the motion up the hill only gravity does work. Take $y = 0$ at the base of the hill.

EXECUTE: First get speed at the top of the hill for the block to clear the pit. $y = \dfrac{1}{2}gt^2$.

$20\text{ m} = \dfrac{1}{2}(9.8\text{ m/s}^2)t^2$. $t = 2.0\text{ s}$. Then $v_{\text{Top}}t = 40\text{ m}$ gives $v_{\text{Top}} = \dfrac{40\text{ m}}{2.0\text{ s}} = 20\text{ m/s}$.

Energy conservation applied to the motion up the hill: $K_{\text{Bottom}} = U_{\text{Top}} + K_{\text{Top}}$ gives

$\frac{1}{2}mv_B^2 = mgh + \frac{1}{2}mv_{Top}^2$. $v_B = \sqrt{v_{Top}^2 + 2gh} = \sqrt{(20\text{ m/s})^2 + 2(9.8\text{ m/s}^2)(70\text{ m})} = 42\text{ m/s}$.

EVALUATE: The result does not depend on the mass of the block.

7.47. **IDENTIFY:** We must use energy conservation. This system has elastic potential energy and gravitational potential energy, and friction does work on it.

SET UP: $U_1 + K_1 + W_{other} = U_2 + K_2$, $U_g = mgy$, $U_{spring} = \frac{1}{2}kx^2$. For the minimum elastic potential energy, the box just stops at the top of the incline. So $K_1 = K_2$ in this case. We want to find the energy stored in the spring.

EXECUTE: $U_1 + K_1 + W_{other} = U_2 + K_2$ gives $U_{1,spring} + W_f = U_{2,g}$, so $U_{1,spring} = U_{2,g} - W_f$. Therefore $U_{1,spring} = mgh - (-f_k)s = mgh + \mu_k ns = mgh + \mu_k mgs\cos\theta = mg(h + \mu_k s\cos\theta)$. Using m = 0.600 kg, s = 2.00 m, θ = 37.0°, h = (2.00 m) sin 37.0°, and μ_k = 0.400 gives $U_{1,spring}$ = 10.8 J.

EVALUATE: The elastic potential energy in the spring must be greater than the gravitational potential energy because friction is doing negative work on the box. $U_g = mgh$ = (0.600 kg)(9.80 m/s^2)(2.00 m)(sin 37.0°) = 7.08 J, which agrees with our expectation.

7.48. **IDENTIFY:** To be at equilibrium at the bottom, with the spring compressed a distance x_0, the spring force must balance the component of the weight down the ramp plus the largest value of the static friction, or $kx_0 = w\sin\theta + f$. Apply energy conservation to the motion down the ramp.

SET UP: $K_2 = 0$, $K_1 = \frac{1}{2}mv^2$, where v is the speed at the top of the ramp. Let $U_2 = 0$, so $U_1 = wL\sin\theta$, where L is the total length traveled down the ramp.

EXECUTE: Energy conservation gives $\frac{1}{2}kx_0^2 = (w\sin\theta - f)L + \frac{1}{2}mv^2$. With the given parameters, $\frac{1}{2}kx_0^2 = 421\text{ J}$ and $kx_0 = 1.066\times10^3\text{ N}$. Solving for k gives $k = 1350\text{ N/m}$.

EVALUATE: $x_0 = 0.790\text{ m}$. $w\sin\theta = 551\text{ N}$. The decrease in gravitational potential energy is larger than the amount of mechanical energy removed by the negative work done by friction. $\frac{1}{2}mv^2 = 243\text{ J}$. The energy stored in the spring is larger than the initial kinetic energy of the crate at the top of the ramp.

7.49. **IDENTIFY:** Use $K_1 + U_1 + W_{other} = K_2 + U_2$. Solve for K_2 and then for v_2.

SET UP: Let point 1 be at his initial position against the compressed spring and let point 2 be at the end of the barrel, as shown in Figure 7.49. Use $F = kx$ to find the amount the spring is initially compressed by the 4400 N force.

$K_1 + U_1 + W_{other} = K_2 + U_2$

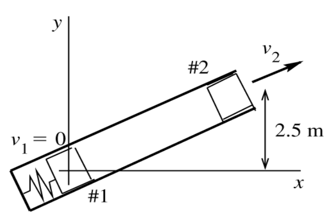

Figure 7.49

Take $y = 0$ at his initial position.

EXECUTE: $K_1 = 0$, $K_2 = \frac{1}{2}mv_2^2$

$W_{other} = W_{fric} = -fs$

$W_{other} = -(40\text{ N})(4.0\text{ m}) = -160\text{ J}$

$U_{1,grav} = 0$, $U_{1,el} = \frac{1}{2}kd^2$, where d is the distance the spring is initially compressed.

$F = kd$ so $d = \frac{F}{k} = \frac{4400\text{ N}}{1100\text{ N/m}} = 4.00\text{ m}$

and $U_{1,\text{el}} = \frac{1}{2}(1100\text{ N/m})(4.00\text{ m})^2 = 8800\text{ J}$

$U_{2,\text{grav}} = mgy_2 = (60\text{ kg})(9.80\text{ m/s}^2)(2.5\text{ m}) = 1470\text{ J}, \;\; U_{2,\text{el}} = 0$

Then $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ gives

$8800\text{ J} - 160\text{ J} = \frac{1}{2}mv_2^2 + 1470\text{ J}$

$\frac{1}{2}mv_2^2 = 7170\text{ J}$ and $v_2 = \sqrt{\dfrac{2(7170\text{ J})}{60\text{ kg}}} = 15.5\text{ m/s}.$

Evaluate: Some of the potential energy stored in the compressed spring is taken away by the work done by friction. The rest goes partly into gravitational potential energy and partly into kinetic energy.

7.50. **Identify:** Apply $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ to the motion of the rocket from the starting point to the base of the ramp. W_{other} is the work done by the thrust and by friction.

Set Up: Let point 1 be at the starting point and let point 2 be at the base of the ramp. $v_1 = 0$, $v_2 = 50.0\text{ m/s}$. Let $y = 0$ at the base and take $+y$ upward. Then $y_2 = 0$ and $y_1 = d\sin 53°$, where d is the distance along the ramp from the base to the starting point. Friction does negative work.

Execute: $K_1 = 0$, $U_2 = 0$. $U_1 + W_{\text{other}} = K_2$. $W_{\text{other}} = (2000\text{ N})d - (500\text{ N})d = (1500\text{ N})d$.

$mgd\sin 53° + (1500\text{ N})d = \frac{1}{2}mv_2^2$.

$$d = \frac{mv_2^2}{2[mg\sin 53° + 1500\text{ N}]} = \frac{(1500\text{ kg})(50.0\text{ m/s})^2}{2[(1500\text{ kg})(9.80\text{ m/s}^2)\sin 53° + 1500\text{ N}]} = 142\text{ m}.$$

Evaluate: The initial height is $y_1 = (142\text{ m})\sin 53° = 113\text{ m}$. An object free-falling from this distance attains a speed $v = \sqrt{2gy_1} = 47.1\text{ m/s}$. The rocket attains a greater speed than this because the forward thrust is greater than the friction force.

7.51. **Identify:** Apply $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ to the system consisting of the two buckets. If we ignore the inertia of the pulley we ignore the kinetic energy it has.

Set Up: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$. Points 1 and 2 in the motion are sketched in Figure 7.51.

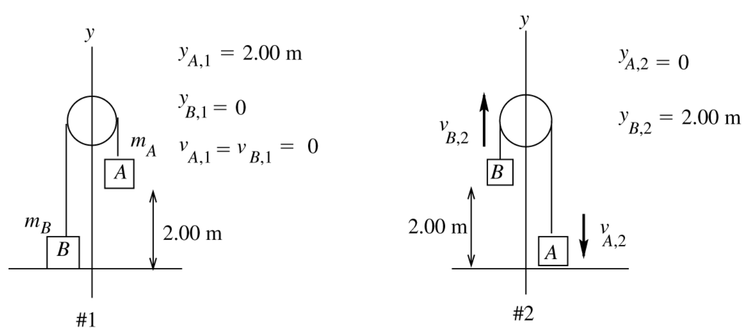

Figure 7.51

The tension force does positive work on the 4.0 kg bucket and an equal amount of negative work on the 12.0 kg bucket, so the net work done by the tension is zero.

Work is done on the system only by gravity, so $W_{\text{other}} = 0$ and $U = U_{\text{grav}}$.

Execute: $K_1 = 0$, $K_2 = \frac{1}{2}m_A v_{A,2}^2 + \frac{1}{2}m_B v_{B,2}^2$. But since the two buckets are connected by a rope they move together and have the same speed: $v_{A,2} = v_{B,2} = v_2$. Thus $K_2 = \frac{1}{2}(m_A + m_B)v_2^2 = (8.00\text{ kg})v_2^2$.

$U_1 = m_A g y_{A,1} = (12.0 \text{ kg})(9.80 \text{ m/s}^2)(2.00 \text{ m}) = 235.2 \text{ J}.$

$U_2 = m_B g y_{B,2} = (4.0 \text{ kg})(9.80 \text{ m/s}^2)(2.00 \text{ m}) = 78.4 \text{ J}.$

Putting all this into $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ gives $U_1 = K_2 + U_2$.

$235.2 \text{ J} = (8.00 \text{ kg})v_2^2 + 78.4 \text{ J}.$ $v_2 = \sqrt{\dfrac{235.2 \text{ J} - 78.4 \text{ J}}{8.00 \text{ kg}}} = 4.4 \text{ m/s}$

EVALUATE: The gravitational potential energy decreases and the kinetic energy increases by the same amount. We could apply $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ to one bucket, but then we would have to include in W_{other} the work done on the bucket by the tension T.

7.52. **IDENTIFY:** We use energy conservation.

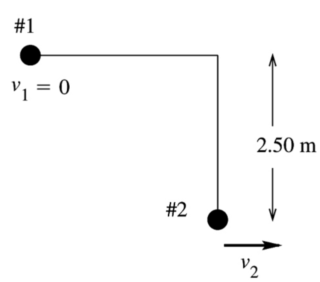
SET UP: $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$, $U_g = mgy$, $K = \frac{1}{2}mv^2$. Call point 1 the instant the block is released against the spring and point 2 when its speed is 4.00 m/s. We want to find the magnitude of the friction force f.

EXECUTE: $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$ becomes $U_{\text{spr}} + W_f = K_2 + U_g$. This gives

$U_1 + K_1 + W_{\text{other}} = U_2 + K_2$, so $f = \dfrac{U_{\text{spr}} - m\left(\dfrac{v_2^2}{2} + gh\right)}{s}$. Using $m = 0.200$ kg, $v_2 = 4.00$ m/s, $s = 3.00$ m, $h = s \sin 53.0° = 2.40$ m, and $U_{\text{spr}} = 8.00$ J, this gives $U_{\text{spr}} = 0.568$ N.

EVALUATE: The coefficient of kinetic friction for this value of kinetic friction would be $\mu_k = f/n = f/(mg \cos\theta) = (0.568 \text{ N})/[(0.200 \text{ kg})(9.80 \text{ m/s}^2)(\cos 53.0°)] = 0.482$, which is a reasonable value according to Table 5.1.

7.53. **(a) IDENTIFY and SET UP:** Apply $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ to the motion of the potato. Let point 1 be where the potato is released and point 2 be at the lowest point in its motion, as shown in Figure 7.53a.



$y_1 = 2.50$ m

$y_2 = 0$

The tension in the string is at all points in the motion perpendicular to the displacement, so $W_r = 0$

The only force that does work on the potato is gravity, so $W_{\text{other}} = 0$.

Figure 7.53a

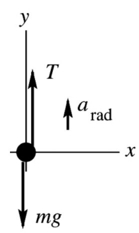
EXECUTE: $K_1 = 0$, $K_2 = \frac{1}{2}mv_2^2$, $U_1 = mgy_1$, $U_2 = 0$. Thus $U_1 = K_2$. $mgy_1 = \frac{1}{2}mv_2^2$, which gives

$v_2 = \sqrt{2gy_1} = \sqrt{2(9.80 \text{ m/s}^2)(2.50 \text{ m})} = 7.00 \text{ m/s}.$

EVALUATE: The speed v_2 is the same as if the potato fell through 2.50 m.

(b) IDENTIFY: Apply $\Sigma\vec{F} = m\vec{a}$ to the potato. The potato moves in an arc of a circle so its acceleration is $\vec{a}_{\text{rad}}$, where $a_{\text{rad}} = v^2/R$ and is directed toward the center of the circle. Solve for one of the forces, the tension T in the string.

SET UP: The free-body diagram for the potato as it swings through its lowest point is given in Figure 7.53b.



The acceleration $\vec{a}_{rad}$ is directed in toward the center of the circular path, so at this point it is upward.

Figure 7.53b

EXECUTE: $\Sigma F_y = ma_y$ gives $T - mg = ma_{rad}$. Solving for T gives $T = m(g + a_{rad}) = m\left(g + \frac{v_2^2}{R}\right)$, where the radius R for the circular motion is the length L of the string. It is instructive to use the algebraic expression for v_2 from part (a) rather than just putting in the numerical value: $v_2 = \sqrt{2gy_1} = \sqrt{2gL}$, so $v_2^2 = 2gL$. Then $T = m\left(g + \frac{v_2^2}{L}\right) = m\left(g + \frac{2gL}{L}\right) = 3mg$. The tension at this point is three times the weight of the potato, so $T = 3mg = 3(0.300\text{ kg})(9.80\text{ m/s}^2) = 8.82\text{ N}$.

EVALUATE: The tension is greater than the weight; the acceleration is upward so the net force must be upward.

7.54. **IDENTIFY:** Apply $K_1 + U_1 + W_{other} = K_2 + U_2$ to each stage of the motion.

SET UP: Let $y = 0$ at the bottom of the slope. In part (a), W_{other} is the work done by friction. In part (b), W_{other} is the work done by friction and the air resistance force. In part (c), W_{other} is the work done by the force exerted by the snowdrift.

EXECUTE: **(a)** The skier's kinetic energy at the bottom can be found from the potential energy at the top minus the work done by friction, $K_1 = mgh - W_f = (60.0\text{ kg})(9.8\text{ N/kg})(65.0\text{ m}) - 10{,}500\text{ J}$, or

$K_1 = 38{,}200\text{ J} - 10{,}500\text{ J} = 27{,}720\text{ J}$. Then $v_1 = \sqrt{\frac{2K_1}{m}} = \sqrt{\frac{2(27{,}720\text{ J})}{60\text{ kg}}} = 30.4\text{ m/s}$.

(b) $K_2 = K_1 - (W_f + W_{air}) = 27{,}720\text{ J} - (\mu_k mgd + f_{air}d)$.

$K_2 = 27{,}720\text{ J} - [(0.2)(588\text{ N})(82\text{ m}) + (160\text{ N})(82\text{ m})]$ or $K_2 = 27{,}720\text{ J} - 22{,}763\text{ J} = 4957\text{ J}$. Then,

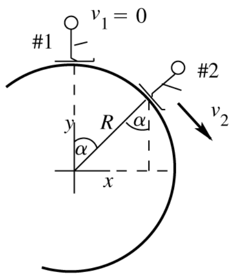
$v_2 = \sqrt{\frac{2K}{m}} = \sqrt{\frac{2(4957\text{ J})}{60\text{ kg}}} = 12.9\text{ m/s}$.

(c) Use the work-energy theorem to find the force. $W = \Delta K$, $F = K/d = (4957\text{ J})/(2.5\text{ m}) = 2000\text{ N}$.

EVALUATE: In each case, W_{other} is negative and removes mechanical energy from the system.

7.55. **IDENTIFY** and **SET UP:** First apply $\Sigma\vec{F} = m\vec{a}$ to the skier.

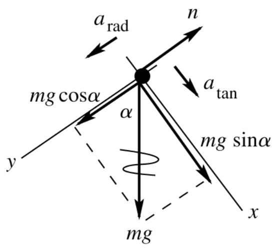
Find the angle α where the normal force becomes zero, in terms of the speed v_2 at this point. Then apply the work-energy theorem to the motion of the skier to obtain another equation that relates v_2 and α. Solve these two equations for α.



Let point 2 be where the skier loses contact with the snowball, as sketched in Figure 7.55a
Loses contact implies $n \to 0$.
$y_1 = R,\ \ y_2 = R\cos\alpha$

Figure 7.55a

First, analyze the forces on the skier when she is at point 2. The free-body diagram is given in Figure 7.55b. For this use coordinates that are in the tangential and radial directions. The skier moves in an arc of a circle, so her acceleration is $a_{\text{rad}} = v^2/R,$ directed in toward the center of the snowball.



EXECUTE: $\Sigma F_y = ma_y$

$mg\cos\alpha - n = mv_2^2/R$

But $n = 0$ so $mg\cos\alpha = mv_2^2/R$

$v_2^2 = Rg\cos\alpha$

Figure 7.55b

Now use conservation of energy to get another equation relating v_2 to α:

$K_1 + U_1 + W_{\text{other}} = K_2 + U_2$

The only force that does work on the skier is gravity, so $W_{\text{other}} = 0.$

$K_1 = 0,\ \ K_2 = \frac{1}{2}mv_2^2$

$U_1 = mgy_1 = mgR,\ \ U_2 = mgy_2 = mgR\cos\alpha$

Then $mgR = \frac{1}{2}mv_2^2 + mgR\cos\alpha$

$v_2^2 = 2gR(1-\cos\alpha)$

Combine this with the $\Sigma F_y = ma_y$ equation:

$Rg\cos\alpha = 2gR(1-\cos\alpha)$

$\cos\alpha = 2 - 2\cos\alpha$

$3\cos\alpha = 2$ so $\cos\alpha = 2/3$ and $\alpha = 48.2°$

EVALUATE: She speeds up and her a_{rad} increases as she loses gravitational potential energy. She loses contact when she is going so fast that the radially inward component of her weight isn't large enough to keep her in the circular path. Note that α where she loses contact does not depend on her mass or on the radius of the snowball.

7.56. **IDENTIFY:** We use energy conservation.

SET UP: $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$ where $W_{\text{other}} = 0$, $U_{\text{spr}} = \dfrac{1}{2}kx^2$, $K = \dfrac{1}{2}mv^2$. Call point 1 when the block's speed is 3.00 m/s and point 2 at maximum compression of the spring. This makes v_1 = 3.00 m/s, x_1 = 0.160 m, and $K_2 = 0$.

EXECUTE: **(a)** $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$ becomes $\frac{1}{2}kx_1^2 + \frac{1}{2}mv_1^2 = \frac{1}{2}mv_{\max}^2$. Now solve for $v_{\max}$:

$v_{\max} = \sqrt{\dfrac{kx_1^2 + mv_1^2}{m}}$. Using $x_1 = 0.160$ m, $v_1 = 3.00$ m/s, and $k = 200$ N/m gives $v_{\max} = 4.67$ m/s.

(b) The maximum compression occurs when the kinetic energy is zero, so $\frac{1}{2}mv_{\max}^2 = \frac{1}{2}kx_{\max}^2$,

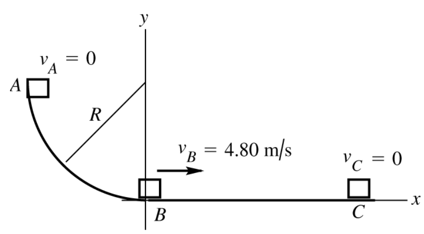
which gives $x_{\max} = v_{\max}\sqrt{m/k} = (4.67\text{ m/s})\sqrt{\dfrac{0.400\text{ kg}}{200\text{ N/m}}} = 0.209$ m.

(c) At maximum compression $v = 0$ and a is a maximum. So $\sum F_x = ma_x$ gives $kx_{\max} = ma$, so

$a = \dfrac{kx_{\max}}{m} = \dfrac{(200\text{ N/m})(0.209\text{ m})}{0.400\text{ kg}} = 104\text{ m/s}^2$.

EVALUATE: At maximum compression, the spring force is a maximum because x is a maximum, so the acceleration is a maximum. But at this instant the block has stopped, so $v = 0$ at maximum acceleration.

7.57. **IDENTIFY** and **SET UP:**



$y_A = R$

$y_B = y_C = 0$

Figure 7.57

(a) Apply conservation of energy to the motion from B to C:

$K_B + U_B + W_{\text{other}} = K_C + U_C$. The motion is described in Figure 7.57.

EXECUTE: The only force that does work on the package during this part of the motion is friction, so $W_{\text{other}} = W_f = f_k(\cos\phi)s = \mu_k\, mg(\cos 180°)s = \mu_k\, mgs$

$K_B = \frac{1}{2}mv_B^2,\quad K_C = 0$

$U_B = 0,\quad U_C = 0$

Thus $K_B + W_f = 0$

$\frac{1}{2}mv_B^2 - \mu_k mgs = 0$

$\mu_k = \dfrac{v_B^2}{2gs} = \dfrac{(4.80\text{ m/s})^2}{2(9.80\text{ m/s}^2)(3.00\text{ m})} = 0.392.$

EVALUATE: The negative friction work takes away all the kinetic energy.

(b) IDENTIFY and **SET UP:** Apply conservation of energy to the motion from A to B:

$$K_A + U_A + W_{\text{other}} = K_B + U_B$$

EXECUTE: Work is done by gravity and by friction, so $W_{\text{other}} = W_f$.

$K_A = 0,\quad K_B = \frac{1}{2}mv_B^2 = \frac{1}{2}(0.200\text{ kg})(4.80\text{ m/s})^2 = 2.304\text{ J}$

$U_A = mgy_A = mgR = (0.200\text{ kg})(9.80\text{ m/s}^2)(1.60\text{ m}) = 3.136\text{ J},\quad U_B = 0$

Thus $U_A + W_f = K_B$

$W_f = K_B - U_A = 2.304\text{ J} - 3.136\text{ J} = \text{-}0.83\text{ J}$

EVALUATE: W_f is negative as expected; the friction force does negative work since it is directed opposite to the displacement.

7.58. IDENTIFY: Apply $K_1+U_1+W_{\text{other}}=K_2+U_2$ to the initial and final positions of the truck.

SET UP: Let $y=0$ at the lowest point of the path of the truck. W_{other} is the work done by friction. $f_{\text{r}}=\mu_{\text{r}}n=\mu_{\text{r}}mg\cos\beta.$

EXECUTE: Denote the distance the truck moves up the ramp by x. $K_1=\frac{1}{2}mv_0^2$, $U_1=mgL\sin\alpha$, $K_2=0$, $U_2=mgx\sin\beta$ and $W_{\text{other}}=-\mu_{\text{r}}mgx\cos\beta$. From $W_{\text{other}}=(K_2+U_2)-(K_1+U_1)$, and solving for x, we get $x=\dfrac{K_1+mgL\sin\alpha}{mg(\sin\beta+\mu_{\text{r}}\cos\beta)}=\dfrac{(v_0^2/2g)+L\sin\alpha}{\sin\beta+\mu_{\text{r}}\cos\beta}$.

EVALUATE: x increases when v_0 increases and decreases when μ_{r} increases.

7.59. (a) IDENTIFY: We are given that $F_x=-\alpha x-\beta x^2$, $\alpha=60.0\text{ N/m}$ and $\beta=18.0\text{ N/m}^2$. Use $W_{F_x}=\int_{x_1}^{x_2}F_x(x)\,dx$ to calculate W and then use $W=-\Delta U$ to identify the potential energy function $U(x)$.

SET UP: $W_{F_x}=U_1-U_2=\int_{x_1}^{x_2}F_x(x)\,dx$

Let $x_1=0$ and $U_1=0$. Let x_2 be some arbitrary point x, so $U_2=U(x)$.

EXECUTE: $U(x)=-\int_0^x F_x(x)\,dx=-\int_0^x(-\alpha x-\beta x^2)\,dx=\int_0^x(\alpha x+\beta x^2)\,dx=\frac{1}{2}\alpha x^2+\frac{1}{3}\beta x^3.$

EVALUATE: If $\beta=0$, the spring does obey Hooke's law, with $k=\alpha$, and our result reduces to $\frac{1}{2}kx^2$.

(b) IDENTIFY: Apply $K_1+U_1+W_{\text{other}}=K_2+U_2$ to the motion of the object.

SET UP: The system at points 1 and 2 is sketched in Figure 7.59.

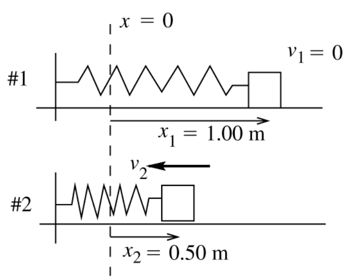


Figure 7.59

$K_1+U_1+W_{\text{other}}=K_2+U_2$

The only force that does work on the object is the spring force, so $W_{\text{other}}=0$.

EXECUTE: $K_1=0$, $K_2=\frac{1}{2}mv_2^2$

$U_1=U(x_1)=\frac{1}{2}\alpha x_1^2+\frac{1}{3}\beta x_1^3=\frac{1}{2}(60.0\text{ N/m})(1.00\text{ m})^2+\frac{1}{3}(18.0\text{ N/m}^2)(1.00\text{ m})^3=36.0\text{ J}$

$U_2=U(x_2)=\frac{1}{2}\alpha x_2^2+\frac{1}{3}\beta x_2^3=\frac{1}{2}(60.0\text{ N/m})(0.500\text{ m})^2+\frac{1}{3}(18.0\text{ N/m}^2)(0.500\text{ m})^3=8.25\text{ J}$

Thus $36.0\text{ J}=\frac{1}{2}mv_2^2+8.25\text{ J}$, which gives $v_2=\sqrt{\dfrac{2(36.0\text{ J}-8.25\text{ J})}{0.900\text{ kg}}}=7.85\text{ m/s}.$

EVALUATE: The elastic potential energy stored in the spring decreases and the kinetic energy of the object increases.

7.60. **IDENTIFY:** Mechanical energy is conserved on the hill, which gives us the speed of the sled at the top. After it leaves the cliff, we must use projectile motion.

SET UP: Use conservation of energy to find the speed of the sled at the edge of the cliff. Let $y_i = 0$ so $y_f = h = 11.0$ m. $K_f + U_f = K_i + U_i$ gives $\frac{1}{2}mv_f^2 + mgh = \frac{1}{2}mv_i^2$ or $v_f = \sqrt{v_i^2 - 2gh}$. Then analyze the projectile motion of the sled: use the vertical component of motion to find the time *t* that the sled is in the air; then use the horizontal component of the motion with $a_x = 0$ to find the horizontal displacement.

EXECUTE: $v_f = \sqrt{(22.5\text{ m/s})^2 - 2(9.80\text{ m/s}^2)(11.0\text{ m})} = 17.1$ m/s. $y_f = v_{i,y}t + \frac{1}{2}a_y t^2$ gives

$t = \sqrt{\dfrac{2y_f}{a_y}} = \sqrt{\dfrac{2(-11.0\text{ m})}{-9.80\text{ m/s}^2}} = 1.50$ s. $x_f = v_{i,x}t + \frac{1}{2}a_x t^2$ gives $x_f = v_{i,x}t = (17.1\text{ m/s})(1.50\text{ s}) = 25.6$ m.

EVALUATE: Conservation of energy can be used to find the speed of the sled at any point of the motion but does not specify how far the sled travels while it is in the air.

7.61. **IDENTIFY:** We have a conservative force, so we can relate the force and the potential energy function. Energy conservation applies.

SET UP: $F_x = -dU/dx$, U goes to 0 as x goes to infinity, and $F(x) = \dfrac{\alpha}{(x+x_0)^2}$.

EXECUTE: **(a)** Using $dU = -F_x dx$, we get $U_x - U_\infty = -\displaystyle\int_\infty^x \frac{\alpha}{(x+x_0)^2}dx = \frac{\alpha}{x+x_0}$.

(b) Energy conservation tells us that $U_1 = K_2 + U_2$. Therefore $\dfrac{\alpha}{x_1+x_0} = \dfrac{1}{2}mv_x^2 + \dfrac{\alpha}{x_2+x_0}$. Putting in $m =$ 0.500 kg, $\alpha = 0.800\text{ N}\cdot\text{m}$, $x_0 = 0.200$ m, $x_1 = 0$, and $x_2 = 0.400$ m, solving for v gives $v = 3.27$ m/s.

EVALUATE: The potential energy is not infinite even though the integral in (a) is taken over an infinite distance because the force rapidly gets smaller with increasing distance x.

7.62. **IDENTIFY:** We need to use energy conservation and apply Newton's second law.

SET UP: $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$ where $W_{\text{other}} = 0$, $U_g = mgy$, and $K = \dfrac{1}{2}mv^2$. $\sum F_{\text{rad}} = ma_{\text{rad}}$, where $a_{\text{rad}} = \dfrac{v^2}{R}$. The ball has momentarily stopped swinging when $\theta = 37.0°$, but it is swinging when $\theta = 25.0°$. Since the ball is swinging in a circular arc, it has radial acceleration toward the center of the circle. The forces causing that acceleration are the tension and the component of gravity toward (or away from) the center of the circle. Fig. 7.62 shows a free-body diagram of the ball. We want to find the tension in the rope at two different angles.

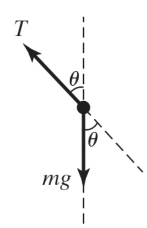

Figure 7.62

EXECUTE: **(a)** At the maximum angle of swing, the ball has stopped, so its radial acceleration (v^2/R) is zero at that instant. This means that the net radial force must be zero. From Fig. 7.62 we can see the force components. Thus $T - mg\cos\theta = 0$, and solving for T gives

$T = mg\cos\theta = (0.200 \text{ kg})(9.80 \text{ m/s}^2)(\cos 37.0°) = 1.57$ N.

(b) The ball is now moving, so it has radial acceleration. Therefore $\sum F_{\text{rad}} = ma_{\text{rad}}$ gives $T - mg\cos\theta = m\dfrac{v^2}{R}$. Solving for T and using $R = L$, we get $T = mg\cos\theta + m\dfrac{v^2}{L}$. To find T, we need to find v^2 when $\theta = 25.0°$. We use $U_1 + K_1 = U_2 + K_2$. Call point 1 when $\theta = 37.0°$ and point 2 when $\theta = 25.0°$. In that case we have $U_1 = K_2 + U_2$, which gives $K_2 = -(U_2 - U_1) = -mg(y_2 - y_1) = -mgL(\cos\theta_1 - \cos\theta_2)$. In terms of v_2, this is $\frac{1}{2}mv_2^2 = -mgL(\cos\theta_1 - \cos\theta_2)$, which simplifies to $v_2^2 = -2gL(\cos\theta_1 - \cos\theta_2)$, so $v_2^2 = -2g(1.40 \text{ m})(\cos 37.0° - \cos 25.0°) = 2.95 \text{ m}^2/\text{s}^2$. Now return to the tension. From earlier work, we have $T = mg\cos\theta_2 + m\dfrac{v^2}{L} = m\left(g\cos\theta_2 + \dfrac{v^2}{L}\right)$. Using $v_2^2 = 2.95 \text{ m}^2/\text{s}^2$, $m = 0.200$ kg, $\theta = 25.0°$, and $L = 1.40$ m, we find that $T = 2.20$ N.

EVALUATE: We have found that the tension T is greater at 25° than at 37° because it helps to accelerate the ball toward the center at 25°.

7.63. **IDENTIFY:** Apply $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ to the motion of the block.

SET UP: Let $y = 0$ at the floor. Let point 1 be the initial position of the block against the compressed spring and let point 2 be just before the block strikes the floor.

EXECUTE: With $U_2 = 0, K_1 = 0,$ $K_2 = U_1$. $\frac{1}{2}mv_2^2 = \frac{1}{2}kx^2 + mgh$. Solving for v_2,

$$v_2 = \sqrt{\frac{kx^2}{m} + 2gh} = \sqrt{\frac{(1900 \text{ N/m})(0.045 \text{ m})^2}{(0.150 \text{ kg})} + 2(9.80 \text{ m/s}^2)(1.20 \text{ m})} = 7.01 \text{ m/s}.$$

EVALUATE: The potential energy stored in the spring and the initial gravitational potential energy all go into the final kinetic energy of the block.

7.64. **IDENTIFY:** At equilibrium the upward spring force equals the weight mg of the object. Apply conservation of energy to the motion of the fish.

SET UP: The distance that the mass descends equals the distance the spring is stretched. $K_1 = K_2 = 0$, so $U_1(\text{gravitational}) = U_2(\text{spring})$

EXECUTE: Following the hint, the force constant k is found from $mg = kd$, or $k = mg/d$. When the fish falls from rest, its gravitational potential energy decreases by mgy; this becomes the potential energy of the spring, which is $\frac{1}{2}ky^2 = \frac{1}{2}(mg/d)y^2$. Equating these, $\frac{1}{2}\frac{mg}{d}y^2 = mgy$, or $y = 2d$.

EVALUATE: At its lowest point the fish is not in equilibrium. The upward spring force at this point is $ky = 2kd$, and this is equal to twice the weight. At this point the net force is mg, upward, and the fish has an upward acceleration equal to g.

7.65. **IDENTIFY:** The spring does positive work on the box but friction does negative work.

SET UP: $U_{\text{el}} = \frac{1}{2}kx^2$ and $W_{\text{other}} = W_f = -\mu_k mgx$.

EXECUTE: **(a)** $U_{\text{el}} + W_{\text{other}} = K$ gives $\frac{1}{2}kx^2 + (-\mu_k mgx) = \frac{1}{2}mv^2$. Using the numbers for the problem, $k = 45.0$ N/m, $x = 0.280$ m, $\mu_k = 0.300$, and $m = 1.60$ kg, solving for v gives $v = 0.747$ m/s.

(b) Call x the distance the spring is compressed when the speed of the box is a maximum and x_0 the initial compression distance of the spring. Using an approach similar to that in part (a) gives $\frac{1}{2}kx_0^2 - \mu_k mg(x_0 - x) = \frac{1}{2}mv^2 + \frac{1}{2}kx^2$. Rearranging gives $mv^2 = kx_0^2 - kx^2 - 2\mu_k mg(x_0 - x)$. For the maximum speed, $d(v^2)/dx = 0$, which gives $-2kx + 2\mu_k mg = 0$. Solving for $x_{\max}$, the compression distance at maximum speed, gives $x_{\max} = \mu_k mg/k$. Now substitute this result into the expression above for mv^2, put in the numbers, and solve for v, giving $v = 0.931$ m/s.

EVALUATE: Another way to find the result in (b) is to realize that the spring force decreases as x decreases, but the friction force remains constant. Eventually these two forces will be equal in magnitude. After that the friction force will be greater than the spring force, and friction will begin to slow down the box. So the maximum box speed occurs when the spring force is equal to the friction force. At that instant, $kx = f_k$, which gives $x = 0.105$ m. Then energy conservation can be used to find v with this value of x.

7.66. **IDENTIFY:** The spring obeys Hooke's law. Gravity and the spring provide the vertical forces on the brick. The mechanical energy of the system is conserved.

SET UP: Use $K_f + U_f = K_i + U_i$. In part (a), setting $y_f = 0$, we have $y_i = x$, the amount the spring will stretch. Also, since $K_i = K_f = 0$, $\frac{1}{2}kx^2 = mgx$. In part (b), $y_i = h + x$, where $h = 1.0$ m.

EXECUTE: **(a)** $x = \dfrac{2mg}{k} = \dfrac{2(3.0\text{ kg})(9.80\text{ m/s}^2)}{1500\text{ N/m}} = 0.039\text{ m} = 3.9\text{ cm}.$

(b) $\frac{1}{2}kx^2 = mg(h + x)$, $kx^2 - 2mgx - 2mgh = 0$ and $x = \dfrac{mg}{k}\left(1 \pm \sqrt{1 + \dfrac{2hk}{mg}}\right)$. Since x must be positive,

we have $x = \dfrac{mg}{k}\left(1+\sqrt{1+\dfrac{2hk}{mg}}\right) = \dfrac{(3.0\text{ kg})(9.80\text{ m/s}^2)}{1500\text{ N/m}}\left(1+\sqrt{1+\dfrac{2(1.0\text{ m})(1500\text{ N/m})}{3.0\text{ kg}(9.80\text{ m/s}^2)}}\right) = 0.22\text{ m} = 22\text{ cm}.$

EVALUATE: In part (b) there is additional initial energy (from gravity), so the spring is stretched more.

7.67. **IDENTIFY:** Only conservative forces (gravity and the spring) act on the fish, so its mechanical energy is conserved.

SET UP: Energy conservation tells us $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$, where $W_{\text{other}} = 0$. $U_g = mgy$, $K = \frac{1}{2}mv^2$, and $U_{spring} = \frac{1}{2}ky^2$.

EXECUTE: **(a)** $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$. Let y be the distance the fish has descended, so $y = 0.0500$ m. $K_1 = 0$, $W_{\text{other}} = 0$, $U_1 = mgy$, $K_2 = \dfrac{1}{2}mv_2^2$, and $U_2 = \dfrac{1}{2}ky^2$. Solving for K_2 gives

$K_2 = U_1 - U_2 = mgy - \dfrac{1}{2}ky^2 = (3.00\text{ kg})(9.8\text{ m/s}^2)(0.0500\text{ m}) - \dfrac{1}{2}(900\text{ N/m})(0.0500\text{ m})^2$

$K_2 = 1.47\text{ J} - 1.125\text{ J} = 0.345\text{ J}$. Solving for v_2 gives $v_2 = \sqrt{\dfrac{2K_2}{m}} = \sqrt{\dfrac{2(0.345\text{ J})}{3.00\text{ kg}}} = 0.480\text{ m/s}.$

(b) The maximum speed is when K_2 is maximum, which is when $dK_2/dy = 0$. Using $K_2 = mgy - \dfrac{1}{2}ky^2$ gives $\dfrac{dK_2}{dy} = mg - ky = 0$. Solving for y gives

$y = \dfrac{mg}{k} = \dfrac{(3.00\text{ kg})(9.8\text{ m/s}^2)}{900\text{ N/m}} = 0.03267\text{ m}$. At this y,

$K_2 = (3.00\text{ kg})(9.8\text{ m/s}^2)(0.03267\text{ m}) - \dfrac{1}{2}(900\text{ N/m})(0.03267\text{ m})^2.$

$K_2 = 0.9604\text{ J} - 0.4803\text{ J} = 0.4801\text{ J}$, so $v_2 = \sqrt{\dfrac{2K_2}{m}} = 0.566\text{ m/s}.$

EVALUATE: The speed in part (b) is greater than the speed in part (a), as it should be since it is the maximum speed.

7.68. **IDENTIFY:** We need to use projectile motion and energy conservation.

SET UP: We work "backwards" in a sense. First use projectile motion to find the horizontal velocity of the wood at the base of the slide. Then use energy conservation to find how much work friction did as the wood slid down the slide. Use $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$, where W_{other} is the work done by friction on the slide, which is what we want to find. The sketch in Fig. 7.68 organizes the quantities in the problem.

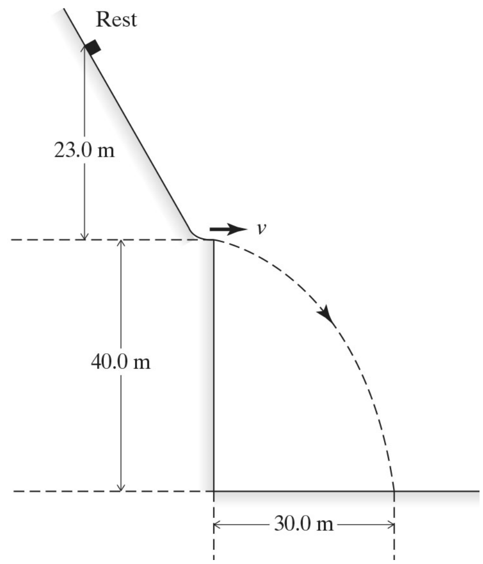

Figure 7.68

EXECUTE: Once the wood leaves the slide, it falls 40.0 m from rest while traveling 30.0 m horizontally at constant horizontal velocity. Using $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ gives $y = \frac{1}{2}gt^2$, so

$t = \sqrt{\frac{2y}{g}} = \sqrt{\frac{80.0\text{ m}}{9.80\text{ m/s}^2}} = 2.857$ s. The constant speed v needed to travel 30.0 m horizontally in 2.857 s is $v = x/t = (30.0\text{ m})/(2.857\text{ s}) = 10.5$ m/s. This is the speed at the bottom of the slide. Now use energy conservation, calling point 1 at the top of the slide and point 2 the bottom of the slide. $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$ becomes $mgh + W_{\text{f}} = \frac{1}{2}mv^2$. Solve for W_{f}: $W_{\text{f}} = m\left(\frac{v^2}{2} - gh\right)$. Using $m =$ 3.00 kg, $v = 10.5$ m/s, and $h = 23.0$ m gives $W_{\text{f}} = -511$ J.

EVALUATE: The work must be negative because friction works *against* the block's motion and therefore takes away mechanical energy.

7.69. **(a) IDENTIFY and SET UP:** Apply $K_A + U_A + W_{\text{other}} = K_B + U_B$ to the motion from A to B.

EXECUTE: $K_A = 0,\ K_B = \frac{1}{2}mv_B^2,\ U_A = 0,\ U_B = U_{\text{el},B} = \frac{1}{2}kx_B^2,$ where $x_B = 0.25$ m, and $W_{\text{other}} = W_F = Fx_B$. Thus $Fx_B = \frac{1}{2}mv_B^2 + \frac{1}{2}kx_B^2$. (The work done by F goes partly to the potential energy of the stretched spring and partly to the kinetic energy of the block.)

$Fx_B = (20.0\text{ N})(0.25\text{ m}) = 5.0\text{ J}$ and $\frac{1}{2}kx_B^2 = \frac{1}{2}(40.0\text{ N/m})(0.25\text{ m})^2 = 1.25\text{ J}$

Thus $5.0\text{ J} = \frac{1}{2}mv_B^2 + 1.25\text{ J}$ and $v_B = \sqrt{\frac{2(3.75\text{ J})}{0.500\text{ kg}}} = 3.87\text{ m/s}.$

(b) IDENTIFY: Apply $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ to the motion of the block. Let point C be where the block is closest to the wall. When the block is at point C the spring is compressed an amount $|x_C|$, so the block is $0.60\text{ m} - |x_C|$ from the wall, and the distance between B and C is $x_B + |x_C|$.

SET UP: The motion from A to B to C is described in Figure 7.69.

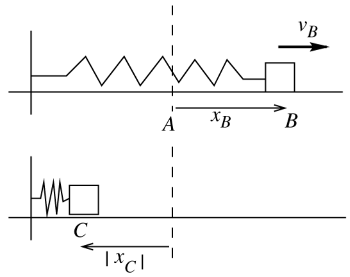

Figure 7.69

$K_B + U_B + W_{\text{other}} = K_C + U_C$

EXECUTE: $W_{\text{other}} = 0$

$K_B = \frac{1}{2}mv_B^2 = 5.0\ \text{J} - 1.25\ \text{J} = 3.75\ \text{J}$ (from part (a))

$U_B = \frac{1}{2}kx_B^2 = 1.25\ \text{J}$

$K_C = 0$ (instantaneously at rest at point closest to wall)

$U_C = \frac{1}{2}k|x_C|^2$

Thus $3.75\ \text{J} + 1.25\ \text{J} = \frac{1}{2}k|x_C|^2$, giving $|x_c| = \sqrt{\dfrac{2(5.0\ \text{J})}{40.0\ \text{N/m}}} = 0.50\ \text{m}$. The distance of the block from the wall is $0.60\ \text{m} - 0.50\ \text{m} = 0.10\ \text{m}$.

EVALUATE: The work $(20.0\ \text{N})(0.25\ \text{m}) = 5.0\ \text{J}$ done by F puts 5.0 J of mechanical energy into the system. No mechanical energy is taken away by friction, so the total energy at points B and C is 5.0 J.

7.70. **IDENTIFY:** Applying Newton's second law, we can use the known normal forces to find the speeds of the block at the top and bottom of the circle. We can then use energy conservation to find the work done by friction, which is the target variable.

SET UP: For circular motion $\Sigma F = m\dfrac{v^2}{R}$. Energy conservation tells us that $K_A + U_A + W_{\text{other}} = K_B + U_B$, where W_{other} is the work done by friction. $U_{\text{g}} = mgy$ and $K = \frac{1}{2}mv^2$.

EXECUTE: Use the given values for the normal force to find the block's speed at points A and B. At point A, Newton's second law gives $n_A - mg = m\dfrac{v_A^2}{R}$. So

$v_A = \sqrt{\dfrac{R}{m}(n_A - mg)} = \sqrt{\dfrac{0.500\ \text{m}}{0.0400\ \text{kg}}(3.95\ \text{N} - 0.392\ \text{N})} = 6.669\ \text{m/s}$. Similarly at point B,

$n_B + mg = m\dfrac{v_B^2}{R}$. Solving for v_{B} gives

$v_B = \sqrt{\dfrac{R}{m}(n_B + mg)} = \sqrt{\dfrac{0.500\ \text{m}}{0.0400\ \text{kg}}(0.680\ \text{N} + 0.392\ \text{N})} = 3.660\ \text{m/s}$. Now apply $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ to find the work done by friction. $K_A + U_A + W_{\text{other}} = K_B + U_B$.

$W_{\text{other}} = K_B + U_B - K_A$.

$W_{\text{other}} = \dfrac{1}{2}(0.040\ \text{kg})(3.66\ \text{m/s})^2 + (0.04\ \text{kg})(9.8\ \text{m/s}^2)(1.0\ \text{m}) - \dfrac{1}{2}(0.04\ \text{kg})(6.669\ \text{m/s})^2$.

$W_{\text{other}} = 0.2679\ \text{J} + 0.392\ \text{J} - 0.8895\ \text{J} = -0.230\ \text{J}$.

EVALUATE: The work done by friction is negative, as it should be. This work is equal to the loss of mechanical energy between the top and bottom of the circle.

7.71. **IDENTIFY:** We can apply Newton's second law to the block. The only forces acting on the block are gravity downward and the normal force from the track pointing toward the center of the circle. The mechanical energy of the block is conserved since only gravity does work on it. The normal force does no work since it is perpendicular to the displacement of the block. The target variable is the normal force at the top of the track.

SET UP: For circular motion $\Sigma F = m\dfrac{v^2}{R}$. Energy conservation tells us that $K_A + U_A + W_{\text{other}} = K_B + U_B$, where $W_{\text{other}} = 0$. $U_g = mgy$ and $K = \frac{1}{2}mv^2$.

EXECUTE: Let point A be at the bottom of the path and point B be at the top of the path. At the bottom of the path, $n_A - mg = m\dfrac{v^2}{R}$ (from Newton's second law).

$v_A = \sqrt{\dfrac{R}{m}(n_A - mg)} = \sqrt{\dfrac{0.800\text{ m}}{0.0500\text{ kg}}(3.40\text{ N} - 0.49\text{ N})} = 6.82\text{ m/s}$. Use energy conservation to find the speed at point B. $K_A + U_A + W_{\text{other}} = K_B + U_B$, giving $\frac{1}{2}mv_A^2 = \frac{1}{2}mv_B^2 + mg(2R)$. Solving for v_B gives $v_B = \sqrt{v_A^2 - 4Rg} = \sqrt{(6.82\text{ m/s})^2 - 4(0.800\text{ m})(9.8\text{ m/s}^2)} = 3.89\text{ m/s}$. Then at point B, Newton's second law gives $n_B + mg = m\dfrac{v_B^2}{R}$. Solving for n_B gives $n_B = m\dfrac{v_B^2}{R} - mg =$

$$(0.0500\text{ kg})\left(\frac{(3.89\text{ m/s})^2}{0.800\text{ m}} - 9.8\text{ m/s}^2\right) = 0.456\text{ N}.$$

EVALUATE: The normal force at the top is considerably less than it is at the bottom for two reasons: the block is moving slower at the top and the downward force of gravity at the top aids the normal force in keeping the block moving in a circle.

7.72. IDENTIFY: Only gravity does work, so apply $K_1 + U_1 = K_2 + U_2$. Use $\Sigma\vec{F} = m\vec{a}$ to calculate the tension.

SET UP: Let $y = 0$ at the bottom of the arc. Let point 1 be when the string makes a $45°$ angle with the vertical and point 2 be where the string is vertical. The rock moves in an arc of a circle, so it has radial acceleration $a_{\text{rad}} = v^2/r$.

EXECUTE: **(a)** At the top of the swing, when the kinetic energy is zero, the potential energy (with respect to the bottom of the circular arc) is $mgl(1 - \cos\theta)$, where l is the length of the string and θ is the angle the string makes with the vertical. At the bottom of the swing, this potential energy has become kinetic energy, so $mgl(1 - \cos\theta) = \frac{1}{2}mv^2$, which gives

$v = \sqrt{2gl(1 - \cos\theta)} = \sqrt{2(9.80\text{ m/s}^2)(0.80\text{ m})(1 - \cos 45°)} = 2.1\text{ m/s}$.

(b) At $45°$ from the vertical, the speed is zero, and there is no radial acceleration; the tension is equal to the radial component of the weight, or $mg\cos\theta = (0.12\text{ kg})(9.80\text{ m/s}^2)\cos 45° = 0.83\text{ N}$.

(c) At the bottom of the circle, the tension is the sum of the weight and the mass times the radial acceleration, $mg + mv_2^2/l = mg(1 + 2(1 - \cos 45°)) = 1.9\text{ N}$.

EVALUATE: When the string passes through the vertical, the tension is greater than the weight because the acceleration is upward.

7.73. IDENTIFY: Apply $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ to the motion of the block.

SET UP: The motion from A to B is described in Figure 7.73.

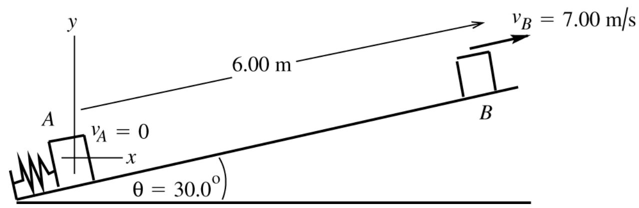

Figure 7.73

The normal force is $n = mg\cos\theta$, so $f_k = \mu_k n = \mu_k mg\cos\theta$. $y_A = 0$; $y_B = (6.00\text{ m})\sin 30.0° = 3.00$ m.
$K_A + U_A + W_{\text{other}} = K_B + U_B$

Execute: Work is done by gravity, by the spring force, and by friction, so $W_{\text{other}} = W_f$ and
$U = U_{\text{el}} + U_{\text{grav}}$

$K_A = 0$, $K_B = \frac{1}{2}mv_B^2 = \frac{1}{2}(1.50\text{ kg})(7.00\text{ m/s})^2 = 36.75$ J

$U_A = U_{\text{el},A} + U_{\text{grav},A} = U_{\text{el},A}$, since $U_{\text{grav},A} = 0$

$U_B = U_{\text{el},B} + U_{\text{grav},B} = 0 + mgy_B = (1.50\text{ kg})(9.80\text{ m/s}^2)(3.00\text{ m}) = 44.1$ J

$W_{\text{other}} = W_f = (f_k\cos\phi)s = \mu_k mg\cos\theta(\cos 180°)s = -\mu_k mg\cos\theta s$

$W_{\text{other}} = -(0.50)(1.50\text{ kg})(9.80\text{ m/s}^2)(\cos 30.0°)(6.00\text{ m}) = -38.19$ J

Thus $U_{\text{el},A} - 38.19\text{ J} = 36.75\text{ J} + 44.10\text{ J}$, giving $U_{\text{el},A} = 38.19\text{ J} + 36.75\text{ J} + 44.10\text{ J} = 119$ J.

Evaluate: U_{el} must always be positive. Part of the energy initially stored in the spring was taken away by friction work; the rest went partly into kinetic energy and partly into an increase in gravitational potential energy.

7.74. **Identify:** We know the potential energy function for a conservative force. Mechanical energy is conserved.

Set Up: $F_x = -dU/dx$ and $U(x) = -\alpha x^2 + \beta x^3$.

Execute: **(a)** $U_1 + K_1 = U_2 + K_2$ gives $0 + 0 = U_2 + K_2$, so $K_2 = -U_2 = -(-\alpha x_2^2 + \beta x_2^3) = \frac{1}{2}mv^2$. Using $m = 0.0900$ kg, $x = 4.00$ m, $\alpha = 2.00$ J/m^2, and $\beta = 0.300$ J/m^3, solving for v gives $v = 16.9$ m/s.

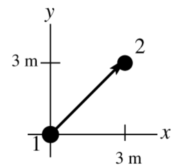
(b) $F_x = -dU/dx = -(-2\alpha x + 3\beta x^2)$. In addition, $F_x = ma_x$, so $a_x = F_x/m$. Using the numbers from (a), gives $a = 17.8$ m/s^2.

(c) The maximum x will occur when $U = 0$ since the total energy is zero. Therefore $-\alpha x^2 + \beta x^3 = 0$, so $x_{\max} = \alpha/\beta = (2.00\text{ J/m}^2)/(0.300\text{ J/m}^3) = 6.67$ m.

Evaluate: The object is released from rest but at a small (but not zero) x. Therefore F_x is small but not zero initially, so it will start the object moving.

7.75. **Identify:** We are given that $\vec{F} = -\alpha xy^2\hat{j}$, $\alpha = 2.50\text{ N/m}^3$. $\vec{F}$ is not constant so use $W = \int_1^2 \vec{F}\cdot d\vec{l}$ to calculate the work. $\vec{F}$ must be evaluated along the path.

(a) SET UP: The path is sketched in Figure 7.75a.



$d\vec{l} = dx\hat{\imath} + dy\hat{\jmath}$

$\vec{F} \cdot d\vec{l} = -\alpha xy^2\, dy$

On the path, $x = y$ so $\vec{F} \cdot d\vec{l} = -\alpha y^3\, dy$

Figure 7.75a

EXECUTE: $W = \int_1^2 \vec{F} \cdot d\vec{l} = \int_{y_1}^{y_2} (-\alpha y^3)\, dy = -(\alpha/4)(y_2^4 - y_1^4)$

$y_1 = 0,\ \ y_2 = 3.00\text{ m},$ so $W = -\frac{1}{4}(2.50\text{ N/m}^3)(3.00\text{ m})^4 = -50.6\text{ J}$

(b) SET UP: The path is sketched in Figure 7.75b.

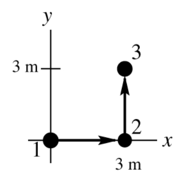


Figure 7.75b

For the displacement from point 1 to point 2, $d\vec{l} = dx\hat{\imath}$, so $\vec{F} \cdot d\vec{l} = 0$ and $W = 0$. (The force is perpendicular to the displacement at each point along the path, so $W = 0$.)

For the displacement from point 2 to point 3, $d\vec{l} = dy\hat{\jmath}$, so $\vec{F} \cdot d\vec{l} = -\alpha xy^2\, dy$. On this path, $x = 3.00$ m, so

$$\vec{F} \cdot d\vec{l} = -(2.50\text{ N/m}^3)(3.00\text{ m})y^2\, dy = -(7.50\text{ N/m}^2)y^2\, dy.$$

EXECUTE: $W = \int_2^3 \vec{F} \cdot d\vec{l} = -(7.50\text{ N/m}^2)\int_{y_2}^{y_3} y^2\, dy = -(7.50\text{ N/m}^2)\frac{1}{3}(y_3^3 - y_2^3)$

$W = -(7.50\text{ N/m}^2)\left(\frac{1}{3}\right)(3.00\text{ m})^3 = -67.5\text{ J}.$

(c) EVALUATE: For these two paths between the same starting and ending points the work is different, so the force is nonconservative.

7.76. IDENTIFY: Use $F_x = -\dfrac{dU}{dx}$ to relate F_x and $U(x)$. The equilibrium is stable where $U(x)$ is a local minimum and the equilibrium is unstable where $U(x)$ is a local maximum.

SET UP: dU/dx is the slope of the graph of U versus x. $K = E - U$, so K is a maximum when U is a minimum. The maximum x is where $E = U$.

EXECUTE: **(a)** The slope of the U *vs*. x curve is negative at point A, so F_x is positive because $F_x = -dU/dx$.

(b) The slope of the curve at point B is positive, so the force is negative.

(c) The kinetic energy is a maximum when the potential energy is a minimum, and that figures to be at around 0.75 m.

(d) The curve at point C looks pretty close to flat, so the force is zero.

(e) The object had zero kinetic energy at point A, and in order to reach a point with more potential energy than $U(A)$, the kinetic energy would need to be negative. Kinetic energy is never negative, so the object can never be at any point where the potential energy is larger than $U(A)$. On the graph, that looks to be at about 2.2 m.

(f) The point of minimum potential (found in part (c)) is a stable point, as is the relative minimum near 1.9 m.

(g) The only potential maximum, and hence the only point of unstable equilibrium, is at point C.

EVALUATE: If E is less than U at point C, the particle is trapped in one or the other of the potential "wells" and cannot move from one allowed region of x to the other.

7.77. IDENTIFY: The mechanical energy of the system is conserved, and Newton's second law applies. As the pendulum swings, gravitational potential energy gets transformed to kinetic energy.

SET UP: For circular motion, $F = mv^2/r$. $U_{\text{grav}} = mgh$.

EXECUTE: **(a)** Conservation of mechanical energy gives $mgh = ½\, mv^2 + mgh_0$, where $h_0 = 0.800$ m. Applying Newton's second law at the bottom of the swing gives $T = mv^2/L + mg$. Combining these two equations and solving for T as a function of h gives $T = (2mg/L)h + mg(1 - 2h_0/L)$. In a graph of T versus h, the slope is $2mg/L$. Graphing the data given in the problem, we get the graph shown in Figure 7.77. Using the best-fit equation, we get $T = (9.293\text{ N/m})h + 257.3$ N. Therefore $2mg/L = 9.293$ N/m. Using $mg = 265$ N and solving for L, we get $L = 2(265\text{ N})/(9.293\text{ N/m}) = 57.0$ m.

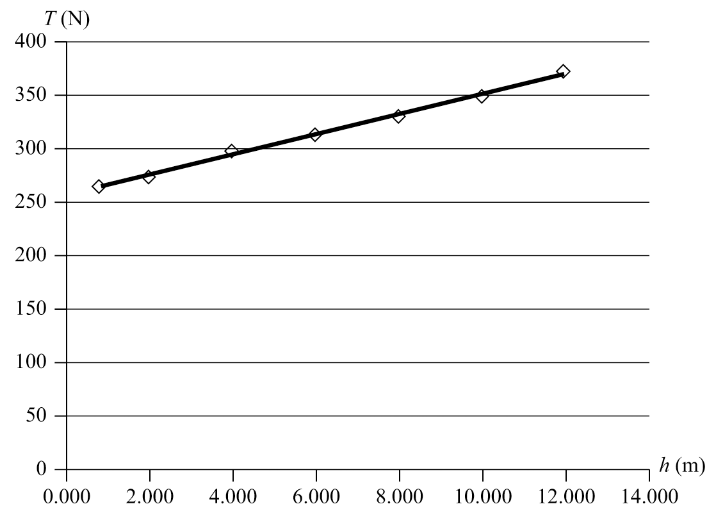

Figure 7.77

(b) $T_{\max} = 822$ N, so $T = T_{\max}/2 = 411$ N. We use the equation for the graph with $T = 411$ N and solve for h. $411\text{ N} = (9.293\text{ N/m})h + 257.3$ N, which gives $h = 16.5$ m.

(c) The pendulum is losing energy because negative work is being done on it by friction with the air and at the point of contact where it swings.

EVALUATE: The length of this pendulum may seem extremely large, but it is not unreasonable for a museum exhibit, which can cover a height of several floor levels.

7.78. IDENTIFY: Friction does negative work, and we can use $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$.

SET UP: $U_1 + W_{\text{other}} = K_2$

EXECUTE: **(a)** Using $K_2 = U_1 + W_{\text{other}}$ gives $\frac{1}{2}mv^2 = mgh - (\mu_k mg\cos\theta)s$ and geometry gives $s = \frac{h}{\sin\theta}$. Combining these equations and solving for h gives $h = \frac{v^2}{2g\left(1 - \frac{\mu_k}{\tan\theta}\right)}$. For each material, θ = 52.0° and $v = 4.00$ m/s. Using the coefficients of sliding friction from the table in the problem, this formula gives the following results for h. (i) 0.92 m (ii) 1.1 m (iii) 2.4 m.

(b) The mass divides out, so h is unchanged and remains at 1.1 m.

(c) In the formula for h in part (a), we solve for v^2 giving $v^2 = 2gh\left(1 - \frac{\mu_k}{\tan\theta}\right)$. As θ increases (but h remains the same), $\tan\theta$ increases, so the quantity in parentheses increases since $\tan\theta$ is in the denominator. Therefore v increases.

EVALUATE: The answer in (c) makes physical sense because with h constant, a larger value for θ means that the normal force decreases so the magnitude of the friction force also decreases, and therefore friction is less able to oppose the motion of the block as it slides down the slope.

7.79. **IDENTIFY:** For a conservative force, mechanical energy is conserved and we can relate the force to its potential energy function.

SET UP: $F_x = -dU/dx$.

EXECUTE: **(a)** $U + K = E =$ constant. If two points have the same kinetic energy, they must have the same potential energy since the sum of U and K is constant. Since the kinetic energy curve symmetric, the potential energy curve must also be symmetric.

(b) At $x = 0$ we can see from the graph with the problem that $E = K + 0 = 0.14$ J. Since E is constant, if $K = 0$ at $x = -1.5$ m, then U must be equal to 0.14 J at that point.

(c) $U(x) = E - K(x) = 0.14\text{ J} - K(x)$, so the graph of $U(x)$ is like the sketch in Figure 7.79.

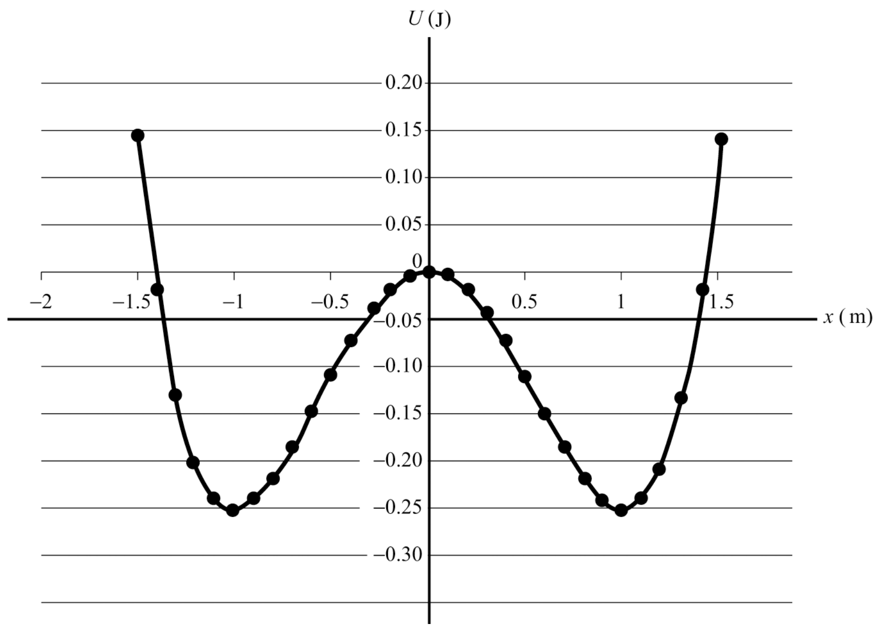

Figure 1.79

(d) Since $F_x = -dU/dx$, $F(x) = 0$ at $x = 0$, +1.0 m, and –1.0 m.

(e) $F(x)$ is positive when the slope of the $U(x)$ curve is negative, and $F(x)$ is negative when the slope of the $U(x)$ curve is positive. Therefore $F(x)$ is positive between $x = -1.5$ m and $x = -1.0$ m and between $x = 0$ and $x = 1.0$ m. $F(x)$ is negative between $x = -1.0$ m and 0 and between $x = 1.0$ m and $x = 1.5$ m.

(f) When released from $x = -1.30$ m, the sphere will move to the right until it reaches $x = -0.55$ m, at which point it has 0.12 J of potential energy, the same as at is original point of release.

EVALUATE: Even though we do not have the equation of the kinetic energy function, we can still learn much about the behavior of the system by studying its graph.

7.80. IDENTIFY: $K = E - U$ determines $v(x)$.

SET UP: v is a maximum when U is a minimum and v is a minimum when U is a maximum. $F_x = -dU/dx$. The extreme values of x are where $E = U(x)$.

EXECUTE: (a) Eliminating β in favor of α and $x_0 (\beta = \alpha/x_0)$,

$$U(x) = \frac{\alpha}{x^2} - \frac{\beta}{x} = \frac{\alpha}{x_0^2}\frac{x_0^2}{x^2} - \frac{\alpha}{x_0 x} = \frac{\alpha}{x_0^2}\left[\left(\frac{x_0}{x}\right)^2 - \left(\frac{x_0}{x}\right)\right].$$

$U(x_0) = \left(\frac{\alpha}{x_0^2}\right)(1-1) = 0.$ $U(x)$ is positive for $x < x_0$ and negative for $x > x_0$ (α and β must be taken as positive). The graph of $U(x)$ is sketched in Figure 7.80a.

(b) $v(x) = \sqrt{-\frac{2}{m}U} = \sqrt{\left(\frac{2\alpha}{mx_0^2}\right)\left(\left(\frac{x_0}{x}\right) - \left(\frac{x_0}{x}\right)^2\right)}$. The proton moves in the positive x-direction, speeding up until it reaches a maximum speed (see part (c)), and then slows down, although it never stops. The minus sign in the square root in the expression for $v(x)$ indicates that the particle will be found only in the region where $U < 0$, that is, $x > x_0$. The graph of $v(x)$ is sketched in Figure 7.80b.

(c) The maximum speed corresponds to the maximum kinetic energy, and hence the minimum potential energy. This minimum occurs when $\frac{dU}{dx} = 0$, or $\frac{dU}{dx} = \frac{\alpha}{x_0}\left[-2\left(\frac{x_0}{x}\right)^3 + \left(\frac{x_0}{x}\right)^2\right] = 0,$

which has the solution $x = 2x_0$. $U(2x_0) = -\frac{\alpha}{4x_0^2}$, so $v = \sqrt{\frac{\alpha}{2mx_0^2}}$.

(d) The maximum speed occurs at a point where $\frac{dU}{dx} = 0$, and since $F_x = -\frac{dU}{dx}$, the force at this point is zero.

(e) $x_1 = 3x_0$, and $U(3x_0) = -\frac{2\alpha}{9x_0^2}$.

$$v(x) = \sqrt{\frac{2}{m}(U(x_1) - U(x))} = \sqrt{\frac{2}{m}\left[\left(\frac{-2}{9}\frac{\alpha}{x_0^2}\right) - \frac{\alpha}{x_0^2}\left(\left(\frac{x_0}{x}\right)^2 - \frac{x_0}{x}\right)\right]} = \sqrt{\frac{2\alpha}{mx_0^2}\left(\left(\frac{x_0}{x}\right) - \left(\frac{x_0}{x}\right)^2 - \frac{2}{9}\right)}.$$

The particle is confined to the region where $U(x) < U(x_1)$. The maximum speed still occurs at $x = 2x_0$, but now the particle will oscillate between x_1 and some minimum value (see part (f)).

(f) Note that $U(x) - U(x_1)$ can be written as

$$\frac{\alpha}{x_0^2}\left[\left(\frac{x_0}{x}\right)^2 - \left(\frac{x_0}{x}\right) + \left(\frac{2}{9}\right)\right] = \frac{\alpha}{x_0^2}\left[\left(\frac{x_0}{x}\right) - \frac{1}{3}\right]\left[\left(\frac{x_0}{x}\right) - \frac{2}{3}\right],$$

which is zero (and hence the kinetic energy is zero) at $x = 3x_0 = x_1$ and $x = \frac{3}{2}x_0$. Thus, when the particle is released from x_0, it goes on to infinity, and doesn't reach any maximum distance. When released from x_1, it oscillates between $\frac{3}{2}x_0$ and $3x_0$.

EVALUATE: In each case the proton is released from rest and $E = U(x_i)$, where x_i is the point where it is released. When $x_i = x_0$ the total energy is zero. When $x_i = x_1$ the total energy is negative. $U(x) \to 0$ as $x \to \infty$, so for this case the proton can't reach $x \to \infty$ and the maximum x it can have is limited.

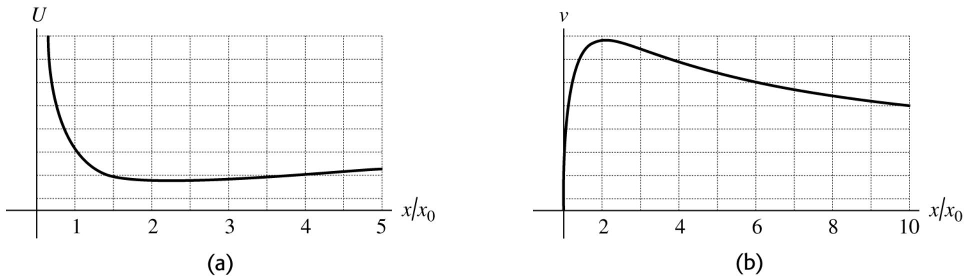

Figure 7.80

7.81. **IDENTIFY:** We model the DNA molecule as an ideal spring.
SET UP: Hooke's law is $F = kx$.
EXECUTE: Since F is proportional to x, if a 3.0-pN force causes a 0.10-nm deflection, a 6.0-pN force, which is twice as great, should use twice as much deflection, or 0.2 nm. This makes choice (c) correct.
EVALUATE: A simple model can give rough but often meaningful insight into the behavior of a complicated system.

7.82. **IDENTIFY** and **SET UP:** If a system obeys Hooke's law, a graph of force versus displacement will be a straight line through the origin having positive slope equal to the force constant.
EXECUTE: The graph is a straight line. Reading its slope from the graph gives (2.0 pN)/(20 nm) = 0.1 pN/nm, which makes choice (b) correct.
EVALUATE: The molecule would obey Hooke's law only over a restricted range of displacements.

7.83. **IDENTIFY** and **SET UP:** The energy is the area under the force-displacement curve.
EXECUTE: Using the area under the triangular section from 0 to 50 nm, we have
$A = \frac{1}{2}(5.0\text{ pN})(50\text{ nm}) = 1.25\times10^{-19}\text{ J} \approx 1.2\times10^{-19}\text{ J}$, which makes choice (b) correct.
EVALUATE: This amount of energy is quite small, but recall that this is the energy of a microscopic molecule.

7.84. **IDENTIFY** and **SET UP:** $P = Fv$ and at constant speed $x = vt$. The DNA follows Hooke's law, so $F = kx$.
EXECUTE: $P = Fv = kxv = k(vt)v = kv^2t$. Since k and v are constant, the power is proportional to the time, so the graph of power versus time should be a straight line through the origin, which fits choice (a).
EVALUATE: The power increases with time because the force increases with x and x increases with t.

8

MOMENTUM, IMPULSE, AND COLLISIONS

VP8.6.1. **IDENTIFY:** This problem involves a one-dimensional collision, so we use momentum conservation. The total momentum before the collision must equal the total momentum after the collision.

SET UP: $p_x = mv_x$ and $P_x = p_{1x} + p_{2x} + \ldots$. Call the x-axis positive horizontally to the right.

EXECUTE: **(a)** After the gliders move free of the spring, their total momentum is conserved. Before the gliders were released, they were at rest so their total momentum was zero. This means that their total momentum will be zero later also. So $P_{1x} = P_{2x}$.

$m_A v_{Ax} + m_B v_{Bx} = 0$

$(0.125 \text{ kg})(0.600 \text{ m/s}) + (0.375 \text{ kg})v_{Bx} \quad \rightarrow \quad v_{Bx} = -0.200 \text{ m/s}$, to the left.

(b) Figure VP8.6.1 shows before and after sketches of the collision. Use momentum conservation.

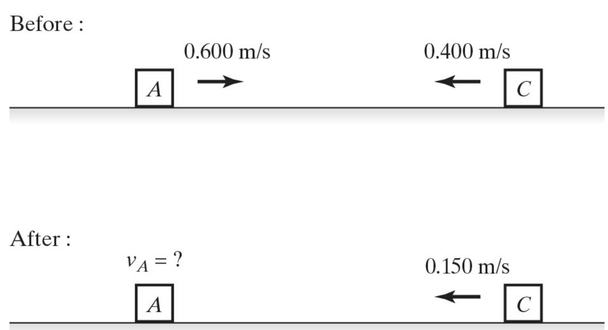

Figure VP8.6.1

$$m_A v_{A1x} + m_C v_{C1x} = m_A v_{A2x} + m_C v_{C2x}$$

$(0.125 \text{ kg})(0.600 \text{ m/s}) + (0.750 \text{ kg})(-0.400 \text{ m/s}) = (0.125 \text{ kg})\, v_{A2x} + (0.750 \text{ kg})(-0.150 \text{ m/s})$

$v_{A2x} = -0.900$ m/s, to the left.

EVALUATE: Since momentum is a vector, we need to pay close attention to the *signs* of its components.

VP8.6.2. **IDENTIFY:** This problem involves a one-dimensional collision, so we use momentum conservation. The total momentum before the collision must equal the total momentum after the collision.

SET UP: $p_x = mv_x$ and $P_x = p_{1x} + p_{2x} + \ldots$. Call the x-axis positive horizontally to the right. Let B stand for Buffy and M for Madeleine. Fig. VP8.6.2 shows before and after sketches.

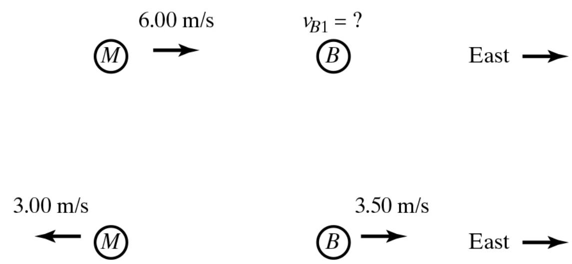

Figure VP8.6.2

EXECUTE: **(a)** $P_{1x} = P_{2x} \quad \rightarrow \quad m_M v_{M1x} + m_B v_{B1x} = m_M v_{M2x} + m_B v_{B2x}$

(65.0 kg)(6.00 m/s) + (55.0 kg) v_{B1x} = (65.0 kg)(–3.00 m/s) + (55.0 kg)(3.50 m/s)

v_{B1x} = –7.14 m/s. The minus sign means it is to the west.

(b) $\Delta v_{Mx} = v_{M2x} - v_{M1x}$ = –3.00 m/s – 6.00 m/s = –9.00 m/s, to the west.

$\Delta v_{Bx} = v_{B2x} - v_{B1x}$ = 3.50 m/s – (–7.14 m/s) = 10.6 m/s, to the east. Buffy has the greater magnitude velocity change.

EVALUATE: It is reasonable that the magnitude of light-weight Buffy's velocity change is greater than that of the heavier Madeleine. Both experience the same magnitude change in *momentum*, but the smaller-mass Buffy needs a larger velocity change than Madeleine so their momentum changes can be equal in magnitude.

VP8.6.3. **IDENTIFY:** This problem involves a two-dimensional collision, so we use momentum conservation. The total momentum before the collision must equal the total momentum after the collision.

SET UP: $p_x = mv_x$ and $P_x = p_{1x} + p_{2x} + \ldots$ and likewise for y-axis. Call A the 2.40-kg stone and B the 4.00-kg stone. Fig. VP8.6.3 shows before and after sketches.

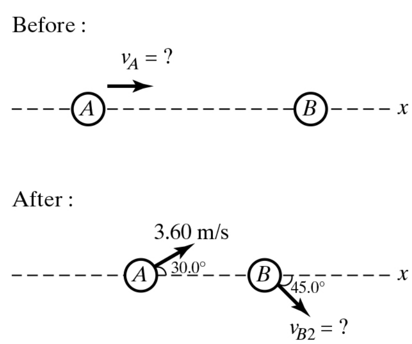

Figure VP8.6.3

EXECUTE: **(a)** $m_A v_{A1y}$ = (2.40 kg)(3.60 m/s) sin 30.0° = 4.32 kg·m/s. The initial y-component of the momentum is zero, so the final y-component must be zero. So p_{B2y} = –4.32 kg·m/s.

(b) $p_{B2y} = m_B v_{B2y} \sin 45.0° \quad \rightarrow \quad$ –4.32 kg·m/s = (4.00 kg) v_{B2y} sin 45.0°

v_{B2y} = –1.53 m/s, so its speed is 1.53 m/s.

(c) $P_x = p_{Ax} + p_{Bx}$

P_x = (2.40 kg)(3.60 m/s) cos 30.0° + (4.00 kg)(1.53 m/s) cos 45.0° = 11.8 kg·m/s.

(d) Initially A has all the x-momentum. Since the x-component of the momentum is conserved (2.40 kg)v_{Ax}= P_x = 11.8 kg·m/s $\quad \rightarrow \quad v_{Ax}$ = 4.92 m/s.

EVALUATE: In a two-dimensional collision, the x-components of the momentum must *always* be treated separately from the y-components.

VP8.6.4. **IDENTIFY:** This problem involves a two-dimensional collision, so we use momentum conservation. The total momentum before the collision must equal the total momentum after the collision.

SET UP: $p_x = mv_x$ and $P_x = p_{1x} + p_{2x} + \ldots$ and likewise for y-axis. Call P the hockey puck and S the stone. Figure VP8.6.4 shows before and after sketches.

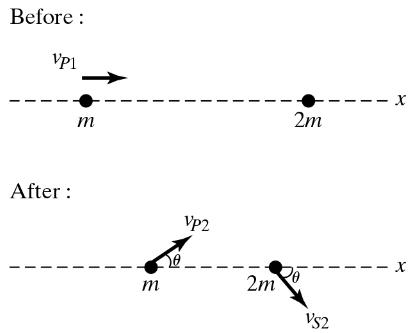

Figure VP8.6.4

EXECUTE: **(a)** The puck and stone must have equal-magnitude y-components of their momentum. $mv_{P2}\sin\theta = (2m)v_{S2} \quad \sin\theta \quad \rightarrow \quad v_{S2}/v_{P2} = ½$.

(b) The x-components of the momentum give $mv_{P1} = mv_{P2}\cos\theta + (2m)v_{S2}\cos\theta$. From part (a) we have $v_{P2} = 2v_{S2}$. Combining these two equations gives $v_{S2} = \dfrac{v_{P1}}{4\cos\theta}$ and $v_{P2} = \dfrac{v_{P1}}{2\cos\theta}$.

EVALUATE: In a two-dimensional collision, the x-components of the momentum must *always* be treated separately from the y-components.

VP8.9.1. **IDENTIFY:** This problem involves a one-dimensional collision in which the colliding objects stick together. This makes it a completely *inelastic* collision. Momentum is conserved.

SET UP: $p_x = mv_x$ and $P_x = p_{1x} + p_{2x} + \ldots$. $K = \dfrac{1}{2}mv^2$.

EXECUTE: **(a)** $K_1 = \dfrac{1}{2}mv_1^2 = \dfrac{1}{2}(1.00\text{ kg})\, v_1^2 = 32.0\text{ J} \quad \rightarrow \quad v_1 = 8.00\text{ m/s}$.

Momentum conservation gives $m_1v_1 = (m_1 + m_2)v_2 \quad \rightarrow \quad (1.00\text{ kg})(8.00\text{ m/s}) = (5.00\text{ kg})v_2$, so $v_2 = 1.60$ m/s.

The lost kinetic energy is

$K_1 - K_2 = K_1 - \dfrac{1}{2}(m_1 + m_2)\, v_2^2 = 32.0\text{ J} - \dfrac{1}{2}(5.00\text{ kg})(1.60\text{ m/s})^2 = 25.6\text{ J}$.

(b) $K = \dfrac{1}{2}mv^2 = \dfrac{1}{2}(4.00\text{ kg})v^2 = 32\text{ J} \quad \rightarrow \quad v = 4.00\text{ m/s}$.

Momentum conservation gives $m_1v_1 = (m_1 + m_2)v_2 \quad \rightarrow \quad (4.00\text{ kg})(4.00\text{ m/s}) = (5.00\text{ kg})v_2$

$v_2 = 3.20$ m/s. The loss of kinetic energy is $K_1 - K_2 = K_1 - \dfrac{1}{2}(m_1 + m_2)v^2$

$K_1 - K_2 = 32.0\text{ J} - \dfrac{1}{2}(5.00\text{ kg})(3.20\text{ m/s})^2 = 6.4\text{ J}$.

(c) More kinetic energy is lost if a light object collides with a stationary heavy object, which is case (i).

EVALUATE: Careful! Even though momentum is always conserved during a collision, kinetic energy may or may not be conserved. The amount of energy lost depends on the nature of the collision and the relative masses of the colliding objects.

VP8.9.2. **IDENTIFY:** During the collision, momentum is conserved. After the collision, energy is conserved. We must break this problem up into two parts.

SET UP: During the collision, we use $p_x = mv_x$ and $P_x = p_{1x} + p_{2x} + \ldots$ and momentum conservation. After the collision we use $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$, where $W_{\text{tot}} = 0$. Take the x-axis to be horizontal in the direction in which the cheese is originally moving. Figure VP8.9.2 shows the given information.

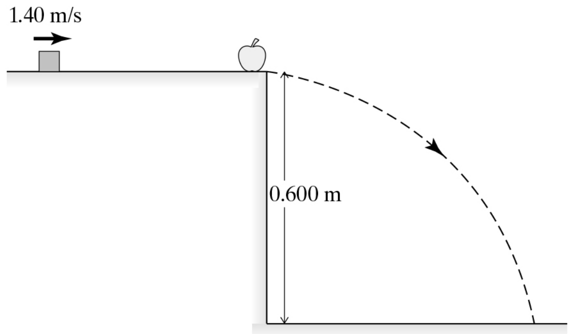

Figure VP8.9.2

EXECUTE: (a) During the collision: $p_{\text{cheese}} = p_{\text{apple + cheese}}$, so $m_c v_c = (m_c + m_a)v$
(0.500 kg)(1.40 m/s) = (0.700 kg)v $\rightarrow$ v = 1.00 m/s. Only momentum is conserved because no net external forces to the apple-cheese system due to the collision. The kinetic energy is *not* conserved because the objects stick together.

(b) Energy conservation after the collision gives $K_1 + U_1 = K_2 + U_2$. Call $y = 0$ at the floor level.
$\frac{1}{2}mv_1^2 + mgh = \frac{1}{2}mv_2^2$, which gives $v_2 = \sqrt{v_1^2 + 2gh} = \sqrt{(1.00 \text{ m/s})^2 + 2(9.80 \text{ m/s}^2)(0.600 \text{ m})} = 3.57$ m/s. Only the total mechanical energy is conserved during the fall. Gravity is an external force acting on the falling object, so its momentum is *not* conserved.

EVALUATE: We cannot do this type of problem in a single step. Some of the initial mechanical energy of the cheese is lost during the collision, and we have no way of knowing how much without examining the collision.

VP8.9.3. **IDENTIFY:** This is a collision, but we do not know if it's elastic or inelastic from the given information. Momentum is conserved during the collision regardless of whether it is elastic or inelastic.

SET UP: During the collision, we use $p_x = mv_x$ and $P_x = p_{1x} + p_{2x} + \ldots$ and momentum conservation. Let C refer to the coffee can and M refer to the macaroni.

EXECUTE: **(a)** The momentum before the collision is equal to the momentum after the collision. Using $m_C v_{C1} = m_C v_{C2} + m_M v_{M2}$ gives (2.40 kg)(1.50 m/s) = (2.40 kg)(0.825 m/s) + (1.20 kg)v_{M2}, so v_{M2} = 1.35 m/s in the $+x$ direction.

(b) $K_{C1} = \frac{1}{2}m_C v_{C1}^2 = \frac{1}{2}(2.40 \text{ kg})(1.50 \text{ m/s})^2 = 2.70$ J.

$K_{C2} = \frac{1}{2}m_C v_{C2}^2 = \frac{1}{2}(2.40 \text{ kg})(0.825 \text{ m/s})^2 = 0.817$ J.

$K_{M2} = \frac{1}{2}m_M v_{M2}^2 = \frac{1}{2}(1.20 \text{ kg})(1.35 \text{ m/s})^2 = 1.09$ J.

(c) $K_1 = K_{C1} = 2.70$ J
$K_2 = K_{C2} + K_{M2} = 0.817 \text{ J} + 1.09 \text{ J} = 1.91$ J
$K_2 < K_1$, so the collision is *inelastic*.

EVALUATE: This collision is inelastic, but it is not *perfectly* elastic because the objects do not stick together.

VP8.9.4. **IDENTIFY:** This is a two-dimensional collision in which the objects stick together, so it is perfectly inelastic. Momentum is conserved during the collision regardless of whether it is elastic or inelastic. We treat the x-components of the momentum separately from the y-components.

SET UP: During the collision, we use $p_x = mv_x$ and $P_x = p_{1x} + p_{2x} + \ldots$ and likewise for P_y. Call the x-axis positive toward the east and y-axis positive toward the north. Let θ be the angle with the $+x$-axis at which the blocks move together after the collision, and let V be their common speed. Figure VP8.9.4 shows before and after sketches.

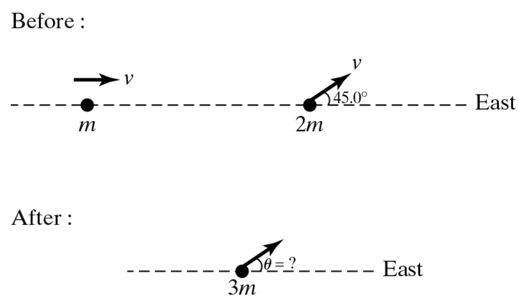

Figure VP8.9.4

EXECUTE: Before the collision the x-components of the momentum are mv and $(2m)v\cos 45.0°$ and the y-component is $(2m)v \sin 45.0°$. After the collision the x-component is $(3m)V\cos\theta$ and the y-component is $(3m)V\sin\theta$. These must also be the components after the collision because momentum is conserved.

Easterly components: $mv + 2mv \cos 45.0° = 3mV\cos\theta \quad \rightarrow \quad v(1 + 2\cos 45.0°) = 3V\cos\theta$

Northerly components: $2mv \sin 45.0° = 3mV\sin\theta \quad \rightarrow \quad 2v \sin 45.0° = 3V\sin\theta$

Dividing these two equations gives $\dfrac{3V\sin\theta}{3V\cos\theta} = \dfrac{2v\sin 45.0°}{v(1+2\cos 45.0°)}$ which simplifies to

$\tan\theta = \dfrac{2\sin 45.0°}{1+2\cos 45.0°} \quad \rightarrow \quad \theta = 30.4°$ north of east.

EVALUATE: The momentum is conserved because the collision generates no external forces on the system of colliding objects. Kinetic energy is not conserved since the objects stick together.

VP8.14.1. **IDENTIFY:** We want to find the location of the center of mass of a system of particles.

SET UP: The x-coordinate of the center of mass is $x_{\text{cm}} = \dfrac{m_1x_1 + m_2x_2 + m_3x_3 + \cdots}{m_1 + m_2 + m_3 + \cdots}$ and likewise for the y-coordinate.

EXECUTE: **(a)** $x_{\text{cm}} = \dfrac{(0.500\text{ kg})(0) + (1.25\text{ kg})(0.150\text{ m}) + (0.750\text{ kg})(0.200\text{ m})}{2.50\text{ kg}} = 0.135\text{ m}.$

$y_{\text{cm}} = \dfrac{(0.500\text{ kg})(0) + (1.25\text{ kg})(0.200\text{ m}) + (0.750\text{ kg})(-0.800\text{ m})}{2.50\text{ kg}} = -0.140\text{ m}.$

(b) Calling d the distance, we can calculate the distance between the center of mass and a given particle. For the 0.500-kg particle, we have

$d_{0.500} = \sqrt{(x_{\text{cm}} - x_{0.5})^2 + (y_{\text{cm}} - y_{0.5})^2} = \sqrt{(0.135\text{ m} - 0)^2 + (-0.140\text{ m} - 0)^2} = 0.1945$ m. Likewise for the 1.25-kg particle we find $d_{1.25} = 0.3403$ m. The result is that the center of mass is closest to the 0.500-kg particle.

EVALUATE: A plot on graph paper indicates that the center of mass is closest to the 0.500-kg particle, as we just calculated.

VP8.14.2. **IDENTIFY:** We know the location of the center of mass of a system of particles and the location of two of them. We want to find the location of the third particle. The particles all lie on the x-axis.

SET UP: The x-coordinate of the center of mass is $x_{\text{cm}} = \dfrac{m_1x_1 + m_2x_2 + m_3x_3}{m_1 + m_2 + m_3}$.

EXECUTE: Putting the known x-coordinates into the center of mass formula gives

$$-0.200\text{ m} = \frac{(3.00\text{ kg})(0) + (2.00\text{ kg})(1.50\text{ m}) + (1.20\text{ kg})x}{6.20\text{ kg}} \quad \to \quad x = -3.53\text{ m}.$$

EVALUATE: Since x_{cm} is negative, the 1.20-kg object must lie on the $-x$ side of the origin and farther from the origin than the center of mass, which it does. So our result is reasonable.

VP8.14.3. **IDENTIFY:** The force of the spring is internal to the two-glider system, so the center of mass of that system does not move.

SET UP: Use $x_{\text{cm}} = \dfrac{m_1x_1 + m_2x_2}{m_1 + m_2}$. Take the origin as the original position of the center of mass of the gliders, which makes $x_{\text{cm}} = 0$.

EXECUTE: $0 = \dfrac{(0.125\text{ kg})(-0.960\text{ m}) + (0.500\text{ kg})x}{0.625\text{ kg}} \quad \to \quad x = 0.240\text{ m}.$

EVALUATE: Since B is more massive than A,it should have moved a shorter distance since both of them felt the same force from the spring. This agrees with our result.

VP8.14.4. **IDENTIFY:** The objects exert forces on each other, but no external forces act on the system of three objects. Therefore the center of mass of this system does not move.

SET UP: The x-coordinate of the center of mass is $x_{\text{cm}} = \dfrac{m_1x_1 + m_2x_2 + m_3x_3}{m_1 + m_2 + m_3}$ and likewise for the y-coordinate. Using the initial conditions, first find the location of the center of mass of the system. Then find the center of mass (which is still the same) after the objects have moved and use it to find the position x of the third object.

EXECUTE: Initially: $x_{\text{cm}} = \dfrac{m(-L) + m(0) + m(L)}{3m} = 0$ and $y_{\text{cm}} = \dfrac{m(0) + m(L) + m(0)}{3m} = \dfrac{L}{3}$. So the center of mass is at $(0, L/3)$ and does not change location.

For the new arrangement: $x_{\text{cm}} = \dfrac{m(-L/3) + m(L/2) + mx}{3m} = 0 \quad \to \quad x = -\dfrac{L}{6}$.

$y_{\text{cm}} = \dfrac{m(L/4) + m(-L) + my}{3m} = \dfrac{L}{3} \quad \to \quad y = \dfrac{7L}{4}$.

EVALUATE: As a check, use the coordinates of the third mass $(-L/6, 7L/4)$ to calculate the location of the center of mass of the new arrangement. The result should come out $(0, L/3)$.

8.1. **IDENTIFY** and **SET UP:** $p = mv$. $K = \frac{1}{2}mv^2$.

EXECUTE: (a) $p = (10{,}000\text{ kg})(12.0\text{ m/s}) = 1.20 \times 10^5\text{ kg} \cdot \text{m/s}$

(b) (i) $v = \dfrac{p}{m} = \dfrac{1.20 \times 10^5\text{ kg} \cdot \text{m/s}}{2000\text{ kg}} = 60.0\text{ m/s}$. (ii) $\frac{1}{2}m_{\text{T}}v_{\text{T}}^2 = \frac{1}{2}m_{\text{SUV}}v_{\text{SUV}}^2$, so

$$v_{\text{SUV}} = \sqrt{\frac{m_{\text{T}}}{m_{\text{SUV}}}}v_{\text{T}} = \sqrt{\frac{10{,}000\text{ kg}}{2000\text{ kg}}}(12.0\text{ m/s}) = 26.8\text{ m/s}$$

EVALUATE: The SUV must have less speed to have the same kinetic energy as the truck than to have the same momentum as the truck.

8.2. IDENTIFY: Each momentum component is the mass times the corresponding velocity component.
SET UP: Let $+x$ be along the horizontal motion of the shotput. Let $+y$ be vertically upward.
$v_x = v\cos\theta,\ \ v_y = v\sin\theta.$

EXECUTE: The horizontal component of the initial momentum is

$$p_x = mv_x = mv\cos\theta = (7.30\text{ kg})(15.0\text{ m/s})\cos 40.0° = 83.9\text{ kg}\cdot\text{m/s}.$$

The vertical component of the initial momentum is

$$p_y = mv_y = mv\sin\theta = (7.30\text{ kg})(15.0\text{ m/s})\sin 40.0° = 70.4\text{ kg}\cdot\text{m/s}.$$

EVALUATE: The initial momentum is directed at $40.0°$ above the horizontal.

8.3. IDENTIFY and SET UP: We use $p = mv$ and add the respective components.
EXECUTE: (a) $P_x = p_{Ax} + p_{Cx} = 0 + (10.0\text{ kg})(-3.0\text{ m/s}) = -30\text{ kg}\cdot\text{m/s}$

$P_y = p_{Ay} + p_{Cy} = (5.0\text{ kg})(-11.0\text{ m/s}) + 0 = -55\text{ kg}\cdot\text{m/s}$

(b) $P_x = p_{Bx} + p_{Cx} = (6.0\text{ kg})(10.0\text{ m/s}\cos 60°) + (10.0\text{ kg})(-3.0\text{ m/s}) = 0$

$P_y = p_{By} + p_{Cy} = (6.0\text{ kg})(10.0\text{ m/s}\sin 60°) + 0 = 52\text{ kg}\cdot\text{m/s}$

(c) $P_x = p_{Ax} + p_{Bx} + p_{Cx} = 0 + (6.0\text{ kg})(10.0\text{ m/s}\cos 60°) + (10.0\text{ kg})(-3.0\text{ m/s}) = 0$

$P_y = p_{Ay} + p_{By} + p_{Cy} = (5.0\text{ kg})(-11.0\text{ m/s}) + (6.0\text{ kg})(10.0\text{ m/s}\sin 60°) + 0 = -3.0\text{ kg}\cdot\text{m/s}$

EVALUATE: A has no x-component of momentum so P_x is the same in (b) and (c). C has no y-component of momentum so P_y in (c) is the sum of P_y in (a) and (b).

8.4. IDENTIFY: For each object $\vec{p} = m\vec{v}$ and the net momentum of the system is $\vec{P} = \vec{p}_A + \vec{p}_B$. The momentum vectors are added by adding components. The magnitude and direction of the net momentum is calculated from its x- and y-components.
SET UP: Let object A be the pickup and object B be the sedan. $v_{Ax} = -14.0\text{ m/s},\ v_{Ay} = 0.\ v_{Bx} = 0,$ $v_{By} = +23.0\text{ m/s}.$

EXECUTE: (a) $P_x = p_{Ax} + p_{Bx} = m_A v_{Ax} + m_B v_{Bx} = (2500\text{ kg})(-14.0\text{ m/s}) + 0 = -3.50\times 10^4\text{ kg}\cdot\text{m/s}$

$$P_y = p_{Ay} + p_{By} = m_A v_{Ay} + m_B v_{By} = (1500\text{ kg})(+23.0\text{ m/s}) = +3.45\times 10^4\text{ kg}\cdot\text{m/s}$$

(b) $P = \sqrt{P_x^2 + P_y^2} = 4.91\times 10^4\text{ kg}\cdot\text{m/s}$. From Figure 8.4, $\tan\theta = \left|\dfrac{P_x}{P_y}\right| = \dfrac{3.50\times 10^4\text{ kg}\cdot\text{m/s}}{3.45\times 10^4\text{ kg}\cdot\text{m/s}}$ and

$\theta = 45.4°$. The net momentum has magnitude $4.91\times 10^4\text{ kg}\cdot\text{m/s}$ and is directed at $45.4°$ west of north.

EVALUATE: The momenta of the two objects must be added as vectors. The momentum of one object is west and the other is north. The momenta of the two objects are nearly equal in magnitude, so the net momentum is directed approximately midway between west and north.

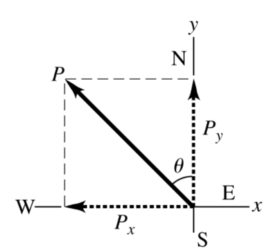

Figure 8.4

8.5. **IDENTIFY:** For each object, $\vec{p} = m\vec{v}$ and $K = \frac{1}{2}mv^2$. The total momentum is the vector sum of the momenta of each object. The total kinetic energy is the scalar sum of the kinetic energies of each object.
SET UP: Let object A be the 110 kg lineman and object B the 125 kg lineman. Let $+x$ be to the right, so $v_{Ax} = +2.75$ m/s and $v_{Bx} = -2.60$ m/s.

EXECUTE: **(a)** $P_x = m_A v_{Ax} + m_B v_{Bx} = (110\text{ kg})(2.75\text{ m/s}) + (125\text{ kg})(-2.60\text{ m/s}) = -22.5\text{ kg}\cdot\text{m/s}$. The net momentum has magnitude $22.5\text{ kg}\cdot\text{m/s}$ and is directed to the left.

(b) $K = \frac{1}{2}m_A v_A^2 + \frac{1}{2}m_B v_B^2 = \frac{1}{2}(110\text{ kg})(2.75\text{ m/s})^2 + \frac{1}{2}(125\text{ kg})(2.60\text{ m/s})^2 = 838\text{ J}$

EVALUATE: The kinetic energy of an object is a scalar and is never negative. It depends only on the magnitude of the velocity of the object, not on its direction. The momentum of an object is a vector and has both magnitude and direction. When two objects are in motion, their total kinetic energy is greater than the kinetic energy of either one. But if they are moving in opposite directions, the net momentum of the system has a smaller magnitude than the magnitude of the momentum of either object.

8.6. **IDENTIFY:** We know the contact time of the ball with the racket, the change in velocity of the ball, and the mass of the ball. From this information we can use the fact that the impulse is equal to the change in momentum to find the force exerted on the ball by the racket.
SET UP: $J_x = \Delta p_x$ and $J_x = F_x \Delta t$. In part (a), take the $+x$-direction to be along the final direction of motion of the ball. The initial speed of the ball is zero. In part (b), take the $+x$-direction to be in the direction the ball is traveling before it is hit by the opponent's racket.

EXECUTE: **(a)** $J_x = mv_{2x} - mv_{1x} = (57\times10^{-3}\text{ kg})(73\text{ m/s} - 0) = 4.16\text{ kg}\cdot\text{m/s}$. Using $J_x = F_x\Delta t$ gives

$$F_x = \frac{J_x}{\Delta t} = \frac{4.16\text{ kg}\cdot\text{m/s}}{30.0\times10^{-3}\text{ s}} = 140\text{ N}.$$

(b) $J_x = mv_{2x} - mv_{1x} = (57\times10^{-3}\text{ kg})(-55\text{ m/s} - 73\text{ m/s}) = -7.30\text{ kg}\cdot\text{m/s}$.

$$F_x = \frac{J_x}{\Delta t} = \frac{-7.30\text{ kg}\cdot\text{m/s}}{30.0\times10^{-3}\text{ s}} = -240\text{ N}.$$

EVALUATE: The signs of J_x and F_x show their direction. $140\text{ N} = 31\text{ lb}$. This very attainable force has a large effect on the light ball. 140 N is 250 times the weight of the ball.

8.7. **IDENTIFY:** The average force on an object and the object's change in momentum are related by $(F_{\text{av}})_x = \dfrac{J_x}{\Delta t}$. The weight of the ball is $w = mg$.

SET UP: Let $+x$ be in the direction of the final velocity of the ball, so $v_{1x} = 0$ and $v_{2x} = 25.0$ m/s.

EXECUTE: $(F_{\text{av}})_x(t_2 - t_1) = mv_{2x} - mv_{1x}$ gives $(F_{\text{av}})_x = \dfrac{mv_{2x} - mv_{1x}}{t_2 - t_1} = \dfrac{(0.0450\text{ kg})(25.0\text{ m/s})}{2.00\times10^{-3}\text{ s}} = 562\text{ N}$.

$w = (0.0450\text{ kg})(9.80\text{ m/s}^2) = 0.441\text{ N}$. The force exerted by the club is much greater than the weight of the ball, so the effect of the weight of the ball during the time of contact is not significant.
EVALUATE: Forces exerted during collisions typically are very large but act for a short time.

8.8. **IDENTIFY:** The change in momentum, the impulse, and the average force are related by $J_x = \Delta p_x$ and $(F_{\text{av}})_x = \dfrac{J_x}{\Delta t}$.

SET UP: Let the direction in which the batted ball is traveling be the $+x$-direction, so $v_{1x} = -45.0$ m/s and $v_{2x} = 55.0$ m/s.

EXECUTE: **(a)** $\Delta p_x = p_{2x} - p_{1x} = m(v_{2x} - v_{1x}) = (0.145\text{ kg})[55.0\text{ m/s} - (-45.0\text{ m/s})] = 14.5\text{ kg}\cdot\text{m/s}$.
$J_x = \Delta p_x$, so $J_x = 14.5\text{ kg}\cdot\text{m/s}$. Both the change in momentum and the impulse have magnitude $14.5\text{ kg}\cdot\text{m/s}$.

(b) $(F_{\text{av}})_x = \dfrac{J_x}{\Delta t} = \dfrac{14.5\ \text{kg}\cdot\text{m/s}}{2.00\times10^{-3}\ \text{s}} = 7250\ \text{N}.$

EVALUATE: The force is in the direction of the momentum change.

8.9. **IDENTIFY:** Use $J_x = p_{2x} - p_{1x}$. We know the initial momentum and the impulse so can solve for the final momentum and then the final velocity.

SET UP: Take the x-axis to be toward the right, so $v_{1x} = +3.00$ m/s. Use $J_x = F_x\Delta t$ to calculate the impulse, since the force is constant.

EXECUTE: **(a)** $J_x = p_{2x} - p_{1x}$

$$J_x = F_x(t_2 - t_1) = (+25.0\ \text{N})(0.050\ \text{s}) = +1.25\ \text{kg}\cdot\text{m/s}$$

Thus $p_{2x} = J_x + p_{1x} = +1.25\ \text{kg}\cdot\text{m/s} + (0.160\ \text{kg})(+3.00\ \text{m/s}) = +1.73\ \text{kg}\cdot\text{m/s}$

$$v_{2x} = \frac{p_{2x}}{m} = \frac{1.73\ \text{kg}\cdot\text{m/s}}{0.160\ \text{kg}} = +10.8\ \text{m/s (to the right)}$$

(b) $J_x = F_x(t_2 - t_1) = (-12.0\ \text{N})(0.050\ \text{s}) = -0.600\ \text{kg}\cdot\text{m/s}$ (negative since force is to left)

$$p_{2x} = J_x + p_{1x} = -0.600\ \text{kg}\cdot\text{m/s} + (0.160\ \text{kg})(+3.00\ \text{m/s}) = -0.120\ \text{kg}\cdot\text{m/s}$$

$$v_{2x} = \frac{p_{2x}}{m} = \frac{-0.120\ \text{kg}\cdot\text{m/s}}{0.160\ \text{kg}} = -0.75\ \text{m/s (to the left)}$$

EVALUATE: In part (a) the impulse and initial momentum are in the same direction and v_x increases. In part (b) the impulse and initial momentum are in opposite directions and the velocity decreases.

8.10. **IDENTIFY:** Apply $J_x = \Delta p_x = mv_{2x} - mv_{1x}$ and $J_y = \Delta p_y = mv_{2y} - mv_{1y}$ to relate the change in momentum to the components of the average force on it.

SET UP: Let $+x$ be to the right and $+y$ be upward.

EXECUTE: $J_x = \Delta p_x = mv_{2x} - mv_{1x} = (0.145\ \text{kg})[-(52.0\ \text{m/s})\cos 30° - 40.0\ \text{m/s}] = -12.33\ \text{kg}\cdot\text{m/s}.$

$J_y = \Delta p_y = mv_{2y} - mv_{1y} = (0.145\ \text{kg})[(52.0\ \text{m/s})\sin 30° - 0] = 3.770\ \text{kg}\cdot\text{m/s}.$

The horizontal component is $12.33\ \text{kg}\cdot\text{m/s}$, to the left and the vertical component is $3.770\ \text{kg}\cdot\text{m/s}$, upward.

$F_{\text{av-}x} = \dfrac{J_x}{\Delta t} = \dfrac{-12.33\ \text{kg}\cdot\text{m/s}}{1.75\times10^{-3}\ \text{s}} = -7050\ \text{N}.$ $F_{\text{av-}y} = \dfrac{J_y}{\Delta t} = \dfrac{3.770\ \text{kg}\cdot\text{m/s}}{1.75\times10^{-3}\ \text{s}} = 2150\ \text{N}.$

The horizontal component is 7050 N, to the left, and the vertical component is 2150 N, upward.

EVALUATE: The ball gains momentum to the left and upward and the force components are in these directions.

8.11. **IDENTIFY:** The force is not constant so $\vec{J} = \int_{t_1}^{t_2} \vec{F}dt$. The impulse is related to the change in velocity by $J_x = m(v_{2x} - v_{1x})$.

SET UP: Only the x-component of the force is nonzero, so $J_x = \int_{t_1}^{t_2} F_x dt$ is the only nonzero component of $\vec{J}$. $J_x = m(v_{2x} - v_{1x})$. $t_1 = 2.00$ s, $t_2 = 3.50$ s.

EXECUTE: **(a)** $A = \dfrac{F_x}{t^2} = \dfrac{781.25\ \text{N}}{(1.25\ \text{s})^2} = 500\ \text{N/s}^2.$

(b) $J_x = \int_{t_1}^{t_2} At^2 dt = \frac{1}{3}A(t_2^3 - t_1^3) = \frac{1}{3}(500\ \text{N/s}^2)([3.50\ \text{s}]^3 - [2.00\ \text{s}]^3) = 5.81\times10^3\ \text{N}\cdot\text{s}.$

(c) $\Delta v_x = v_{2x} - v_{1x} = \dfrac{J_x}{m} = \dfrac{5.81\times10^3\ \text{N}\cdot\text{s}}{2150\ \text{kg}} = 2.70\ \text{m/s}.$ The x-component of the velocity of the rocket increases by 2.70 m/s.

EVALUATE: The change in velocity is in the same direction as the impulse, which in turn is in the direction of the net force. In this problem the net force equals the force applied by the engine, since that is the only force on the rocket.

8.12. **IDENTIFY:** This problem requires the graphical interpretation of impulse and momentum.

SET UP: The impulse is the area under the curve on a graph of force versus time. Impulse is equal to the change in momentum: $J_x = p_{2x} - p_{1x}$, where $p_x = mv_x$. Fig. 8.12 shows a graph of F versus t.

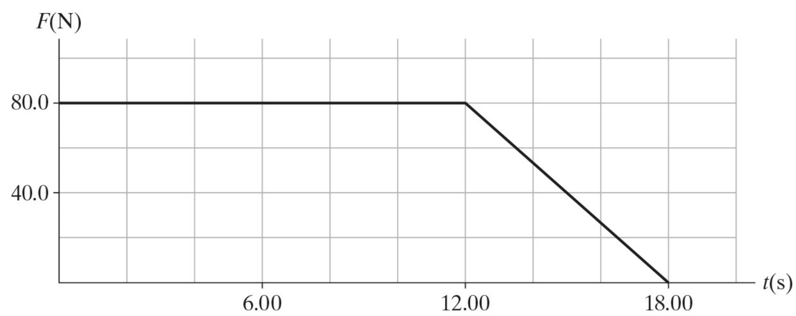

Figure 8.12

EXECUTE: To compute the area under the F-t graph, break it into two figures, a rectangle and a triangle. Using the numbers on the graph, we have $J_x = (80.0\text{ N})(12.0\text{ s}) + \frac{1}{2}(80.0\text{ N})(6.0\text{ s}) = 1200$ $\text{N}\cdot\text{s}$. $J_x = p_{2x} - p_{1x} = mv - 0 \quad \rightarrow \quad (80.0\text{ kg})v = 1200\ \text{N}\cdot\text{s} \quad \rightarrow \quad v = 15.0\text{ m/s}$.

EVALUATE: The longer a force acts, the more it changes the momentum of an object.

8.13. **IDENTIFY:** The force is constant during the 1.0 ms interval that it acts, so $\vec{J} = \vec{F}\Delta t$.
$\vec{J} = \vec{p}_2 - \vec{p}_1 = m(\vec{v}_2 - \vec{v}_1)$.

SET UP: Let $+x$ be to the right, so $v_{1x} = +5.00\text{ m/s}$. Only the x-component of $\vec{J}$ is nonzero, and $J_x = m(v_{2x} - v_{1x})$.

EXECUTE: **(a)** The magnitude of the impulse is $J = F\Delta t = (2.50\times 10^3\text{ N})(1.00\times 10^{-3}\text{ s}) = 2.50\text{ N}\cdot\text{s}$. The direction of the impulse is the direction of the force.

(b) (i) $v_{2x} = \dfrac{J_x}{m} + v_{1x}$. $J_x = +2.50\text{ N}\cdot\text{s}$. $v_{2x} = \dfrac{+2.50\text{ N}\cdot\text{s}}{2.00\text{ kg}} + 5.00\text{ m/s} = 6.25\text{ m/s}$. The stone's velocity has magnitude 6.25 m/s and is directed to the right. (ii) Now $J_x = -2.50\text{ N}\cdot\text{s}$ and

$$v_{2x} = \frac{-2.50\text{ N}\cdot\text{s}}{2.00\text{ kg}} + 5.00\text{ m/s} = 3.75\text{ m/s}.$$ The stone's velocity has magnitude 3.75 m/s and is directed to the right.

EVALUATE: When the force and initial velocity are in the same direction the speed increases, and when they are in opposite directions the speed decreases.

8.14. **IDENTIFY:** We know the force acting on a box as a function of time and its initial momentum and want to find its momentum at a later time. The target variable is the final momentum.

SET UP: Use $\int_{t_1}^{t_2} \vec{F}(t)dt = \vec{p}_2 - \vec{p}_1$ to find $\vec{p}_2$ since we know $\vec{p}_1$ and $\vec{F}(t)$.

EXECUTE: $\vec{p}_1 = (-3.00 \text{ kg}\cdot\text{m/s})\hat{i} + (4.00 \text{ kg}\cdot\text{m/s})\hat{j}$ at $t_1 = 0$, and $t_2 = 2.00$ s. Work with the components of the force and momentum. $\int_{t_1}^{t_2} F_x(t)dt = (0.280 \text{ N/s})\int_{t_1}^{t_2} t\,dt = (0.140 \text{ N/s})t_2^2 = 0.560 \text{ N}\cdot\text{s}$

$p_{2x} = p_{1x} + 0.560 \text{ N}\cdot\text{s} = -3.00 \text{ kg}\cdot\text{m/s} + 0.560 \text{ N}\cdot\text{s} = -2.44 \text{ kg}\cdot\text{m/s}.$

$\int_{t_1}^{t_2} F_y(t)dt = (-0.450 \text{ N/s}^2)\int_{t_1}^{t_2} t^2 dt = (-0.150 \text{ N/s}^2)t_2^3 = -1.20 \text{ N}\cdot\text{s}.$

$p_{2y} = p_{1y} + (-1.20 \text{ N}\cdot\text{s}) = 4.00 \text{ kg}\cdot\text{m/s} + (-1.20 \text{ N}\cdot\text{s}) = +2.80 \text{ kg}\cdot\text{m/s}.$ So

$\vec{p}_2 = (-2.44 \text{ kg}\cdot\text{m/s})\hat{i} + (2.80 \text{ kg}\cdot\text{m/s})\hat{j}$

EVALUATE: Since the given force has *x*- and *y*-components, it changes both components of the box's momentum.

8.15. **IDENTIFY:** This problem requires the use of momentum, impulse, and kinetic energy.

SET UP: $p_x = mv_x$, $J_x = p_{2x} - p_{1x}$, $K = \frac{1}{2}mv^2$.

EXECUTE: **(a)** $p_x = mv_x = (40.0 \text{ kg})(20.0 \text{ m/s}) = 800 \text{ kg}\cdot\text{m/s}$.

(b) $K = \frac{1}{2}mv^2 = \frac{1}{2}(40.0 \text{ kg})(20.0 \text{ m/s})^2 = 8.00\times10^3$ J.

(c) $J_x = p_{2x} - p_{1x} = 0 - p_{1x}$, so $Ft = -p_1$ gives $F(5.00 \text{ s}) = -800 \text{ kg}\cdot\text{m/s}$. $F = -160$ N. The minus sign tells us that the force is opposite to her velocity.

EVALUATE: Unlike kinetic energy, momentum has components that can be negative as well as positive.

8.16. **IDENTIFY:** Apply conservation of momentum to the system of the astronaut and tool.

SET UP: Let *A* be the astronaut and *B* be the tool. Let $+x$ be the direction in which she throws the tool, so $v_{B2x} = +3.20$ m/s. Assume she is initially at rest, so $v_{A1x} = v_{B1x} = 0$. Solve for v_{A2x}.

EXECUTE: $P_{1x} = P_{2x}$. $P_{1x} = m_A v_{A1x} + m_B v_{B1x} = 0$. $P_{2x} = m_A v_{A2x} + m_B v_{B2x} = 0$ and

$v_{A2x} = -\frac{m_B v_{A2x}}{m_A} = -\frac{(2.25 \text{ kg})(3.20 \text{ m/s})}{68.5 \text{ kg}} = -0.105$ m/s. Her speed is 0.105 m/s and she moves opposite to the direction in which she throws the tool.

EVALUATE: Her mass is much larger than that of the tool, so to have the same magnitude of momentum as the tool her speed is much less.

8.17. **IDENTIFY:** Since the rifle is loosely held there is no net external force on the system consisting of the rifle, bullet, and propellant gases and the momentum of this system is conserved. Before the rifle is fired everything in the system is at rest and the initial momentum of the system is zero.

SET UP: Let $+x$ be in the direction of the bullet's motion. The bullet has speed $601 \text{ m/s} - 1.85 \text{ m/s} = 599 \text{ m/s}$ relative to the earth. $P_{2x} = p_{rx} + p_{bx} + p_{gx}$, the momenta of the rifle, bullet, and gases. $v_{rx} = -1.85$ m/s and $v_{bx} = +599$ m/s.

EXECUTE: $P_{2x} = P_{1x} = 0$. $p_{rx} + p_{bx} + p_{gx} = 0$.

$p_{gx} = -p_{rx} - p_{bx} = -(2.80 \text{ kg})(-1.85 \text{ m/s}) - (0.00720 \text{ kg})(599 \text{ m/s})$ and

$p_{gx} = +5.18 \text{ kg}\cdot\text{m/s} - 4.31 \text{ kg}\cdot\text{m/s} = 0.87 \text{ kg}\cdot\text{m/s}.$ The propellant gases have momentum $0.87 \text{ kg}\cdot\text{m/s}$, in the same direction as the bullet is traveling.

EVALUATE: The magnitude of the momentum of the recoiling rifle equals the magnitude of the momentum of the bullet plus that of the gases as both exit the muzzle.

8.18. **IDENTIFY:** The total momentum of the two skaters is conserved, but not their kinetic energy.

SET UP: There is no horizontal external force so, $P_{i,x} = P_{f,x}$, $p = mv$, $K = ½\, mv^2$.

EXECUTE: **(a)** $P_{i,x} = P_{f,x}$. The skaters are initially at rest so $P_{i,x} = 0$. $0 = m_A(v_{A,f})_x + m_B(v_{B,f})_x$

$(v_{A,f})_x = -\dfrac{m_B(v_{B,f})_x}{m_A} = -\dfrac{(74.0\text{ kg})(1.50\text{ m/s})}{63.8\text{ kg}} = -1.74\text{ m/s}$. The lighter skater travels to the left at 1.74 m/s.

(b) $K_i = 0$. $K_f = \frac{1}{2}m_A v_{A,f}{}^2 + \frac{1}{2}m_B v_{B,f}{}^2 = \frac{1}{2}(63.8\text{ kg})(1.74\text{ m/s})^2 + \frac{1}{2}(74.0\text{ kg})(1.50\text{ m/s})^2 = 180\text{ J}$.

EVALUATE: The kinetic energy of the system was produced by the work the two skaters do on each other.

8.19. **IDENTIFY:** Since drag effects are neglected, there is no net external force on the system of squid plus expelled water, and the total momentum of the system is conserved. Since the squid is initially at rest, with the water in its cavity, the initial momentum of the system is zero. For each object, $K = \frac{1}{2}mv^2$.

SET UP: Let A be the squid and B be the water it expels, so $m_A = 6.50\text{ kg} - 1.75\text{ kg} = 4.75\text{ kg}$. Let $+x$ be the direction in which the water is expelled. $v_{A2x} = -2.50\text{ m/s}$. Solve for v_{B2x}.

EXECUTE: **(a)** $P_{1x} = 0$. $P_{2x} = P_{1x}$, so $0 = m_A v_{A2x} + m_B v_{B2x}$.

$v_{B2x} = -\dfrac{m_A v_{A2x}}{m_B} = -\dfrac{(4.75\text{ kg})(-2.50\text{ m/s})}{1.75\text{ kg}} = +6.79\text{ m/s}$.

(b) $K_2 = K_{A2} + K_{B2} = \frac{1}{2}m_A v_{A2}^2 + \frac{1}{2}m_B v_{B2}^2 = \frac{1}{2}(4.75\text{ kg})(2.50\text{ m/s})^2 + \frac{1}{2}(1.75\text{ kg})(6.79\text{ m/s})^2 = 55.2\text{ J}$. The initial kinetic energy is zero, so the kinetic energy produced is $K_2 = 55.2\text{ J}$.

EVALUATE: The two objects end up with momenta that are equal in magnitude and opposite in direction, so the total momentum of the system remains zero. The kinetic energy is created by the work done by the squid as it expels the water.

8.20. **IDENTIFY:** Apply conservation of momentum to the system of you and the ball. In part (a) both objects have the same final velocity.

SET UP: Let $+x$ be in the direction the ball is traveling initially. $m_A = 0.600\text{ kg}$ (ball). $m_B = 70.0\text{ kg}$ (you).

EXECUTE: **(a)** $P_{1x} = P_{2x}$ gives $(0.600\text{ kg})(10.0\text{ m/s}) = (0.600\text{ kg} + 70.0\text{ kg})v_2$ so $v_2 = 0.0850\text{ m/s}$.

(b) $P_{1x} = P_{2x}$ gives $(0.600\text{ kg})(10.0\text{ m/s}) = (0.600\text{ kg})(-8.00\text{ m/s}) + (70.0\text{ kg})v_{B2}$ so $v_{B2} = 0.154\text{ m/s}$.

EVALUATE: When the ball bounces off it has a greater change in momentum and you acquire a greater final speed.

8.21. **IDENTIFY:** Apply conservation of momentum to the system of the two pucks.

SET UP: Let $+x$ be to the right.

EXECUTE: **(a)** $P_{1x} = P_{2x}$ says $(0.250\text{ kg})v_{A1} = (0.250\text{ kg})(-0.120\text{ m/s}) + (0.350\text{ kg})(0.650\text{ m/s})$ and $v_{A1} = 0.790\text{ m/s}$.

(b) $K_1 = \frac{1}{2}(0.250\text{ kg})(0.790\text{ m/s})^2 = 0.0780\text{ J}$.

$K_2 = \frac{1}{2}(0.250\text{ kg})(0.120\text{ m/s})^2 + \frac{1}{2}(0.350\text{ kg})(0.650\text{ m/s})^2 = 0.0757\text{ J}$ and $\Delta K = K_2 - K_1 = -0.0023\text{ J}$.

EVALUATE: The total momentum of the system is conserved but the total kinetic energy decreases.

8.22. **IDENTIFY:** Since road friction is neglected, there is no net external force on the system of the two cars and the total momentum of the system is conserved. For each object, $K = \frac{1}{2}mv^2$.

SET UP: Let A be the 1750 kg car and B be the 1450 kg car. Let $+x$ be to the right, so $v_{A1x} = +1.50\text{ m/s}$, $v_{B1x} = -1.10\text{ m/s}$, and $v_{A2x} = +0.250\text{ m/s}$. Solve for v_{B2x}.

EXECUTE: **(a)** $P_{1x} = P_{2x}$. $m_A v_{A1x} + m_B v_{B1x} = m_A v_{A2x} + m_B v_{B2x}$. $v_{B2x} = \dfrac{m_A v_{A1x} + m_B v_{B1x} - m_A v_{A2x}}{m_B}$.

$$v_{B2x} = \frac{(1750 \text{ kg})(1.50 \text{ m/s}) + (1450 \text{ kg})(-1.10 \text{ m/s}) - (1750 \text{ kg})(0.250 \text{ m/s})}{1450 \text{ kg}} = 0.409 \text{ m/s}.$$

After the collision the lighter car is moving to the right with a speed of 0.409 m/s.

(b) $K_1 = \frac{1}{2}m_A v_{A1}^2 + \frac{1}{2}m_B v_{B1}^2 = \frac{1}{2}(1750 \text{ kg})(1.50 \text{ m/s})^2 + \frac{1}{2}(1450 \text{ kg})(1.10 \text{ m/s})^2 = 2846 \text{ J}.$

$$K_2 = \frac{1}{2}m_A v_{A2}^2 + \frac{1}{2}m_B v_{B2}^2 = \frac{1}{2}(1750 \text{ kg})(0.250 \text{ m/s})^2 + \frac{1}{2}(1450 \text{ kg})(0.409 \text{ m/s})^2 = 176 \text{ J}.$$

The change in kinetic energy is $\Delta K = K_2 - K_1 = 176 \text{ J} - 2846 \text{ J} = -2670 \text{ J}.$

EVALUATE: The total momentum of the system is constant because there is no net external force during the collision. The kinetic energy of the system decreases because of negative work done by the forces the cars exert on each other during the collision.

8.23. IDENTIFY: The momentum and the mechanical energy of the system are both conserved. The mechanical energy consists of the kinetic energy of the masses and the elastic potential energy of the spring. The potential energy stored in the spring is transformed into the kinetic energy of the two masses.

SET UP: Let the system be the two masses and the spring. The system is sketched in Figure 8.23, in its initial and final situations. Use coordinates where $+x$ is to the right. Call the masses A and B.

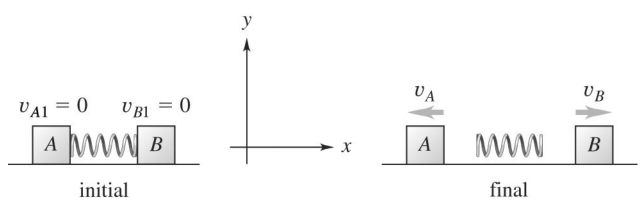

Figure 8.23

EXECUTE: $P_{1x} = P_{2x}$ so $0 = (0.900 \text{ kg})(-v_A) + (0.900 \text{ kg})(v_B)$ and, since the masses are equal, $v_A = v_B$. Energy conservation says the potential energy originally stored in the spring is all converted into kinetic energy of the masses, so $\frac{1}{2}kx_1^2 = \frac{1}{2}mv_A^2 + \frac{1}{2}mv_B^2$. Since $v_A = v_B$, this equation gives

$$v_A = x_1\sqrt{\frac{k}{2m}} = (0.200 \text{ m})\sqrt{\frac{175 \text{ N/m}}{2(0.900 \text{ kg})}} = 1.97 \text{ m/s}.$$

EVALUATE: If the objects have different masses they will end up with different speeds. The lighter one will have the greater speed, since they end up with equal magnitudes of momentum.

8.24. IDENTIFY: In part (a) no horizontal force implies P_x is constant. In part (b) use $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ to find the potential energy initially in the spring.

SET UP: Initially both blocks are at rest.

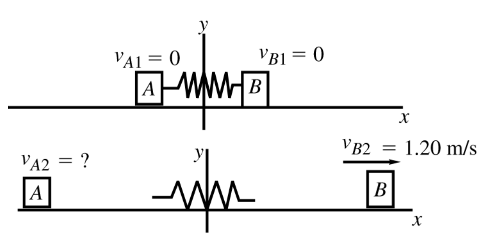

Figure 8.24

EXECUTE: **(a)** $m_A v_{A1x} + m_B v_{B1x} = m_A v_{A2x} + m_B v_{B2x}$

$$0 = m_A v_{A2x} + m_B v_{B2x}$$

$$v_{A2x} = -\left(\frac{m_B}{m_A}\right) v_{B2x} = -\left(\frac{3.00\text{ kg}}{1.00\text{ kg}}\right)(+1.20\text{ m/s}) = -3.60\text{ m/s}$$

Block A has a final speed of 3.60 m/s, and moves off in the opposite direction to B.

(b) Use energy conservation: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$.

Only the spring force does work so $W_{\text{other}} = 0$ and $U = U_{\text{el}}$.

$K_1 = 0$ (the blocks initially are at rest)

$U_2 = 0$ (no potential energy is left in the spring)

$$K_2 = \tfrac{1}{2} m_A v_{A2}^2 + \tfrac{1}{2} m_B v_{B2}^2 = \tfrac{1}{2}(1.00\text{ kg})(3.60\text{ m/s})^2 + \tfrac{1}{2}(3.00\text{ kg})(1.20\text{ m/s})^2 = 8.64\text{ J}$$

$U_1 = U_{1,\text{el}}$ the potential energy stored in the compressed spring.

Thus $U_{1,\text{el}} = K_2 = 8.64$ J.

EVALUATE: The blocks have equal and opposite momenta as they move apart, since the total momentum is zero. The kinetic energy of each block is positive and doesn't depend on the direction of the block's velocity, just on its magnitude.

8.25. **IDENTIFY:** Since friction at the pond surface is neglected, there is no net external horizontal force, and the horizontal component of the momentum of the system of hunter plus bullet is conserved. Both objects are initially at rest, so the initial momentum of the system is zero. Gravity and the normal force exerted by the ice together produce a net vertical force while the rifle is firing, so the vertical component of momentum is not conserved.

SET UP: Let object A be the hunter and object B be the bullet. Let $+x$ be the direction of the horizontal component of velocity of the bullet. Solve for v_{A2x}.

EXECUTE: **(a)** $v_{B2x} = +965$ m/s. $P_{1x} = P_{2x} = 0$. $0 = m_A v_{A2x} + m_B v_{B2x}$ and

$$v_{A2x} = -\frac{m_B}{m_A} v_{B2x} = -\left(\frac{4.20\times10^{-3}\text{ kg}}{72.5\text{ kg}}\right)(965\text{ m/s}) = -0.0559\text{ m/s}.$$

(b) $v_{B2x} = v_{B2}\cos\theta = (965\text{ m/s})\cos 56.0° = 540$ m/s. $v_{A2x} = -\left(\dfrac{4.20\times10^{-3}\text{ kg}}{72.5\text{ kg}}\right)(540\text{ m/s}) = -0.0313$ m/s.

EVALUATE: The mass of the bullet is much less than the mass of the hunter, so the final mass of the hunter plus gun is still 72.5 kg, to three significant figures. Since the hunter has much larger mass, his final speed is much less than the speed of the bullet.

8.26. **IDENTIFY:** Assume the nucleus is initially at rest. $K = \tfrac{1}{2}mv^2$.

SET UP: Let $+x$ be to the right. $v_{A2x} = -v_A$ and $v_{B2x} = +v_B$.

EXECUTE: **(a)** $P_{2x} = P_{1x} = 0$ gives $m_A v_{A2x} + m_B v_{B2x} = 0$. $v_B = \left(\dfrac{m_A}{m_B}\right) v_A$.

(b) $\dfrac{K_A}{K_B} = \dfrac{\tfrac{1}{2} m_A v_A^2}{\tfrac{1}{2} m_B v_B^2} = \dfrac{m_A v_A^2}{m_B (m_A v_A / m_B)^2} = \dfrac{m_B}{m_A}$.

EVALUATE: The lighter fragment has the greater kinetic energy.

8.27. **IDENTIFY:** Each horizontal component of momentum is conserved. $K = \tfrac{1}{2}mv^2$.

SET UP: Let $+x$ be the direction of Rebecca's initial velocity and let the $+y$ axis make an angle of $36.9°$ with respect to the direction of her final velocity. $v_{\text{D}1x} = v_{\text{D}1y} = 0$. $v_{\text{R}1x} = 13.0$ m/s; $v_{\text{R}1y} = 0$.

$v_{R2x} = (8.00 \text{ m/s})\cos 53.1° = 4.80 \text{ m/s}$; $v_{R2y} = (8.00 \text{ m/s})\sin 53.1° = 6.40 \text{ m/s}$. Solve for v_{D2x} and v_{D2y}.

EXECUTE: (a) $P_{1x} = P_{2x}$ gives $m_R v_{R1x} = m_R v_{R2x} + m_D v_{D2x}$.

$$v_{D2x} = \frac{m_R(v_{R1x} - v_{R2x})}{m_D} = \frac{(45.0 \text{ kg})(13.0 \text{ m/s} - 4.80 \text{ m/s})}{65.0 \text{ kg}} = 5.68 \text{ m/s}.$$

$P_{1y} = P_{2y}$ gives $0 = m_R v_{R2y} + m_D v_{D2y}$. $v_{D2y} = -\frac{m_R}{m_D} v_{R2y} = -\left(\frac{45.0 \text{ kg}}{65.0 \text{ kg}}\right)(6.40 \text{ m/s}) = -4.43 \text{ m/s}$.

The directions of $\vec{v}_{R1}$, $\vec{v}_{R2}$ and $\vec{v}_{D2}$ are sketched in Figure 8.27. $\tan\theta = \left|\frac{v_{D2y}}{v_{D2x}}\right| = \frac{4.43 \text{ m/s}}{5.68 \text{ m/s}}$ and $\theta = 38.0°$. $v_D = \sqrt{v_{D2x}^2 + v_{D2y}^2} = 7.20 \text{ m/s}$.

(b) $K_1 = \frac{1}{2} m_R v_{R1}^2 = \frac{1}{2}(45.0 \text{ kg})(13.0 \text{ m/s})^2 = 3.80 \times 10^3 \text{ J}$.

$K_2 = \frac{1}{2} m_R v_{R2}^2 + \frac{1}{2} m_D v_{D2}^2 = \frac{1}{2}(45.0 \text{ kg})(8.00 \text{ m/s})^2 + \frac{1}{2}(65.0 \text{ kg})(7.20 \text{ m/s})^2 = 3.12 \times 10^3 \text{ J}$.

$\Delta K = K_2 - K_1 = -680 \text{ J}$.

EVALUATE: Each component of momentum is separately conserved. The kinetic energy of the system decreases.

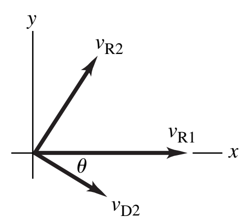

Figure 8.27

8.28. IDENTIFY and **SET UP:** Let the $+x$-direction be horizontal, along the direction the rock is thrown. There is no net horizontal force, so P_x is constant. Let object A be you and object B be the rock.

EXECUTE: $0 = -m_A v_A + m_B v_B \cos 35.0°$ gives $v_A = \frac{m_B v_B \cos 35.0°}{m_A} = 0.421 \text{ m/s}$.

EVALUATE: P_y is not conserved because there is a net external force in the vertical direction; as you throw the rock the normal force exerted on you by the ice is larger than the total weight of the system.

8.29. IDENTIFY: In the absence of a horizontal force, we know that momentum is conserved.
SET UP: $p = mv$. Let $+x$ be the direction you are moving. Before you catch it, the flour sack has no momentum along the x-axis. The total mass of you and your skateboard is 60 kg. You, the skateboard, and the flour sack are all moving with the same velocity, after the catch.
EXECUTE: (a) Since $P_{i,x} = P_{f,x}$, we have $(60 \text{ kg})(4.5 \text{ m/s}) = (62.5 \text{ kg})v_{f,x}$. Solving for the final velocity we obtain $v_{f,x} = 4.3 \text{ m/s}$.

(b) To bring the flour sack up to your speed, you must exert a horizontal force on it. Consequently, it exerts an equal and opposite force on you, which slows you down.
(c) Since you exert a vertical force on the flour sack, your horizontal speed does not change and remains at 4.3 m/s. Since the flour sack is only accelerated in the vertical direction, its horizontal velocity-component remains at 4.3 m/s as well.
EVALUATE: Unless you or the flour sack are deflected by an outside force, you will need to be ready to catch the flour sack as it returns to your arms!

8.30. **IDENTIFY:** The x- and y-components of the momentum of the system of the two asteroids are separately conserved.
SET UP: The before and after diagrams are given in Figure 8.30 and the choice of coordinates is indicated. Each asteroid has mass m.
EXECUTE: **(a)** $P_{1x} = P_{2x}$ gives $mv_{A1} = mv_{A2}\cos 30.0° + mv_{B2}\cos 45.0°$.
$40.0\text{ m/s} = 0.866v_{A2} + 0.707v_{B2}$ and $0.707v_{B2} = 40.0\text{ m/s} - 0.866v_{A2}$.
$P_{2y} = P_{2y}$ gives $0 = mv_{A2}\sin 30.0° - mv_{B2}\sin 45.0°$ and $0.500v_{A2} = 0.707v_{B2}$.
Combining these two equations gives $0.500v_{A2} = 40.0\text{ m/s} - 0.866v_{A2}$ and $v_{A2} = 29.3\text{ m/s}$. Then

$$v_{B2} = \left(\frac{0.500}{0.707}\right)(29.3\text{ m/s}) = 20.7\text{ m/s}.$$

(b) $K_1 = \frac{1}{2}mv_{A1}^2$. $K_2 = \frac{1}{2}mv_{A2}^2 + \frac{1}{2}mv_{B2}^2$. $\dfrac{K_2}{K_1} = \dfrac{v_{A2}^2 + v_{B2}^2}{v_{A1}^2} = \dfrac{(29.3\text{ m/s})^2 + (20.7\text{ m/s})^2}{(40.0\text{ m/s})^2} = 0.804.$

$$\frac{\Delta K}{K_1} = \frac{K_2 - K_1}{K_1} = \frac{K_2}{K_1} - 1 = -0.196.$$

19.6% of the original kinetic energy is dissipated during the collision.
EVALUATE: We could use any directions we wish for the x- and y-coordinate directions, but the particular choice we have made is especially convenient.

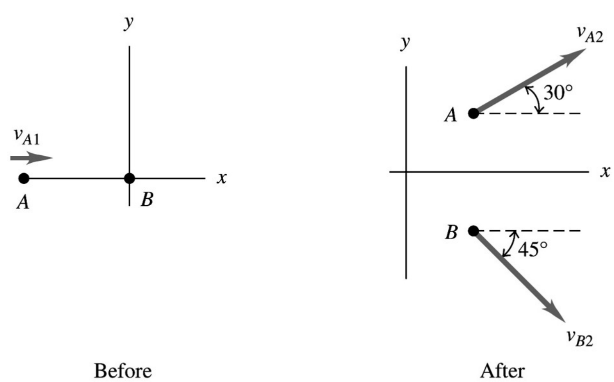

Figure 8.30

8.31. **IDENTIFY:** Momentum is conserved during the collision.
SET UP: $p_x = mv_x$. Call the $+x$-axis pointing northward. We want the speed v of the hockey players after they collide and become intertwined.
EXECUTE: The momentum before the collision is equal to the momentum after the collision.
$m_1v_1 + m_2v_2 = (m_1 + m_2)v \rightarrow$ (70 kg)(5.5 m/s) + (110 kg)(–4.0 m/s) = (180 kg)v $\rightarrow$ $v = -0.31$ m/s. The minus sign tells that they are traveling toward the south.
EVALUATE: Even though the heavier player was traveling slower than the lighter player, his larger mass gave him greater momentum than that of the faster lighter player.

8.32. **IDENTIFY:** There is no net external force on the system of the two skaters and the momentum of the system is conserved.
SET UP: Let object A be the skater with mass 70.0 kg and object B be the skater with mass 65.0 kg. Let $+x$ be to the right, so $v_{A1x} = +4.00\text{ m/s}$ and $v_{B1x} = -2.50\text{ m/s}$. After the collision, the two objects are combined and move with velocity $\vec{v}_2$. Solve for v_{2x}.
EXECUTE: $P_{1x} = P_{2x}$. $m_Av_{A1x} + m_Bv_{B1x} = (m_A + m_B)v_{2x}$.

$v_{2x} = \dfrac{m_A v_{A1x} + m_B v_{B1x}}{m_A + m_B} = \dfrac{(70.0\text{ kg})(4.00\text{ m/s}) + (65.0\text{ kg})(-2.50\text{ m/s})}{70.0\text{ kg} + 65.0\text{ kg}} = 0.870\text{ m/s}$. The two skaters move to the right at 0.870 m/s.

EVALUATE: There is a large decrease in kinetic energy.

8.33. **IDENTIFY:** Since drag effects are neglected there is no net external force on the system of two fish and the momentum of the system is conserved. The mechanical energy equals the kinetic energy, which is $K = \frac{1}{2}mv^2$ for each object.

SET UP: Let object A be the 15.0 kg fish and B be the 4.50 kg fish. Let $+x$ be the direction the large fish is moving initially, so $v_{A1x} = 1.10$ m/s and $v_{B1x} = 0$. After the collision the two objects are combined and move with velocity $\vec{v}_2$. Solve for v_{2x}.

EXECUTE: **(a)** $P_{1x} = P_{2x}$. $m_A v_{A1x} + m_B v_{B1x} = (m_A + m_B)v_{2x}$.

$$v_{2x} = \frac{m_A v_{A1x} + m_B v_{B1x}}{m_A + m_B} = \frac{(15.0\text{ kg})(1.10\text{ m/s}) + 0}{15.0\text{ kg} + 4.50\text{ kg}} = 0.846\text{ m/s}.$$

(b) $K_1 = \frac{1}{2}m_A v_{A1}^2 + \frac{1}{2}m_B v_{B1}^2 = \frac{1}{2}(15.0\text{ kg})(1.10\text{ m/s})^2 = 9.08$ J.

$K_2 = \frac{1}{2}(m_A + m_B)v_2^2 = \frac{1}{2}(19.5\text{ kg})(0.846\text{ m/s})^2 = 6.98$ J.

$\Delta K = K_2 - K_1 = \mathbf{2}2.10$ J. 2.10 J of mechanical energy is dissipated.

EVALUATE: The total kinetic energy always decreases in a collision where the two objects become combined.

8.34. **IDENTIFY:** This problem requires use of conservation of momentum and conservation of energy. We need to break it into two parts: the collision and the motion after the collision.

SET UP: During the collision momentum is conserved. After the collision energy is conserved. We use $p_x = mv_x$, $K = \dfrac{1}{2}mv^2$, $U_g = mgh$, and $U_1 + K_1 = U_2 + K_2$. We want to find the maximum height the apple will reach after being hit by the dart.

EXECUTE: <u>Collision</u>: Use momentum conservation to find the speed v of the apple-dart system just after the collision. $\dfrac{M}{4}v_0 = \left(M + \dfrac{M}{4}\right)v$, so $v = \dfrac{v_0}{5}$.

<u>After collision</u>: Use energy conservation with the initial speed $v = \dfrac{v_0}{5}$ and the final speed zero.

$U_1 + K_1 = U_2 + K_2$ gives $\dfrac{1}{2}\left(M + \dfrac{M}{4}\right)\left(\dfrac{v_0}{5}\right)^2 = \left(M + \dfrac{M}{4}\right)gh \quad \rightarrow \quad h = \dfrac{v_0^2}{50g}$.

EVALUATE: The momentum is conserved but the kinetic energy is *not* conserved. After the collision the mechanical energy is conserved but the momentum is *not* conserved.

8.35. **IDENTIFY:** This problem involves a collision, so momentum is conserved.

SET UP: We use $p_x = mv_x$ and $K = \dfrac{1}{2}mv^2$. The total momentum P_x before the collision is equal to the total momentum after the collision, where $P_x = p_{1x} + p_{2x}$. Call the $+x$-axis eastward. We want to find the decrease in kinetic energy during the collision. Start by making a before-and-after sketch of the collision, as shown in Fig. 8.35.

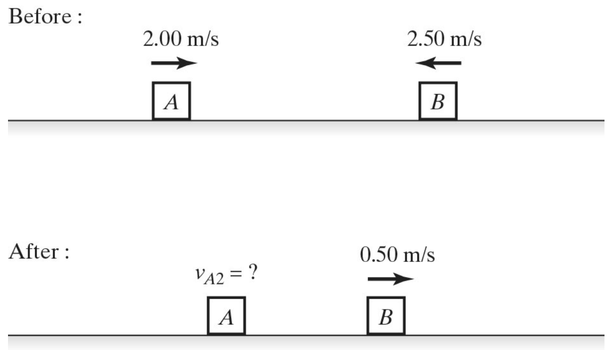

Figure 8.35

EXECUTE: We first need to find the velocity of A after the collision. Using $P_{1x} = P_{2x}$ gives $p_{A1} + p_{B1} = p_{A2} + p_{B2}$, so $m_A v_{A1} + m_B v_{B1} = m_A v_{A2} + m_B v_{B2}$. Putting in the numbers gives us (4.00 kg)(2.00 m/s) – (6.00 kg)(2.50 m/s) = (4.00 kg)v_{A2} + (6.00 kg)(0.50 m/s) , so $v_{A2} = -2.50$ m/s.

Now find the decrease in kinetic energy, which is the initial value minus the final value. Using v_{A2} = –2.50 m/s and the quantities given in the problem, we get

$$\text{Decrease} = K_1 - K_2 = \frac{1}{2}m_A v_{A1}^2 + \frac{1}{2}m_B v_{B1}^2 - \left(\frac{1}{2}m_A v_{A2}^2 + \frac{1}{2}m_B v_{B2}^2\right) = 13.5\text{ J.}$$

EVALUATE: We see that the momentum is conserved during this collision but the kinetic energy is not conserved. The final kinetic energy is 13.5 J less than the initial kinetic energy.

8.36. **IDENTIFY:** The forces the two vehicles exert on each other during the collision are much larger than the horizontal forces exerted by the road, and it is a good approximation to assume momentum conservation.

SET UP: Let $+x$ be eastward. After the collision two vehicles move with a common velocity $\vec{v}_2$.

EXECUTE: **(a)** $P_{1x} = P_{2x}$ gives $m_{\text{SC}}v_{\text{SC}x} + m_{\text{T}}v_{\text{T}x} = (m_{\text{SC}} + m_{\text{T}})v_{2x}$.

$$v_{2x} = \frac{m_{\text{SC}}v_{\text{SC}x} + m_{\text{T}}v_{\text{T}x}}{m_{\text{SC}} + m_{\text{T}}} = \frac{(1050\text{ kg})(-15.0\text{ m/s}) + (6320\text{ kg})(+10.0\text{ m/s})}{1050\text{ kg} + 6320\text{ kg}} = 6.44\text{ m/s.}$$

The final velocity is 6.44 m/s, eastward.

(b) $P_{1x} = P_{2x} = 0$ gives $m_{\text{SC}}v_{\text{SC}x} + m_{\text{T}}v_{\text{T}x} = 0$. $v_{\text{T}x} = -\left(\frac{m_{\text{SC}}}{m_{\text{T}}}\right)v_{\text{SC}x} = -\left(\frac{1050\text{ kg}}{6320\text{ kg}}\right)(-15.0\text{ m/s}) = 2.50\text{ m/s.}$

The truck would need to have initial speed 2.50 m/s.

(c) part (a):

$\Delta K = \frac{1}{2}(7370\text{ kg})(6.44\text{ m/s})^2 - \frac{1}{2}(1050\text{ kg})(15.0\text{ m/s})^2 - \frac{1}{2}(6320\text{ kg})(10.0\text{ m/s})^2 = -2.81\times10^5\text{ J}$

part (b): $\Delta K = 0 - \frac{1}{2}(1050\text{ kg})(15.0\text{ m/s})^2 - \frac{1}{2}(6320\text{ kg})(2.50\text{ m/s})^2 = -1.38\times10^5\text{ J}$. The change in kinetic energy has the greater magnitude in part (a).

EVALUATE: In part (a) the eastward momentum of the truck has a greater magnitude than the westward momentum of the car and the wreckage moves eastward after the collision. In part (b) the two vehicles have equal magnitudes of momentum, the total momentum of the system is zero and the wreckage is at rest after the collision.

8.37. **IDENTIFY:** The forces the two players exert on each other during the collision are much larger than the horizontal forces exerted by the slippery ground and it is a good approximation to assume momentum conservation. Each component of momentum is separately conserved.

SET UP: Let $+x$ be east and $+y$ be north. After the collision the two players have velocity $\vec{v}_2$. Let the linebacker be object *A* and the halfback be object *B*, so $v_{A1x} = 0$, $v_{A1y} = 8.8$ m/s, $v_{B1x} = 7.2$ m/s and $v_{B1y} = 0$. Solve for v_{2x} and v_{2y}.

EXECUTE: $P_{1x} = P_{2x}$ gives $m_A v_{A1x} + m_B v_{B1x} = (m_A + m_B)v_{2x}$.

$$v_{2x} = \frac{m_A v_{A1x} + m_B v_{B1x}}{m_A + m_B} = \frac{(85 \text{ kg})(7.2 \text{ m/s})}{110 \text{ kg} + 85 \text{ kg}} = 3.14 \text{ m/s}.$$

$P_{1y} = P_{2y}$ gives $m_A v_{A1y} + m_B v_{B1y} = (m_A + m_B)v_{2y}$.

$$v_{2y} = \frac{m_A v_{A1y} + m_B v_{B1y}}{m_A + m_B} = \frac{(110 \text{ kg})(8.8 \text{ m/s})}{110 \text{ kg} + 85 \text{ kg}} = 4.96 \text{ m/s}.$$

$v = \sqrt{v_{2x}^2 + v_{2y}^2} = 5.9$ m/s.

$$\tan\theta = \frac{v_{2y}}{v_{2x}} = \frac{4.96 \text{ m/s}}{3.14 \text{ m/s}} \text{ and } \theta = 58°.$$

The players move with a speed of 5.9 m/s and in a direction 58° north of east.

EVALUATE: Each component of momentum is separately conserved.

8.38. **IDENTIFY:** The momentum is conserved during the collision. Since the motions involved are in two dimensions, we must consider the components separately.

SET UP: Use coordinates where $+x$ is east and $+y$ is south. The system of two cars before and after the collision is sketched in Figure 8.38. Neglect friction from the road during the collision. The enmeshed cars have a total mass of $2000 \text{ kg} + 1500 \text{ kg} = 3500 \text{ kg}$. Momentum conservation tells us that $P_{1x} = P_{2x}$ and $P_{1y} = P_{2y}$.

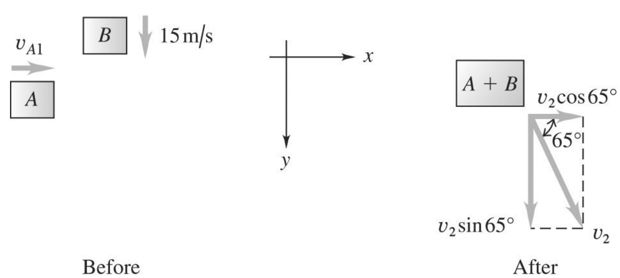

Figure 8.38

EXECUTE: There are no external horizontal forces during the collision, so $P_{1x} = P_{2x}$ and $P_{1y} = P_{2y}$.

(a) $P_{1x} = P_{2x}$ gives $(1500 \text{ kg})(15 \text{ m/s}) = (3500 \text{ kg})v_2 \sin 65°$ and $v_2 = 7.1$ m/s.

(b) $P_{1y} = P_{2y}$ gives $(2000 \text{ kg})v_{A1} = (3500 \text{ kg})v_2 \cos 65°$. And then using $v_2 = 7.1$ m/s, we have $v_{A1} = 5.2$ m/s.

EVALUATE: Momentum is a vector so we must treat each component separately.

8.39. **IDENTIFY:** The collision generates only internal forces to the Jack-Jill system, so momentum is conserved.

SET UP: Call the *x*-axis Jack's initial direction (eastward), and the *y*-axis perpendicular to that (northward). The initial *y*-component of the momentum is zero. Call *v* Jill's speed just after the collision and call θ the angle her velocity makes with the $+x$-axis.

EXECUTE: In the *x*-direction: (55.0 kg)(8.00 m/s) = (55.0 kg)(5.00 m/s)(cos34.0°) + (48.0 kg)$v \cos\theta$.
In the *y*-direction: (55.0 kg)(5.00 m/s)(sin34.0°) = (48.0 kg)$v \sin\theta$.
Separating $v \sin\theta$ and $v \cos\theta$ and dividing gives

$\tan\theta$ = (5.00 m/s)(sin34.0°)/[8.00 m/s – (5.00 m/s)(cos34.0°)] = 0.72532, so θ = 36.0° south of east. Using the y-direction momentum equation gives
v = (55.0 kg)(5.00 m/s)(sin34.0°)/[(48.0 kg)(sin36.0°) = 5.46 m/s.
EVALUATE: Jill has a bit less mass than Jack, so the angle her momentum makes with the $+x$-axis (36.0°) has to be a bit larger than Jack's (34.0°) for their y-component momenta to be equal in magnitude.

8.40. **IDENTIFY:** The collision forces are large so gravity can be neglected during the collision. Therefore, the horizontal and vertical components of the momentum of the system of the two birds are conserved.
SET UP: The system before and after the collision is sketched in Figure 8.40. Use the coordinates shown.

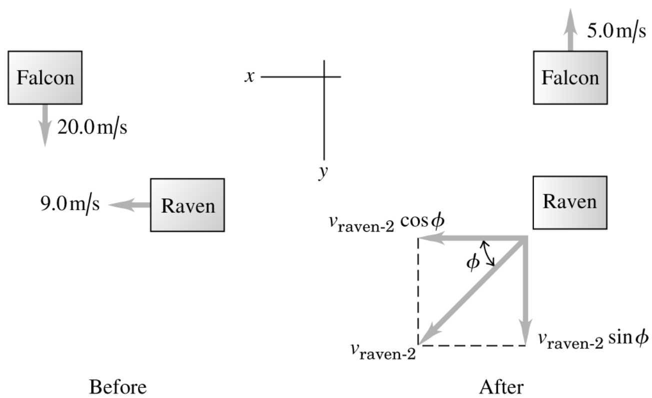

Figure 8.40

EXECUTE: **(a)** There is no external force on the system so $P_{1x} = P_{2x}$ and $P_{1y} = P_{2y}$.
$P_{1x} = P_{2x}$ gives $(1.5\text{ kg})(9.0\text{ m/s}) = (1.5\text{ kg})v_{\text{raven-2}}\cos\phi$ and $v_{\text{raven-2}}\cos\phi = 9.0\text{ m/s}$.
$P_{1y} = P_{2y}$ gives $(0.600\text{ kg})(20.0\text{ m/s}) = (0.600\text{ kg})(-5.0\text{ m/s}) + (1.5\text{ kg})v_{\text{raven-2}}\sin\phi$ and $v_{\text{raven-2}}\sin\phi = 10.0\text{ m/s}$.

Combining these two equations gives $\tan\phi = \dfrac{10.0\text{ m/s}}{9.0\text{ m/s}}$ and $\phi = 48°$.

(b) $v_{\text{raven-2}} = 13.5$ m/s
EVALUATE: Due to its large initial speed the lighter falcon was able to produce a large change in the raven's direction of motion.

8.41. **IDENTIFY:** Since friction forces from the road are ignored, the x- and y-components of momentum are conserved.
SET UP: Let object A be the subcompact and object B be the truck. After the collision the two objects move together with velocity $\vec{v}_2$. Use the x- and y-coordinates given in the problem. $v_{A1y} = v_{B1x} = 0$.
$v_{2x} = (16.0\text{ m/s})\sin 24.0° = 6.5\text{ m/s}$; $v_{2y} = (16.0\text{ m/s})\cos 24.0° = 14.6\text{ m/s}$.
EXECUTE: $P_{1x} = P_{2x}$ gives $m_A v_{A1x} = (m_A + m_B)v_{2x}$.

$$v_{A1x} = \left(\frac{m_A + m_B}{m_A}\right)v_{2x} = \left(\frac{950\text{ kg} + 1900\text{ kg}}{950\text{ kg}}\right)(6.5\text{ m/s}) = 19.5\text{ m/s}.$$

$P_{1y} = P_{2y}$ gives $m_B v_{B1y} = (m_A + m_B)v_{2y}$.

$$v_{B1y} = \left(\frac{m_A + m_B}{m_B}\right)v_{2y} = \left(\frac{950\text{ kg} + 1900\text{ kg}}{1900\text{ kg}}\right)(14.6\text{ m/s}) = 21.9\text{ m/s}.$$

Before the collision the subcompact car has speed 19.5 m/s and the truck has speed 21.9 m/s.

EVALUATE: Each component of momentum is independently conserved.

8.42. **IDENTIFY:** Apply conservation of momentum to the collision. Apply conservation of energy to the motion of the block after the collision.

SET UP: Conservation of momentum applied to the collision between the bullet and the block: Let object A be the bullet and object B be the block. Let v_A be the speed of the bullet before the collision and let V be the speed of the block with the bullet inside just after the collision.

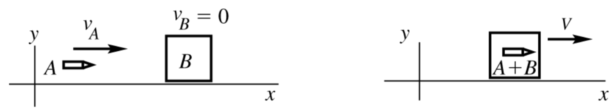

Figure 8.42a

P_x is constant gives $m_A v_A = (m_A + m_B)V$.

Conservation of energy applied to the motion of the block after the collision:

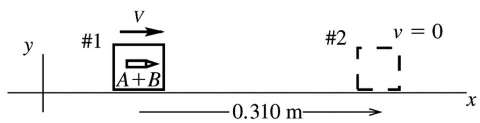

Figure 8.42b

$K_1 + U_1 + W_{\text{other}} = K_2 + U_2$

EXECUTE: Work is done by friction so $W_{\text{other}} = W_f = (f_k \cos\phi)s = -f_k s = -\mu_k mgs$

$U_1 = U_2 = 0$ (no work done by gravity)

$K_1 = \frac{1}{2}mV^2$; $+y$ (block has come to rest)

Thus $\frac{1}{2}mV^2 - \mu_k mgs = 0$

$V = \sqrt{2\mu_k gs} = \sqrt{2(0.20)(9.80\text{ m/s}^2)(0.310\text{ m})} = 1.1\text{ m/s}$

Use this result in the conservation of momentum equation

$v_A = \left(\dfrac{m_A + m_B}{m_A}\right)V = \left(\dfrac{5.00\times10^{-3}\text{ kg} + 1.20\text{ kg}}{5.00\times10^{-3}\text{ kg}}\right)(1.1\text{ m/s}) = 266\text{ m/s}$, which rounds to 270 m/s.

EVALUATE: When we apply conservation of momentum to the collision we are ignoring the impulse of the friction force exerted by the surface during the collision. This is reasonable since this force is much smaller than the forces the bullet and block exert on each other during the collision. This force does work as the block moves after the collision, and takes away all the kinetic energy.

8.43. **IDENTIFY:** Apply conservation of momentum to the collision and conservation of energy to the motion after the collision. After the collision the kinetic energy of the combined object is converted to gravitational potential energy.

SET UP: Immediately after the collision the combined object has speed V. Let h be the vertical height through which the pendulum rises.

EXECUTE: **(a)** Conservation of momentum applied to the collision gives

$(12.0\times10^{-3}\text{ kg})(380\text{ m/s}) = (6.00\text{ kg} + 12.0\times10^{-3}\text{ kg})V$ and $V = 0.758\text{ m/s}$.

Conservation of energy applied to the motion after the collision gives $\frac{1}{2}m_{\text{tot}}V^2 = m_{\text{tot}}gh$ and

$$h = \frac{V^2}{2g} = \frac{(0.758\text{ m/s})^2}{2(9.80\text{ m/s}^2)} = 0.0293\text{ m} = 2.93\text{ cm}.$$

(b) $K = \frac{1}{2}m_b v_b^2 = \frac{1}{2}(12.0\times10^{-3}\text{ kg})(380\text{ m/s})^2 = 866\text{ J}.$

(c) $K = \frac{1}{2}m_{tot}V^2 = \frac{1}{2}(6.00\text{ kg} + 12.0\times10^{-3}\text{ kg})(0.758\text{ m/s})^2 = 1.73\text{ J}.$

EVALUATE: Most of the initial kinetic energy of the bullet is dissipated in the collision.

8.44. **IDENTIFY:** During the collision, momentum is conserved. After the collision, mechanical energy is conserved.

SET UP: The collision occurs over a short time interval and the block moves very little during the collision, so the spring force during the collision can be neglected. Use coordinates where $+x$ is to the right. During the collision, momentum conservation gives $P_{1x} = P_{2x}$. After the collision, $\frac{1}{2}mv^2 = \frac{1}{2}kx^2$.

EXECUTE: *Collision*: There is no external horizontal force during the collision and $P_{1x} = P_{2x}$, so $(3.00\text{ kg})(8.00\text{ m/s}) = (15.0\text{ kg})v_{\text{block, 2}} - (3.00\text{ kg})(2.00\text{ m/s})$ and $v_{\text{block, 2}} = 2.00\text{ m/s}$.

Motion after the collision: When the spring has been compressed the maximum amount, all the initial kinetic energy of the block has been converted into potential energy $\frac{1}{2}kx^2$ that is stored in the compressed spring. Conservation of energy gives $\frac{1}{2}(15.0\text{ kg})(2.00\text{ m/s})^2 = \frac{1}{2}(500.0\text{ kg})x^2$, so $x = 0.346\text{ m}$.

EVALUATE: We cannot say that the momentum was converted to potential energy, because momentum and energy are different types of quantities.

8.45. **IDENTIFY:** The missile gives momentum to the ornament causing it to swing in a circular arc and thereby be accelerated toward the center of the circle.

SET UP: After the collision the ornament moves in an arc of a circle and has acceleration $a_{rad} = \frac{v^2}{r}$.

During the collision, momentum is conserved, so $P_{1x} = P_{2x}$. The free-body diagram for the ornament plus missile is given in Figure 8.45. Take $+y$ to be upward, since that is the direction of the acceleration. Take the $+x$-direction to be the initial direction of motion of the missile.

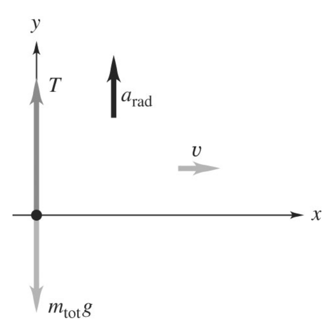

Figure 8.45

EXECUTE: Apply conservation of momentum to the collision. Using $P_{1x} = P_{2x}$, we get $(0.200\text{ kg})(12.0\text{ m/s}) = (1.00\text{ kg})V$, which gives $V = 2.40\text{ m/s}$, the speed of the ornament immediately after the collision. Then $\Sigma F_y = ma_y$ gives $T - m_{tot}g = m_{tot}\frac{v^2}{r}$. Solving for T gives

$$T = m_{tot}\left(g + \frac{v^2}{r}\right) = (1.00\text{ kg})\left(9.80\text{ m/s}^2 + \frac{(2.40\text{ m/s})^2}{1.50\text{ m}}\right) = 13.6\text{ N}.$$

Evaluate: We cannot use energy conservation during the collision because it is an inelastic collision (the objects stick together).

8.46. **Identify:** No net external horizontal force so P_x is conserved. Elastic collision so $K_1 = K_2$ and can use $v_{B2x} - v_{A2x} = -(v_{B1x} - v_{A1x})$.

Set Up:

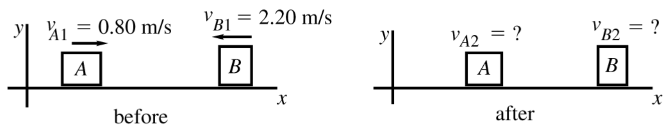

Figure 8.46

Execute: From conservation of x-component of momentum:

$$m_A v_{A1x} + m_B v_{B1x} = m_A v_{A2x} + m_B v_{B2x}$$

$$m_A v_{A1} - m_B v_{B1} = m_A v_{A2x} + m_B v_{B2x}$$

$$(0.150 \text{ kg})(0.80 \text{ m/s}) - (0.300 \text{ kg})(2.20 \text{ m/s}) = (0.150 \text{ kg})v_{A2x} + (0.300 \text{ kg})v_{B2x}$$

$$-3.60 \text{ m/s} = v_{\text{A}2x} + 2v_{B2x}$$

From the relative velocity equation for an elastic collision Eq. 8.27:

$$v_{B2x} - v_{A2x} = -(v_{B1x} - v_{A1x}) = -(-2.20 \text{ m/s} - 0.80 \text{ m/s}) = +3.00 \text{ m/s}$$

$$3.00 \text{ m/s} = -v_{\text{A}2x} + v_{B2x}$$

Adding the two equations gives $-0.60 \text{ m/s} = 3v_{B2x}$ and $v_{B2x} = -0.20$ m/s. Then $v_{A2x} = v_{B2x} - 3.00 \text{ m/s} = -3.20$ m/s.

The 0.150 kg glider (A) is moving to the left at 3.20 m/s and the 0.300 kg glider (B) is moving to the left at 0.20 m/s.

Evaluate: We can use our v_{A2x} and v_{B2x} to show that P_x is constant and $K_1 = K_2$.

8.47. **Identify:** When the spring is compressed the maximum amount the two blocks aren't moving relative to each other and have the same velocity $\vec{V}$ relative to the surface. Apply conservation of momentum to find V and conservation of energy to find the energy stored in the spring. Since the collision is elastic, $v_{A2x} = \left(\dfrac{m_A - m_B}{m_A + m_B}\right)v_{A1x}$ and $v_{B2x} = \left(\dfrac{2m_A}{m_A + m_B}\right)v_{A1x}$ give the final velocity of each block after the collision.

Set Up: Let $+x$ be the direction of the initial motion of A.

Execute: **(a)** Momentum conservation gives $(2.00 \text{ kg})(2.00 \text{ m/s}) = (8.00 \text{ kg})V$ so $V = 0.500$ m/s. Both blocks are moving at 0.500 m/s, in the direction of the initial motion of block A. Conservation of energy says the initial kinetic energy of A equals the total kinetic energy at maximum compression plus the potential energy U_b stored in the bumpers: $\frac{1}{2}(2.00 \text{ kg})(2.00 \text{ m/s})^2 = U_\text{b} + \frac{1}{2}(8.00 \text{ kg})(0.500 \text{ m/s})^2$ so $U_\text{b} = 3.00$ J.

(b) $v_{A2x} = \left(\dfrac{m_A - m_B}{m_A + m_B}\right)v_{A1x} = \left(\dfrac{2.00 \text{ kg} - 6.0 \text{ kg}}{8.00 \text{ kg}}\right)(2.00 \text{ m/s}) = -1.00$ m/s. Block A is moving in the $-x$-direction at 1.00 m/s.

$v_{B2x} = \left(\dfrac{2m_A}{m_A + m_B}\right) v_{A1x} = \dfrac{2(2.00\text{ kg})}{8.00\text{ kg}}(2.00\text{ m/s}) = +1.00\text{ m/s}$. Block B is moving in the $+x$-direction at 1.00 m/s.

EVALUATE: When the spring is compressed the maximum amount, the system must still be moving in order to conserve momentum.

8.48. **IDENTIFY:** Since the collision is elastic, both momentum conservation and equation $v_{B2x} - v_{A2x} = -(v_{B1x} - v_{A1x})$ apply.

SET UP: Let object A be the 30.0 g marble and let object B be the 10.0 g marble. Let $+x$ be to the right.

EXECUTE: **(a)** Conservation of momentum gives
$(0.0300\text{ kg})(0.200\text{ m/s}) + (0.0100\text{ kg})(-0.400\text{ m/s}) = (0.0300\text{ kg})v_{A2x} + (0.0100\text{ kg})v_{B2x}$.
$3v_{A2x} + v_{B2x} = 0.200\text{ m/s}$. $v_{B2x} - v_{A2x} = -(v_{B1x} - v_{A1x})$ says
$v_{B2x} - v_{A2x} = -(-0.400\text{ m/s} - 0.200\text{ m/s}) = +0.600\text{ m/s}$. Solving this pair of equations gives
$v_{A2x} = -0.100\text{ m/s}$ and $v_{B2x} = +0.500\text{ m/s}$. The 30.0 g marble is moving to the left at 0.100 m/s and the 10.0 g marble is moving to the right at 0.500 m/s.

(b) For marble A, $\Delta P_{Ax} = m_A v_{A2x} - m_A v_{A1x} = (0.0300\text{ kg})(-0.100\text{ m/s} - 0.200\text{ m/s}) = -0.00900\text{ kg}\cdot\text{m/s}$.
For marble B, $\Delta P_{Bx} = m_B v_{B2x} - m_B v_{B1x} = (0.0100\text{ kg})(0.500\text{ m/s} - [-0.400\text{ m/s}]) = +0.00900\text{ kg}\cdot\text{m/s}$.
The changes in momentum have the same magnitude and opposite sign.

(c) For marble A, $\Delta K_A = \frac{1}{2}m_A v_{A2}^2 - \frac{1}{2}m_A v_{A1}^2 = \frac{1}{2}(0.0300\text{ kg})([0.100\text{ m/s}]^2 - [0.200\text{ m/s}]^2) = -4.5\times10^{-4}\text{ J}$.
For marble B, $\Delta K_B = \frac{1}{2}m_B v_{B2}^2 - \frac{1}{2}m_B v_{B1}^2 = \frac{1}{2}(0.0100\text{ kg})([0.500\text{ m/s}]^2 - [0.400\text{ m/s}]^2) = +4.5\times10^{-4}\text{ J}$.
The changes in kinetic energy have the same magnitude and opposite sign.

EVALUATE: The results of parts (b) and (c) show that momentum and kinetic energy are conserved in the collision.

8.49. **IDENTIFY:** Equation $v_{A2x} = \left(\dfrac{m_A - m_B}{m_A + m_B}\right) v_{A1x}$ applyies, with object A being the neutron.

SET UP: Let $+x$ be the direction of the initial momentum of the neutron. The mass of a neutron is $m_\text{n} = 1.0\text{ u}$.

EXECUTE: **(a)** $v_{A2x} = \left(\dfrac{m_A - m_B}{m_A + m_B}\right) v_{A1x} = \dfrac{1.0\text{ u} - 2.0\text{ u}}{1.0\text{ u} + 2.0\text{ u}} v_{A1x} = -v_{A1x}/3.0$. The speed of the neutron after the collision is one-third its initial speed.

(b) $K_2 = \frac{1}{2}m_\text{n}v_\text{n}^2 = \frac{1}{2}m_\text{n}(v_{A1}/3.0)^2 = \dfrac{1}{9.0}K_1$.

(c) After n collisions, $v_{A2} = \left(\dfrac{1}{3.0}\right)^n v_{A1}$. $\left(\dfrac{1}{3.0}\right)^n = \dfrac{1}{59{,}000}$, so $3.0^n = 59{,}000$. $n\log 3.0 = \log 59{,}000$ and $n = 10$.

EVALUATE: Since the collision is elastic, in each collision the kinetic energy lost by the neutron equals the kinetic energy gained by the deuteron.

8.50. **IDENTIFY:** Elastic collision. Solve for mass and speed of target nucleus.

SET UP: **(a)** Let A be the proton and B be the target nucleus. The collision is elastic, all velocities lie along a line, and B is at rest before the collision. Hence the results of equations $v_{A2x} = \left(\dfrac{m_A - m_B}{m_A + m_B}\right) v_{A1x}$ and $v_{B2x} = \left(\dfrac{2m_A}{m_A + m_B}\right) v_{A1x}$ apply.

EXECUTE: $v_{A2x} = \left(\dfrac{m_A - m_B}{m_A + m_B}\right) v_{A1x}$: $m_B(v_x + v_{Ax}) = m_A(v_x - v_{Ax})$, where v_x is the velocity component of *A* before the collision and v_{Ax} is the velocity component of *A* after the collision. Here, $v_x = 1.50\times10^7$ m/s (take direction of incident beam to be positive) and $v_{Ax} = -1.20\times10^7$ m/s (negative since traveling in direction opposite to incident beam).

$$m_B = m_A\left(\frac{v_x - v_{Ax}}{v_x + v_{Ax}}\right) = m\left(\frac{1.50\times10^7 \text{ m/s} + 1.20\times10^7 \text{ m/s}}{1.50\times10^7 \text{ m/s} - 1.20\times10^7 \text{ m/s}}\right) = m\left(\frac{2.70}{0.30}\right) = 9.00m.$$

(b) $v_{B2x} = \left(\dfrac{2m_A}{m_A + m_B}\right) v_{A1x}$: $v_{Bx} = \left(\dfrac{2m_A}{m_A + m_B}\right) v_x = \left(\dfrac{2m}{m + 9.00m}\right)(1.50\times10^7 \text{ m/s}) = 3.00\times10^6 \text{ m/s}.$

EVALUATE: Can use our calculated v_{Bx} and m_B to show that P_x is constant and that $K_1 = K_2$.

8.51. **IDENTIFY:** In any collision, momentum is conserved. But in this one, kinetic energy is conserved because it is an *elastic* collision.

SET UP: We use $p_x = mv_x$ and $K = \dfrac{1}{2}mv^2$. The total momentum is $P_x = p_{1x} + p_{2x}$. Call the +*x*-axis the original direction of object *A*. Start by making a before-and-after sketch of the collision, as shown in Fig. 8.51. Call v_0 the original speed of *A*. We want to find v_A after the collision.

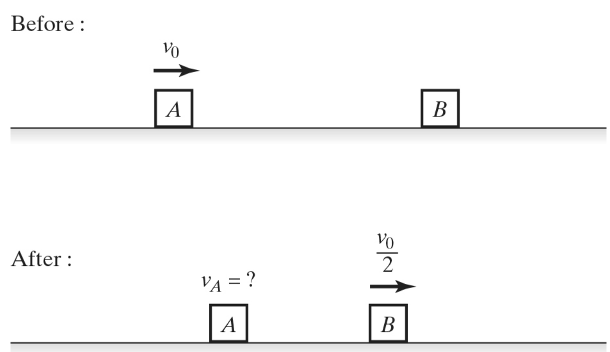

Figure 8.51

EXECUTE: **(a)** Which has greater mass, *A* or *B*? Apply momentum conservation and energy conservation to the collision. We know that $v_B = v_0/2$ after the collision. See the figure for the quantities used.

Momentum conservation: $m_A v_0 = m_A v_A + m_B \dfrac{v_0}{2}$ (Eq. 1)

Energy conservation: $\dfrac{1}{2}m_A v_0^2 = \dfrac{1}{2}m_A v_A^2 + \dfrac{1}{2}m_B\left(\dfrac{v_0}{2}\right)^2$ (Eq. 2)

Defining $R = m_B/m_A$, Eq. 1 becomes $v_A = v_0\left(1 - \dfrac{R}{2}\right)$. Using this result and simplifying, Eq. 2 becomes $1 = \left(1 - \dfrac{R}{2}\right)^2 + \dfrac{R}{4}$. Squaring and solving for *R* gives *R* =3.

(b) Therefore $m_B/m_A = 3$, so *B* has 3 times the mass of *A*.

(c) From our result in part (a), $v_A = v_0\left(1 - \dfrac{R}{2}\right) = v_0\left(1 - \dfrac{3}{2}\right) = -\dfrac{v_0}{2} = -\dfrac{6.0 \text{ m/s}}{2} = -3.0 \text{ m/s}$. The minus sign tells us that *A* is moving opposite to its original direction.

EVALUATE: Use our results to calculate the kinetic energy before and after the collision. $K_1 = \frac{1}{2}m_A v_0^2$ and $K_2 = \frac{1}{2}m_A\left(\frac{v_0}{2}\right)^2 + \frac{1}{2}(3m_A)\left(\frac{v_0}{2}\right)^2 = \frac{1}{2}m_A v_0^2 = K_1$. This agrees with the fact that it is an elastic collision.

8.52. IDENTIFY: Calculate x_{cm}.

SET UP: Apply $x_{\text{cm}} = \frac{m_1x_1 + m_2x_2 + m_3x_3 + \cdots}{m_1 + m_2 + m_3 + \cdots}$ with the sun as mass 1 and Jupiter as mass 2. Take the origin at the sun and let Jupiter lie on the positive x-axis.

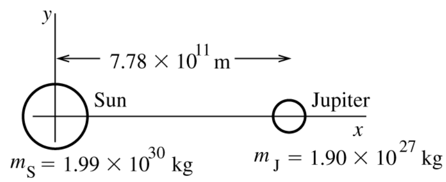

Figure 8.52

$$x_{\text{cm}} = \frac{m_1x_1 + m_2x_2}{m_1 + m_2}$$

EXECUTE: $x_1 = 0$ and $x_2 = 7.78\times10^{11}$ m

$$x_{\text{cm}} = \frac{(1.90\times10^{27}\text{ kg})(7.78\times10^{11}\text{ m})}{1.99\times10^{30}\text{ kg} + 1.90\times10^{27}\text{ kg}} = 7.42\times10^{8}\text{ m}$$

The center of mass is 7.42×10^8 m from the center of the sun and is on the line connecting the centers of the sun and Jupiter. The sun's radius is 6.96×10^8 m so the center of mass lies just outside the sun.

EVALUATE: The mass of the sun is much greater than the mass of Jupiter, so the center of mass is much closer to the sun. For each object we have considered all the mass as being at the center of mass (geometrical center) of the object.

8.53. IDENTIFY: The location of the center of mass is given by $x_{\text{cm}} = \frac{m_1x_1 + m_2x_2 + m_3x_3 + \cdots}{m_1 + m_2 + m_3 + \cdots}$. The mass can be expressed in terms of the diameter. Each object can be replaced by a point mass at its center.

SET UP: Use coordinates with the origin at the center of Pluto and the $+x$-direction toward Charon, so $x_{\text{P}} = 0$, $x_{\text{C}} = 19{,}700$ km. $m = \rho V = \rho\frac{4}{3}\pi r^3 = \frac{1}{6}\rho\pi d^3$.

EXECUTE: $x_{\text{cm}} = \frac{m_{\text{P}}x_{\text{P}} + m_{\text{C}}x_{\text{C}}}{m_{\text{P}} + m_{\text{C}}} = \left(\frac{m_{\text{C}}}{m_{\text{P}} + m_{\text{C}}}\right)x_{\text{C}} = \left(\frac{\frac{1}{6}\rho\pi d_{\text{C}}^3}{\frac{1}{6}\rho\pi d_{\text{P}}^3 + \frac{1}{6}\rho\pi d_{\text{C}}^3}\right)x_{\text{C}} = \left(\frac{d_{\text{C}}^3}{d_{\text{P}}^3 + d_{\text{C}}^3}\right)x_{\text{C}}$.

$$x_{\text{cm}} = \left(\frac{[1250\text{ km}]^3}{[2370\text{ km}]^3 + [1250\text{ km}]^3}\right)(19{,}700\text{ km}) = 2.52\times10^3\text{ km}.$$

The center of mass of the system is 2.52×10^3 km from the center of Pluto.

EVALUATE: The center of mass is closer to Pluto because Pluto has more mass than Charon.

8.54. IDENTIFY: Apply $x_{\text{cm}} = \frac{m_1x_1 + m_2x_2 + m_3x_3 + \cdots}{m_1 + m_2 + m_3 + \cdots}$, $v_{\text{cm},x} = \frac{m_Av_{A,x} + m_Bv_{B,x}}{m_A + m_B}$, and $P_x = Mv_{\text{cm}-x}$. There is only one component of position and velocity.

SET UP: $m_A = 1200\text{ kg}$, $m_B = 1800\text{ kg}$. $M = m_A + m_B = 3000\text{ kg}$. Let $+x$ be to the right and let the origin be at the center of mass of the station wagon.

EXECUTE: **(a)** $x_{\text{cm}} = \dfrac{m_A x_A + m_B x_B}{m_A + m_B} = \dfrac{0 + (1800\text{ kg})(40.0\text{ m})}{1200\text{ kg} + 1800\text{ kg}} = 24.0\text{ m}.$

The center of mass is between the two cars, 24.0 m to the right of the station wagon and 16.0 m behind the lead car.

(b) $P_x = m_A v_{A,x} + m_B v_{B,x} = (1200\text{ kg})(12.0\text{ m/s}) + (1800\text{ kg})(20.0\text{ m/s}) = 5.04 \times 10^4\text{ kg} \cdot \text{m/s}.$

(c) $v_{\text{cm},x} = \dfrac{m_A v_{A,x} + m_B v_{B,x}}{m_A + m_B} = \dfrac{(1200\text{ kg})(12.0\text{ m/s}) + (1800\text{ kg})(20.0\text{ m/s})}{1200\text{ kg} + 1800\text{ kg}} = 16.8\text{ m/s}.$

(d) $P_x = M v_{\text{cm}-x} = (3000\text{ kg})(16.8\text{ m/s}) = 5.04 \times 10^4\text{ kg} \cdot \text{m/s}$, the same as in part (b).

EVALUATE: The total momentum can be calculated either as the vector sum of the momenta of the individual objects in the system, or as the total mass of the system times the velocity of the center of mass.

8.55. **IDENTIFY:** This problem requires finding the location of the center of mass of a system of two objects.

SET UP: We can treat each object as a point mass located at its center of mass and use the formula $y_{\text{cm}} = \dfrac{m_1 y_1 + m_2 y_2}{m_1 + m_2}$. We want to find the location of the center of mass of the two-mass sytstem.

EXECUTE: We'll use $y_{\text{cm}} = \dfrac{m_1 y_1 + m_2 y_2}{m_1 + m_2}$, but first we find the dimensions of the cube. Its volume is x^3 = 0.0270 m^3, so $x = 0.300\text{ m}$, so its center of mass is 0.150 m above the floor. The center of mass of the sphere is 0.400 m above the top of the cube. The locations of each center of mass are $y_1 = y_{\text{cube}} = 0.150$ m and $y_2 = y_{\text{sphere}} = 0.400\text{ m} + 0.300\text{ m} = 0.700\text{ m}$. Now use the center of mass formula with the origin at the floor. $y_{\text{cm}} = \dfrac{m_1 y_1 + m_2 y_2}{m_1 + m_2} = \dfrac{(0.500\text{ kg})(0.150\text{ m}) + (0.800\text{ kg})(0.700\text{ m})}{1.300\text{ kg}} = 0.488\text{ m}$ above the floor.

EVALUATE: The center of mass is closer to the center of the sphere than to the center of the cube since the sphere has more mass.

8.56. **IDENTIFY:** Use $x_{\text{cm}} = \dfrac{m_1 x_1 + m_2 x_2 + m_3 x_3 + \cdots}{m_1 + m_2 + m_3 + \cdots}$.

SET UP: The target variable is m_1.

EXECUTE: $x_{\text{cm}} = 2.0\text{ m}$, $y_{\text{cm}} = 0$

$$x_{\text{cm}} = \frac{m_1 x_1 + m_2 x_2}{m_1 + m_2} = \frac{m_1(0) + (0.10\text{ kg})(8.0\text{ m})}{m_1 + (0.10\text{ kg})} = \frac{0.80\text{ kg} \cdot \text{m}}{m_1 + 0.10\text{ kg}}.$$

$$x_{\text{cm}} = 2.0\text{ m gives } 2.0\text{ m} = \frac{0.80\text{ kg} \cdot \text{m}}{m_1 + 0.10\text{ kg}}.$$

$$m_1 + 0.10\text{ kg} = \frac{0.80\text{ kg} \cdot \text{m}}{2.0\text{ m}} = 0.40\text{ kg}.$$

$$m_1 = 0.30\text{ kg}.$$

EVALUATE: The cm is closer to m_1 so its mass is larger then m_2.

(b) IDENTIFY: Use $\vec{P} = M\vec{v}_{\text{cm}}$ to calculate $\vec{P}$.

SET UP: $\vec{v}_{\text{cm}} = (5.0\text{ m/s})\hat{i}$.

$$\vec{P} = M\vec{v}_{\text{cm}} = (0.10\text{ kg} + 0.30\text{ kg})(5.0\text{ m/s})\hat{i} = (2.0\text{ kg} \cdot \text{m/s})\hat{i}.$$

(c) IDENTIFY: Use $\vec{v}_{\text{cm}} = \dfrac{m_1\vec{v}_1 + m_2\vec{v}_2}{m_1 + m_2}$.

SET UP: $\vec{v}_{cm} = \dfrac{m_1\vec{v}_1 + m_2\vec{v}_2}{m_1 + m_2}$. The target variable is $\vec{v}_1$. Particle 2 at rest says $v_2 = 0$.

EXECUTE: $\vec{v}_1 = \left(\dfrac{m_1 + m_2}{m_1}\right)\vec{v}_{cm} = \left(\dfrac{0.30 \text{ kg} + 0.10 \text{ kg}}{0.30 \text{ kg}}\right)(5.00 \text{ m/s})\hat{\boldsymbol{i}} = (6.7 \text{ m/s})\hat{\boldsymbol{i}}$.

EVALUATE: Using the result of part (c) we can calculate $\vec{p}_1$ and $\vec{p}_2$ and show that $\vec{P}$ as calculated in part (b) does equal $\vec{p}_1 + \vec{p}_2$.

8.57. IDENTIFY: There is no net external force on the system of James, Ramon, and the rope; the momentum of the system is conserved, and the velocity of its center of mass is constant. Initially there is no motion, and the velocity of the center of mass remains zero after Ramon has started to move.

SET UP: Let $+x$ be in the direction of Ramon's motion. Ramon has mass $m_R = 60.0$ kg and James has mass $m_J = 90.0$ kg.

EXECUTE: $v_{cm\text{-}x} = \dfrac{m_R v_{Rx} + m_J v_{Jx}}{m_R + m_J} = 0.$

$v_{Jx} = -\left(\dfrac{m_R}{m_J}\right)v_{Rx} = -\left(\dfrac{60.0 \text{ kg}}{90.0 \text{ kg}}\right)(1.10 \text{ m/s}) = -0.733 \text{ m/s}$. James' speed is 0.733 m/s.

EVALUATE: As they move, the two men have momenta that are equal in magnitude and opposite in direction, and the total momentum of the system is zero. Also, Example 8.14 shows that Ramon moves farther than James in the same time interval. This is consistent with Ramon having a greater speed.

8.58. (a) IDENTIFY and SET UP: Apply $y_{cm} = \dfrac{m_1 y_1 + m_2 y_2 + m_3 y_3 + \cdots}{m_1 + m_2 + m_3 + \cdots}$ and solve for m_1 and m_2.

EXECUTE: $y_{cm} = \dfrac{m_1 y_1 + m_2 y_2}{m_1 + m_2}$

$m_1 + m_2 = \dfrac{m_1 y_1 + m_2 y_2}{y_{cm}} = \dfrac{m_1(0) + (0.50 \text{ kg})(6.0 \text{ m})}{2.4 \text{ m}} = 1.25 \text{ kg}$ and $m_1 = 0.75$ kg.

EVALUATE: y_{cm} is closer to m_1 since $m_1 > m_2$.

(b) IDENTIFY and SET UP: Apply $\vec{a} = d\vec{v}/dt$ for the cm motion.

EXECUTE: $\vec{a}_{cm} = \dfrac{d\vec{v}_{cm}}{dt} = (1.5 \text{ m/s}^3)t\hat{\boldsymbol{i}}$.

(c) IDENTIFY and SET UP: Apply $\sum\vec{F}_{ext} = M\vec{a}_{cm}$.

EXECUTE: $\sum\vec{F}_{ext} = M\vec{a}_{cm} = (1.25 \text{ kg})(1.5 \text{ m/s}^3)t\hat{\boldsymbol{i}}$.

At $t = 3.0$ s, $\sum\vec{F}_{ext} = (1.25 \text{ kg})(1.5 \text{ m/s}^3)(3.0 \text{ s})\hat{\boldsymbol{i}} = (5.6 \text{ N})\hat{\boldsymbol{i}}$.

EVALUATE: $v_{cm\text{-}x}$ is positive and increasing so $a_{cm\text{-}x}$ is positive and $\vec{F}_{ext}$ is in the $+x$-direction. There is no motion and no force component in the y-direction.

8.59. IDENTIFY: Apply $\sum\vec{F} = \dfrac{d\vec{P}}{dt}$ to the airplane.

SET UP: $\dfrac{d}{dt}(t^n) = nt^{n-1}$. $1 \text{ N} = 1 \text{ kg}\cdot\text{m/s}^2$

EXECUTE: $\dfrac{d\vec{P}}{dt} = [-(1.50 \text{ kg}\cdot\text{m/s}^3)t]\hat{\boldsymbol{i}} + (0.25 \text{ kg}\cdot\text{m/s}^2)\hat{\boldsymbol{j}}$. $F_x = -(1.50 \text{ N/s})t$, $F_y = 0.25$ N, $F_z = 0$.

EVALUATE: There is no momentum or change in momentum in the z-direction and there is no force component in this direction.

8.60. IDENTIFY: This problem requires finding the location of the center of mass of a system of three objects.

SET UP: We can treat each object as a point mass located at its center of mass and use the formula $x_{cm} = \dfrac{m_1x_1 + m_2x_2 + m_3x_3 + \cdots}{m_1 + m_2 + m_3 + \cdots}$ We want to find the location of the center of mass of the three-mass sytstem. The center of mass of the bottom piece is a distance $L/4$ before the edge of the table, that of the middle piece is above the edge of the table, and that of the upper piece is $L/4$ beyond the edge of the table. We treat each square of wood as a point mass located at its center of mass. Call the origin of the x-axis at the edge of the table.

EXECUTE: Using $x_{cm} = \dfrac{m_1x_1 + m_2x_2 + m_3x_3}{m_1 + m_2 + m_3} = \dfrac{m(-L/4) + m(0) + m(L/4)}{3m} = 0$, so the center of mass is directly above the edge of the table.

EVALUATE: Our result is reasonable because of the symmetry of the arrangement. We have a mass $L/4$ before the edge, an equal mass mass $L/4$ beyond the edge, and a mass at the edge, so the center of mass should be at the edge. The vertical location of the center of mass would be at the middle of the middle piece.

8.61. IDENTIFY: $a = -\dfrac{v_{ex}}{m}\dfrac{dm}{dt}$. Assume that dm/dt is constant over the 5.0 s interval, since m doesn't change much during that interval. The thrust is $F = -v_{ex}\dfrac{dm}{dt}$.

SET UP: Take m to have the constant value $110\text{ kg} + 70\text{ kg} = 180\text{ kg}$. dm/dt is negative since the mass of the MMU decreases as gas is ejected.

EXECUTE: (a) $\dfrac{dm}{dt} = -\dfrac{m}{v_{ex}}a = -\left(\dfrac{180\text{ kg}}{490\text{ m/s}}\right)(0.029\text{ m/s}^2) = -0.0106\text{ kg/s}$. In 5.0 s the mass that is ejected is $(0.0106\text{ kg/s})(5.0\text{ s}) = 0.053\text{ kg}$.

(b) $F = -v_{ex}\dfrac{dm}{dt} = -(490\text{ m/s})(-0.0106\text{ kg/s}) = 5.19\text{ N}$.

EVALUATE: The mass change in the 5.0 s is a very small fraction of the total mass m, so it is accurate to take m to be constant.

8.62. IDENTIFY: Use $F = -v_{ex}\dfrac{\Delta m}{\Delta t}$, applied to a finite time interval.

SET UP: $v_{ex} = 1600\text{ m/s}$

EXECUTE: (a) $F = -v_{ex}\dfrac{\Delta m}{\Delta t} = -(1600\text{ m/s})\dfrac{-0.0500\text{ kg}}{1.00\text{ s}} = +80.0\text{ N}$.

(b) The absence of atmosphere would not prevent the rocket from operating. The rocket could be steered by ejecting the gas in a direction with a component perpendicular to the rocket's velocity and braked by ejecting it in a direction parallel (as opposed to antiparallel) to the rocket's velocity.

EVALUATE: The thrust depends on the speed of the ejected gas relative to the rocket and on the mass of gas ejected per second.

8.63. IDENTIFY: This problem involves both static and kinetic friction as well as the impulse-momentum theorem and energy conservation.

SET UP: Once we start the crate moving, the friction force on it is kinetic friction. Impulse is $J_x = F_xt$, where F_x is the net force acting. The impulse-momentum theorem is $J_x = p_{2x} - p_{1x}$, where $p_x = mv_x$. Energy conservation says that $U_1 + K_1 + W_{other} = U_2 + K_2$, and $W = Fs\cos\phi$. Call the push P.

EXECUTE: (a) Estimate: The heaviest crate weighs about 100 lb, so the maximum force need to start it moving is $f_{max} = \mu_s n = (0.500)(100\text{ lb}) = 50\text{ lb} \approx 220\text{ N}$. The mass of a 100-lb weight is about 45 kg.

(b) Now the friction force is due to kinetic friction, so we use $f_k = \mu_k n = \mu_k mg$, so the net force is $F_{net} = P - f_k = P - \mu_k mg$. The impulse-momentum theorem gives $F_{net} = P - f_k = P - \mu_k mg$, so $t = \dfrac{mv}{P - \mu_k mg} = \dfrac{(45 \text{ kg})(8.0 \text{ m/s})}{220 \text{ N} - (0.300)(450 \text{ N})} = 4.2 \text{ s}.$

(c) Using $U_1 + K_1 + W_{other} = U_2 + K_2$, we have $U_1 = U_2 = 0$, $K_1 = 0$, and $W_{tot} = W_P + W_f$. Using $W = Fs\cos\phi$ gives $W_{tot} = -\mu_k mgs + Ps$, so energy conservation gives $-\mu_k mgs + Ps = \frac{1}{2}mv^2$. Solving for s gives $s = \dfrac{\frac{1}{2}mv^2}{P - \mu_k mg} = s = \dfrac{\frac{1}{2}(45 \text{ kg})(8.0 \text{ m/s})^2}{220 \text{ N} - (0.300)(450 \text{ N})} = 17 \text{ m}.$

EVALUATE: As a check, use $\sum F_x = ma_x$: $-\mu_k mg + P = ma_x$ gives $a_x = 1.89 \text{ m/s}^2$. Then use $v_x^2 = v_{0x}^2 + 2a_x(x - x_0)$, which gives $x - x_0 = 17$ m, as we just found.

8.64. **IDENTIFY:** Use the heights to find v_{1y} and v_{2y}, the velocity of the ball just before and just after it strikes the slab. Then apply $J_y = F_y\Delta t = \Delta p_y$.

SET UP: Let $+y$ be downward.

EXECUTE: **(a)** $\frac{1}{2}mv^2 = mgh$ so $v = \pm\sqrt{2gh}$.

$v_{1y} = +\sqrt{2(9.80 \text{ m/s}^2)(2.00 \text{ m})} = 6.26 \text{ m/s}.$ $v_{2y} = -\sqrt{2(9.80 \text{ m/s}^2)(1.60 \text{ m})} = -5.60 \text{ m/s}.$

$$J_y = \Delta p_y = m(v_{2y} - v_{1y}) = (40.0\times10^{-3} \text{ kg})(-5.60 \text{ m/s} - 6.26 \text{ m/s}) = -0.474 \text{ kg}\cdot\text{m/s}.$$

The impulse is $0.474 \text{ kg}\cdot\text{m/s}$, upward.

(b) $F_y = \dfrac{J_y}{\Delta t} = \dfrac{-0.474 \text{ kg}\cdot\text{m/s}}{2.00\times10^{-3} \text{ s}} = -237 \text{ N}.$ The average force on the ball is 237 N, upward.

EVALUATE: The upward force, on the ball changes the direction of its momentum.

8.65. **IDENTIFY:** The impulse, force, and change in velocity are related by $J_x = F_x\Delta t$.

SET UP: $m = w/g = 0.0571$ kg. Since the force is constant, $\vec{F} = \vec{F}_{av}$.

EXECUTE: **(a)** $J_x = F_x\Delta t = (-380 \text{ N})(3.00\times10^{-3} \text{ s}) = -1.14 \text{ N}\cdot\text{s}.$

$J_y = F_y\Delta t = (110 \text{ N})(3.00\times10^{-3} \text{ s}) = 0.330 \text{ N}\cdot\text{s}.$

(b) $v_{2x} = \dfrac{J_x}{m} + v_{1x} = \dfrac{-1.14 \text{ N}\cdot\text{s}}{0.0571 \text{ kg}} + 20.0 \text{ m/s} = 0.04 \text{ m/s}.$

$v_{2y} = \dfrac{J_y}{m} + v_{1y} = \dfrac{0.330 \text{ N}\cdot\text{s}}{0.0571 \text{ kg}} + (-4.0 \text{ m/s}) = +1.8 \text{ m/s}.$

EVALUATE: The change in velocity $\Delta\vec{v}$ is in the same direction as the force, so $\Delta\vec{v}$ has a negative x-component and a positive y-component.

8.66. **IDENTIFY:** We use the impulse-momentum theorem.

SET UP: The impulse-momentum theorem is $J_x = p_{2x} - p_{1x}$, where $p_x = mv_x$. For a variable force, we use $J_x = \int F_x dt$. From the information given, $F_x = (3.00 \text{ N/s})t$.

EXECUTE: The impulse is $J_x = \int F_x dt = \int (3.00 \text{ N/s})t dt = (1.50 \text{ N/s})t^2$, where we have used $J_x = 0$ when $t = 0$. Now use $J_x = p_{2x} - p_{1x}$, giving $(1.50 \text{ N/s})t^2 = mv - 0$. Solving for t gives

$t = \sqrt{\dfrac{mv}{1.50 \text{ N/s}}} = \sqrt{\dfrac{(2.00 \text{ kg})(9.00 \text{ m/s})}{1.50 \text{ N/s}}} = 3.46$ s. Therefore $F = (3.00 \text{ N/s})(3.464 \text{ s}) = 10.4$ N.

EVALUATE: We could find the impulse graphically as the area under the F versus t graph. This area is a triangle of base t and height F, where F = (3.00 N/s)t. The area of a triangle is $\frac{1}{2}bh$, so the impulse is $J_x = \frac{1}{2}Ft = \frac{1}{2}(3.00\text{ N/s})t = (1.50\text{ N/s})t^2.$

8.67. **IDENTIFY** and **SET UP:** When the spring is compressed the maximum amount the two blocks aren't moving relative to each other and have the same velocity V relative to the surface. Apply conservation of momentum to find V and conservation of energy to find the energy stored in the spring. Let $+x$ be the direction of the initial motion of A. The collision is elastic.
SET UP: $p = mv$, $K = ½\, mv^2$, $v_{B2x} - v_{A2x} = -(v_{B1x} - v_{A1x})$ for an elastic collision.

EXECUTE: **(a)** The maximum energy stored in the spring is at maximum compression, at which time the blocks have the same velocity. Momentum conservation gives $m_A v_{A1} + m_B v_{B1} = (m_A + m_B)V$. Putting in the numbers we have (2.00 kg)(2.00 m/s) + (10.0 kg)(–0.500 m/s) = (12.0 kg)V, giving V = –0.08333 m/s. The energy U_{spring} stored in the spring is the loss of kinetic of the system. Therefore $U_{\text{spring}} = K_1 - K_2 = \frac{1}{2}m_A v_{A1}^2 + \frac{1}{2}m_B v_{V1}^2 - \frac{1}{2}(m_A + m_B)V^2$. Putting in the same set of numbers as above, and using V = –0.08333 m/s, we get U_{spring} = 5.21 J. At this time, the blocks are both moving to the left, so their velocities are each –0.0833 m/s.
(b) Momentum conservation gives $m_A v_{A1} + m_B v_{B1} = m_A v_{A2} + m_B v_{B2}$. Putting in the numbers gives –1 m/s = $2v_{A2} + 10v_{B2}$. Using $v_{B2x} - v_{A2x} = -(v_{B1x} - v_{A1x})$ we get $v_{B2x} - v_{A2x}$ = –(–0.500 m/s – 2.00 m/s) = +2.50 m/s. Solving this equation and the momentum equation simultaneously gives v_{A2x} = 2.17 m/s and v_{B2x} = 0.333 m/s.
EVALUATE: The total kinetic energy before the collision is 5.25 J, and it is the same after, which is consistent with an elastic collision.

8.68. **IDENTIFY:** Use a coordinate system attached to the ground. Take the x-axis to be east (along the tracks) and the y-axis to be north (parallel to the ground and perpendicular to the tracks). Then P_x is conserved and P_y is *not* conserved, due to the sideways force exerted by the tracks, the force that keeps the handcar on the tracks.
(a) SET UP: Let A be the 25.0 kg mass and B be the car (mass 175 kg). After the mass is thrown sideways relative to the car it still has the same eastward component of velocity, 5.00 m/s as it had before it was thrown.

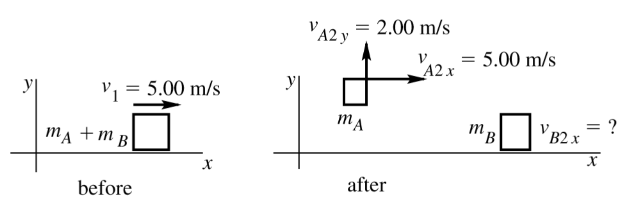

Figure 8.68a

P_x is conserved so $(m_A + m_B)v_1 = m_A v_{A2x} + m_B v_{B2x}$
EXECUTE: $(200\text{ kg})(5.00\text{ m/s}) = (25.0\text{ kg})(5.00\text{ m/s}) + (175\text{ kg})v_{B2x}$.

$$v_{B2x} = \frac{1000\text{ kg}\cdot\text{m/s} - 125\text{ kg}\cdot\text{m/s}}{175\text{ kg}} = 5.00\text{ m/s}.$$

The final velocity of the car is 5.00 m/s, east (unchanged).

EVALUATE: The thrower exerts a force on the mass in the y-direction and by Newton's third law the mass exerts an equal and opposite force in the $-y$-direction on the thrower and car.

(b) SET UP: We are applying $P_x = \text{constant}$ in coordinates attached to the ground, so we need the final velocity of A relative to the ground. Use the relative velocity addition equation. Then use $P_x = \text{constant}$ to find the final velocity of the car.

EXECUTE: $\vec{v}_{A/E} = \vec{v}_{A/B} + \vec{v}_{B/E}$

$v_{B/E} = +5.00\text{ m/s}$

$v_{A/B} = -5.00\text{ m/s}$ (minus since the mass is moving west relative to the car). This gives $v_{A/E} = 0$; the mass is at rest relative to the earth after it is thrown backwards from the car.

As in part (a) $(m_A + m_B)v_1 = m_A v_{A2x} + m_B v_{B2x}$.

Now $v_{A2x} = 0$, so $(m_A + m_B)v_1 = m_B v_{B2x}$.

$$v_{B2x} = \left(\frac{m_A + m_B}{m_B}\right)v_1 = \left(\frac{200\text{ kg}}{175\text{ kg}}\right)(5.00\text{ m/s}) = 5.71\text{ m/s}.$$

The final velocity of the car is 5.71 m/s, east.

EVALUATE: The thrower exerts a force in the $-x$-direction so the mass exerts a force on him in the $+x$-direction, and he and the car speed up.

(c) SET UP: Let A be the 25.0 kg mass and B be the car (mass $m_B = 200\text{ kg}$).

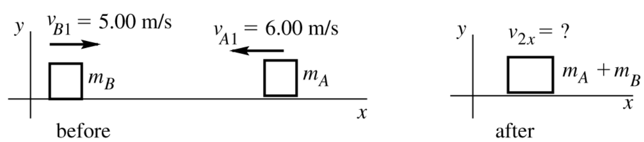

Figure 8.68b

P_x is conserved so $m_A v_{A1x} + m_B v_{B1x} = (m_A + m_B)v_{2x}$.

EXECUTE: $-m_A v_{A1} + m_B v_{B1} = (m_A + m_B)v_{2x}$.

$$v_{2x} = \frac{m_B v_{B1} - m_A v_{A1}}{m_A + m_B} = \frac{(200\text{ kg})(5.00\text{ m/s}) - (25.0\text{ kg})(6.00\text{ m/s})}{200\text{ kg} + 25.0\text{ kg}} = 3.78\text{ m/s}.$$

The final velocity of the car is 3.78 m/s, east.

EVALUATE: The mass has negative p_x so reduces the total P_x of the system and the car slows down.

8.69. IDENTIFY: The x- and y-components of the momentum of the system are conserved.

SET UP: After the collision the combined object with mass $m_{\text{tot}} = 0.100\text{ kg}$ moves with velocity $\vec{v}_2$. Solve for v_{Cx} and v_{Cy}.

EXECUTE: **(a)** $P_{1x} = P_{2x}$ gives $m_A v_{Ax} + m_B v_{Bx} + m_C v_{Cx} = m_{\text{tot}} v_{2x}$.

$$v_{Cx} = -\frac{m_A v_{Ax} + m_B v_{Bx} - m_{\text{tot}} v_{2x}}{m_C}$$

$$v_{Cx} = -\frac{(0.020\text{ kg})(-1.50\text{ m/s}) + (0.030\text{ kg})(-0.50\text{ m/s})\cos 60° - (0.100\text{ kg})(0.50\text{ m/s})}{0.050\text{ kg}}.$$

$$v_{Cx} = 1.75\text{ m/s}.$$

$P_{1y} = P_{2y}$ gives $m_A v_{Ay} + m_B v_{By} + m_C v_{Cy} = m_{\text{tot}} v_{2y}$.

$$v_{Cy} = -\frac{m_A v_{Ay} + m_B v_{By} - m_{\text{tot}} v_{2y}}{m_C} = -\frac{(0.030\text{ kg})(-0.50\text{ m/s})\sin 60°}{0.050\text{ kg}} = +0.260\text{ m/s}.$$

(b) $v_C = \sqrt{v_{Cx}^2 + v_{Cy}^2} = 1.77$ m/s. $\Delta K = K_2 - K_1$.

$\Delta K = \frac{1}{2}(0.100 \text{ kg})(0.50 \text{ m/s})^2 - [\frac{1}{2}(0.020 \text{ kg})(1.50 \text{ m/s})^2 + \frac{1}{2}(0.030 \text{ kg})(0.50 \text{ m/s})^2 + \frac{1}{2}(0.050 \text{ kg})(1.77 \text{ m/s})^2]$
$\Delta K = -0.092$ J.

EVALUATE: Since there is no horizontal external force the vector momentum of the system is conserved. The forces the spheres exert on each other do negative work during the collision and this reduces the kinetic energy of the system.

8.70. **IDENTIFY:** We need to use the impulse-momentum theorem.
SET UP: The impulse-momentum theorem is $J_x = p_{2x} - p_{1x}$, where $p_x = mv_x$. The impulse is equal to the area under a graph of *F* versus *t*.
EXECUTE: **(a)** Figure 8.70 shows the graph of *F* versus *t*.

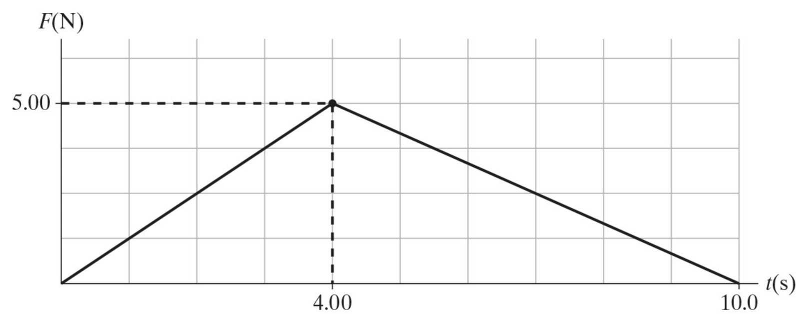

Figure 8.70

(b) Using the area of a triangle, the area under the graph is $\frac{1}{2}(5.00 \text{ N})(10.0 \text{ s}) = 25.0 \text{ N} \cdot \text{s}$. Now use $J_x = p_{2x} - p_{1x}$: $25.0 \text{ N} \cdot \text{s} = (3.00 \text{ kg})v$, so $v = 8.33$ m/s.

EVALUATE: Using the area under the curve to find the J_x is much easier than integrating $\int F_x dt$ because the force changes at 4.00 s, so the integral would have to be done in two parts.

8.71. **IDENTIFY:** Momentum is conserved during the collision, and the wood (with the clay attached) is in free fall as it falls since only gravity acts on it.
SET UP: Apply conservation of momentum to the collision to find the velocity *V* of the combined object just after the collision. After the collision, the wood's downward acceleration is *g* and it has no horizontal acceleration, so we can use the standard kinematics equations: $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ and $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$.

EXECUTE: Momentum conservation gives $(0.500 \text{ kg})(24.0 \text{ m/s}) = (8.50 \text{ kg})V$, so $V = 1.412$ m/s. Consider the projectile motion after the collision: $a_y = +9.8 \text{ m/s}^2$, $v_{0y} = 0$, $y - y_0 = +2.20$ m, and *t* is unknown. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = \sqrt{\frac{2(y - y_0)}{a_y}} = \sqrt{\frac{2(2.20 \text{ m})}{9.8 \text{ m/s}^2}} = 0.6701$ s. The horizontal acceleration is zero so $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2 = (1.412 \text{ m/s})(0.6701 \text{ s}) = 0.946$ m.

EVALUATE: The momentum is *not* conserved after the collision because an external force (gravity) acts on the system. Mechanical energy is *not* conserved during the collision because the clay and block stick together, making it an inelastic collision.

8.72. **IDENTIFY:** An inelastic collision (the objects stick together) occurs during which momentum is conserved, followed by a swing during which mechanical energy is conserved. The target variable is the initial speed of the bullet.

SET UP: Newton's second law, $\Sigma\vec{F} = m\vec{a}$, will relate the tension in the cord to the speed of the block during the swing. Mechanical energy is conserved after the collision, and momentum is conserved during the collision.

EXECUTE: First find the speed v of the block, at a height of 0.800 m. The mass of the combined object is 0.812 kg. $\cos\theta = \dfrac{0.8\text{ m}}{1.6\text{ m}} = 0.50$ so $\theta = 60.0^\circ$ is the angle the cord makes with the vertical. At this position, Newton's second law gives $T - mg\cos\theta = m\dfrac{v^2}{R}$, where we have taken force components toward the center of the circle. Solving for v gives

$v = \sqrt{\dfrac{R}{m}(T - mg\cos\theta)} = \sqrt{\dfrac{1.6\text{ m}}{0.812\text{ kg}}(4.80\text{ N} - 3.979\text{ N})} = 1.272\text{ m/s}.$ Now apply conservation of energy to find the velocity V of the combined object just after the collision: $\dfrac{1}{2}mV^2 = mgh + \dfrac{1}{2}mv^2$. Solving for V gives $V = \sqrt{2gh + v^2} = \sqrt{2(9.8\text{ m/s}^2)(0.8\text{ m}) + (1.272\text{ m/s})^2} = 4.159\text{ m/s}.$ Now apply conservation of momentum to the collision: $(0.012\text{ kg})v_0 = (0.812\text{ kg})(4.159\text{ m/s}),$ which gives $v_0 = 281\text{ m/s}.$

EVALUATE: We cannot solve this problem in a single step because different conservation laws apply to the collision and the swing.

8.73. **IDENTIFY:** During the collision, momentum is conserved, but after the collision mechanical energy is conserved. We cannot solve this problem in a single step because the collision and the motion after the collision involve different conservation laws.

SET UP: Use coordinates where $+x$ is to the right and $+y$ is upward. Momentum is conserved during the collision, so $P_{1x} = P_{2x}$. Energy is conserved after the collision, so $K_1 = U_2$, where $K = \frac{1}{2}mv^2$ and $U = mgh$.

EXECUTE: *Collision*: There is no external horizontal force during the collision so $P_{1x} = P_{2x}$. This gives $(5.00\text{ kg})(12.0\text{ m/s}) = (10.0\text{ kg})v_2$ and $v_2 = 6.0\text{ m/s}.$

Motion after the collision: Only gravity does work and the initial kinetic energy of the combined chunks is converted entirely to gravitational potential energy when the chunk reaches its maximum height h above the valley floor. Conservation of energy gives $\frac{1}{2}m_{\text{tot}}v^2 = m_{\text{tot}}gh$ and

$$h = \frac{v^2}{2g} = \frac{(6.0\text{ m/s})^2}{2(9.8\text{ m/s}^2)} = 1.8\text{ m}.$$

EVALUATE: After the collision the energy of the system is $\frac{1}{2}m_{\text{tot}}v^2 = \frac{1}{2}(10.0\text{ kg})(6.0\text{ m/s})^2 = 180\text{ J}$ when it is all kinetic energy and the energy is $m_{\text{tot}}gh = (10.0\text{ kg})(9.8\text{ m/s}^2)(1.8\text{ m}) = 180\text{ J}$ when it is all gravitational potential energy. Mechanical energy is conserved during the motion after the collision. But before the collision the total energy of the system is $\frac{1}{2}(5.0\text{ kg})(12.0\text{ m/s})^2 = 360\text{ J}$; 50% of the mechanical energy is dissipated during the inelastic collision of the two chunks.

8.74. **IDENTIFY:** Momentum is conserved during the collision. After that we use energy conservation for B.

SET UP: $P_1 = P_2$ during the collision. For B, $K_1 + U_1 = K_2 + U_2$ after the collision.

EXECUTE: For the collision, $P_1 = P_2$: (2.00 kg)(8.00 m/s) = (2.00 kg)(–2.00 m/s) + (4.00 kg)v_B, which gives v_B = 5.00 m/s. Now look at B after the collision and apply $K_1 + U_1 = K_2 + U_2$.

$K_1 + U_1 = K_2 + 0$: $\frac{1}{2} m v_B^2 + mgh = \frac{1}{2} mv^2$

$v^2 = (5.00\text{ m/s})^2 + 2(9.80\text{ m/s}^2)(2.60\text{ m})$, which gives v = 8.72 m/s.

EVALUATE: We cannot do this problem in a single step because we have two different conservation laws involved: momentum during the collision and energy after the collision. The energy is not conserved during the collision, and the momentum of B is not conserved after the collision.

8.75. **IDENTIFY:** We use momentum conservation during the collision of the carts. Half the initial kinetic energy is lost during the collision.

SET UP: Use $m_A v_{A1x} + m_B v_{B1x} = m_A v_{A2x} + m_B v_{B2x}$ and $K = \frac{1}{2}mv^2$. Call the $+x$-axis the original direction that cart A is moving. Fig. 8.75 shows a before and after sketch. The carts have equal masses, the final kinetic energy is one-half the initial kinetic energy, and we want to find the speed of each cart after the collision.

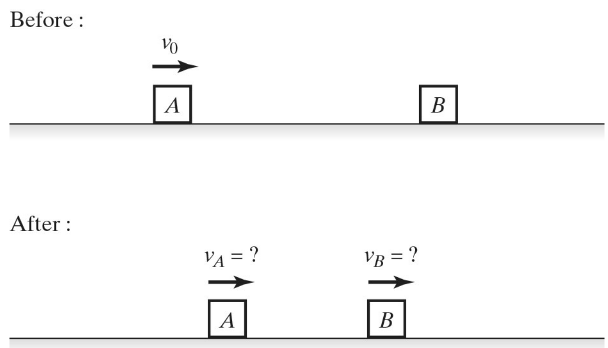

Figure 8.75

EXECUTE: Using the notation in the figure, momentum conservation gives us $mv_0 = mv_A + mv_B$, so $v_0 = v_A + v_B$. (Eq. 1)

Half the kinetic energy is lost, so $K_2 = \frac{1}{2}K_1 = \frac{1}{2}\left(\frac{1}{2}mv_0^2\right) = \frac{1}{4}mv_0^2$, which simplifies to

$v_A^2 + v_B^2 = \frac{1}{2}v_0^2$. (Eq. 2)

Solve Eq. 1 and Eq. 2 together, which gives $v_B = \frac{v_0}{2}$. Now find v_A using Eq. 1:

$v_A = v_0 - v_B = v_0 - \frac{v_0}{2} = \frac{v_0}{2}$. Returning to the notation stated in the problem, we find that each cart has speed $\frac{v_A}{2}$ after the collision.

EVALUATE: To check, we calculate the kinetic energy before and after the collision. $K_1 = \frac{1}{2}mv_0^2$ and

$K_2 = \frac{1}{2}mv_A^2 + \frac{1}{2}mv_B^2 = \frac{1}{2}m\left(\frac{v_0^2}{4} + \frac{v_0^2}{4}\right) = \frac{1}{2}\left(\frac{1}{2}mv_0^2\right) = \frac{1}{2}K_1$. Our result checks.

8.76. **IDENTIFY:** During the inelastic collision, momentum is conserved but not mechanical energy. After the collision, momentum is not conserved and the kinetic energy of the cars is dissipated by nonconservative friction.

SET UP: Treat the collision and motion after the collision as separate events. Apply conservation of momentum to the collision and conservation of energy to the motion after the collision. The friction force on the combined cars is $\mu_k(m_A + m_B)g$.

EXECUTE: *Motion after the collision*: The kinetic energy of the combined cars immediately after the collision is taken away by the negative work done by friction: $\frac{1}{2}(m_A + m_B)V^2 = \mu_k(m_A + m_B)gd$, where $d = 7.15$ m. This gives $V = \sqrt{2\mu_k gd} = 9.54$ m/s.

Collision: Momentum conservation gives $m_A v_A = (m_A + m_B)V$, which gives

$$v_A = \left(\frac{m_A + m_B}{m_A}\right)V = \left(\frac{1500 \text{ kg} + 1900 \text{ kg}}{1500 \text{ kg}}\right)(9.54 \text{ m/s}) = 21.6 \text{ m/s}.$$

(b) $v_A = 21.6$ m/s $= 48$ mph, which is 13 mph greater than the speed limit.

EVALUATE: We cannot solve this problem in a single step because the collision and the motion after the collision involve different principles (momentum conservation and energy conservation).

8.77. IDENTIFY: During the inelastic collision, momentum is conserved (in two dimensions), but after the collision we must use energy principles.

SET UP: The friction force is $\mu_k m_{\text{tot}} g$. Use energy considerations to find the velocity of the combined object immediately after the collision. Apply conservation of momentum to the collision. Use coordinates where $+x$ is west and $+y$ is south. For momentum conservation, we have $P_{1x} = P_{2x}$ and $P_{1y} = P_{2y}$.

EXECUTE: *Motion after collision*: The negative work done by friction takes away all the kinetic energy that the combined object has just after the collision. Calling ϕ the angle south of west at which the enmeshed cars slid, we have $\tan\phi = \dfrac{6.43 \text{ m}}{5.39 \text{ m}}$ and $\phi = 50.0°$. The wreckage slides 8.39 m in a direction 50.0° south of west. Energy conservation gives $\frac{1}{2}m_{\text{tot}}V^2 = \mu_k m_{\text{tot}} gd$, so

$V = \sqrt{2\mu_k gd} = \sqrt{2(0.75)(9.80 \text{ m/s}^2)(8.39 \text{ m})} = 11.1$ m/s. The velocity components are

$V_x = V\cos\phi = 7.13$ m/s; $V_y = V\sin\phi = 8.50$ m/s.

Collision: $P_{1x} = P_{2x}$ gives $(2200 \text{ kg})v_{\text{SUV}} = (1500 \text{ kg} + 2200 \text{ kg})V_x$ and $v_{\text{SUV}} = 12$ m/s. $P_{1y} = P_{2y}$ gives $(1500 \text{ kg})v_{\text{sedan}} = (1500 \text{ kg} + 2200 \text{ kg})V_y$ and $v_{\text{sedan}} = 21$ m/s.

EVALUATE: We cannot solve this problem in a single step because the collision and the motion after the collision involve different principles (momentum conservation and energy conservation).

8.78. IDENTIFY: Find k for the spring from the forces when the frame hangs at rest, use constant acceleration equations to find the speed of the putty just before it strikes the frame, apply conservation of momentum to the collision between the putty and the frame, and then apply conservation of energy to the motion of the frame after the collision.

SET UP: Use the free-body diagram in Figure 8.78a for the frame when it hangs at rest on the end of the spring to find the force constant k of the spring. Let s be the amount the spring is stretched.

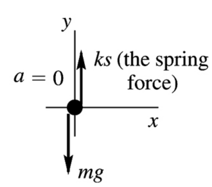

Figure 8.78a

EXECUTE: $\Sigma F_y = ma_y$ gives $-mg + ks = 0$. $k = \dfrac{mg}{s} = \dfrac{(0.150 \text{ kg})(9.80 \text{ m/s}^2)}{0.0400 \text{ m}} = 36.75$ N/m.

SET UP: Next find the speed of the putty when it reaches the frame. The putty falls with acceleration $a = g$, downward (see Figure 8.78b).

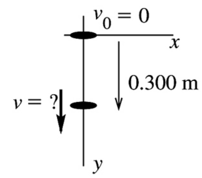

Figure 8.78b

$v_0 = 0,\ \ y - y_0 = 0.300$ m, $a = +9.80\ \text{m/s}^2$, and we want to find v. The constant-acceleration $v^2 = v_0^2 + 2a(y - y_0)$ applies to this motion.

EXECUTE: $v = \sqrt{2a(y - y_0)} = \sqrt{2(9.80\ \text{m/s}^2)(0.300\ \text{m})} = 2.425\ \text{m/s}$.

SET UP: Apply conservation of momentum to the collision between the putty (A) and the frame (B). See Figure 8.78c.

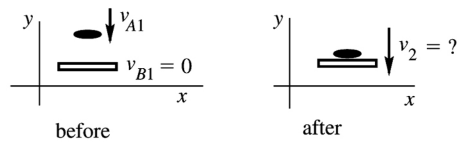

Figure 8.78c

P_y is conserved, so $-m_A v_{A1} = -(m_A + m_B)v_2$.

EXECUTE: $v_2 = \left(\dfrac{m_A}{m_A + m_B}\right)v_{A1} = \left(\dfrac{0.200\ \text{kg}}{0.350\ \text{kg}}\right)(2.425\ \text{m/s}) = 1.386\ \text{m/s}$.

SET UP: Apply conservation of energy to the motion of the frame on the end of the spring after the collision. Let point 1 be just after the putty strikes and point 2 be when the frame has its maximum downward displacement. Let d be the amount the frame moves downward (see Figure 8.78d).

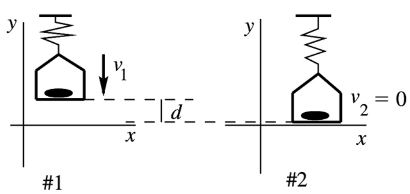

Figure 8.78d

When the frame is at position 1 the spring is stretched a distance $x_1 = 0.0400$ m. When the frame is at position 2 the spring is stretched a distance $x_2 = 0.040\ \text{m} + d$. Use coordinates with the y-direction upward and $y = 0$ at the lowest point reached by the frame, so that $y_1 = d$ and $y_2 = 0$. Work is done on the frame by gravity and by the spring force, so $W_{\text{other}} = 0$, and $U = U_{\text{el}} + U_{\text{gravity}}$.

EXECUTE: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$. $W_{\text{other}} = 0$.

$K_1 = \frac{1}{2}mv_1^2 = \frac{1}{2}(0.350\ \text{kg})(1.386\ \text{m/s})^2 = 0.3362\ \text{J}$.

$U_1 = U_{1,\text{el}} + U_{1,\text{grav}} = \frac{1}{2}kx_1^2 + mgy_1 = \frac{1}{2}(36.75\ \text{N/m})(0.0400\ \text{m})^2 + (0.350\ \text{kg})(9.80\ \text{m/s}^2)d$.

$U_1 = 0.02940\ \text{J} + (3.43\ \text{N})d$. $U_2 = U_{2,\text{el}} + U_{2,\text{grav}} = \frac{1}{2}kx_2^2 + mgy_2 = \frac{1}{2}(36.75\ \text{N/m})(0.0400\ \text{m} + d)^2$.

$U_2 = 0.02940\ \text{J} + (1.47\ \text{N})d + (18.375\ \text{N/m})d^2$. Thus

$0.3362\ \text{J} + 0.02940\ \text{J} + (3.43\ \text{N})d = 0.02940\ \text{J} + (1.47\ \text{N})d + (18.375\ \text{N/m})d^2$.

$(18.375\text{ N/m})d^2 - (1.96\text{ N})d - 0.3362\text{ J} = 0.$ Using the quadratic formula, with the positive solution, we get $d = 0.199$ m.

EVALUATE: The collision is inelastic and mechanical energy is lost. Thus the decrease in gravitational potential energy is *not* equal to the increase in potential energy stored in the spring.

8.79. **IDENTIFY:** Apply conservation of momentum to the collision and conservation of energy to the motion after the collision.

SET UP: Let $+x$ be to the right. The total mass is $m = m_{\text{bullet}} + m_{\text{block}} = 1.00$ kg. The spring has force constant $k = \dfrac{|F|}{|x|} = \dfrac{0.750\text{ N}}{0.250\times10^{-2}\text{ m}} = 300$ N/m. Let V be the velocity of the block just after impact.

EXECUTE: **(a)** Conservation of energy for the motion after the collision gives $K_1 = U_{\text{el}2}$. $\frac{1}{2}mV^2 = \frac{1}{2}kx^2$ and

$$V = x\sqrt{\frac{k}{m}} = (0.150\text{ m})\sqrt{\frac{300\text{ N/m}}{1.00\text{ kg}}} = 2.60\text{ m/s}.$$

(b) Conservation of momentum applied to the collision gives $m_{\text{bullet}}v_1 = mV$.

$$v_1 = \frac{mV}{m_{\text{bullet}}} = \frac{(1.00\text{ kg})(2.60\text{ m/s})}{8.00\times10^{-3}\text{ kg}} = 325\text{ m/s}.$$

EVALUATE: The initial kinetic energy of the bullet is 422 J. The energy stored in the spring at maximum compression is 3.38 J. Most of the initial mechanical energy of the bullet is dissipated in the collision.

8.80. **IDENTIFY:** The horizontal components of momentum of the system of bullet plus stone are conserved. The collision is elastic if $K_1 = K_2$.

SET UP: Let A be the bullet and B be the stone.

(a)

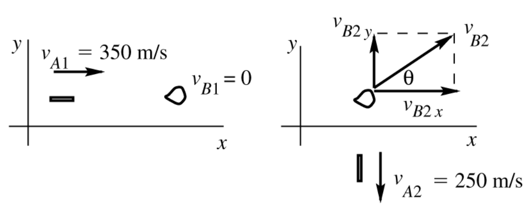

Figure 8.80

EXECUTE: P_x is conserved so $m_A v_{A1x} + m_B v_{B1x} = m_A v_{A2x} + m_B v_{B2x}$.

$m_A v_{A1} = m_B v_{B2x}$.

$$v_{B2x} = \left(\frac{m_A}{m_B}\right)v_{A1} = \left(\frac{6.00\times10^{-3}\text{ kg}}{0.100\text{ kg}}\right)(350\text{ m/s}) = 21.0\text{ m/s}$$

P_y is conserved so $m_A v_{A1y} + m_B v_{B1y} = m_A v_{A2y} + m_B v_{B2y}$.

$0 = -m_A v_{A2} + m_B v_{B2y}$.

$$v_{B2y} = \left(\frac{m_A}{m_B}\right)v_{A2} = \left(\frac{6.00\times10^{-3}\text{ kg}}{0.100\text{ kg}}\right)(250\text{ m/s}) = 15.0\text{ m/s}.$$

$$v_{B2} = \sqrt{v_{B2x}^2 + v_{B2y}^2} = \sqrt{(21.0\text{ m/s})^2 + (15.0\text{ m/s})^2} = 25.8\text{ m/s}.$$

$\tan\theta = \dfrac{v_{B2y}}{v_{B2x}} = \dfrac{15.0\text{ m/s}}{21.0\text{ m/s}} = 0.7143;$ $\theta = 35.5°$ (defined in the sketch).

(b) To answer this question compare K_1 and K_2 for the system:

$$K_1 = \tfrac{1}{2}m_A v_{A1}^2 + \tfrac{1}{2}m_B v_{B1}^2 = \tfrac{1}{2}(6.00\times10^{-3}\text{ kg})(350\text{ m/s})^2 = 368\text{ J}.$$

$$K_2 = \tfrac{1}{2}m_A v_{A2}^2 + \tfrac{1}{2}m_B v_{B2}^2 = \tfrac{1}{2}(6.00\times10^{-3}\text{ kg})(250\text{ m/s})^2 + \tfrac{1}{2}(0.100\text{ kg})(25.8\text{ m/s})^2 = 221\text{ J}.$$

$$\Delta K = K_2 - K_1 = 221\text{ J} - 368\text{ J} = -147\text{ J}.$$

EVALUATE: The kinetic energy of the system decreases by 147 J as a result of the collision; the collision is *not* elastic. Momentum is conserved because $\Sigma \boldsymbol{F}_{\text{ext},x} = 0$ and $\Sigma \boldsymbol{F}_{\text{ext},y} = 0$. But there are internal forces between the bullet and the stone. These forces do negative work that reduces K.

8.81. **IDENTIFY:** Apply conservation of momentum to the collision between the two people. Apply conservation of energy to the motion of the stuntman before the collision and to the entwined people after the collision.

SET UP: For the motion of the stuntman, $y_1 - y_2 = 5.0$ m. Let v_S be the magnitude of his horizontal velocity just before the collision. Let V be the speed of the entwined people just after the collision. Let d be the distance they slide along the floor.

EXECUTE: **(a)** Motion before the collision: $K_1 + U_1 = K_2 + U_2$. $K_1 = 0$ and $\tfrac{1}{2}mv_S^2 = mg(y_1 - y_2)$.

$v_S = \sqrt{2g(y_1 - y_2)} = \sqrt{2(9.80\text{ m/s}^2)(5.0\text{ m})} = 9.90\text{ m/s}.$

Collision: $m_S v_S = m_{\text{tot}}V$. $V = \dfrac{m_S}{m_{\text{tot}}}v_S = \left(\dfrac{80.0\text{ kg}}{150.0\text{ kg}}\right)(9.90\text{ m/s}) = 5.28\text{ m/s}.$

(b) Motion after the collision: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ gives $\tfrac{1}{2}m_{\text{tot}}V^2 - \mu_k m_{\text{tot}}gd = 0$.

$d = \dfrac{V^2}{2\mu_k g} = \dfrac{(5.28\text{ m/s})^2}{2(0.250)(9.80\text{ m/s}^2)} = 5.7\text{ m}.$

EVALUATE: Mechanical energy is dissipated in the inelastic collision, so the kinetic energy just after the collision is less than the initial potential energy of the stuntman.

8.82. **IDENTIFY:** Apply conservation of energy to the motion before and after the collision and apply conservation of momentum to the collision.

SET UP: Let v be the speed of the mass released at the rim just before it strikes the second mass. Let each object have mass m.

EXECUTE: Conservation of energy says $\tfrac{1}{2}mv^2 = mgR$; $v = \sqrt{2gR}$.

SET UP: This is speed v_1 for the collision. Let v_2 be the speed of the combined object just after the collision.

EXECUTE: Conservation of momentum applied to the collision gives $mv_1 = 2mv_2$ so $v_2 = v_1/2 = \sqrt{gR/2}$.

SET UP: Apply conservation of energy to the motion of the combined object after the collision. Let y_3 be the final height above the bottom of the bowl.

EXECUTE: $\tfrac{1}{2}(2m)v_2^2 = (2m)gy_3$.

$y_3 = \dfrac{v_2^2}{2g} = \dfrac{1}{2g}\left(\dfrac{gR}{2}\right) = R/4.$

EVALUATE: Mechanical energy is lost in the collision, so the final gravitational potential energy is less than the initial gravitational potential energy.

8.83. **IDENTIFY:** This collision is elastic, so kinetic energy and momentum are both conserved.

SET UP: Use $v_A = \dfrac{m_A - m_B}{m_A + m_B} v_0$ (Eq. 8.24) and $v_B = \dfrac{2m_A}{m_A + m_B} v_0$ (Eq. 8.25), as well as $K = \dfrac{1}{2}mv^2$. Call the $+x$-axis the original direction that object A is moving. Where we let $v_{Ai} = v_0$ and we have simplified the notation of Eq. 8.24 and Eq. 8.25 somewhat. We have $m_A = \alpha m_B$.

EXECUTE: **(a)** Using Eq. 8.25 gives the final kinetic energy of B.

$K_{B,f} = \dfrac{1}{2}m_B v_B^2 = \dfrac{1}{2}m_B\left(\dfrac{2m_A v_0}{m_A + m_B}\right)^2 = \dfrac{1}{2}m_B\left(\dfrac{2m_A}{m_A + m_B}\right)^2 v_0^2$. This is equal to the initial kinetic energy of A, which is $K_{A,i} = \dfrac{1}{2}m_A v_0^2 = \dfrac{1}{2}\alpha m_B v_0^2$. Equating the two kinetic energies gives

$\dfrac{1}{2}\alpha m_B v_0^2 = \dfrac{1}{2}m_B\left(\dfrac{2m_A}{m_A + m_B}\right)^2 v_0^2$, which simplifies to $\alpha = \left(\dfrac{2m_A}{m_A + m_B}\right)^2$. Using $m_A = \alpha m_B$ gives

$\alpha = \left(\dfrac{2\alpha m_B}{\alpha m_B + m_B}\right)^2 = \left(\dfrac{2\alpha}{\alpha + 1}\right)^2$. Solving for α gives $\alpha = 1$. This means that the masses are equal.

(b) In this case, after the collision $K_A = K_B$, so $\dfrac{1}{2}m_A v_A^2 = \dfrac{1}{2}m_B v_B^2$. Using $m_A = \alpha m_B$ and simplifying gives $\alpha v_A^2 = v_B^2$. Now use Eq. 24 and Eq. 25 in the last equation, which gives

$\alpha\left(\dfrac{m_A - m_B}{m_A + m_B} v_0\right)^2 = \left(\dfrac{2m_A v_0}{m_A + m_B}\right)^2$. Using $m_A = \alpha m_B$ and simplifying gives $\alpha(\alpha - 1)^2 = 4\alpha^2$. The resulting quadratic equation has solutions $\alpha = 3 + 2\sqrt{2} \approx 5.83$ and $\alpha = 3 - 2\sqrt{2} \approx 0.172$.

EVALUATE: When $\alpha = 1$, $m_A = m_B$. Object A stops and object B moves ahead with the same speed that A had. Object A has lost all of its momentum and kinetic energy and object B has gained it all, so both momentum and kinetic energy are conserved.

8.84. **IDENTIFY:** Apply conservation of energy to the motion before and after the collision. Apply conservation of momentum to the collision.

SET UP: First consider the motion after the collision. The combined object has mass $m_{\text{tot}} = 25.0$ kg. Apply $\Sigma\vec{F} = m\vec{a}$ to the object at the top of the circular loop, where the object has speed v_3. The acceleration is $a_{\text{rad}} = v_3^2/R$, downward.

EXECUTE: $T + mg = m\dfrac{v_3^2}{R}$.

The minimum speed v_3 for the object not to fall out of the circle is given by setting $T = 0$. This gives $v_3 = \sqrt{Rg}$, where $R = 2.80$ m.

SET UP: Next, use conservation of energy with point 2 at the bottom of the loop and point 3 at the top of the loop. Take $y = 0$ at point 2. Only gravity does work, so $K_2 + U_2 = K_3 + U_3$

EXECUTE: $\frac{1}{2}m_{\text{tot}}v_2^2 = \frac{1}{2}m_{\text{tot}}v_3^2 + m_{\text{tot}}g(2R)$.

Use $v_3 = \sqrt{Rg}$ and solve for v_2: $v_2 = \sqrt{5gR} = 11.71$ m/s.

SET UP: Now apply conservation of momentum to the collision between the dart and the sphere. Let v_1 be the speed of the dart before the collision.

EXECUTE: $(5.00\text{ kg})v_1 = (25.0\text{ kg})(11.71\text{ m/s})$, which gives $v_1 = 58.6$ m/s.

EVALUATE: The collision is inelastic and mechanical energy is removed from the system by the negative work done by the forces between the dart and the sphere.

8.85. **IDENTIFY:** Apply conservation of momentum to the collision between the bullet and the block and apply conservation of energy to the motion of the block after the collision.

(a) SET UP: For the collision between the bullet and the block, let object A be the bullet and object B be the block. Apply momentum conservation to find the speed v_{B2} of the block just after the collision (see Figure 8.85a).

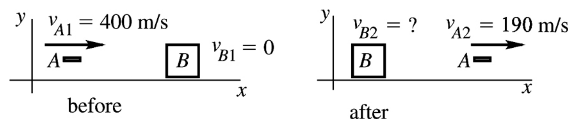

Figure 8.85a

EXECUTE: P_x is conserved so $m_A v_{A1x} + m_B v_{B1x} = m_A v_{A2x} + m_B v_{B2x}$. $m_A v_{A1} = m_A v_{A2} + m_B v_{B2x}$.

$$v_{B2x} = \frac{m_A(v_{A1} - v_{A2})}{m_B} = \frac{4.00\times10^{-3}\ \text{kg}(400\ \text{m/s} - 190\ \text{m/s})}{0.800\ \text{kg}} = 1.05\ \text{m/s}.$$

SET UP: For the motion of the block after the collision, let point 1 in the motion be just after the collision, where the block has the speed 1.05 m/s calculated above, and let point 2 be where the block has come to rest (see Figure 8.85b).
$K_1 + U_1 + W_{\text{other}} = K_2 + U_2$.

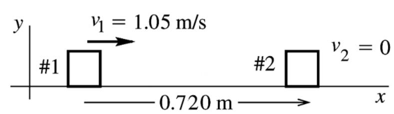

Figure 8.85b

EXECUTE: Work is done on the block by friction, so $W_{\text{other}} = W_f$.

$W_{\text{other}} = W_f = (f_k \cos\phi)s = -f_k s = -\mu_k mgs$, where $s = 0.720$ m. $U_1 = 0$, $U_2 = 0$, $K_1 = \frac{1}{2}mv_1^2$, $K_2 = 0$ (the block has come to rest). Thus $\frac{1}{2}mv_1^2 - \mu_k mgs = 0$. Therefore

$$\mu_k = \frac{v_1^2}{2gs} = \frac{(1.05\ \text{m/s})^2}{2(9.80\ \text{m/s}^2)(0.720\ \text{m})} = 0.0781.$$

(b) For the bullet, $K_1 = \frac{1}{2}mv_1^2 = \frac{1}{2}(4.00\times10^{-3}\ \text{kg})(400\ \text{m/s})^2 = 320\ \text{J}$ and

$K_2 = \frac{1}{2}mv_2^2 = \frac{1}{2}(4.00\times10^{-3}\ \text{kg})(190\ \text{m/s})^2 = 72.2\ \text{J}$. $\Delta K = K_2 - K_1 = 72.2\ \text{J} - 320\ \text{J} = -248\ \text{J}$. The kinetic energy of the bullet decreases by 248 J.

(c) Immediately after the collision the speed of the block is 1.05 m/s, so its kinetic energy is
$K = \frac{1}{2}mv^2 = \frac{1}{2}(0.800\ \text{kg})(1.05\ \text{m/s})^2 = 0.441\ \text{J}$.

EVALUATE: The collision is highly inelastic. The bullet loses 248 J of kinetic energy but only 0.441 J is gained by the block. But momentum is conserved in the collision. All the momentum lost by the bullet is gained by the block.

8.86. IDENTIFY: Apply conservation of momentum to the collision and conservation of energy to the motion of the block after the collision.

SET UP: Let $+x$ be to the right. Let the bullet be A and the block be B. Let V be the velocity of the block just after the collision.

EXECUTE: *Motion of block after the collision*: $K_1 = U_{\text{grav}2}$. $\frac{1}{2}m_B V^2 = m_B gh$.

$$V = \sqrt{2gh} = \sqrt{2(9.80\ \text{m/s}^2)(0.38\times10^{-2}\ \text{m})} = 0.273\ \text{m/s}.$$

Collision: $v_{B2} = 0.273$ m/s. $P_{1x} = P_{2x}$ gives $m_A v_{A1} = m_A v_{A2} + m_B v_{B2}$.

$$v_{A2} = \frac{m_A v_{A1} - m_B v_{B2}}{m_A} = \frac{(5.00\times10^{-3}\text{ kg})(450\text{ m/s}) - (1.00\text{ kg})(0.273\text{ m/s})}{5.00\times10^{-3}\text{ kg}} = 395\text{ m/s}.$$

EVALUATE: We assume the block moves very little during the time it takes the bullet to pass through it.

8.87. **IDENTIFY:** Apply conservation of energy to the motion of the package before the collision and apply conservation of the horizontal component of momentum to the collision.

(a) SET UP: Apply conservation of energy to the motion of the package from point 1 as it leaves the chute to point 2 just before it lands in the cart. Take $y = 0$ at point 2, so $y_1 = 4.00$ m. Only gravity does work, so

$$K_1 + U_1 = K_2 + U_2.$$

EXECUTE: $\frac{1}{2}mv_1^2 + mgy_1 = \frac{1}{2}mv_2^2$.

$v_2 = \sqrt{v_1^2 + 2gy_1} = 9.35$ m/s.

(b) SET UP: In the collision between the package and the cart, momentum is conserved in the horizontal direction. (But not in the vertical direction, due to the vertical force the floor exerts on the cart.) Take $+x$ to be to the right. Let *A* be the package and *B* be the cart.

EXECUTE: P_x is constant gives $m_A v_{A1x} + m_B v_{B1x} = (m_A + m_B)v_{2x}$.

$v_{B1x} = -5.00$ m/s.

$v_{A1x} = (3.00\text{ m/s})\cos 37.0°$. (The horizontal velocity of the package is constant during its free fall.)

Solving for v_{2x} gives $v_{2x} = -3.29$ m/s. The cart is moving to the left at 3.29 m/s after the package lands in it.

EVALUATE: The cart is slowed by its collision with the package, whose horizontal component of momentum is in the opposite direction to the motion of the cart.

8.88. **IDENTIFY:** Apply conservation of momentum to the system of the neutron and its decay products.

SET UP: Let the proton be moving in the $+x$-direction with speed v_p after the decay. The initial momentum of the neutron is zero, so to conserve momentum the electron must be moving in the $-x$-direction after the decay. Let the speed of the electron be v_e.

EXECUTE: $P_{1x} = P_{2x}$ gives $0 = m_p v_p - m_e v_e$ and $v_e = \left(\frac{m_p}{m_e}\right)v_p$. The total kinetic energy after the decay is $K_{tot} = \frac{1}{2}m_e v_e^2 + \frac{1}{2}m_p v_p^2 = \frac{1}{2}m_e\left(\frac{m_p}{m_e}\right)^2 v_p^2 + \frac{1}{2}m_p v_p^2 = \frac{1}{2}m_p v_p^2\left(1 + \frac{m_p}{m_e}\right)$.

Thus, $\dfrac{K_p}{K_{tot}} = \dfrac{1}{1 + m_p/m_e} = \dfrac{1}{1+1836} = 5.44\times10^{-4} = 0.0544\%$.

EVALUATE: Most of the released energy goes to the electron, since it is much lighter than the proton.

8.89. **IDENTIFY:** We have a collision, so we use momentum conservation. After the collision we have projectile motion. Fig. 8.89 illustrates this process.

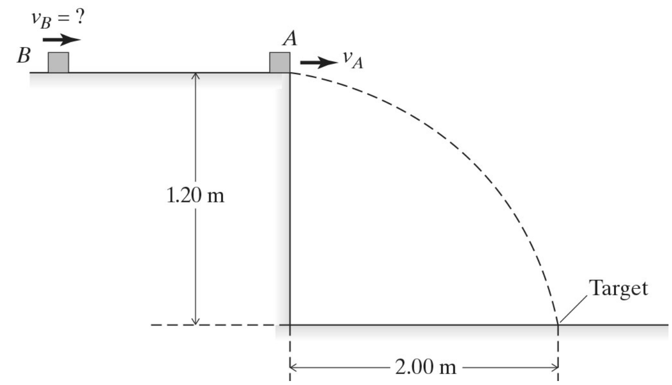

Figure 8.89

SET UP: We use projectile motion to find the speed that A needs at the top of the table to hit the target. We use momentum conservation during the collision to find the speed that B needed to give A the necessary speed. The collision is elastic, so we can use $v_A = \dfrac{m_A - m_B}{m_A + m_B} v_0$ (Eq. 8.24) and $v_B = \dfrac{2m_A}{m_A + m_B} v_0$ (Eq. 8.25). In this problem A and B are interchanged from the equations in the text because B is moving and A is initially at rest, so we must be careful. Eq. 8.24 tells us that if the masses are equal, B stops and A moves forward with the same velocity that B had.

EXECUTE: Look at the projectile motion after the collision. The constant-acceleration equations apply. The block needs to travel 2.00 m at constant horizontal velocity v_A in the same time that it falls 1.20 m starting from rest vertically. The vertical motion gives $y = \dfrac{1}{2}gt^2$, so $t = \sqrt{2y/g} = \sqrt{\dfrac{2(1.20\text{ m})}{9.80\text{ m/s}^2}} = 0.4949$ s. Horizontally $x = v_A t = 2.00$ m, so $v_A = (2.00\text{ m})/(0.4949\text{ s}) = 4.04\text{ m/s} = v_B$.

EVALUATE: If the collision were inelastic, B would have had a velocity after the collision.

8.90. **IDENTIFY:** Since there is no friction, the horizontal component of momentum of the system of Jonathan, Jane, and the sleigh is conserved.

SET UP: Let $+x$ be to the right. $w_A = 800$ N, $w_B = 600$ N and $w_C = 1000$ N.

EXECUTE: $P_{1x} = P_{2x}$ gives $0 = m_A v_{A2x} + m_B v_{B2x} + m_C v_{C2x}$.

$$v_{C2x} = -\frac{m_A v_{A2x} + m_B v_{B2x}}{m_C} = -\frac{w_A v_{A2x} + w_B v_{B2x}}{w_C}.$$

$$v_{C2x} = -\frac{(800\text{ N})[-(5.00\text{ m/s})\cos 30.0°] + (600\text{ N})[+(7.00\text{ m/s})\cos 36.9°]}{1000\text{ N}} = 0.105\text{ m/s}.$$

The sleigh's velocity is 0.105 m/s, to the right.

EVALUATE: The vertical component of the momentum of the system consisting of the two people and the sleigh is not conserved, because of the net force exerted on the sleigh by the ice while they jump.

8.91. **IDENTIFY:** No net external force acts on the Burt-Ernie-log system, so the center of mass of the system does not move.

SET UP: $x_{\text{cm}} = \dfrac{m_1 x_1 + m_2 x_2 + m_3 x_3}{m_1 + m_2 + m_3}$.

EXECUTE: Use coordinates where the origin is at Burt's end of the log and where $+x$ is toward Ernie, which makes $x_1 = 0$ for Burt initially. The initial coordinate of the center of mass is

$x_{\text{cm},1} = \dfrac{(20.0\text{ kg})(1.5\text{ m}) + (40.0\text{ kg})(3.0\text{ m})}{90.0\text{ kg}}$. Let d be the distance the log moves toward Ernie's original position. The final location of the center of mass is

$x_{\text{cm},2} = \dfrac{(30.0\text{ kg})d + (1.5\text{ kg} + d)(20.0\text{ kg}) + (40.0\text{ kg})d}{90.0\text{ kg}}$. The center of mass does not move, so

$x_{\text{cm},1} = x_{\text{cm},2}$, which gives

$(20.0\text{ kg})(1.5\text{ m}) + (40.0\text{ kg})(3.0\text{ m}) = (30.0\text{ kg})d + (20.0\text{ kg})(1.5\text{ m} + d) + (40.0\text{ kg})d$. Solving for d gives $d = 1.33$ m.

EVALUATE: Burt, Ernie, and the log all move, but the center of mass of the system does not move.

8.92. **IDENTIFY:** There is no net horizontal external force so v_{cm} is constant.

SET UP: Let $+x$ be to the right, with the origin at the initial position of the left-hand end of the canoe. $m_{\text{A}} = 45.0$ kg, $m_B = 60.0$ kg. The center of mass of the canoe is at its center.

EXECUTE: Initially, $v_{\text{cm}} = 0$, so the center of mass doesn't move. Initially, $x_{\text{cm1}} = \dfrac{m_A x_{A1} + m_B x_{B1}}{m_A + m_B}$.

After she walks, $x_{\text{cm2}} = \dfrac{m_A x_{A2} + m_B x_{B2}}{m_A + m_B}$. $x_{\text{cm1}} = x_{\text{cm2}}$ gives $m_A x_{A1} + m_B x_{B1} = m_A x_{A2} + m_B x_{B2}$. She walks to a point 1.00 m from the right-hand end of the canoe, so she is 1.50 m to the right of the center of mass of the canoe and $x_{A2} = x_{B2} + 1.50$ m.

$$(45.0\text{ kg})(1.00\text{ m}) + (60.0\text{ kg})(2.50\text{ m}) = (45.0\text{ kg})(x_{B2} + 1.50\text{ m}) + (60.0\text{ kg})x_{B2}.$$

$(105.0\text{ kg})x_{B2} = 127.5\text{ kg}\cdot\text{m}$ and $x_{B2} = 1.21$ m. $x_{B2} - x_{B1} = 1.21\text{ m} - 2.50\text{ m} = -1.29$ m. The canoe moves 1.29 m to the left.

EVALUATE: When the woman walks to the right, the canoe moves to the left. The woman walks 3.00 m to the right relative to the canoe and the canoe moves 1.29 m to the left, so she moves $3.00\text{ m} - 1.29\text{ m} = 1.71\text{ m}$ to the right relative to the water. Note that this distance is $(60.0\text{ kg}/45.0\text{ kg})(1.29\text{ m})$.

8.93. **IDENTIFY:** This process involves a swing, a collision, and another swing. Energy is conserved during the two swings and momentum is conserved during the collision.

SET UP: We must break this problem into three parts: the first swing, the collision, and the second swing. We cannot solve it in a single step. We want to find h_{max}, the maximum height the combined spheres reach during the second swing after the collision.

EXECUTE: Swing of B: Energy conservation gives $mgH = \frac{1}{2}mv_B^2$, so $v_B = \sqrt{2gH}$.

Collision: Momentum conservation gives $mv_B = (3m)v_{AB}$, so $v_{AB} = \dfrac{v_B}{3} = \dfrac{1}{3}\sqrt{2gH}$.

Swing of $A + B$: Energy conservation gives $\frac{1}{2}(3m)v_{AB}^2 = 3mgh_{\text{max}}$. Using v_{AB}, this becomes

$\dfrac{1}{2}\left(\dfrac{1}{3}\sqrt{2gH}\right)^2 = gh_{\text{max}}$. Solving for h_{max} gives $h_{\text{max}} = \dfrac{H}{9}$.

EVALUATE: It is reasonable that we get $h_{\text{max}} < H$ because mechanical energy is lost during the inelastic collision.

8.94. **IDENTIFY:** The explosion produces only internal forces for the fragments, so the momentum of the two-fragment system is conserved. Therefore the explosion does not affect the motion of the center of mass of this system.

SET UP: The center of mass follows a parabolic path just as a single particle would. Its horizontal range is $R = \dfrac{v_0^2 \sin(2\alpha)}{g}$. The center of mass of a two-particle system is $x_{\text{cm}} = \dfrac{m_1 x_1 + m_2 x_2}{m_1 + m_2}$.

EXECUTE: **(a)** The range formula gives $R = (18.0\text{ m/s})^2(\sin 102°)/(9.80\text{ m/s}^2) = 32.34$ m, which rounds to 32.3 m.

(b) The center of mass is 32.3 m from the firing point and one fragment lands at $x_2 = 26.0$ m. Using the center of mass formula, with the origin at the firing point and calling m the mass of each fragment, we have 32.34 m = $[m(26.0\text{ m}) + mx_2]/(2m)$, which gives $x_2 = 38.68$ m, which rounds to 38.7 m.

EVALUATE: Since the fragments have equal masses, their center of mass should be midway between them. So it should be at (26.0 m + 38.68 m)/2 = 32.3 m, which it is.

8.95. **IDENTIFY:** The collision is inelastic since the blocks stick together. Momentum is conserved during the collision and energy is conserved before and after the collision.

SET UP: Hooke's law: $F = kx$. The elastic energy stored in a spring is $U_{\text{spr}} = \frac{1}{2}kx^2$. Energy conservation gives $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$ and momentum is $p_x = mv_x$.

EXECUTE: **(a)** First find the distance the spring is compressed using Hooke's law. $mg = kx$, so $x = \dfrac{mg}{k} = \dfrac{(0.500\text{ kg})(9.80\text{ m/s}^2)}{80.0\text{ N/m}} = 0.06125$ m. The energy stored with this compression is

$$U_{\text{spr}} = \frac{1}{2}kx^2 = \frac{1}{2}(80.0\text{ N})(0.06125\text{ m})^2 = 0.150\text{ J}.$$

(b) After the collision, the two-block system has kinetic energy, which can be transferred to the spring. As the spring compresses, gravity also does work on the masses. Fig. 8.95 shows the system just after the collision.

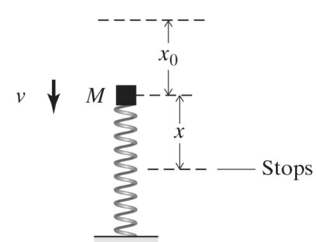

Figure 8.95

First we need to find v, the speed of the two-block system just after the collision. We do this in two steps: conservation of energy as the first block is dropped and reaches the block on the spring, followed by momentum conservation during the collision. Call v_0 the speed of the single block just before it hits the block on the spring. Energy conservation gives $mgh = \frac{1}{2}mv_0^2$, so $v_0 = \sqrt{2gh}$. Momentum conservation during the collision gives $mv_0 = (2m)v$, which gives

$$v = \frac{v_0}{2} = \frac{\sqrt{2gh}}{2} = \frac{\sqrt{2(9.80\text{ m/s}^2)(4.00\text{ m})}}{2} = 19.60\text{ m/s}.$$

Now we use energy conservation after the collision. $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$ with $W_{\text{other}} = 0$. Choose point 1 to be the instant after the collision and point 2 to be when the spring has its maximum compression. At that point, the blocks stop, so $K_2 = 0$. Call x the maximum distance that the spring will compress after the collision (see Fig. 8.25). At point 1 the blocks have gravitational potential energy, which is $U_{\text{g}} = mgx$. At point 1 the system has two forms of potential, U_{g} and the elastic potential energy that is already stored in the spring. In part (a) we saw that this is 0.150 J. At point 2 the system has only elastic potential energy because the spring is now compressed a *total* distance of $x_0 + x$, where x_0 = 0.06125 m from part (a). Calling M the total mass of the system, $U_1 + K_1 = U_2 + K_2$ becomes $Mgx + U_1 + \frac{1}{2}Mv^2 = \frac{1}{2}k(x_0 + x)^2$. Expanding the square, realizing that $U_1 = \frac{1}{2}kx_0^2$, and collecting terms, this equation becomes

$-kx^2 + (2Mg - 2kx_0)x + Mv^2 = 0.$ Using k = 80.0 N/m, v = 19.60 m/s, M = 1.00 kg, and x_0 = 0.06125 m, the quadratic formula gives two solutions. One of the solutions is negative, so we discard it as nonphysical. The other solution is x = 0.560 m. This is the maximum distance that the system compresses the spring *after* the collision. But the spring was already compressed by 0.06125 m before the collision, so the *total* distance that the spring is compressed at the instant the blocks stop moving is x_{total} = 0.560 m + 0.06125 m. Therefore the maximum elastic energy stored in the spring is

$U_{max} = \frac{1}{2}kx_{max}^2 = \frac{1}{2}k(x + x_0)^2 = \frac{1}{2}(80 \text{ N/m})(0.560 \text{ m} + 0.06125 \text{ m})^2 = 15.4 \text{ J}.$

(c) As shown in part (b), x = 0.560 m.

EVALUATE: We cannot overlook the gravitational potential energy in solving this problem because it could be significant compared to the elastic energy in the spring.

8.96. **IDENTIFY:** Conservation of x- and y-components of momentum applies to the collision. At the highest point of the trajectory the vertical component of the velocity of the projectile is zero.

SET UP: Let $+y$ be upward and $+x$ be horizontal and to the right. Let the two fragments be A and B, each with mass m. For the projectile before the explosion and the fragments after the explosion. $a_x = 0$, $a_y = -9.80 \text{ m/s}^2$.

EXECUTE: **(a)** $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ with $v_y = 0$ gives that the maximum height of the projectile is

$h = -\frac{v_{0y}^2}{2a_y} = -\frac{[(80.0 \text{ m/s})\sin 60.0°]^2}{2(-9.80 \text{ m/s}^2)} = 244.9 \text{ m}.$ Just before the explosion the projectile is moving to the right with horizontal velocity $v_x = v_{0x} = v_0 \cos 60.0° = 40.0 \text{ m/s}.$ After the explosion $v_{Ax} = 0$ since fragment A falls vertically. Conservation of momentum applied to the explosion gives $(2m)(40.0 \text{ m/s}) = mv_{Bx}$ and $v_{Bx} = 80.0 \text{ m/s}.$ Fragment B has zero initial vertical velocity so $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives a time of fall of $t = \sqrt{-\frac{2h}{a_y}} = \sqrt{-\frac{2(244.9 \text{ m})}{-9.80 \text{ m/s}^2}} = 7.07 \text{ s}.$ During this time the fragment travels horizontally a distance $(80.0 \text{ m/s})(7.07 \text{ s}) = 566 \text{ m}.$ It also took the projectile 7.07 s to travel from launch to maximum height and during this time it travels a horizontal distance of $([80.0 \text{ m/s}]\cos 60.0°)(7.07 \text{ s}) = 283 \text{ m}.$ The second fragment lands $283 \text{ m} + 566 \text{ m} = 849 \text{ m}$ from the firing point.

(b) For the explosion, $K_1 = \frac{1}{2}(20.0 \text{ kg})(40.0 \text{ m/s})^2 = 1.60 \times 10^4 \text{ J}.$

$K_2 = \frac{1}{2}(10.0 \text{ kg})(80.0 \text{ m/s})^2 = 3.20 \times 10^4 \text{ J}.$ The energy released in the explosion is 1.60×10^4 J.

EVALUATE: The kinetic energy of the projectile just after it is launched is 6.40×10^4 J. We can calculate the speed of each fragment just before it strikes the ground and verify that the total kinetic energy of the fragments just before they strike the ground is $6.40 \times 10^4 \text{ J} + 1.60 \times 10^4 \text{ J} = 8.00 \times 10^4 \text{ J}.$ Fragment A has speed 69.3 m/s just before it strikes the ground, and hence has kinetic energy 2.40×10^4 J. Fragment B has speed $\sqrt{(80.0 \text{ m/s})^2 + (69.3 \text{ m/s})^2} = 105.8 \text{ m/s}$ just before it strikes the ground, and hence has kinetic energy 5.60×10^4 J. Also, the center of mass of the system has the same horizontal range $R = \frac{v_0^2}{g}\sin(2\alpha_0) = 565 \text{ m}$ that the projectile would have had if no explosion had occurred. One fragment lands at $R/2$ so the other, equal mass fragment lands at a distance $3R/2$ from the launch point.

8.97. **IDENTIFY:** The rocket moves in projectile motion before the explosion and its fragments move in projectile motion after the explosion. Apply conservation of energy and conservation of momentum to the explosion.

(a) SET UP: Apply conservation of energy to the explosion. Just before the explosion the rocket is at its maximum height and has zero kinetic energy. Let *A* be the piece with mass 1.40 kg and *B* be the piece with mass 0.28 kg. Let v_A and v_B be the speeds of the two pieces immediately after the collision.

EXECUTE: $\frac{1}{2}m_A v_A^2 + \frac{1}{2}m_B v_B^2 = 860\text{ J}$

SET UP: Since the two fragments reach the ground at the same time, their velocities just after the explosion must be horizontal. The initial momentum of the rocket before the explosion is zero, so after the explosion the pieces must be moving in opposite horizontal directions and have equal magnitude of momentum: $m_A v_A = m_B v_B$.

EXECUTE: Use this to eliminate v_A in the first equation and solve for v_B:

$$\tfrac{1}{2}m_B v_B^2(1 + m_B / m_A) = 860\text{ J} \text{ and } v_B = 71.6\text{ m/s}.$$

Then $v_A = (m_B/m_A)v_B = 14.3\text{ m/s}$.

(b) SET UP: Use the vertical motion from the maximum height to the ground to find the time it takes the pieces to fall to the ground after the explosion. Take $+y$ downward.

$$v_{0y} = 0,\ \ a_y = +9.80\text{ m/s}^2,\ \ y - y_0 = 80.0\text{ m},\ \ t = ?$$

EXECUTE: $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = 4.04\text{ s}$.

During this time the horizontal distance each piece moves is $x_A = v_A t = 57.8\text{ m}$ and $x_B = v_B t = 289.1\text{ m}$. They move in opposite directions, so they are $x_A + x_B = 347\text{ m}$ apart when they land.

EVALUATE: Fragment *A* has more mass so it is moving slower right after the collision, and it travels horizontally a smaller distance as it falls to the ground.

8.98. **IDENTIFY:** Apply conservation of momentum to the explosion. At the highest point of its trajectory the shell is moving horizontally. If one fragment received some upward momentum in the explosion, the other fragment would have had to receive a downward component. Since they each hit the ground at the same time, each must have zero vertical velocity immediately after the explosion.

SET UP: Let $+x$ be horizontal, along the initial direction of motion of the projectile and let $+y$ be upward. At its maximum height the projectile has $v_x = v_0\cos 55.0° = 86.0\text{ m/s}$. Let the heavier fragment be *A* and the lighter fragment be *B*. $m_A = 9.00\text{ kg}$ and $m_B = 3.00\text{ kg}$.

EXECUTE: Since fragment *A* returns to the launch point, immediately after the explosion it has $v_{Ax} = -86.0\text{ m/s}$. Conservation of momentum applied to the explosion gives $(12.0\text{ kg})(86.0\text{ m/s}) = (9.00\text{ kg})(-86.0\text{ m/s}) + (3.00\text{ kg})v_{Bx}$ and $v_{Bx} = 602\text{ m/s}$. The horizontal range of the projectile, if no explosion occurred, would be $R = \dfrac{v_0^2}{g}\sin(2\alpha_0) = 2157\text{ m}$. The horizontal distance each fragment travels is proportional to its initial speed and the heavier fragment travels a horizontal distance $R/2 = 1078\text{ m}$ after the explosion, so the lighter fragment travels a horizontal distance $\left(\dfrac{602\text{ m}}{86\text{ m}}\right)(1078\text{ m}) = 7546\text{ m}$ from the point of explosion and $1078\text{ m} + 7546\text{ m} = 8624\text{ m}$ from the launch point. The energy released in the explosion is

$K_2 - K_1 = \frac{1}{2}(9.00\text{ kg})(86.0\text{ m/s})^2 + \frac{1}{2}(3.00\text{ kg})(602\text{ m/s})^2 - \frac{1}{2}(12.0\text{ kg})(86.0\text{ m/s})^2 = 5.33\times 10^5\text{ J}.$

EVALUATE: The center of mass of the system has the same horizontal range $R = 2157$ m as if the explosion didn't occur. This gives $(12.0 \text{ kg})(2157 \text{ m}) = (9.00 \text{ kg})(0) + (3.00 \text{ kg})d$ and $d = 8630$ m, where d is the distance from the launch point to where the lighter fragment lands. This agrees with our calculation.

8.99. **IDENTIFY:** Apply conservation of energy to the motion of the wagon before the collision. After the collision the combined object moves with constant speed on the level ground. In the collision the horizontal component of momentum is conserved.

SET UP: Let the wagon be object A and treat the two people together as object B. Let $+x$ be horizontal and to the right. Let V be the speed of the combined object after the collision.

EXECUTE: **(a)** The speed v_{A1} of the wagon just before the collision is given by conservation of energy applied to the motion of the wagon prior to the collision. $U_1 = K_2$ says

$m_A g([50 \text{ m}][\sin 6.0°]) = \frac{1}{2} m_A v_{A1}^2$. $v_{A1} = 10.12$ m/s. $P_{1x} = P_{2x}$ for the collision says $m_A v_{A1} = (m_A + m_B)V$

and $V = \left(\dfrac{300 \text{ kg}}{300 \text{ kg} + 75.0 \text{ kg} + 60.0 \text{ kg}}\right)(10.12 \text{ m/s}) = 6.98$ m/s. In 5.0 s the wagon travels

$(6.98 \text{ m/s})(5.0 \text{ s}) = 34.9$ m, and the people will have time to jump out of the wagon before it reaches the edge of the cliff.

(b) For the wagon, $K_1 = \frac{1}{2}(300 \text{ kg})(10.12 \text{ m/s})^2 = 1.54 \times 10^4$ J. Assume that the two heroes drop from a small height, so their kinetic energy just before the wagon can be neglected compared to K_1 of the wagon. $K_2 = \frac{1}{2}(435 \text{ kg})(6.98 \text{ m/s})^2 = 1.06 \times 10^4$ J. The kinetic energy of the system decreases by $K_1 - K_2 = 4.8 \times 10^3$ J.

EVALUATE: The wagon slows down when the two heroes drop into it. The mass that is moving horizontally increases, so the speed decreases to maintain the same horizontal momentum. In the collision the vertical momentum is not conserved, because of the net external force due to the ground.

8.100. **IDENTIFY:** Impulse is equal to the area under the curve in a graph of force versus time.

SET UP: $J_x = \Delta p_x = F_x \Delta t$.

EXECUTE: **(a)** Impulse is the area under *F-t* curve

$J_x = [7500 \text{ N} + ½ (7500 \text{ N} + 3500 \text{ N}) + 3500 \text{ N}](1.50 \text{ s}) = 2.475 \times 10^4 \text{ N} \cdot \text{s}$.

(b) The total mass of the car and driver is $(3071 \text{ lb})(4.448 \text{ N/lb})/(9.80 \text{ m/s}^2) = 1394$ kg.

$J_x = \Delta p_x = mv_x - 0$, so $v_x = J_x/m = (2.475 \times 10^4 \text{ N} \cdot \text{s})/(1394 \text{ kg}) = 17.8$ m/s.

(c) The braking force must produce an impulse opposite to the one that accelerated the car, so $J_x = -2.475 \times 10^4 \text{ N} \cdot \text{s}$. Therefore $J_x = F_x \Delta t$ gives $\Delta t = J_x/F_x = (-24{,}750 \text{ N} \cdot \text{s})/(-5200 \text{ N}) = 4.76$ s.

(d) $W_{\text{brake}} = \Delta K = -K = -½ mv^2 = -½ (1394 \text{ kg})(17.76 \text{ m/s})^2 = -2.20 \times 10^5$ J.

(e) $W_{\text{brake}} = -B_x s$, so $s = -W_{\text{brake}}/B_x = -(2.20 \times 10^5 \text{ J})/(-5200 \text{ N}) = 42.3$ m.

EVALUATE: The result in (e) could be checked by using kinematics with an average velocity of (17.8 m/s)/2 for 4.76 s.

8.101. **IDENTIFY:** As the bullet strikes and embeds itself in the block, momentum is conserved. After that, we use $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$, where W_{other} is due to kinetic friction.

SET UP: Momentum conservation during the collision gives $m_b v_b = (m_b + m)V$, where m is the mass of the block and m_b is the mass of the bullet. After the collision, $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ gives

$\frac{1}{2}MV^2 - \mu_k Mgd = \frac{1}{2}kd^2$, where M is the mass of the block plus the bullet.

EXECUTE: **(a)** From the energy equation above, we can see that the greatest compression of the spring will occur for the greatest V (since $M >> m_b$), and the greatest V will occur for the bullet with the greatest initial momentum. Using the data in the table with the problem, we get the following momenta expressed in units of grain · ft/s.

A: 1.334×10^5 grain · ft/s B: 1.181×10^5 grain · ft/s C: 2.042×10^5 grain · ft/s

D: 1.638×10^5 grain · ft/s E: 1.869×10^5 grain · ft/s

From these results, it is clear that bullet C will produce the maximum compression of the spring and bullet B will produce the least compression.

(b) For bullet C, we use $p_b = m_b v_b = (m_b + m)V$. Converting mass (in grains) and speed to SI units gives $m_b = 0.01555$ kg and $v_b = 259.38$ m/s, we have

(0.01555 kg)(259.38 m/s) = (0.01555 kg + 2.00 kg)V, so $V = 2.001$ m/s.

Now use $\frac{1}{2}MV^2 - \mu_k Mgd = \frac{1}{2}kd^2$ and solve for k, giving

$k = (2.016\text{ kg})[(2.001\text{ m/s})^2 - 2(0.38)(9.80\text{ m/s}^2)(0.25\text{ m})]/(0.25\text{ m})^2 = 69.1$ N/m, which rounds to 69 N/m.

(c) For bullet B, m_b =125 grains = 0.00810 kg and v_b = 945 ft/s = 288.0 m/s. Momentum conservation gives

$V = (0.00810\text{ kg})(288.0\text{ m/s})/(2.00810\text{ kg}) = 1.162$ m/s.

Using $\frac{1}{2}MV^2 - \mu_k Mgd = \frac{1}{2}kd^2$, the above numbers give $33.55d^2 + 7.478d - 1.356 = 0$. The quadratic formula, using the positive square root, gives $d = 0.118$ m, which rounds to 0.12 m.

EVALUATE: This method for measuring muzzle velocity involves a spring displacement of around 12 cm, which should be readily measurable.

8.102. **IDENTIFY** Momentum is conserved during the collision. After the collision, we can use energy methods.

SET UP: $p = mv$, $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$, where W_{other} is due to kinetic friction. We need to use components of momentum. Call $+x$ eastward and $+y$ northward.

EXECUTE: **(a)** Momentum conservation gives

$p_x = [6500\text{ lb})/g]v_D = [(9542\text{ lb})/g]v_w\cos(39°)$

$p_y = [(3042\text{ lb})/g](50\text{ mph}) = [(9542\text{ lb})/g]v_w\sin(39°)$

Solving for v_D gives v_D = 28.9 mph, which rounds to 29 mph.

(b) The above equations also give that the velocity of the wreckage just after impact is 25.3 mph = 37.1 ft/s. Using $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$, we have $\frac{1}{2}mv_1^2 - \mu_k mgd = \frac{1}{2}mv_2^2$. Solving for v_2 gives

$v_2 = \sqrt{v_1^2 - 2\mu_k gd}$. Using v_1 = 37.1 ft/s, g = 32.2 ft/s^2 and d = 35 ft, we get v_2 = 19.1 ft/s = 13 mph.

EVALUATE: We were able to minimize unit conversions by working in British units instead of SI units since the data was given in British units.

8.103. **IDENTIFY:** From our analysis of motion with constant acceleration, if $v = at$ and a is constant, then $x - x_0 = v_0 t + \frac{1}{2}at^2$.

SET UP: Take $v_0 = 0$, $x_0 = 0$ and let $+x$ downward.

EXECUTE: **(a)** $\frac{dv}{dt} = a$, $v = at$ and $x = \frac{1}{2}at^2$. Substituting into $xg = x\frac{dv}{dt} + v^2$ gives

$\frac{1}{2}at^2 g = \frac{1}{2}at^2 a + a^2t^2 = \frac{3}{2}a^2t^2$. The nonzero solution is $a = g/3$.

(b) $x = \frac{1}{2}at^2 = \frac{1}{6}gt^2 = \frac{1}{6}(9.80\text{ m/s}^2)(3.00\text{ s})^2 = 14.7$ m.

(c) $m = kx = (2.00\text{ g/m})(14.7\text{ m}) = 29.4$ g.

EVALUATE: The acceleration is less than g because the small water droplets are initially at rest, before they adhere to the falling drop. The small droplets are suspended by buoyant forces that we ignore for the raindrops.

8.104. **IDENTIFY** and **SET UP:** $dm = \rho dV$. $dV = Adx$. Since the thin rod lies along the x-axis, $y_{\text{cm}} = 0$. The mass of the rod is given by $M = \int dm$.

EXECUTE: **(a)** $x_{\text{cm}} = \dfrac{1}{M}\int_0^L x dm = \dfrac{\rho}{M} A\int_0^L x dx = \dfrac{\rho A}{M}\dfrac{L^2}{2}$. The volume of the rod is AL and $M = \rho AL$.

$x_{\text{cm}} = \dfrac{\rho AL^2}{2\rho AL} = \dfrac{L}{2}$. The center of mass of the uniform rod is at its geometrical center, midway between its ends.

(b) $x_{\text{cm}} = \dfrac{1}{M}\int_0^L x dm = \dfrac{1}{M}\int_0^L x\rho A dx = \dfrac{A\alpha}{M}\int_0^L x^2 dx = \dfrac{A\alpha L^3}{3M}$. $M = \int dm = \int_0^L \rho A dx = \alpha A\int_0^L x dx = \dfrac{\alpha AL^2}{2}$.

Therefore, $x_{\text{cm}} = \left(\dfrac{A\alpha L^3}{3}\right)\left(\dfrac{2}{\alpha AL^2}\right) = \dfrac{2L}{3}$.

EVALUATE: When the density increases with x, the center of mass is to the right of the center of the rod.

8.105. **IDENTIFY:** $x_{\text{cm}} = \dfrac{1}{M}\int x dm$ and $y_{\text{cm}} = \dfrac{1}{M}\int y dm$. At the upper surface of the plate, $y^2 + x^2 = a^2$.

SET UP: To find x_{cm}, divide the plate into thin strips parallel to the y-axis, as shown in Figure 8.105a. To find y_{cm}, divide the plate into thin strips parallel to the x-axis as shown in Figure 8.105b. The plate has volume one-half that of a circular disk, so $V = \frac{1}{2}\pi a^2 t$ and $M = \frac{1}{2}\rho\pi a^2 t$.

EXECUTE: In Figure 8.105a each strip has length $y = \sqrt{a^2 - x^2}$. $x_{\text{cm}} = \dfrac{1}{M}\int x dm$, where

$dm = \rho t y dx = \rho t\sqrt{a^2 - x^2}\, dx$. $x_{\text{cm}} = \dfrac{\rho t}{M}\int_{-a}^{a} x\sqrt{a^2 - x^2}\, dx = 0$, since the integrand is an odd function of x.

$x_{\text{cm}} = 0$ because of symmetry. In Figure 8.105b each strip has length $2x = 2\sqrt{a^2 - y^2}$. $y_{\text{cm}} = \dfrac{1}{M}\int y dm$,

where $dm = 2\rho t x dy = 2\rho t\sqrt{a^2 - y^2}\, dy$. $y_{\text{cm}} = \dfrac{2\rho t}{M}\int_{-a}^{a} y\sqrt{a^2 - y^2}\, dy$. The integral can be evaluated using

$u = a^2 - y^2$, $du = -2y dy$. This substitution gives

$$y_{\text{cm}} = \frac{2\rho t}{M}\left(-\frac{1}{2}\right)\int_{a^2}^{0} u^{1/2} du = \frac{2\rho t a^3}{3M} = \left(\frac{2\rho t a^3}{3}\right)\left(\frac{2}{\rho\pi a^2 t}\right) = \frac{4a}{3\pi}.$$

EVALUATE: $\dfrac{4}{3\pi} = 0.424$. y_{cm} is less than $a/2$, as expected, since the plate becomes wider as y decreases.

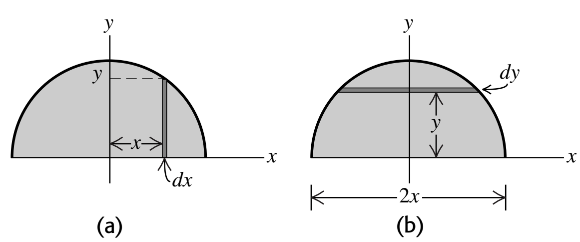

Figure 8.105

8.106. **IDENTIFY** and **SET UP:** $p = mv$.
EXECUTE: $p = mv = (0.30 \times 10^{-3}\text{ kg})(2.5\text{ m/s}) = 7.5 \times 10^{-4}\text{ kg}\cdot\text{m/s}$, which makes choice (a) correct.

EVALUATE: This is a small amount of momentum for a speed of 2.5 m/s, but the water drop is very light.

8.107. **IDENTIFY** and **SET UP:** Momentum is conserved, $p = mv$.
EXECUTE: $(65 \times 10^{-3}\text{ kg})v_{\text{fish}} = 7.5 \times 10^{-4}\text{ kg}\cdot\text{m/s}$, so $v_{\text{fish}} = 0.012$ m/s, which makes choice (b) correct.
EVALUATE: The fish is much ligher than the water drop and thus moves much slower.

8.108. **IDENTIFY** and **SET UP:** $J = F_{\text{av}}t = \Delta p$.
EXECUTE: $F_{\text{av}} = \Delta p/t = (7.5\times10^{-4}\text{ kg}\cdot\text{m/s})/(0.0050\text{ s}) = 0.15\text{ N}$, which is choice (d).

EVALUATE: This is a rather small force, but it acts on a very light-weight water drop, so it can give the water considerable speed.

8.109. **IDENTIFY** and **SET UP:** Momentum is conserved in the collision with the insect. $p = mv$.
EXECUTE: Using $P_1 = P_2$ gives $7.5 \times 10^{-4}\text{ kg}\cdot\text{m/s} = (m_{\text{insect}} + 3.0 \times 10^{-4}\text{ kg})(2.0\text{ m/s})$, which gives $m_{\text{insect}} = 0.075$ g, so choice (b) is correct.
EVALUATE: The insect has considerably less mass than the water drop.

9

ROTATION OF RIGID BODIES

VP9.3.1. **IDENTIFY:** We are dealing with angular motion having constant angular acceleration, so the constant angular acceleration formulas apply.

SET UP: A $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$

EXECUTE: **(a)** (3.25 rad/s)^2 = (0.500 rad/s)^2 + 2(2.50 rad/s^2) $(\theta - \theta_0)$ $\rightarrow$ $\theta - \theta_0$ = 2.06 rad.

(b) Convert using π rad = 180°: 2.06 rad $\left(\dfrac{180°}{\pi\text{ rad}}\right)$ = 118°.

(c) Convert using 1 rev = 2π rad: 2.06 rad $\left(\dfrac{1\text{ rev}}{2\pi\text{ rad}}\right)$ = 0.328 rev.

EVALUATE: The conversion factors in (b) and (c) are very useful to remember.

VP9.3.2. **IDENTIFY:** The constant angular acceleration formulas apply.

SET UP: $\theta - \theta_0 = \omega_{0z}t + \frac{1}{2}\alpha_z t^2$ applies.

EXECUTE: **(a)** Use $\theta - \theta_0 = \omega_{0z}t + \frac{1}{2}\alpha_z t^2$ to find α_z .

8.00 rad = (1.25 rad/s)(2.00 s) + $\frac{1}{2}$ α_z (2.00 s)^2 $\rightarrow$ α_z = 2.75 rad/s^2.

(b) Now use $\theta - \theta_0 = \omega_{0z}t + \frac{1}{2}\alpha_z t^2$ again to find $\theta - \theta_0$.

$\theta - \theta_0$ = (1.25 rad/s)(4.00 s) + $\frac{1}{2}$(2.75 rad/s^2)(4.00 s)^2 = 27.0 rad.

EVALUATE: During the first 2.00 s the rotor turned through 8.00 rad and during the first 4.00 s it turned through 27.0 rad. This means that during the *second* 2.00 s it turned through 19.0 rad, which is considerably more than 8.00 rad. The difference shows us that the rotor is speeding up due to angular acceleration, so it turns much farther during the second 2.00 s than during the first 2.00 s.

VP9.3.3. **IDENTIFY:** The constant angular acceleration formulas apply.

SET UP: We need α_z to find the time to slow down from 185 rad/s to 105 rad/s, so we use $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$ and $\omega_z = \omega_{0z} + \alpha_z t$.

EXECUTE: First convert 16.0 rev to rad: 16.0 rev = (16.0)(2π) rad.

Now use $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$ to find α_z .

(105 rad/s)^2 = (185 rad/s)^2 + 2 α_z (16.0)(2π rad) $\rightarrow$ α_z = –115. 4 rad/s^2.

Now use $\omega_z = \omega_{0z} + \alpha_z t$ to find the time for the wheel to slow down.

105 rad/s = 185 rad/s + (–115.4 rad/s^2)t $\rightarrow$ t = 0.693 s.

EVALUATE: The minus sign for α_z means that it is in the opposite angular direction from ω_z. This is reasonable because the wheel is slowing down. If α_z and ω_z were in the same direction, the wheel would be increasing its angular speed.

VP9.3.4. **IDENTIFY:** The constant angular acceleration formulas apply.

SET UP: We need the time to turn through a given angle θ, so we use $\theta - \theta_0 = \omega_{0z}t + \frac{1}{2}\alpha_z t^2$.

EXECUTE: The angular displacement is θ, so we use $\theta = \omega_{0z}t + \frac{1}{2}\alpha_z t^2$ and solve for *t*. Using the quadratic formula gives $t = \dfrac{-\omega_{0z} + \sqrt{\omega_{0z}^2 + 2\alpha_z\theta}}{\alpha_z}$.

EVALUATE: We used the positive square root because the time *t* should be positive.

VP9.5.1. **IDENTIFY:** We need to relate angular quantities to linear quantities.

SET UP: $a_{\tan} = r\alpha$, $a_{\text{rad}} = \omega^2 r$, and $a = \sqrt{a_{\tan}^2 + a_{\text{rad}}^2}$ all apply.

EXECUTE: **(a)** $a_{\tan} = r\alpha = (0.152\text{ m})(8.00\text{ rad/s}) = 1.22\text{ m/s}^2$.

(b) $a_{\text{rad}} = \omega^2 r = (1.60\text{ rad/s})^2(0.152\text{ m}) = 0.389\text{ m/s}^2$.

(c) $a = \sqrt{a_{\tan}^2 + a_{\text{rad}}^2} = \sqrt{(0.122\text{ m/s}^2)^2 + (0.399\text{ m/s}^2)^2} = 1.28\text{ m/s}^2$.

EVALUATE: Careful! In order to use the formulas $a_{\tan} = r\alpha$ and $a_{\text{rad}} = \omega^2 r$, the angular quantities *must* be in *radian* measure. If they are in revolutions or degrees, you must convert them to radians before using these formulas.

VP9.5.2. **IDENTIFY:** We need to relate angular quantities to linear quantities.

SET UP: $v_{\tan} = r\omega$, $a_{\tan} = r\alpha$, and $a_{\text{rad}} = \omega^2 r$ apply. The magnitude *A* of a vector is $A = \sqrt{A_x^2 + A_y^2}$.

EXECUTE: **(a)** The end of the hammer has two components to its velocity: a horizontal component due to its rotation and the vertical component of 2.00 m/s. The horizontal component is its tangential speed: $v_{\tan} = r\omega = (1.50\text{ m})(6.00\text{ rad/s}) = 9.00\text{ m/s}$. Its speed *v* is

$v = \sqrt{v_{\tan}^2 + v_y^2} = \sqrt{(9.00\text{ m/s})^2 + (2.00\text{ m/s})^2} = 9.22\text{ m/s}$.

(b) $a_{\tan} = 0$ and $a_y = 0$. $a_{\text{rad}} = \omega^2 r = (6.00\text{ rad/s})^2(1.50\text{ m}) = 54.0\text{ m/s}^2$. The direction is toward the center of the circular path of the end of the hammer.

EVALUATE: The end of the hammer has a very large acceleration, so it must take a large force to give it this acceleration.

VP9.5.3. **IDENTIFY:** We want to relate angular quantities to linear quantities.

SET UP: $a_{\tan} = r\alpha$, $a_{\text{rad}} = \omega^2 r$, and $a = \sqrt{a_{\tan}^2 + a_{\text{rad}}^2}$ apply.

EXECUTE: The maximum acceleration of the blade tip is $a_{\max}$. We need to relate this to ω.

$a_{\max} = \sqrt{a_{\tan}^2 + a_{\text{rad}}^2} = \sqrt{\left(\omega^2 r\right)^2 + (r\alpha)^2} = r\sqrt{\omega^4 + \alpha^2}$. Squaring and solving for sa ω gives

$$\omega = \left(\frac{a_{\max}^2}{r^2} - \alpha^2\right)^{1/4}.$$

EVALUATE: Our result says that the smaller $a_{\max}$, the smaller ω can be. This is reasonable because it is the fast spin that causes a large acceleration of the tip.

VP9.5.4. **IDENTIFY:** We want to relate angular quantities to linear quantities.

SET UP: $a_{\tan} = r\alpha$ and $a_{\text{rad}} = \omega^2 r$ apply. The angle between the acceleration vector and the velocity vector is 30°. The velocity vector is tangent to the circular path, so the angle between the acceleration vector and the tangent is also 30°. This tells us that tan 30° = $a_{\text{rad}}/a_{\tan}$. (See Fig. VP9.5.4.)

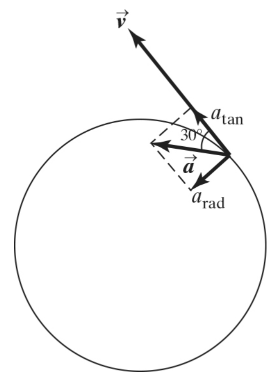

Figure VP9.5.4

EXECUTE: **(a)** $\tan 30° = \dfrac{a_{\text{rad}}}{a_{\tan}} = \dfrac{\omega^2 R}{R\alpha} = \dfrac{\omega^2}{\alpha} \quad \rightarrow \quad \dfrac{1}{\sqrt{3}} = \dfrac{\omega^2}{\alpha} \quad \rightarrow \quad \alpha = \omega^2\sqrt{3}$.

(b) This point is $R/2$ from the center of the circle. Using our work in (a) and using θ for the unknown angle, we see that $\tan\theta = \dfrac{a_{\text{rad}}}{a_{\tan}} = \dfrac{\omega^2 R/2}{(R/2)\alpha} = \dfrac{\omega^2}{\alpha}$. The result is independent of R, so the angle is 30° as before.

EVALUATE: Careful! In our analysis we cannot say that tan 30° = a/v because a and v have different units. This would give tan 30° units of s^{-1}, which is not possible because the $\tan\theta$ is always dimensionless.

VP9.8.1. **IDENTIFY:** We are dealing with the rotation of a solid object having rotational kinetic energy. Work is done on it, so we can apply the work-energy theorem.

SET UP: $K = \dfrac{1}{2}I\omega^2$ for a rotating object, $I = \dfrac{1}{12}M\left(a^2 + b^2\right)$ for a rectangular plate, and the work-energy theorem is $W = K_2 - K_1$.

EXECUTE: **(a)** We want to find the work to change the angular speed.

$W = K_2 = \dfrac{1}{2}I\omega^2 = \dfrac{1}{2}\left[\dfrac{1}{12}M\left(a^2 + b^2\right)\right]\omega^2$. In this case, $a = b = 0.150$ m, so the equation reduces to $W = \dfrac{1}{12}Ma^2\omega^2 = \dfrac{1}{12}(0.600\text{ kg})(0.150\text{ m})^2(40.0\text{ rad/s})^2 = 1.80$ J.

(b) $W = K_2 - K_1 = \dfrac{1}{12}Ma^2\left(\omega_2^2 - \omega_1^2\right) = \dfrac{1}{12}(0.600\text{ kg})(0.150\text{ m})^2[(80.0\text{ rad/s})^2 - (40.0\text{ rad/s})^2]$.

$W = 5.4$ J.

EVALUATE: Notice that in both cases, we changed the angular speed by 40.0 rad/s, yet the work required to do this was different. This is because the kinetic energy depends on the *square* of ω. Also note that in all of these formulas relating linear and rotational quantities, the angular measure must always be in terms of *radians*.

VP9.8.2. **IDENTIFY:** We are dealing with the rotation of a solid object having rotational kinetic energy. Work is done on it, so we can apply the work-energy theorem.

SET UP: $K = \frac{1}{2}I\omega^2$ for a rotating object, $I = \frac{1}{2}MR^2$ for a solid cylinder, and the work-energy theorem is $W = K_2 - K_1$.

EXECUTE: **(a)** We know the work and want to find the final angular velocity if $\omega_1 = 0$.

$$W = K_2 - K_1 = \frac{1}{2}I\omega^2 = \frac{1}{2}\left[\frac{1}{2}MR^2\right]\omega^2 \quad \rightarrow \quad \omega = \sqrt{\frac{4(75.0\text{ J})}{(12.0\text{ kg})(0.250\text{ m})^2}} = 20.0\text{ rad/s}.$$

(b) We follow exactly the same procedure except that $K_1 = \frac{1}{2}I\omega_1^2 \neq 0$. This gives

$W = K_2 - K_1 = \frac{1}{2}I\left(\omega_2^2 - \omega_1^2\right) = \frac{1}{2}\left[\frac{1}{2}MR^2\right]\left(\omega_2^2 - \omega_1^2\right)$. Solving for ω_2 and using the same numbers as in (a) except $\omega_1 = 12.0$ rad/s, we get $\omega_2 = 23.2$ rad/s.

EVALUATE: In both cases, 75.0 J of work was done on the cylinder. When starting from rest, the angular velocity increased by 20.0 rad/s, but when starting from 12.0 rad/s, it increased by only 11.2 rad/s (23.2 rad/s – 12.0 rad/s). The kinetic energy increased by the same amount (75.0 J) in both cases, but the increase in the angular velocity was different.

VP9.8.3. **IDENTIFY:** We are dealing with the rotation of a cylinder that is connected to a piece of cheese. As the cheese falls, it causes the cylinder to turn. Work is done on the system by gravity, so we can apply energy conservation. The kinetic energy of the cheese is due to its linear motion and that of the cylinder is due to its rotation.

SET UP: $K = \frac{1}{2}I\omega^2$ for a rotating object and $K = \frac{1}{2}mv^2$ for a moving object. For a hollow cylinder $I = \frac{1}{2}M\left(R_1^2 + R_2^2\right)$ and energy conservation is $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$. Measure y from the floor level, so $U_2 = 0$ and $U_1 = mgy_1 = mgh$. There is no friction, so $W_{\text{other}} = 0$, and $K_1 = 0$. The speed v of the cheese is $v = v_{\text{tan}} = r\omega$, so $\omega = v/R_2$. Call m the mass of the cheese and M the mass of the cylinder.

EXECUTE: **(a)** We want to find h. Energy conservation gives $mgh = \frac{1}{2}I\omega^2 + \frac{1}{2}mv^2$. Putting in the expressions for I and ω and solving for h, we get $h = \dfrac{\frac{M}{4}\left(R_1^2 + R_2^2\right)\left(\frac{v}{R_2}\right)^2 + \frac{1}{2}mv^2}{mg}$. Using $m = 0.500$ kg, $M = 2.00$ kg, $R_1 = 0.100$ m, $R_2 = 0.200$ m, and $v = 4.00$ m/s, we get $h = 2.86$ m.

(b) $\omega = v_{\text{tan}}/R_2 = v/R_2 = (4.00\text{ m/s})/(0.200\text{ m}) = 20.0$ rad/s.

EVALUATE: Checking for the proper units in the equation for h is a good way to spot algebraic errors in the solution.

VP9.8.4. **IDENTIFY:** We are dealing with the rotation of a cylinder that is connected to a textbook. As the book falls, it causes the cylinder to turn. Work is done on the system by gravity and by friction at the shaft of the cylinder, so we can apply energy conservation. The kinetic energy of the book is due to its linear motion and that of the cylinder is due to its rotation.

SET UP: $K = \frac{1}{2}I\omega^2$ for a rotating object and $K = \frac{1}{2}mv^2$ for a moving object. For a solid cylinder $I = \frac{1}{2}MR^2$ and energy conservation is $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$, where $K_1 = 0$. Measure y from the floor level, so $U_2 = 0$ and $U_1 = mgh$. The speed v of the textbook is $v = v_{\text{tan}} = R\omega$. Call m the mass of the book and M the mass of the cylinder.

EXECUTE: **(a)** $v = v_{\text{tan}} = R\omega = (0.240\text{ m})(10.0\text{ rad/s}) = 2.40$ m/s.

(b) From $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$ we get $mgh + W_{\text{f}} = \frac{1}{2}I\omega^2 + \frac{1}{2}mv^2$. Solving for W_{f} using the expressions for v and I gives $W_{\text{f}} = \frac{1}{2}\left(m + \frac{M}{2}\right)(R\omega)^2 - mgh$. Putting in m = 2.00 kg, M = 1.50 kg, R = 0.240 m, and ω = 10.0 rad/s gives $W_{\text{f}} = -9.72$ J.

EVALUATE: Friction does negative work, which is reasonable because it opposes the turning motion at the axle of the cylinder.

9.1. **IDENTIFY:** $s = r\theta,$ with θ in radians.

SET UP: $\pi \text{ rad} = 180°.$

EXECUTE: **(a)** $\theta = \dfrac{s}{r} = \dfrac{1.50 \text{ m}}{2.50 \text{ m}} = 0.600 \text{ rad} = 34.4°$

(b) $r = \dfrac{s}{\theta} = \dfrac{14.0 \text{ cm}}{(128°)(\pi \text{ rad}/180°)} = 6.27 \text{ cm}$

(c) $s = r\theta = (1.50 \text{ m})(0.700 \text{ rad}) = 1.05 \text{ m}$

EVALUATE: An angle is the ratio of two lengths and is dimensionless. But, when $s = r\theta$ is used, θ must be in radians. Or, if $\theta = s/r$ is used to calculate $\theta,$ the calculation gives θ in radians.

9.2. **IDENTIFY:** $\theta - \theta_0 = \omega t,$ since the angular velocity is constant.

SET UP: $1 \text{ rpm} = (2\pi/60) \text{ rad/s}.$

EXECUTE: **(a)** $\omega = (1900)(2\pi \text{ rad}/60 \text{ s}) = 199 \text{ rad/s}$

(b) $35° = (35°)(\pi/180°) = 0.611 \text{ rad}.$ $t = \dfrac{\theta - \theta_0}{\omega} = \dfrac{0.611 \text{ rad}}{199 \text{ rad/s}} = 3.1\times10^{-3} \text{ s}$

EVALUATE: In $t = \dfrac{\theta - \theta_0}{\omega}$ we must use the same angular measure (radians, degrees or revolutions) for both $\theta - \theta_0$ and $\omega.$

9.3. **IDENTIFY:** $\alpha_z(t) = \dfrac{d\omega_z}{dt}.$ Using $\omega_z = d\theta/dt$ gives $\theta - \theta_0 = \int_{t_1}^{t_2} \omega_z dt.$

SET UP: $\dfrac{d}{dt}t^n = nt^{n-1}$ and $\int t^n dt = \dfrac{1}{n+1}t^{n+1}$

EXECUTE: **(a)** A must have units of rad/s and B must have units of $\text{rad/s}^3.$

(b) $\alpha_z(t) = 2Bt = (3.00 \text{ rad/s}^3)t.$ (i) For $t = 0,$ $\alpha_z = 0.$ (ii) For $t = 5.00$ s, $\alpha_z = 15.0 \text{ rad/s}^2.$

(c) $\theta_2 - \theta_1 = \int_{t_1}^{t_2} (A + Bt^2)dt = A(t_2 - t_1) + \frac{1}{3}B(t_2^3 - t_1^3).$ For $t_1 = 0$ and $t_2 = 2.00$ s,

$\theta_2 - \theta_1 = (2.75 \text{ rad/s})(2.00 \text{ s}) + \frac{1}{3}(1.50 \text{ rad/s}^3)(2.00 \text{ s})^3 = 9.50 \text{ rad}.$

EVALUATE: Both α_z and ω_z are positive and the angular speed is increasing.

9.4. **IDENTIFY:** $\alpha_z = d\omega_z/dt.$ $\alpha_{\text{av-}z} = \dfrac{\Delta\omega_z}{\Delta t}.$

SET UP: $\dfrac{d}{dt}(t^2) = 2t$

EXECUTE: **(a)** $\alpha_z(t) = \dfrac{d\omega_z}{dt} = -2\beta t = (-1.60 \text{ rad/s}^3)t.$

(b) $\alpha_z(3.0 \text{ s}) = (-1.60 \text{ rad/s}^3)(3.0 \text{ s}) = -4.80 \text{ rad/s}^2.$

$$\alpha_{\text{av-}z} = \frac{\omega_z(3.0 \text{ s}) - \omega_z(0)}{3.0 \text{ s}} = \frac{-2.20 \text{ rad/s} - 5.00 \text{ rad/s}}{3.0 \text{ s}} = -2.40 \text{ rad/s}^2,$$

which is half as large (in magnitude) as the acceleration at $t = 3.0$ s.

EVALUATE: $\alpha_z(t)$ increases linearly with time, so $\alpha_{\text{av-}z} = \dfrac{\alpha_z(0) + \alpha_z(3.0\text{ s})}{2}$. $\alpha_z(0) = 0$.

9.5. **IDENTIFY** and **SET UP:** Use $\omega_z = \dfrac{d\theta}{dt}$ to calculate the angular velocity and $\omega_{\text{av-}z} = \dfrac{\Delta\theta}{\Delta t} = \dfrac{\theta_2 - \theta_1}{t_2 - t_1}$ to calculate the average angular velocity for the specified time interval.

EXECUTE: $\theta = \gamma t + \beta t^3$; $\gamma = 0.400$ rad/s, $\beta = 0.0120\text{ rad/s}^3$

(a) $\omega_z = \dfrac{d\theta}{dt} = \gamma + 3\beta t^2$

(b) At $t = 0$, $\omega_z = \gamma = 0.400$ rad/s

(c) At $t = 5.00$ s, $\omega_z = 0.400\text{ rad/s} + 3(0.0120\text{ rad/s}^3)(5.00\text{ s})^2 = 1.30$ rad/s

$$\omega_{\text{av-}z} = \frac{\Delta\theta}{\Delta t} = \frac{\theta_2 - \theta_1}{t_2 - t_1}$$

For $t_1 = 0$, $\theta_1 = 0$.

For $t_2 = 5.00$ s, $\theta_2 = (0.400\text{ rad/s})(5.00\text{ s}) + (0.012\text{ rad/s}^3)(5.00\text{ s})^3 = 3.50$ rad

So $\omega_{\text{av-}z} = \dfrac{3.50\text{ rad} - 0}{5.00\text{ s} - 0} = 0.700$ rad/s.

EVALUATE: The average of the instantaneous angular velocities at the beginning and end of the time interval is $\frac{1}{2}(0.400\text{ rad/s} + 1.30\text{ rad/s}) = 0.850$ rad/s. This is larger than $\omega_{\text{av-}z}$, because $\omega_z(t)$ is increasing faster than linearly.

9.6. **IDENTIFY:** $\omega_z(t) = \dfrac{d\theta}{dt}$. $\alpha_z(t) = \dfrac{d\omega_z}{dt}$. $\omega_{\text{av}-z} = \dfrac{\Delta\theta}{\Delta t}$.

SET UP: $\omega_z = (250\text{ rad/s}) - (40.0\text{ rad/s}^2)t - (4.50\text{ rad/s}^3)t^2$. $\alpha_z = -(40.0\text{ rad/s}^2) - (9.00\text{ rad/s}^3)t$.

EXECUTE: **(a)** Setting $\omega_z = 0$ results in a quadratic in *t*. The only positive root is $t = 4.23$ s.

(b) At $t = 4.23$ s, $\alpha_z = -78.1\text{ rad/s}^2$.

(c) At $t = 4.23$ s, $\theta = 586\text{ rad} = 93.3$ rev.

(d) At $t = 0$, $\omega_z = 250$ rad/s.

(e) $\omega_{\text{av-}z} = \dfrac{586\text{ rad}}{4.23\text{ s}} = 138$ rad/s.

EVALUATE: Between $t = 0$ and $t = 4.23$ s, ω_z decreases from 250 rad/s to zero. ω_z is not linear in *t*, so $\omega_{\text{av-}z}$ is not midway between the values of ω_z at the beginning and end of the interval.

9.7. **IDENTIFY:** $\omega_z(t) = \dfrac{d\theta}{dt}$. $\alpha_z(t) = \dfrac{d\omega_z}{dt}$. Use the values of θ and ω_z at $t = 0$ and α_z at 1.50 s to calculate *a*, *b*, and *c*.

SET UP: $\dfrac{d}{dt}t^n = nt^{n-1}$

EXECUTE: **(a)** $\omega_z(t) = b - 3ct^2$. $\alpha_z(t) = -6ct$. At $t = 0$, $\theta = a = \pi/4$ rad and $\omega_z = b = 2.00$ rad/s. At $t = 1.50$ s, $\alpha_z = -6c(1.50\text{ s}) = 1.25\text{ rad/s}^2$ and $c = -0.139\text{ rad/s}^3$.

(b) $\theta = \pi/4$ rad and $\alpha_z = 0$ at $t = 0$.

(c) $\alpha_z = 3.50\text{ rad/s}^2$ at $t = -\dfrac{\alpha_z}{6c} = -\dfrac{3.50\text{ rad/s}^2}{6(-0.139\text{ rad/s}^3)} = 4.20$ s. At $t = 4.20$ s,

$$\theta = \frac{\pi}{4}\text{ rad} + (2.00\text{ rad/s})(4.20\text{ s}) - (-0.139\text{ rad/s}^3)(4.20\text{ s})^3 = 19.5\text{ rad}.$$

$\omega_z = 2.00\ \text{rad/s} - 3(-0.139\ \text{rad/s}^3)(4.20\ \text{s})^2 = 9.36\ \text{rad/s}.$

EVALUATE: θ, ω_z, and α_z all increase as t increases.

9.8. IDENTIFY: $\alpha_z = \dfrac{d\omega_z}{dt}$. $\theta - \theta_0 = \omega_{\text{av-}z}t$. When ω_z is linear in t, $\omega_{\text{av-}z}$ for the time interval t_1 to t_2 is $\omega_{\text{av-}z} = \dfrac{\omega_{z1} + \omega_{z2}}{t_2 - t_1}$.

SET UP: From the information given, $\alpha_z = \dfrac{\Delta\omega}{\Delta t} = \dfrac{4.00\ \text{rad/s} - (-6.00\ \text{rad/s})}{7.00\ \text{s}} = 1.429\ \text{rad/s}^2$.

$\omega_z(t) = -6.00\ \text{rad/s} + (1.429\ \text{rad/s}^2)t.$

EXECUTE: **(a)** The angular acceleration is positive, since the angular velocity increases steadily from a negative value to a positive value.

(b) It takes time $t = -\dfrac{\omega_{0z}}{\alpha_z}$ = –(–6.00 rad/s)/(1.429 rad/s^2) = 4.20 s for the wheel to stop ($\omega_z = 0$). During this time its speed is decreasing. For the next 2.80 s its speed is increasing from 0 rad/s to +4.00 rad/s.

(c) The average angular velocity is $\dfrac{-6.00\ \text{rad/s} + 4.00\ \text{rad/s}}{2} = -1.00\ \text{rad/s}$. $\theta - \theta_0 = \omega_{\text{av-}z}t$ then leads to displacement of –7.00 rad after 7.00 s.

EVALUATE: When α_z and ω_z have the same sign, the angular speed is increasing; this is the case for $t = 4.20$ s to $t = 7.00$ s. When α_z and ω_z have opposite signs, the angular speed is decreasing; this is the case between $t = 0$ and $t = 4.20$ s.

9.9. IDENTIFY: Apply the constant angular acceleration equations.

SET UP: Let the direction the wheel is rotating be positive.

EXECUTE: **(a)** $\omega_z = \omega_{0z} + \alpha_z t = 1.50\ \text{rad/s} + (0.200\ \text{rad/s}^2)(2.50\ \text{s}) = 2.00\ \text{rad/s}.$

(b) $\theta - \theta_0 = \omega_{0z}t + \frac{1}{2}\alpha_z t^2 = (1.50\ \text{rad/s})(2.50\ \text{s}) + \frac{1}{2}(0.200\ \text{rad/s}^2)(2.50\ \text{s})^2 = 4.38\ \text{rad}.$

EVALUATE: $\theta - \theta_0 = \left(\dfrac{\omega_{0z} + \omega_z}{2}\right)t = \left(\dfrac{1.50\ \text{rad/s} + 2.00\ \text{rad/s}}{2}\right)(2.50\ \text{s}) = 4.38\ \text{rad}$, the same as calculated with another equation in part (b).

9.10. IDENTIFY: Apply the constant angular acceleration equations to the motion of the fan.

(a) SET UP: $\omega_{0z} = (500\ \text{rev/min})(1\ \text{min}/60\ \text{s}) = 8.333\ \text{rev/s}$,

$\omega_z = (200\ \text{rev/min})(1\ \text{min}/60\ \text{s}) = 3.333\ \text{rev/s}$, $t = 4.00$ s, $\alpha_z = ?$

$\omega_z = \omega_{0z} + \alpha_z t$

EXECUTE: $\alpha_z = \dfrac{\omega_z - \omega_{0z}}{t} = \dfrac{3.333\ \text{rev/s} - 8.333\ \text{rev/s}}{4.00\ \text{s}} = -1.25\ \text{rev/s}^2$

$\theta - \theta_0 = ?$

$\theta - \theta_0 = \omega_{0z}t + \frac{1}{2}\alpha_z t^2 = (8.333\ \text{rev/s})(4.00\ \text{s}) + \frac{1}{2}(-1.25\ \text{rev/s}^2)(4.00\ \text{s})^2 = 23.3\ \text{rev}$

(b) SET UP: $\omega_z = 0$ (comes to rest); $\omega_{0z} = 3.333\ \text{rev/s}$; $\alpha_z = -1.25\ \text{rev/s}^2$; $t = ?$

$\omega_z = \omega_{0z} + \alpha_z t$

EXECUTE: $t = \dfrac{\omega_z - \omega_{0z}}{\alpha_z} = \dfrac{0 - 3.333\ \text{rev/s}}{-1.25\ \text{rev/s}^2} = 2.67\ \text{s}$

EVALUATE: The angular acceleration is negative because the angular velocity is decreasing. The average angular velocity during the 4.00 s time interval is 350 rev/min and $\theta - \theta_0 = \omega_{\text{av-}z} t$ gives $\theta - \theta_0 = 23.3\ \text{rev},$ which checks.

9.11. **IDENTIFY:** Apply the constant angular acceleration equations to the motion. The target variables are t and $\theta - \theta_0$.

SET UP: **(a)** $\alpha_z = 1.50\ \text{rad/s}^2$; $\omega_{0z} = 0$ (starts from rest); $\omega_z = 36.0\ \text{rad/s}$; $t = ?$

$\omega_z = \omega_{0z} + \alpha_z t$

EXECUTE: $t = \dfrac{\omega_z - \omega_{0z}}{\alpha_z} = \dfrac{36.0\ \text{rad/s} - 0}{1.50\ \text{rad/s}^2} = 24.0\ \text{s}$

(b) $\theta - \theta_0 = ?$

$\theta - \theta_0 = \omega_{0z} t + \frac{1}{2}\alpha_z t^2 = 0 + \frac{1}{2}(1.50\ \text{rad/s}^2)(24.0\ \text{s})^2 = 432\ \text{rad}$

$\theta - \theta_0 = 432\ \text{rad}(1\ \text{rev}/2\pi\ \text{rad}) = 68.8\ \text{rev}$

EVALUATE: We could use $\theta - \theta_0 = \frac{1}{2}(\omega_z + \omega_{0z})t$ to calculate

$\theta - \theta_0 = \frac{1}{2}(0 + 36.0\ \text{rad/s})(24.0\ \text{s}) = 432\ \text{rad},$ which checks.

9.12. **IDENTIFY:** We use the constant-angular acceleration equations.

SET UP: $\theta - \theta_0 = \omega_{0z} t + \dfrac{1}{2}\alpha_z t^2$. The target variable is the angle the wheel turns through.

EXECUTE: First us $\theta - \theta_0 = \omega_{0z} t + \dfrac{1}{2}\alpha_z t^2$ to find α_z : 8.00 rev = $\dfrac{1}{2}$ α_z $(2.50\ \text{s})^2$, which gives α_z = $2.56\ \text{rev/s}^2$. Now use the same formula to find $\theta - \theta_0$ during the first 7.50 s. This gives $\theta - \theta_0 = \dfrac{1}{2}\alpha_z t^2$ $= \dfrac{1}{2}(2.56\ \text{rev/s}^2)(7.50\ \text{s})^2$ = 72.0 rev. The wheel turned through 72.0 rev during the first 5.00 s and 8.00 rev during the first 2.50 s, so during the second 5.00 s it turned through an angle of 72.0 rev – 8.00 rev = 64.0 rev.

EVALUATE: It turned through a greater angle during the next 5.00 s because the time was longer and because it was turning faster than during the first 2.50 s.

9.13. **IDENTIFY:** Use a constant angular acceleration equation and solve for ω_{0z}.

SET UP: Let the direction of rotation of the flywheel be positive.

EXECUTE: $\theta - \theta_0 = \omega_{0z} t + \frac{1}{2}\alpha_z t^2$ gives

$\omega_{0z} = \dfrac{\theta - \theta_0}{t} - \frac{1}{2}\alpha_z\, t = \dfrac{30.0\ \text{rad}}{4.00\ \text{s}} - \frac{1}{2}(2.25\ \text{rad/s}^2)(4.00\ \text{s}) = 3.00\ \text{rad/s}.$

EVALUATE: At the end of the 4.00 s interval, $\omega_z = \omega_{0z} + \alpha_z t = 12.0\ \text{rad/s}.$

$\theta - \theta_0 = \left(\dfrac{\omega_{0z} + \omega_z}{2}\right)t = \left(\dfrac{3.00\ \text{rad/s} + 12.0\ \text{rad/s}}{2}\right)(4.00\ \text{s}) = 30.0\ \text{rad},$ which checks.

9.14. **IDENTIFY:** Apply the constant angular acceleration equations.

SET UP: Let the direction of the rotation of the blade be positive. $\omega_{0z} = 0.$

EXECUTE: $\omega_z = \omega_{0z} + \alpha_z t$ gives $\alpha_z = \dfrac{\omega_z - \omega_{0z}}{t} = \dfrac{140\ \text{rad/s} - 0}{6.00\ \text{s}} = 23.3\ \text{rad/s}^2.$

$(\theta - \theta_0) = \left(\dfrac{\omega_{0z} + \omega_z}{2}\right)t = \left(\dfrac{0 + 140\ \text{rad/s}}{2}\right)(6.00\ \text{s}) = 420\ \text{rad}.$

EVALUATE: We could also use $\theta-\theta_0=\omega_{0z}t+\frac{1}{2}\alpha_z t^2$. This equation gives $\theta-\theta_0=\frac{1}{2}(23.3\text{ rad/s}^2)(6.00\text{ s})^2=419\text{ rad},$ in agreement with the result obtained above.

9.15. **IDENTIFY:** Apply constant angular acceleration equations.
SET UP: Let the direction the flywheel is rotating be positive.
$\theta-\theta_0=200\text{ rev}$, $\omega_{0z}=500\text{ rev/min}=8.333\text{ rev/s}$, $t=30.0\text{ s}$.

EXECUTE: **(a)** $\theta-\theta_0=\left(\dfrac{\omega_{0z}+\omega_z}{2}\right)t$ gives $\omega_z=5.00\text{ rev/s}=300\text{ rpm}$.

(b) Use the information in part (a) to find α_z: $\omega_z=\omega_{0z}+\alpha_z t$ gives $\alpha_z=-0.1111\text{ rev/s}^2$. Then $\omega_z=0$, $\alpha_z=-0.1111\text{ rev/s}^2$, $\omega_{0z}=8.333\text{ rev/s}$ in $\omega_z=\omega_{0z}+\alpha_z t$ gives $t=75.0\text{ s}$ and $\theta-\theta_0=\left(\dfrac{\omega_{0z}+\omega_z}{2}\right)t$ gives $\theta-\theta_0=312\text{ rev}$.

EVALUATE: The mass and diameter of the flywheel are not used in the calculation.

9.16. **IDENTIFY:** Apply the constant angular acceleration equations separately to the time intervals 0 to 2.00 s and 2.00 s until the wheel stops.
(a) SET UP: Consider the motion from $t=0$ to $t=2.00\text{ s}$:
$\theta-\theta_0=?$; $\omega_{0z}=24.0\text{ rad/s}$; $\alpha_z=30.0\text{ rad/s}^2$; $t=2.00\text{ s}$

EXECUTE: $\theta-\theta_0=\omega_{0z}t+\frac{1}{2}\alpha_z t^2=(24.0\text{ rad/s})(2.00\text{ s})+\frac{1}{2}(30.0\text{ rad/s}^2)(2.00\text{ s})^2$
$\theta-\theta_0=48.0\text{ rad}+60.0\text{ rad}=108\text{ rad}$
Total angular displacement from $t=0$ until stops: $108\text{ rad}+432\text{ rad}=540\text{ rad}$

Note: At $t=2.00\text{ s}$, $\omega_z=\omega_{0z}+\alpha_z t=24.0\text{ rad/s}+(30.0\text{ rad/s}^2)(2.00\text{ s})=84.0\text{ rad/s}$; angular speed when breaker trips.
(b) SET UP: Consider the motion from when the circuit breaker trips until the wheel stops. For this calculation let $t=0$ when the breaker trips.

$t=?$; $\theta-\theta_0=432\text{ rad}$; $\omega_z=0$; $\omega_{0z}=84.0\text{ rad/s}$ (from part (a)). Use $\theta-\theta_0=\left(\dfrac{\omega_{0z}+\omega_z}{2}\right)t$.

EXECUTE: $t=\dfrac{2(\theta-\theta_0)}{\omega_{0z}+\omega_z}=\dfrac{2(432\text{ rad})}{84.0\text{ rad/s}+0}=10.3\text{ s}$

The wheel stops 10.3 s after the breaker trips so $2.00\text{ s}+10.3\text{ s}=12.3\text{ s}$ from the beginning.
(c) SET UP: $\alpha_z=?$; consider the same motion as in part (b):
$\omega_z=\omega_{0z}+\alpha_z t$

EXECUTE: $\alpha_z=\dfrac{\omega_z-\omega_{0z}}{t}=\dfrac{0-84.0\text{ rad/s}}{10.3\text{ s}}=-8.16\text{ rad/s}^2$.

EVALUATE: The angular acceleration is positive while the wheel is speeding up and negative while it is slowing down. We could also use $\omega_z^2=\omega_{0z}^2+2\alpha_z(\theta-\theta_0)$ to calculate

$\alpha_z=\dfrac{\omega_z^2-\omega_{0z}^2}{2(\theta-\theta_0)}=\dfrac{0-(84.0\text{ rad/s})^2}{2(432\text{ rad})}=-8.16\text{ rad/s}^2$ for the acceleration after the breaker trips.

9.17. **IDENTIFY:** Apply $\omega_z^2=\omega_{z0}^2+2\alpha_z(\theta-\theta_0)$ to relate ω_z to $\theta-\theta_0$.
SET UP: Establish a proportionality.
EXECUTE: From $\omega_z^2=\omega_{z0}^2+2\alpha_z(\theta-\theta_0)$, with $\omega_{0z}=0$, the number of revolutions is proportional to the square of the initial angular velocity, so tripling the initial angular velocity increases the number of revolutions by 9, to 9.00 rev.

Evaluate: We don't have enough information to calculate α_z; all we need to know is that it is constant.

9.18. **Identify:** The linear distance the elevator travels, its speed and the magnitude of its acceleration are equal to the tangential displacement, speed and acceleration of a point on the rim of the disk. $s = r\theta$, $v = r\omega$ and $a = r\alpha$. In these equations the angular quantities must be in radians.

Set Up: 1 rev $= 2\pi$ rad. 1 rpm $= 0.1047$ rad/s. π rad $= 180°$. For the disk, $r = 1.25$ m.

Execute: **(a)** $v = 0.250$ m/s so $\omega = \dfrac{v}{r} = \dfrac{0.250\text{ m/s}}{1.25\text{ m}} = 0.200\text{ rad/s} = 1.91\text{ rpm}.$

(b) $a = \frac{1}{8}g = 1.225\text{ m/s}^2$. $\alpha = \dfrac{a}{r} = \dfrac{1.225\text{ m/s}^2}{1.25\text{ m}} = 0.980\text{ rad/s}^2.$

(c) $s = 3.25$ m. $\theta = \dfrac{s}{r} = \dfrac{3.25\text{ m}}{1.25\text{ m}} = 2.60\text{ rad} = 149°.$

Evaluate: When we use $s = r\theta$, $v = r\omega$ and $a_{\text{tan}} = r\alpha$ to solve for θ, ω and α, the results are in rad, rad/s, and rad/s^2.

9.19. **Identify:** We relate angular quantities to linear quantities.

Set Up: Estimate: Tub diameter ≈ 50 cm, so $r \approx 25$ cm. $v_{\text{tan}} = r\omega$ and $a_{\text{rad}} = \omega^2 r$.

Execute: **(a)** $a_{\text{rad}} = \omega^2 r = 3g$, so $\omega = \sqrt{\dfrac{3g}{r}} = \sqrt{\dfrac{3(9.80\text{ m/s}^2)}{0.25\text{ m}}} = 10.8$ rad/s, which rounds to 11 rad/s.

Now convert this result to rpm (rev/min). $\omega = \left(10.8\dfrac{\text{rad}}{\text{s}}\right)\left(\dfrac{60\text{ s}}{1\text{ min}}\right)\left(\dfrac{1\text{ rev}}{2\pi\text{ rad}}\right) \approx 100$ rev/min.

(b) $v_{\text{tan}} = r\omega = (0.25\text{ m})(10.8\text{ rad/s}) = 2.7\text{ m/s}.$

Evaluate: When using the formulas relating linear and angular quantities, the angular measures must *always* be in *radian* measure, such as rad/s or rad/s^2.

9.20. **Identify:** Linear and angular velocities are related by $v = r\omega$. Use $\omega_z = \omega_{0z} + \alpha_z t$ to calculate α_z.

Set Up: $\omega = v/r$ gives ω in rad/s.

Execute: **(a)** $\dfrac{1.25\text{ m/s}}{25.0\times10^{-3}\text{ m}} = 50.0\text{ rad/s}$, $\dfrac{1.25\text{ m/s}}{58.0\times10^{-3}\text{ m}} = 21.6\text{ rad/s}.$

(b) $(1.25\text{ m/s})(74.0\text{ min})(60\text{ s/min}) = 5.55\text{ km}.$

(c) $\alpha_z = \dfrac{21.55\text{ rad/s} - 50.0\text{ rad/s}}{(74.0\text{ min})(60\text{ s/min})} = -6.41\times10^{-3}\text{ rad/s}^2.$

Evaluate: The width of the tracks is very small, so the total track length on the disc is huge.

9.21. **Identify:** Use constant acceleration equations to calculate the angular velocity at the end of two revolutions. $v = r\omega$.

Set Up: 2 rev $= 4\pi$ rad. $r = 0.200$ m.

Execute: **(a)** $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$. $\omega_z = \sqrt{2\alpha_z(\theta - \theta_0)} = \sqrt{2(3.00\text{ rad/s}^2)(4\pi\text{ rad})} = 8.68\text{ rad/s}.$

$a_{\text{rad}} = r\omega^2 = (0.200\text{ m})(8.68\text{ rad/s})^2 = 15.1\text{ m/s}^2.$

(b) $v = r\omega = (0.200\text{ m})(8.68\text{ rad/s}) = 1.74\text{ m/s}$. $a_{\text{rad}} = \dfrac{v^2}{r} = \dfrac{(1.74\text{ m/s})^2}{0.200\text{ m}} = 15.1\text{ m/s}^2.$

Evaluate: $r\omega^2$ and v^2/r are completely equivalent expressions for a_{rad}.

9.22. **Identify:** $v = r\omega$ and $a_{\text{tan}} = r\alpha$.

Set Up: The linear acceleration of the bucket equals a_{tan} for a point on the rim of the axle.

EXECUTE: **(a)** $v = R\omega$. $2.00\text{ cm/s} = R\left(\dfrac{7.5\text{ rev}}{\text{min}}\right)\left(\dfrac{1\text{ min}}{60\text{ s}}\right)\left(\dfrac{2\pi\text{ rad}}{1\text{ rev}}\right)$ gives $R = 2.55$ cm.

$D = 2R = 5.09$ cm.

(b) $a_{\tan} = R\alpha$. $\alpha = \dfrac{a_{\tan}}{R} = \dfrac{0.400\text{ m/s}^2}{0.0255\text{ m}} = 15.7\text{ rad/s}^2$.

EVALUATE: In $v = R\omega$ and $a_{\tan} = R\alpha$, ω and α must be in radians.

9.23. **IDENTIFY:** We relate angular speed to linear speed.

SET UP: Estimate: Diameter is about 7 in., so $r \approx 3.5$ in. $v_{\tan} = r\omega$. We want the tangential velocity.

EXECUTE: First convert 2600 rev/min to rad/s and 3.5 in. to m.

$r =$ 3.5 in.$\left(\dfrac{1\text{ m}}{39.37\text{ in.}}\right)$ = 0.0889 m and $\omega = \left(2600\dfrac{\text{rev}}{\text{min}}\right)\left(\dfrac{1\text{ min}}{60\text{ s}}\right)\left(\dfrac{2\pi\text{ rad}}{1\text{ rev}}\right)$ = 26,000 rad/s. Now use

$v_{\tan} = r\omega$ = (0.0889 m)(26,000 rad/s) = 2300 m/s.

EVALUATE: When using the formula $v_{\tan} = r\omega$, ω *must* be in *radian* measure, such as rad/s or rad/min.

9.24. **IDENTIFY:** Apply constant angular acceleration equations. $v = r\omega$. A point on the rim has both tangential and radial components of acceleration.

SET UP: $a_{\tan} = r\alpha$ and $a_{\text{rad}} = r\omega^2$.

EXECUTE: **(a)** a_{rad}

(Note that since ω_{0z} and a α_z are given in terms of revolutions, it's not necessary to convert to radians).

(b) $\omega_{\text{av-}z}\Delta t = (0.340\text{ rev/s})(0.2\text{ s}) = 0.068$ rev.

(c) Here, the conversion to radians must be made to use $v = r\omega$, and

$$v = r\omega = \left(\frac{0.750\text{ m}}{2}\right)(0.430\text{ rev/s})(2\pi\text{ rad/rev}) = 1.01\text{ m/s}.$$

(d) Combining $a_{\text{rad}} = r\omega^2$ and $a_{\tan} = R\alpha$,

$a = \sqrt{a_{\text{rad}}^2 + a_{\tan}^2} = \sqrt{(\omega^2 r)^2 + (\alpha r)^2}$.

$a = \sqrt{\left[[(0.430\text{ rev/s})(2\pi\text{ rad/rev})]^2(0.375\text{ m})\right]^2 + \left[(0.900\text{ rev/s}^2)(2\pi\text{ rad/rev})(0.375\text{ m})\right]^2}$.

$a = 3.46\text{ m/s}^2$.

EVALUATE: If the angular acceleration is constant, $a_{\tan}$ is constant but a_{rad} increases as ω increases.

9.25. **IDENTIFY:** Use $a_{\text{rad}} = r\omega^2$ and solve for r.

SET UP: $a_{\text{rad}} = r\omega^2$ so $r = a_{\text{rad}}/\omega^2$, where ω must be in rad/s

EXECUTE: $a_{\text{rad}} = 3000g = 3000(9.80\text{ m/s}^2) = 29{,}400\text{ m/s}^2$

$\omega = (5000\text{ rev/min})\left(\dfrac{1\text{ min}}{60\text{ s}}\right)\left(\dfrac{2\pi\text{ rad}}{1\text{ rev}}\right) = 523.6$ rad/s

Then $r = \dfrac{a_{\text{rad}}}{\omega^2} = \dfrac{29{,}400\text{ m/s}^2}{(523.6\text{ rad/s})^2} = 0.107$ m.

EVALUATE: The diameter is then 0.214 m, which is larger than 0.127 m, so the claim is *not* realistic.

9.26. **IDENTIFY:** $a_{\tan} = r\alpha$, $v = r\omega$ and $a_{\text{rad}} = v^2/r$. $\theta - \theta_0 = \omega_{\text{av-}z}t$.

SET UP: When α_z is constant, $\omega_{\text{av-}z} = \dfrac{\omega_{0z} + \omega_z}{2}$. Let the direction the wheel is rotating be positive.

EXECUTE: **(a)** $\alpha = \dfrac{a_{\tan}}{r} = \dfrac{-10.0\text{ m/s}^2}{0.200\text{ m}} = -50.0\text{ rad/s}^2$

(b) At $t = 3.00$ s, $v = 50.0$ m/s and $\omega = \dfrac{v}{r} = \dfrac{50.0\text{ m/s}}{0.200\text{ m}} = 250\text{ rad/s}$ and at $t = 0$,

$v = 50.0\text{ m/s} + (-10.0\text{ m/s}^2)(0 - 3.00\text{ s}) = 80.0\text{ m/s},\ \ \omega = 400\text{ rad/s}.$

(c) $\omega_{\text{av-}z}t = (325\text{ rad/s})(3.00\text{ s}) = 975\text{ rad} = 155\text{ rev}.$

(d) $v = \sqrt{a_{\text{rad}}r} = \sqrt{(9.80\text{ m/s}^2)(0.200\text{ m})} = 1.40\text{ m/s}$. This speed will be reached at time $\dfrac{50.0\text{ m/s} - 1.40\text{ m/s}}{10.0\text{ m/s}^2} = 4.86\text{ s}$ after $t = 3.00$ s, or at $t = 7.86$ s. (There are many equivalent ways to do this calculation.)

EVALUATE: At $t = 0$, $a_{\text{rad}} = r\omega^2 = 3.20 \times 10^4\text{ m/s}^2$. At $t = 3.00$ s, $a_{\text{rad}} = 1.25 \times 10^4\text{ m/s}^2$. For $a_{\text{rad}} = g$ the wheel must be rotating more slowly than at 3.00 s so it occurs some time after 3.00 s.

9.27. **IDENTIFY:** We relate angular speed to linear speed and use the constant-angular acceleration equations.

SET UP: Use $v_{\tan} = r\omega$ and $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$. We want the angular acceleration.

EXECUTE: First find the initial and final angular velocities. $v_{\tan} = r\omega$ gives $\omega = \dfrac{v_{\tan}}{r}$. Therefore $\omega_1 = \dfrac{3.00\text{ m/s}}{0.300\text{ m}} = 10.0\text{ rad/s}$ and $\omega_2 = 20.0$ rad/s. Now use $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$ to find α_z. The wheel turns through 4 rev, which is 8π rad, so $(20.0\text{ rad/s})^2 = (10.0\text{ rad/s})^2 + 2\alpha_z(8\pi\text{ rad})$, so $\alpha_z = 5.97$ rad/s^2.

EVALUATE: Notice that in many cases, the units of radians do not actually emerge, but must be inferred. For example in the calculation $\omega_1 = \dfrac{3.00\text{ m/s}}{0.300\text{ m}}$, the units are 1/s (or s^{-1}), so the radians must be put in. This is not a problem because a radian has no dimensions; it is a pure number since it is defined as the length of an arc of a circle divided by the radius of the circle: θ (in rad) = *s/r*.

9.28. **IDENTIFY:** We relate angular quantities to linear quantities.

SET UP: Use $v_{\tan} = r\omega$ and $a_{\text{rad}} = \omega^2 r$. For constant angular speed, $\omega = \dfrac{\Delta\theta}{\Delta t}$. We want the tangential speed and radial acceleration of a point on the earth's equator.

EXECUTE: First find the angular speed using $\omega = \dfrac{\Delta\theta}{\Delta t} = \dfrac{2\pi\text{ rad}}{24\text{ h}} = \dfrac{2\pi\text{ rad}}{(24)(3600\text{ s})} = 7.27 \times 10^{-5}\text{ rad/s}.$

Therefore $v_{\tan} = r\omega = \dfrac{1}{2}(1.27 \times 10^7\text{ m})(7.27 \times 10^{-5}\text{ rad/s}) = 462\text{ m/s}$, and now use $a_{\text{rad}} = \omega^2 r$ to get $a_{\text{rad}} = (7.27 \times 10^{-5}\text{ rad/s})^2 \dfrac{1}{2}(1.27 \times 10^7\text{ m}) = 0.0336\text{ m/s}^2$.

EVALUATE: The radial acceleration is *much* less than *g*, so we normally are not even aware of it and can ignore it in most calculations.

9.29. **IDENTIFY:** We relate angular quantities to linear quantities and use the constant-angular accleration equations.

SET UP: Use $a_{\tan} = r\alpha$, $a_{\text{rad}} = \omega^2 r$, $a = \sqrt{a_{\tan}^2 + a_{\text{rad}}^2}$, and $\omega_z = \omega_{0z} + \alpha_z t$.

EXECUTE: First find ω at the end of 2.00 s.

$\omega_z = \omega_{0z} + \alpha_z t = 0 + (0.600\text{ rad/s}^2)(2.00\text{ s})^2 = 1.20\text{ rad/s}.$

$a_{tan} = r\alpha = (0.300\text{ m})(0.600\text{ rad/s}^2) = 0.180\text{ m/s}^2$.

$a_{rad} = \omega^2 r = (1.20\text{ rad/s})^2(0.300\text{ m}) = 0.432\text{ m/s}^2$.

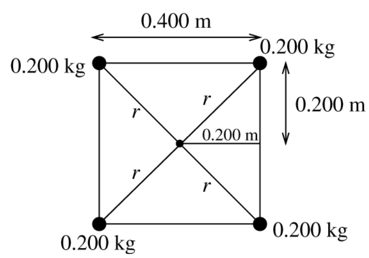
$a = \sqrt{a_{tan}^2 + a_{rad}^2} = \sqrt{(0.180\text{ m/s}^2)^2 + (0.432\text{ m/s}^2)^2} = 0.468\text{ m/s}^2$.

EVALUATE: There is only a tangential acceleration when the object has an angular acceleration, but there is a radial acceleration even if there is no angular acceleration.

9.30. IDENTIFY and **SET UP:** Use $I = \sum m_i r_i^2$. Treat the spheres as point masses and ignore I of the light rods.

EXECUTE: The object is shown in Figure 9.30a.

(a)



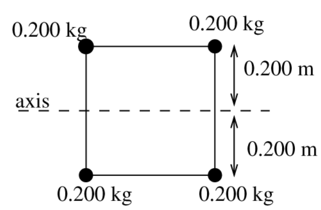
$r = \sqrt{(0.200\text{ m})^2 + (0.200\text{ m})^2} = 0.2828\text{ m}$

$I = \sum m_i r_i^2 = 4(0.200\text{ kg})(0.2828\text{ m})^2$

$I = 0.0640\text{ kg}\cdot\text{m}^2$

Figure 9.30a

(b) The object is shown in Figure 9.30b.



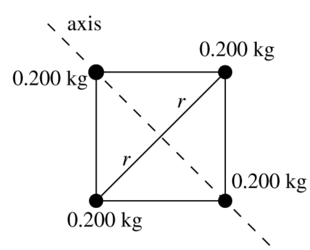
$r = 0.200\text{ m}$

$I = \sum m_i r_i^2 = 4(0.200\text{ kg})(0.200\text{ m})^2$

$I = 0.0320\text{ kg}\cdot\text{m}^2$

Figure 9.30b

(c) The object is shown in Figure 9.30c.



$r = 0.2828\text{ m}$

$I = \sum m_i r_i^2 = 2(0.200\text{ kg})(0.2828\text{ m})^2$

$I = 0.0320\text{ kg}\cdot\text{m}^2$

Figure 9.30c

EVALUATE: In general I depends on the axis and our answer for part (a) is larger than for parts (b) and (c). It just happens that I is the same in parts (b) and (c).

9.31. IDENTIFY: Use Table 9.2. The correct expression to use in each case depends on the shape of the object and the location of the axis.

SET UP: In each case express the mass in kg and the length in m, so the moment of inertia will be in $\text{kg}\cdot\text{m}^2$.

EXECUTE: **(a)** (i) $I=\frac{1}{3}ML^2=\frac{1}{3}(2.50\text{ kg})(0.750\text{ m})^2=0.469\text{ kg}\cdot\text{m}^2.$

(ii) $I=\frac{1}{12}ML^2=\frac{1}{4}(0.469\text{ kg}\cdot\text{m}^2)=0.117\text{ kg}\cdot\text{m}^2.$ (iii) For a very thin rod, all of the mass is at the axis and $I=0.$

(b) (i) $I=\frac{2}{5}MR^2=\frac{2}{5}(3.00\text{ kg})(0.190\text{ m})^2=0.0433\text{ kg}\cdot\text{m}^2.$

(ii) $I=\frac{2}{3}MR^2=\frac{5}{3}(0.0433\text{ kg}\cdot\text{m}^2)=0.0722\text{ kg}\cdot\text{m}^2.$

(c) (i) $I=MR^2=(8.00\text{ kg})(0.0600\text{ m})^2=0.0288\text{ kg}\cdot\text{m}^2.$

(ii) $I=\frac{1}{2}MR^2=\frac{1}{2}(8.00\text{ kg})(0.0600\text{ m})^2=0.0144\text{ kg}\cdot\text{m}^2.$

EVALUATE: I depends on how the mass of the object is distributed relative to the axis.

9.32. **IDENTIFY:** Treat each block as a point mass, so for each block $I=mr^2,$ where r is the distance of the block from the axis. The total I for the object is the sum of the I for each of its pieces.

SET UP: In part (a) two blocks are a distance $L/2$ from the axis and the third block is on the axis. In part (b) two blocks are a distance $L/4$ from the axis and one is a distance $3L/4$ from the axis.

EXECUTE: **(a)** $I=2m(L/2)^2=\frac{1}{2}mL^2.$

(b) $I=2m(L/4\,)^2+m(3L/4)^2=\dfrac{1}{16}mL^2(2+9)=\dfrac{11}{16}mL^2.$

EVALUATE: For the same object I is in general different for different axes.

9.33. **IDENTIFY:** I for the object is the sum of the values of I for each part.

SET UP: For the bar, for an axis perpendicular to the bar, use the appropriate expression from Table 9.2. For a point mass, $I=mr^2,$ where r is the distance of the mass from the axis.

EXECUTE: **(a)** $I=I_{\text{bar}}+I_{\text{balls}}=\dfrac{1}{12}M_{\text{bar}}L^2+2m_{\text{balls}}\left(\dfrac{L}{2}\right)^2.$

$$I=\frac{1}{12}(4.00\text{ kg})(2.00\text{ m})^2+2(0.300\text{ kg})(1.00\text{ m})^2=1.93\text{ kg}\cdot\text{m}^2$$

(b) $I=\dfrac{1}{3}m_{\text{bar}}L^2+m_{\text{ball}}L^2=\dfrac{1}{3}(4.00\text{ kg})(2.00\text{ m})^2+(0.300\text{ kg})(2.00\text{ m})^2=6.53\text{ kg}\cdot\text{m}^2$

(c) $I=0$ because all masses are on the axis.

(d) All the mass is a distance $d=0.500$ m from the axis and

$I=m_{\text{bar}}d^2+2m_{\text{ball}}d^2=M_{\text{Total}}d^2=(4.60\text{ kg})(0.500\text{ m})^2=1.15\text{ kg}\cdot\text{m}^2.$

EVALUATE: I for an object depends on the location and direction of the axis.

9.34. **IDENTIFY:** Moment of inertia of a bar.

SET UP: $I_{\text{end}}=\dfrac{1}{3}ML^2,\ I_{\text{center}}=\dfrac{1}{12}ML^2$

EXECUTE: **(a)** $\dfrac{1}{12}ML^2=(0.400\text{ kg})(0.600\text{ m})^2/12=0.0120\text{ kg}\cdot\text{m}^2.$

(b) Now we want the moment of inertia of two bars about their ends. Each has mass $M/2$ and length $L/2$.

$\dfrac{1}{3}ML^2=\dfrac{1}{3}\left(\dfrac{M}{2}\right)\left(\dfrac{L}{2}\right)^2+\dfrac{1}{3}\left(\dfrac{M}{2}\right)\left(\dfrac{L}{2}\right)^2=\dfrac{1}{12}ML^2=0.0120\text{ kg}\cdot\text{m}^2.$

EVALUATE: Neither the bend nor the 60° angle affects the moment of inertia. In (a) and (b), we can think of the rod as two 0.200-kg rods, each 0.300 m long, with the moment of inertia calculated about one end.

9.35. **IDENTIFY** and **SET UP:** $I = \sum m_i r_i^2$ implies $I = I_{\text{rim}} + I_{\text{spokes}}$

EXECUTE: $I_{\text{rim}} = MR^2 = (1.40 \text{ kg})(0.300 \text{ m})^2 = 0.126 \text{ kg} \cdot \text{m}^2$

Each spoke can be treated as a slender rod with the axis through one end, so

$I_{\text{spokes}} = 8\left(\frac{1}{3}ML^2\right) = \frac{8}{3}(0.280 \text{ kg})(0.300 \text{ m})^2 = 0.0672 \text{ kg} \cdot \text{m}^2$

$I = I_{\text{rim}} + I_{\text{spokes}} = 0.126 \text{ kg} \cdot \text{m}^2 + 0.0672 \text{ kg} \cdot \text{m}^2 = 0.193 \text{ kg} \cdot \text{m}^2.$

EVALUATE: Our result is smaller than $m_{\text{tot}}R^2 = (3.64 \text{ kg})(0.300 \text{ m})^2 = 0.328 \text{ kg} \cdot \text{m}^2$, since the mass of each spoke is distributed between $r = 0$ and $r = R$.

9.36. **IDENTIFY:** This problem requires moment of inertia calculations.

SET UP: The disk has the same mass and radius as the sphere. $I_\text{d} = \frac{1}{2}MR^2$, $I_1 = \frac{2}{5}MR^2$.

EXECUTE: Take the ratio of I_d to I_1. $\frac{I_\text{d}}{I_1} = \frac{\frac{1}{2}MR^2}{\frac{2}{5}MR^2} = \frac{5}{4}$, so $I_\text{d} = 5I_1/4$.

EVALUATE: Even though the disk and sphere have the same mass and radius, their moments of inertia are different because the mass is distributed differently.

9.37. **IDENTIFY:** The flywheel has kinetic energy due to its rotation, but it is slowing down. We need to use rotational kinetic energy and constant-angular acceleration equations.

SET UP: $K = \frac{1}{2}I\omega^2$, $\omega_z = \omega_{0z} + \alpha_z t$. We want to find the time for the flywheel to lose half of its kinetic energy.

EXECUTE: First use kinetic energy to find the initial and final angular velocities. We know that $K_2 = \frac{1}{2}K_1$, so $\frac{1}{2}I\omega_2^2 = \frac{1}{2}\left(\frac{1}{2}I\omega_1^2\right)$, which gives $\omega_2 = \frac{\omega_1}{\sqrt{2}}$. Now use $K = \frac{1}{2}I\omega^2$ to find ω_1. $\frac{1}{2}I\omega_1^2 = K_1$ gives $\omega_1 = \sqrt{\frac{2K_1}{I}} = \sqrt{\frac{2(30.0 \text{ J})}{12.0 \text{ kg} \cdot \text{m}^2}} = 2.236$ rad/s. $\omega_2 = \frac{\omega_1}{\sqrt{2}} = \frac{2.236 \text{ rad/s}}{\sqrt{2}} = 1.581$ rad/s. Now use $\omega_z = \omega_{0z} + \alpha_z t$ to find t: 1.581 rad/s = 2.236 rad/s + $\left((-0.500)(2\pi) \text{ rad/s}\right)t$, which gives $t = 0.208$ s.

EVALUATE: We must use radian measure in the formula $K = \frac{1}{2}I\omega^2$, but we could use any type of angular measure in the equation $\omega_z = \omega_{0z} + \alpha_z t$.

9.38. **IDENTIFY:** $K = \frac{1}{2}I\omega^2$. Use Table 9.2 to calculate I.

SET UP: $I = \frac{1}{12}ML^2$. 1 rpm = 0.1047 rad/s

EXECUTE: **(a)** $I = \frac{1}{12}(117 \text{ kg})(2.08 \text{ m})^2 = 42.2 \text{ kg} \cdot \text{m}^2$.

$\omega = (2400 \text{ rev/min})\left(\frac{0.1047 \text{ rad/s}}{1 \text{ rev/min}}\right) = 251 \text{ rad/s}.$ $K = \frac{1}{2}I\omega^2 = \frac{1}{2}(42.2 \text{ kg} \cdot \text{m}^2)(251 \text{ rad/s})^2 = 1.33 \times 10^6 \text{ J}.$

(b) $K_1 = \frac{1}{12}M_1L_1^2\omega_1^2$, $K_2 = \frac{1}{12}M_2L_2^2\omega_2^2$. $L_1 = L_2$ and $K_1 = K_2$, so $M_1\omega_1^2 = M_2\omega_2^2$.

$\omega_2 = \omega_1\sqrt{\frac{M_1}{M_2}} = (2400 \text{ rpm})\sqrt{\frac{M_1}{0.750M_1}} = 2770 \text{ rpm}$

EVALUATE: The rotational kinetic energy is proportional to the square of the angular speed and directly proportional to the mass of the object.

9.39. **IDENTIFY:** This problem requires moment of inertia calculations.

SET UP: The two spheres have the same mass, radius, and kinetic energy, but one is solid and the other is a hollow shell. $I_h = \frac{2}{3}MR^2$ and $I_s = \frac{2}{5}MR^2$. $K = \frac{1}{2}I\omega^2$. The solid sphere has angular speed ω_1 and we want to find the angular speed ω_h of the hollow sphere.

EXECUTE: Equate the kinetic energies of the two spheres: $\frac{2}{5}MR^2\omega_1^2 = \frac{2}{3}MR^2\omega_h^2$ which gives $\omega_h = \omega_1\sqrt{3/5}$.

EVALUATE: From our result, we see that the hollow sphere is spinning slower than the solid sphere. This is reasonable because the hollow sphere has a greater moment of inertia than the solid sphere because more of its mass is located farther from the axis of rotation.

9.40. **IDENTIFY:** We can use angular kinematics (for constant angular acceleration) to find the angular velocity of the wheel. Then knowing its kinetic energy, we can find its moment of inertia, which is the target variable.

SET UP: $\theta - \theta_0 = \left(\frac{\omega_{0z} + \omega_z}{2}\right)t$ and $K = \frac{1}{2}I\omega^2$.

EXECUTE: Converting the angle to radians gives $\theta - \theta_0 = (8.20 \text{ rev})(2\pi \text{ rad/1 rev}) = 51.52 \text{ rad}$.

$\theta - \theta_0 = \left(\frac{\omega_{0z} + \omega_z}{2}\right)t$ gives $\omega_z = \frac{2(\theta - \theta_0)}{t} = \frac{2(51.52 \text{ rad})}{12.0 \text{ s}} = 8.587 \text{ rad/s}$. Solving $K = \frac{1}{2}I\omega^2$ for I gives $I = \frac{2K}{\omega^2} = \frac{2(36.0 \text{ J})}{(8.587 \text{ rad/s})^2} = 0.976 \text{ kg}\cdot\text{m}^2$.

EVALUATE: The angular velocity must be in radians to use the formula $K = \frac{1}{2}I\omega^2$.

9.41. **IDENTIFY:** Knowing the kinetic energy, mass and radius of the sphere, we can find its angular velocity. From this we can find the tangential velocity (the target variable) of a point on the rim.

SET UP: $K = \frac{1}{2}I\omega^2$ and $I = \frac{2}{5}MR^2$ for a solid uniform sphere. The tagential velocity is $v = r\omega$.

EXECUTE: $I = \frac{2}{5}MR^2 = \frac{2}{5}(28.0 \text{ kg})(0.380 \text{ m})^2 = 1.617 \text{ kg}\cdot\text{m}^2$. $K = \frac{1}{2}I\omega^2$ so

$\omega = \sqrt{\frac{2K}{I}} = \sqrt{\frac{2(236 \text{ J})}{1.617 \text{ kg}\cdot\text{m}^2}} = 17.085 \text{ rad/s}$.

$v = r\omega = (0.380 \text{ m})(17.085 \text{ rad/s}) = 6.49 \text{ m/s}$.

EVALUATE: This is the speed of a point on the surface of the sphere that is farthest from the axis of rotation (the "equator" of the sphere). Points off the "equator" would have smaller tangential velocity but the same angular velocity.

9.42. **IDENTIFY:** Knowing the angular acceleration of the sphere, we can use angular kinematics (with constant angular acceleration) to find its angular velocity. Then using its mass and radius, we can find its kinetic energy, the target variable.

SET UP: $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$, $K = \frac{1}{2}I\omega^2$, and $I = \frac{2}{3}MR^2$ for a uniform hollow spherical shell.

EXECUTE: $I = \frac{2}{3}MR^2 = \frac{2}{3}(8.20 \text{ kg})(0.220 \text{ m})^2 = 0.2646 \text{ kg}\cdot\text{m}^2$. Converting the angle to radians gives $\theta - \theta_0 = (6.00 \text{ rev})(2\pi \text{ rad/1 rev}) = 37.70 \text{ rad}$. The angular velocity is $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$, which gives $\omega_z = \sqrt{2\alpha_z(\theta - \theta_0)} = \sqrt{2(0.890 \text{ rad/s}^2)(37.70 \text{ rad})} = 8.192 \text{ rad/s}$.

$K = \frac{1}{2}(0.2646 \text{ kg}\cdot\text{m}^2)(8.192 \text{ rad/s})^2 = 8.88 \text{ J}$.

EVALUATE: The angular velocity must be in radians to use the formula $K = \frac{1}{2}I\omega^2$.

9.43. **IDENTIFY:** We need to use rotational kinetic energy.

SET UP: $K = \frac{1}{2}I\omega^2$. We know that $I_A = 3I_B$ and $\omega_B = 4\omega_A$, and we want to compare the kinetic energies of the wheels.

EXECUTE: **(a)** Using what we know gives $K_A = \frac{1}{2}I_A\omega_A^2$ and $K_B = \frac{1}{2}I_B\omega_B^2 = \frac{1}{2}\left(\frac{I_A}{3}\right)(4\omega_A)^2$. For K_B this becomes $K_B = \frac{1}{2}\left(\frac{I_A}{3}\right)(4\omega_A)^2 = \frac{16}{3}\left(\frac{1}{2}I_A\omega_A^2\right) = \frac{16}{3}K_A$, which tells us the B has more kinetic energy than A.

(b) $\dfrac{K_A}{K_B} = \dfrac{\frac{1}{2}I_A\omega_A^2}{\left(\frac{16}{3}\right)\left(\frac{1}{2}I_A\omega_A^2\right)} = \dfrac{3}{16}.$

EVALUATE: Wheel A has 3 times the moment of inertia of B but only ¼ the angular speed and therefore only 1/16 the *square* of the angular speed, so it has less kinetic energy than B.

9.44. **IDENTIFY:** $K = \frac{1}{2}I\omega^2$. Use Table 9.2 to relate I to the mass M of the disk.

SET UP: 45.0 rpm = 4.71 rad/s. For a uniform solid disk, $I = \frac{1}{2}MR^2$.

EXECUTE: **(a)** $I = \dfrac{2K}{\omega^2} = \dfrac{2(0.250\text{ J})}{(4.71\text{ rad/s})^2} = 0.0225\text{ kg}\cdot\text{m}^2.$

(b) $I = \frac{1}{2}MR^2$ and $M = \dfrac{2I}{R^2} = \dfrac{2(0.0225\text{ kg}\cdot\text{m}^2)}{(0.300\text{ m})^2} = 0.500\text{ kg}.$

EVALUATE: No matter what the shape is, the rotational kinetic energy is proportional to the mass of the object.

9.45. **IDENTIFY** and **SET UP:** Combine $K = \frac{1}{2}I\omega^2$ and $a_{\text{rad}} = r\omega^2$ to solve for K. Use Table 9.2 to get I.

EXECUTE: $K = \frac{1}{2}I\omega^2$

$a_{\text{rad}} = R\omega^2$, so $\omega = \sqrt{a_{\text{rad}}/R} = \sqrt{(3500\text{ m/s}^2)/1.20\text{ m}} = 54.0\text{ rad/s}$

For a disk, $I = \frac{1}{2}MR^2 = \frac{1}{2}(70.0\text{ kg})(1.20\text{ m})^2 = 50.4\text{ kg}\cdot\text{m}^2$

Thus $K = \frac{1}{2}I\omega^2 = \frac{1}{2}(50.4\text{ kg}\cdot\text{m}^2)(54.0\text{ rad/s})^2 = 7.35\times10^4\text{ J}$

EVALUATE: The limit on a_{rad} limits ω which in turn limits K.

9.46. **IDENTIFY:** In order to meet the specifications, we need to use rotational kinetic energy and constant-angular acceleration equations.
SET UP: The flywheel should have 240 J of kinetic energy after it has turned through 30.0 rev starting from rest. We want to know its moment of inertia. We know that $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$ and $K = \frac{1}{2}I\omega^2$.

EXECUTE: First use $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$ to find ω^2 and then use $K = \frac{1}{2}I\omega^2$ to find I. Using $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$ gives $\omega^2 = 2\alpha_z\Delta\theta$. Now solve $K = \frac{1}{2}I\omega^2$ for I, which gives

$$I = \frac{2K}{\omega^2} = \frac{2K}{2\alpha_z\Delta\theta} = \frac{240\text{ J}}{(0.400\pi\text{ rad/s}^2)(60.0\pi\text{ rad})} = 1.01\text{ kg}\cdot\text{m}^2.$$

EVALUATE: Since $I = \frac{1}{2}MR^2$, we could increase either M or R to increase I, but it would be more effective to increase R since I is proportional to the *square* of R.

9.47. **IDENTIFY:** Apply conservation of energy to the system of stone plus pulley. $v = r\omega$ relates the motion of the stone to the rotation of the pulley.

SET UP: For a uniform solid disk, $I = \frac{1}{2}MR^2$. Let point 1 be when the stone is at its initial position and point 2 be when it has descended the desired distance. Let $+y$ be upward and take $y = 0$ at the initial position of the stone, so $y_1 = 0$ and $y_2 = -h$, where h is the distance the stone descends.

EXECUTE: **(a)** $K_p = \frac{1}{2}I_p\omega^2$. $I_p = \frac{1}{2}M_pR^2 = \frac{1}{2}(2.50 \text{ kg})(0.200 \text{ m})^2 = 0.0500 \text{ kg}\cdot\text{m}^2$.

$\omega = \sqrt{\dfrac{2K_p}{I_p}} = \sqrt{\dfrac{2(4.50 \text{ J})}{0.0500 \text{ kg}\cdot\text{m}^2}} = 13.4 \text{ rad/s}$. The stone has speed

$v = R\omega = (0.200 \text{ m})(13.4 \text{ rad/s}) = 2.68 \text{ m/s}$. The stone has kinetic energy

$K_s = \frac{1}{2}mv^2 = \frac{1}{2}(1.50 \text{ kg})(2.68 \text{ m/s})^2 = 5.39 \text{ J}$. $K_1 + U_1 = K_2 + U_2$ gives $0 = K_2 + U_2$.

$0 = 4.50 \text{ J} + 5.39 \text{ J} + mg(-h)$. $h = \dfrac{9.89 \text{ J}}{(1.50 \text{ kg})(9.80 \text{ m/s}^2)} = 0.673 \text{ m}$.

(b) $K_{tot} = K_p + K_s = 9.89 \text{ J}$. $I = 2MR^2$,

EVALUATE: The gravitational potential energy of the pulley doesn't change as it rotates. The tension in the wire does positive work on the pulley and negative work of the same magnitude on the stone, so no net work on the system.

9.48. **IDENTIFY:** $K_p = \frac{1}{2}I\omega^2$ for the pulley and $K_b = \frac{1}{2}mv^2$ for the bucket. The speed of the bucket and the rotational speed of the pulley are related by $v = R\omega$.

SET UP: $K_p = \frac{1}{2}K_b$

EXECUTE: $\frac{1}{2}I\omega^2 = \frac{1}{2}(\frac{1}{2}mv^2) = \frac{1}{4}mR^2\omega^2$. $I = \frac{1}{2}mR^2$.

EVALUATE: The result is independent of the rotational speed of the pulley and the linear speed of the mass.

9.49. **IDENTIFY:** With constant acceleration, we can use kinematics to find the speed of the falling object. Then we can apply the work-energy expression to the entire system and find the moment of inertia of the wheel. Finally, using its radius we can find its mass, the target variable.

SET UP: With constant acceleration, $y - y_0 = \left(\dfrac{v_{0y} + v_y}{2}\right)t$. The angular velocity of the wheel is related to the linear velocity of the falling mass by $\omega_z = \dfrac{v_y}{R}$. The work-energy theorem is $K_1 + U_1 + W_{other} = K_2 + U_2$, and the moment of inertia of a uniform disk is $I = \frac{1}{2}MR^2$.

EXECUTE: Find v_y, the velocity of the block after it has descended 3.00 m. $y - y_0 = \left(\dfrac{v_{0y} + v_y}{2}\right)t$ gives $v_y = \dfrac{2(y - y_0)}{t} = \dfrac{2(3.00 \text{ m})}{2.00 \text{ s}} = 3.00 \text{ m/s}$. For the wheel, $\omega_z = \dfrac{v_y}{R} = \dfrac{3.00 \text{ m/s}}{0.280 \text{ m}} = 10.71 \text{ rad/s}$. Apply the work-energy expression: $K_1 + U_1 + W_{other} = K_2 + U_2$, giving $mg(3.00 \text{ m}) = \dfrac{1}{2}mv^2 + \dfrac{1}{2}I\omega^2$. Solving for I gives $I = \dfrac{2}{\omega^2}\left[mg(3.00 \text{ m}) - \dfrac{1}{2}mv^2\right]$.

$I = \dfrac{2}{(10.71\ \text{rad/s})^2}\left[(4.20\ \text{kg})(9.8\ \text{m/s}^2)(3.00\ \text{m}) - \dfrac{1}{2}(4.20\ \text{kg})(3.00\ \text{m/s})^2\right]$. $I = 1.824\ \text{kg}\cdot\text{m}^2$. For a solid disk, $I = \frac{1}{2}MR^2$ gives $M = \dfrac{2I}{R^2} = \dfrac{2(1.824\ \text{kg}\cdot\text{m}^2)}{(0.280\ \text{m})^2} = 46.5\ \text{kg}$.

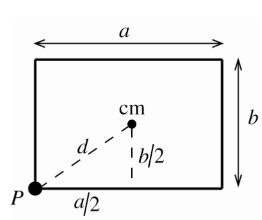
EVALUATE: The gravitational potential of the falling object is converted into the kinetic energy of that object and the rotational kinetic energy of the wheel.

9.50. **IDENTIFY:** Apply the parallel-axis theorem.
SET UP: The center of mass of the hoop is at its geometrical center.
EXECUTE: In the parallel-axis theorem, $I_{\text{cm}} = MR^2$ and $d = R^2$, so $I_P = 2MR^2$.
EVALUATE: I is larger for an axis at the edge than for an axis at the center. Some mass is closer than distance R from the axis but some is also farther away. Since I for each piece of the hoop is proportional to the square of the distance from the axis, the increase in distance has a larger effect.

9.51. **IDENTIFY:** Use the parallel-axis theorem to relate I for the wood sphere about the desired axis to I for an axis along a diameter.
SET UP: For a thin-walled hollow sphere, axis along a diameter, $I = \frac{2}{3}MR^2$.
For a solid sphere with mass M and radius R, $I_{\text{cm}} = \frac{2}{5}MR^2$, for an axis along a diameter.
EXECUTE: Find d such that $I_P = I_{\text{cm}} + Md^2$ with $I_P = \frac{2}{3}MR^2$:
$\frac{2}{3}MR^2 = \frac{2}{5}MR^2 + Md^2$
The factors of M divide out and the equation becomes $(\frac{2}{3} - \frac{2}{5})R^2 = d^2$
$d = \sqrt{(10-6)/15}R = 2R/\sqrt{15} = 0.516R$.
The axis is parallel to a diameter and is $0.516R$ from the center.
EVALUATE: $I_{\text{cm}}(\text{lead}) > I_{\text{cm}}(\text{wood})$ even though M and R are the same since for a hollow sphere all the mass is a distance R from the axis. The parallel-axis theorem says $I_P > I_{\text{cm}}$, so there must be a d where $I_P(\text{wood}) = I_{\text{cm}}(\text{lead})$.

9.52. **IDENTIFY:** Consider the plate as made of slender rods placed side-by-side.
SET UP: The expression in Table 9.2 gives I for a rod and an axis through the center of the rod.
EXECUTE: **(a)** I is the same as for a rod with length a: $I = \frac{1}{12}Ma^2$.
(b) I is the same as for a rod with length b: $I = \frac{1}{12}Mb^2$.
EVALUATE: I is smaller when the axis is through the center of the plate than when it is along one edge.

9.53. **IDENTIFY** and **SET UP:** Use the parallel-axis theorem. The cm of the sheet is at its geometrical center. The object is sketched in Figure 9.53.
EXECUTE: $I_P = I_{\text{cm}} + Md^2$.



From Table 9.2,
$I_{\text{cm}} = \frac{1}{12}M(a^2 + b^2)$.
The distance d of P from the cm is
$d = \sqrt{(a/2)^2 + (b/2)^2}$.

Figure 9.53

Thus $I_P = I_{\text{cm}} + Md^2 = \frac{1}{12}M(a^2+b^2) + M(\frac{1}{4}a^2 + \frac{1}{4}b^2) = (\frac{1}{12}+\frac{1}{4})M(a^2+b^2) = \frac{1}{3}M(a^2+b^2)$

EVALUATE: $I_P = 4I_{\text{cm}}$. For an axis through P mass is farther from the axis.

9.54. **IDENTIFY:** Use the equations in Table 9.2. I for the rod is the sum of I for each segment. The parallel-axis theorem says $I_{\text{p}} = I_{\text{cm}} + Md^2$.

SET UP: The bent rod and axes a and b are shown in Figure 9.54. Each segment has length $L/2$ and mass $M/2$.

EXECUTE: **(a)** For each segment the moment of inertia is for a rod with mass $M/2$, length $L/2$ and the axis through one end. For one segment, $I_{\text{s}} = \frac{1}{3}\left(\frac{M}{2}\right)\left(\frac{L}{2}\right)^2 = \frac{1}{24}ML^2$. For the rod, $I_{\text{a}} = 2I_{\text{s}} = \frac{1}{12}ML^2$.

(b) The center of mass of each segment is at the center of the segment, a distance of $L/4$ from each end. For each segment, $I_{\text{cm}} = \frac{1}{12}\left(\frac{M}{2}\right)\left(\frac{L}{2}\right)^2 = \frac{1}{96}ML^2$. Axis b is a distance $L/4$ from the cm of each segment, so for each segment the parallel axis theorem gives I for axis b to be

$I_{\text{s}} = \frac{1}{96}ML^2 + \frac{M}{2}\left(\frac{L}{4}\right)^2 = \frac{1}{24}ML^2$ and $I_{\text{b}} = 2I_{\text{s}} = \frac{1}{12}ML^2$.

EVALUATE: I for these two axes are the same.

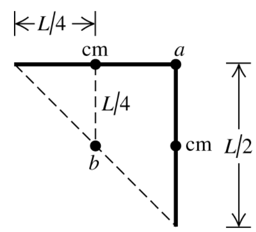


Figure 9.54

9.55. **IDENTIFY:** Apply $I = \int r^2\, dm$.

SET UP: $dm = \rho dV = \rho(2\pi rL\; dr)$, where L is the thickness of the disk. $M = \pi L\rho R^2$.

EXECUTE: The analysis is identical to that of Example 9.10, with the lower limit in the integral being zero and the upper limit being R. The result is $I = \frac{1}{2}MR^2$.

9.56. **IDENTIFY:** Use $I = \int r^2\, dm$.

SET UP:

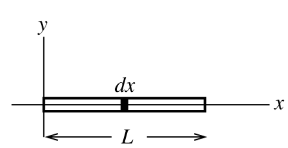

Figure 9.56

Take the x-axis to lie along the rod, with the origin at the left end. Consider a thin slice at coordinate x and width dx, as shown in Figure 9.56. The mass per unit length for this rod is M/L, so the mass of this slice is $dm = (M/L)\, dx$.

EXECUTE: $I = \int_0^L x^2(M/L)\,dx = (M/L)\int_0^L x^2\,dx = (M/L)(L^3/3) = \frac{1}{3}ML^2$

EVALUATE: This result agrees with the table in the text.

9.57. **IDENTIFY:** Apply $I = \int r^2\,dm$ and $M = \int dm$.

SET UP: For this case, $dm = \gamma x\,dx$.

EXECUTE: **(a)** $M = \int dm = \int_0^L \gamma x\,dx = \gamma \frac{x^2}{2}\Big|_0^L = \frac{\gamma L^2}{2}$

(b) $I = \int_0^L x^2(\gamma x)dx = \gamma \frac{x^4}{4}\Big|_0^L = \frac{\gamma L^4}{4} = \frac{M}{2}L^2$. This is larger than the moment of inertia of a uniform rod of the same mass and length, since the mass density is greater farther away from the axis than nearer the axis.

(c) $I = \int_0^L (L-x)^2 \gamma x dx = \gamma \int_0^L (L^2 x - 2Lx^2 + x^3)dx = \gamma\left(L^2\frac{x^2}{2} - 2L\frac{x^3}{3} + \frac{x^4}{4}\right)\Bigg|_0^L = \gamma\frac{L^4}{12} = \frac{M}{6}L^2$.

This is a third of the result of part (b), reflecting the fact that more of the mass is concentrated at the right end.

EVALUATE: For a uniform rod with an axis at one end, $I = \frac{1}{3}ML^2$. The result in (b) is larger than this and the result in (c) is smaller than this.

9.58. **IDENTIFY:** Using the equation for the angle as a function of time, we can find the angular acceleration of the disk at a given time and use this to find the linear acceleration of a point on the rim (the target variable).

SET UP: We can use the definitions of the angular velocity and the angular acceleration: $\omega_z(t) = \frac{d\theta}{dt}$ and $\alpha_z(t) = \frac{d\omega_z}{dt}$. The acceleration components are $a_{\text{rad}} = R\omega^2$ and $a_{\text{tan}} = R\alpha$, and the magnitude of the acceleration is $a = \sqrt{a_{\text{rad}}^2 + a_{\text{tan}}^2}$.

EXECUTE: $\omega_z(t) = \frac{d\theta}{dt} = 1.10\text{ rad/s} + (12.6\text{ rad/s}^2)t$. $\alpha_z(t) = \frac{d\omega_z}{dt} = 12.6\text{ rad/s}^2$ (constant).

$\theta = 0.100\text{ rev} = 0.6283\text{ rad}$ gives $6.30t^2 + 1.10t - 0.6283 = 0$, so $t = 0.2403\text{ s}$, using the positive root. At this t, $\omega_z(t) = 4.1278\text{ rad/s}$ and $\alpha_z(t) = 12.6\text{ rad/s}^2$. For a point on the rim, $a_{\text{rad}} = R\omega^2 = 6.815\text{ m/s}^2$ and $a_{\text{tan}} = R\alpha = 5.04\text{ m/s}^2$, so $a = \sqrt{a_{\text{rad}}^2 + a_{\text{tan}}^2} = 8.48\text{ m/s}^2$.

EVALUATE: Since the angular acceleration is constant, we could use the constant acceleration formulas as a check. For example, the coefficient of t^2 is $\frac{1}{2}\alpha_z = 6.30\text{ rad/s}^2$ gives $\alpha_z = 12.6\text{ rad/s}^2$.

9.59. **IDENTIFY:** The target variable is the horizontal distance the piece travels before hitting the floor. Using the angular acceleration of the blade, we can find its angular velocity when the piece breaks off. This will give us the linear horizontal speed of the piece. It is then in free fall, so we can use the linear kinematics equations.

SET UP: $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$ for the blade, and $v = r\omega$ is the horizontal velocity of the piece. $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ for the falling piece.

EXECUTE: Find the initial horizontal velocity of the piece just after it breaks off.
$\theta-\theta_0=(155\text{ rev})(2\pi\text{ rad/1 rev})=973.9\text{ rad}.$

$\alpha_z=(2.00\text{ rev/s}^2)(2\pi\text{ rad/1 rev})=12.566\text{ rad/s}^2.$ $\omega_z^2=\omega_{0z}^2+2\alpha_z(\theta-\theta_0).$

$\omega_z=\sqrt{2\alpha_z(\theta-\theta_0)}=\sqrt{2(12.566\text{ rad/s}^2)(973.9\text{ rad})}=156.45\text{ rad/s}.$ The horizontal velocity of the piece is $v=r\omega=(0.120\text{ m})(156.45\text{ rad/s})=18.774\text{ m/s}.$ Now consider the projectile motion of the piece. Take $+y$ downward and use the vertical motion to find t. Solving $y-y_0=v_{0y}t+\frac{1}{2}a_yt^2$ for t gives

$t=\sqrt{\dfrac{2(y-y_0)}{a_y}}=\sqrt{\dfrac{2(0.820\text{ m})}{9.8\text{ m/s}^2}}=0.4091\text{ s}.$ Then

$x-x_0=v_{0x}t+\frac{1}{2}a_xt^2=(18.774\text{ m/s})(0.4091\text{ s})=7.68\text{ m}.$

EVALUATE: Once the piece is free of the blade, the only force acting on it is gravity so its acceleration is g downward.

9.60. **IDENTIFY** and **SET UP:** Use $\omega_z=\dfrac{d\theta}{dt}$ and $\alpha_z=\dfrac{d\omega_z}{dt}$. As long as $\alpha_z>0$, ω_z increases. At the t when $\alpha_z=0$, ω_z is at its maximum positive value and then starts to decrease when α_z becomes negative.

$\theta(t)=\gamma t^2-\beta t^3;$ $\gamma=3.20\text{ rad/s}^2,$ $\beta=0.500\text{ rad/s}^3$

EXECUTE: **(a)** $\omega_z(t)=\dfrac{d\theta}{dt}=\dfrac{d(\gamma t^2-\beta t^3)}{dt}=2\gamma t-3\beta t^2$

(b) $\alpha_z(t)=\dfrac{d\omega_z}{dt}=\dfrac{d(2\gamma t-3\beta t^2)}{dt}=2\gamma-6\beta t$

(c) The maximum angular velocity occurs when $\alpha_z=0.$

$2\gamma-6\beta t=0$ implies $t=\dfrac{2\gamma}{6\beta}=\dfrac{\gamma}{3\beta}=\dfrac{3.20\text{ rad/s}^2}{3(0.500\text{ rad/s}^3)}=2.133\text{ s}$

At this t, $\omega_z=2\gamma t-3\beta t^2=2(3.20\text{ rad/s}^2)(2.133\text{ s})-3(0.500\text{ rad/s}^3)(2.133\text{ s})^2=6.83\text{ rad/s}$

The maximum positive angular velocity is 6.83 rad/s and it occurs at 2.13 s.

EVALUATE: For large t both ω_z and α_z are negative and ω_z increases in magnitude. In fact, $\omega_z\to-\infty$ at $t\to\infty$. So the answer in (c) is not the largest angular speed, just the largest positive angular velocity.

9.61. **IDENTIFY:** The angular acceleration α of the disk is related to the linear acceleration a of the ball by $a=R\alpha$. Since the acceleration is not constant, use $\omega_z-\omega_{0z}=\int_0^t\alpha_z dt$ and $\theta-\theta_0=\int_0^t\omega_z dt$ to relate θ, ω_z, α_z, and t for the disk. $\omega_{0z}=0.$

SET UP: $\int t^n dt=\dfrac{1}{n+1}t^{n+1}.$ In $a=R\alpha$, α is in rad/s^2.

EXECUTE: **(a)** $A=\dfrac{a}{t}=\dfrac{1.80\text{ m/s}^2}{3.00\text{ s}}=0.600\text{ m/s}^3$

(b) $\alpha=\dfrac{a}{R}=\dfrac{(0.600\text{ m/s}^3)t}{0.250\text{ m}}=(2.40\text{ rad/s}^3)t$

(c) $\omega_z=\int_0^t(2.40\text{ rad/s}^3)tdt=(1.20\text{ rad/s}^3)t^2.$ $\omega_z=15.0\text{ rad/s}$ for $t=\sqrt{\dfrac{15.0\text{ rad/s}}{1.20\text{ rad/s}^3}}=3.54\text{ s}.$

(d) $\theta-\theta_0=\int_0^t\omega_z dt=\int_0^t(1.20\text{ rad/s}^3)t^2dt=(0.400\text{ rad/s}^3)t^3.$ For $t=3.54$ s, $\theta-\theta_0=17.7$ rad.

Evaluate: If the disk had turned at a constant angular velocity of 15.0 rad/s for 3.54 s it would have turned through an angle of 53.1 rad in 3.54 s. It actually turns through less than half this because the angular velocity is increasing in time and is less than 15.0 rad/s at all but the end of the interval.

9.62. Identify: The flywheel gains rotational kinetic energy as it spins. This kinetic energy depends on the flywheel's rate of spin but also on its moment of inertia. The angular acceleration is constant.

Set Up: $K = \frac{1}{2}I\omega^2,\ I = \frac{1}{2}mR^2,\ \ \omega = \omega_0 + \alpha t,\ \ m = \rho V = \rho\pi R^2 h.$

Execute: $K = \frac{1}{2}I\omega^2\ =\ \frac{1}{2}(\frac{1}{2}mR^2)(\omega_0 + \alpha t)^2\ =\ \frac{1}{4}\left[(\rho\pi R^2 h)R^2\right](0 + \alpha t)^2$. Solving for h gives

$h = \dfrac{4K}{\rho\pi R^4(\alpha t)^2}$ = 4(800 J)/[π(8600 kg/m^3)(0.250 m)^4(3.00 rad/s^2)^2(8.00 s)^2] = 0.0526 m = 5.26 cm.

Evaluate: If we could turn the disk into a thin-walled cylinder of the same mass and radius, the moment of inertia would be twice as great, so we could store twice as much energy as for the given disk.

9.63. Identify: We use energy conservation for this problem. The accelerations are constant, so we can use the constant-acceleration equations.

Set Up: We can use $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$, $K_{\text{rot}} = \dfrac{1}{2}I\omega^2$, $K_{\text{tr}} = \dfrac{1}{2}mv^2$, $U_{\text{g}} = mgy$, $\omega_z = \omega_{0z} + \alpha_z t$, $I = \dfrac{1}{2}MR^2$, and $\theta - \theta_0 = \omega_{0z}t + \dfrac{1}{2}\alpha_z t^2$. The system starts from rest, and the wheel turns through 8.00 rev in the first 5.00 s. We want to find the mass of the block.

Execute: First use $\theta - \theta_0 = \omega_{0z}t + \dfrac{1}{2}\alpha_z t^2$ to find α. 16π rad = 0 + $\dfrac{1}{2}\alpha(5.00\text{ s})^2$, which gives α = 4.021 rad/s^2. Now use $\omega_z = \omega_{0z} + \alpha_z t$ to find the angular speed of the wheel at the end of 5.00 s. $\omega = 0 + (4.021\text{ rad/s}^2)(5.00\text{ s})$ = 20.11 rad/s. Now use energy conservation for the system, $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$. $W_{\text{other}} = 0$ and $K_1 = 0$. For gravitational potential energy, call $y = 0$ the level of the block at the end of the first 5.00 s. This makes $U_2 = 0$ and $U_1 = mgy$, where y is the length of rope that has come off the rim of the wheel as it turns through 8.00 rev (which is 16.00π rad). This length is R(16.00π rad) = (0.800 m)(16.00π rad) = 40.21 m; therefore y = 40.21 m. Putting this into the energy equation gives $m_B gy = \dfrac{1}{2}m_B v^2 + \dfrac{1}{2}I\omega^2$. Using $I = \dfrac{1}{2}MR^2$ and $v = R\omega$, the energy equation becomes

$m_B gy = \dfrac{1}{2}m_B(R\omega)^2 + \dfrac{1}{2}\left(\dfrac{1}{2}m_{\text{wheel}}R^2\right)\omega^2$. Solving for m_B gives $m_B = \dfrac{\frac{1}{4}m_{\text{wheel}}R^2\omega^2}{gy - \frac{1}{2}R^2\omega^2}$. Putting in m_{wheel} = 5.00 kg, R = 0.800 m, ω = 20.11 rad/s, and y = 40.21 m, we get m_B = 1.22 kg.

Evaluate: As the block falls, its gravitational potential energy is converted to kinetic energy, but part of that kinetic energy goes to the wheel and part goes to the block.

9.64. Identify: Apply conservation of energy to the system of drum plus falling mass, and compare the results for earth and for Mars.

Set Up: $K_{\text{drum}} = \frac{1}{2}I\omega^2.\ \ K_{\text{mass}} = \frac{1}{2}mv^2.\ \ v = R\omega$ so if K_{drum} is the same, ω is the same and v is the same on both planets. Therefore, K_{mass} is the same. Let $y = 0$ at the initial height of the mass and take $+y$ upward. Configuration 1 is when the mass is at its initial position and 2 is when the mass has descended 5.00 m, so $y_1 = 0$ and $y_2 = -h$, where h is the height the mass descends.

Execute: (a) $K_1 + U_1 = K_2 + U_2$ gives $0 = K_{\text{drum}} + K_{\text{mass}} - mgh.$ $K_{\text{drum}} + K_{\text{mass}}$ are the same on both planets, so $mg_{\text{E}}h_{\text{E}} = mg_{\text{M}}h_{\text{M}}.$ $h_{\text{M}} = h_{\text{E}}\left(\dfrac{g_{\text{E}}}{g_{\text{M}}}\right) = (5.00\text{ m})\left(\dfrac{9.80\text{ m/s}^2}{3.71\text{ m/s}^2}\right) = 13.2\text{ m}.$

(b) $mg_{\rm M}h_{\rm M} = K_{\rm drum} + K_{\rm mass}$. $\tfrac{1}{2}mv^2 = mg_{\rm M}h_{\rm M} - K_{\rm drum}$ and

$$v = \sqrt{2g_{\rm M}h_{\rm M} - \frac{2K_{\rm drum}}{m}} = \sqrt{2(3.71\text{ m/s}^2)(13.2\text{ m}) - \frac{2(250.0\text{ J})}{15.0\text{ kg}}} = 8.04\text{ m/s}$$

EVALUATE: We did the calculations without knowing the moment of inertia I of the drum, or the mass and radius of the drum.

9.65. **IDENTIFY:** We use energy conservation. The kinetic energy is shared between the two blocks and the pulley.

SET UP: We can use $U_1 + K_1 + W_{\rm other} = U_2 + K_2$, $K_{\rm rot} = \dfrac{1}{2}I\omega^2$, $K_{\rm tr} = \dfrac{1}{2}mv^2$, and $U_{\rm g} = mgy$. The system starts from rest, and the pulley is turning at 8.00 rad/s after block B has descended 1.20 m. We want to find the mass of block A.

EXECUTE: First use $v_{\rm tan} = r\omega$ to find the speed of the block when ω = 8.00 rad/s.
$v_B = v_{\rm tan} = R\omega = (0.200\text{ m})(8.00\text{ rad/s}) = 1.60\text{ m/s}$. Now use energy conservation,
$U_1 + K_1 + W_{\rm other} = U_2 + K_2$. $K_1 = 0$ and $W_{\rm other} = 0$. $K_2 = K_A + K_B + K_{\rm pulley}$. Choose $y = 0$ at 1.20 m below the starting point of B, which makes $U_2 = 0$ and $U_1 = mgy$, where $y = 1.20$ m. We also know that $v_A = v_B = v = 1.60$ m/s. Therefore we have $m_Bgy = \dfrac{1}{2}m_Av^2 + \dfrac{1}{2}m_Bv^2 + \dfrac{1}{2}I\omega^2$. Solving for m_A gives

$m_A = \dfrac{2m_Bgy - m_Bv^2 - I\omega^2}{v^2}$. Using $m_B = 5.00$ kg, $y = 1.20$ m, $I = 1.30\ \text{kg}\cdot\text{m}^2$, $v = 1.60$ m/s, and ω = 8.00 rad/s, we get $m_A = 8.44$ kg.

EVALUATE: As block B falls, its gravitational potential energy gets converted to kinetic energy which is shared between itself, block A, and the pulley. This is a case where the pulley is *not* massless!

9.66. **IDENTIFY:** The speed of all points on the belt is the same, so $r_1\omega_1 = r_2\omega_2$ applies to the two pulleys.

SET UP: The second pulley, with half the diameter of the first, must have twice the angular velocity, and this is the angular velocity of the saw blade. $a_{\rm tan} = R\alpha$

EXECUTE: **(a)** $v_2 = (2(3450\text{ rev/min}))\left(\dfrac{\pi}{30}\dfrac{\text{rad/s}}{\text{rev/min}}\right)\left(\dfrac{0.208\text{ m}}{2}\right) = 75.1\text{ m/s}.$

(b) $a_{\rm rad} = \omega^2 r = \left(2(3450\text{ rev/min})\left(\dfrac{\pi}{30}\dfrac{\text{rad/s}}{\text{rev/min}}\right)\right)^2\left(\dfrac{0.208\text{ m}}{2}\right) = 5.43\times10^4\text{ m/s}^2,$

so the force holding sawdust on the blade would have to be about 5500 times as strong as gravity.

EVALUATE: In $v = r\omega$ and $a_{\rm rad} = r\omega^2$, ω must be in rad/s.

9.67. **IDENTIFY:** Apply $v = r\omega$.

SET UP: Points on the chain all move at the same speed, so $r_{\rm r}\omega_{\rm r} = r_{\rm f}\omega_{\rm f}$.

EXECUTE: The angular velocity of the rear wheel is $\omega_{\rm r} = \dfrac{v_{\rm r}}{r_{\rm r}} = \dfrac{5.00\text{ m/s}}{0.330\text{ m}} = 15.15\text{ rad/s}.$

The angular velocity of the front wheel is $\omega_{\rm f} = 0.600\text{ rev/s} = 3.77\text{ rad/s}$. $r_{\rm r} = r_{\rm f}(\omega_{\rm f}/\omega_{\rm r}) = 2.99\text{ cm}$.

EVALUATE: The rear sprocket and wheel have the same angular velocity and the front sprocket and wheel have the same angular velocity. α is the same for both, so the rear sprocket has a smaller radius since it has a larger angular velocity. The speed of a point on the chain is
$v = r_{\rm r}\omega_{\rm r} = (2.99\times10^{-2}\text{ m})(15.15\text{ rad/s}) = 0.453\text{ m/s}$. The linear speed of the bicycle is 5.00 m/s.

9.68. **IDENTIFY:** Use the constant angular acceleration equations, applied to the first revolution and to the first two revolutions.

SET UP: Let the direction the disk is rotating be positive. $\text{kg}\cdot\text{m}^2$. Let t be the time for the first revolution. The time for the first two revolutions is $t + 0.0865\text{ s}$.

EXECUTE: **(a)** $\theta - \theta_0 = \omega_{0z}t + \frac{1}{2}\alpha_z t^2$ applied to the first revolution and then to the first two revolutions gives $2\pi\text{ rad} = \frac{1}{2}\alpha_z t^2$ and $4\pi\text{ rad} = \frac{1}{2}\alpha_z (t + 0.0865\text{ s})^2$. Eliminating α_z between these equations gives $4\pi\text{ rad} = \dfrac{2\pi\text{ rad}}{t^2}(t + 0.0865\text{ s})^2$. $2t^2 = (t + 0.0865\text{ s})^2$. $\sqrt{2}t = \pm(t + 0.0865\text{ s})$. The positive root is $t = \dfrac{0.0865\text{ s}}{\sqrt{2} - 1} = 0.209\text{ s}$.

(b) $2\pi\text{ rad} = \frac{1}{2}\alpha_z t^2$ and $t = 0.209\text{ s}$ gives $\alpha_z = 288\text{ rad/s}^2$

EVALUATE: At the start of the second revolution, $\omega_{0z} = (288\text{ rad/s}^2)(0.209\text{ s}) = 60.19\text{ rad/s}$. The distance the disk rotates in the next 0.0865 s is $\theta - \theta_0 = \omega_{0z}t + \frac{1}{2}\alpha_z t^2 = (60.19\text{ rad/s})(0.0865\text{ s}) + \frac{1}{2}(288\text{ rad/s}^2)(0.0865\text{ s})^2 = 6.28\text{ rad}$, which is two revolutions.

9.69. **IDENTIFY:** This problem involves energy conservation and Newton's second law.

SET UP: Only conservative forces act on the system, so $U_1 + K_1 = U_2 + K_2$. The kinetic energy is due to the translation of the block and the rotation of the wheel, and $K_1 = 0$. Call point 2 the location of the block after it has fallen for 2.00 s. This makes $U_2 = 0$ and $U_1 = mgy$. We also use $v_y = v_{0y} + a_y t$, $y = y_0 + v_{0y}t + \dfrac{1}{2}a_y t^2$, and $\sum F_y = ma_y$. We want to find the kinetic energy of the wheel 2.00 s after motion has begun.

EXECUTE: $U_1 + K_1 = U_2 + K_2$ gives $mgy = \dfrac{1}{2}mv^2 + K_{\text{wheel}}$. We need to find v, so apply $K = \frac{1}{2}I\omega^2 + \frac{1}{2}m(\omega R)^2 = \frac{1}{2}(I + mR^2)\omega^2$. to the block, taking downward positive because that is the direction of its acceleration. This gives $mg - T = ma$ so Using $I = \frac{1}{2}mR^2$ and solving for ω, = $9.80\text{ m/s}^2 - \dfrac{9.00\text{ N}}{1.50\text{ kg}}$ = 3.80 m/s². Now use $v_y = v_{0y} + a_y t$ to find v, which gives

$v = 0 + (3.80\text{ m/s}^2)(2.00\text{ s})$ = 7.60 m/s. Find y using $y = y_0 + v_{0y}t + \dfrac{1}{2}a_y t^2$, from which we get

$y = \dfrac{1}{2}at^2 = \dfrac{1}{2}(3.80\text{ m/s}^2)(2.00\text{ s})^2$ = 7.60 m. Now return to energy conservation, where we found that $mgy = \dfrac{1}{2}mv^2 + K_{\text{wheel}}$. Solve for K_{wheel} to get

$$K_{\text{wheel}} = m\left(gy - \frac{v^2}{2}\right) = (1.50\text{ kg})\left[(9.80\text{ m/s}^2)(7.60\text{ m}) - \frac{(7.60\text{ m/s})^2}{2}\right] = 68.4\text{ J}.$$

EVALUATE: The kinetic energy of the block is $K_{\text{block}} = \dfrac{1}{2}mv^2 = \dfrac{1}{2}(1.50\text{ kg})(7.60\text{ m/s})^2$ = 43.3 J, which is around 2/3 the kinetic energy of the wheel. So the wheel has a large effect on the motion.

9.70. **IDENTIFY:** The moment of inertia of the section that is removed must be one-half the moment of inertia of the original disk.

SET UP: For a solid disk, $I = \frac{1}{2}mR^2$. Call m the mass of the removed piece and R its radius.

$I_m = \dfrac{1}{2}I_{M_0}$.

EXECUTE: $I_m = \frac{1}{2} I_{M_0}$ gives $\frac{1}{2}mR^2 = \frac{1}{2}(\frac{1}{2}M_0R_0^2)$. We need to find m. Since the disk is uniform, the mass of a given segment will be proportional to the area of that segment. In this case, the segment is the piece cut out of the center. So $\dfrac{m}{M_0} = \dfrac{A_R}{A_{R_0}} = \dfrac{\pi R^2}{\pi R_0^2} = \dfrac{R^2}{R_0^2}$, which gives $m = M_0\left(\dfrac{R^2}{R_0^2}\right)$. Combining the two results gives $\frac{1}{2}M_0\left(\dfrac{R^2}{R_0^2}\right)R^2 = \frac{1}{2}(\frac{1}{2}M_0R_0^2)$, from which we get $R = \dfrac{R_0}{2^{1/4}} = 0.841R_0$.

EVALUATE: Notice that the piece that is removed does not have one-half the mass of the original disk, nor is its radius one-half the original radius.

9.71. **IDENTIFY:** The falling wood accelerates downward as the wheel undergoes angular acceleration. Newton's second law applies to the wood and the wheel, and the linear kinematics formulas apply to the wood because it has constant acceleration.

SET UP: $\Sigma\vec{F} = m\vec{a}$, $\tau = I\alpha$, $a_{\text{tan}} = R\alpha$, $y - y_0 = v_{0y}t + \dfrac{1}{2}a_yt^2$.

EXECUTE: First use $y - y_0 = v_{0y}t + \frac{1}{2}a_yt^2$ to find the downward acceleration of the wood. With $v_0 = 0$, we have $a_y = 2(y - y_0)/t^2 = 2(12.0\text{ m})/(4.00\text{ s})^2 = 1.50\text{ m/s}^2$. Now apply Newton's second to the wood to find the tension in the rope. $\Sigma\vec{F} = m\vec{a}$ gives $mg - T = ma$, $T = m(g - a)$, which gives
$T = (8.20\text{ kg})(9.80\text{ m/s}^2 - 1.50\text{ m/s}^2) = 68.06\text{ N}$. Now use $a_{\text{tan}} = R\alpha$ and apply Newton's second law (in its rotational form) to the wheel. $\tau = I\alpha$ gives $TR = I\alpha$, $I = TR/\alpha = TR/(a/R) = TR^2/a$

$I = (68.06\text{ N})(0.320\text{ m})^2/(1.50\text{ m/s}^2) = 4.65\ \text{kg}\cdot\text{m}^2$.

EVALUATE: The tension in the rope affects the acceleration of the wood and causes the angular acceleration of the wheel.

9.72. **IDENTIFY:** Using energy considerations, the system gains as kinetic energy the lost potential energy, mgR.

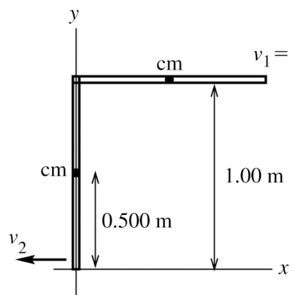
SET UP: The kinetic energy is $K = \frac{1}{2}I\omega^2 + \frac{1}{2}mv^2$, with $I = \frac{1}{2}mR^2$ for the disk. $v = R\omega$.

EXECUTE: $K = \frac{1}{2}I\omega^2 + \frac{1}{2}m(\omega R)^2 = \frac{1}{2}(I + mR^2)\omega^2$. Using $I = \frac{1}{2}mR^2$ and solving for ω, $\omega^2 = \dfrac{4}{3}\dfrac{g}{R}$ and $\omega = \sqrt{\dfrac{4}{3}\dfrac{g}{R}}$.

EVALUATE: The small object has speed $v = \sqrt{\dfrac{2}{3}}\sqrt{2gR}$. If it was not attached to the disk and was dropped from a height h, it would attain a speed $\sqrt{2gR}$. Being attached to the disk reduces its final speed by a factor of $\sqrt{\dfrac{2}{3}}$.

9.73. **IDENTIFY:** Use conservation of energy. The stick rotates about a fixed axis so $K = \frac{1}{2}I\omega^2$. Once we have ω use $v = r\omega$ to calculate v for the end of the stick.

SET UP: The object is sketched in Figure 9.73.



Take the origin of coordinates at the lowest point reached by the stick and take the positive y-direction to be upward.

Figure 9.73

EXECUTE: **(a)** Use $U = Mgy_{\text{cm}}$. $\Delta U = U_2 - U_1 = Mg(y_{\text{cm}2} - y_{\text{cm}1})$. The center of mass of the meter stick is at its geometrical center, so $y_{\text{cm}1} = 1.00\text{ m}$ and $y_{\text{cm}2} = 0.50\text{ m}$. Then

$\Delta U = (0.180\text{ kg})(9.80\text{ m/s}^2)(0.50\text{ m} - 1.00\text{ m}) = -0.882\text{ J}$.

(b) Use conservation of energy: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$. Gravity is the only force that does work on the meter stick, so $W_{\text{other}} = 0$. $K_1 = 0$. Thus $K_2 = U_1 - U_2 = -\Delta U$, where ΔU was calculated in part (a). $K_2 = \frac{1}{2}I\omega_2^2$ so $\frac{1}{2}I\omega_2^2 = -\Delta U$ and $\omega_2 = \sqrt{2(-\Delta U)/I}$. For stick pivoted about one end, $I = \frac{1}{3}ML^2$ where $L = 1.00\text{ m}$, so $\omega_2 = \sqrt{\dfrac{6(-\Delta U)}{ML^2}} = \sqrt{\dfrac{6(0.882\text{ J})}{(0.180\text{ kg})(1.00\text{ m})^2}} = 5.42\text{ rad/s}$.

(c) $v = r\omega = (1.00\text{ m})(5.42\text{ rad/s}) = 5.42\text{ m/s}$.

(d) For a particle in free fall, with $+y$ upward, $v_{0y} = 0$; $y - y_0 = -1.00\text{ m}$; $a_y = -9.80\text{ m/s}^2$; and $v_y = ?$ Solving the equation $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ for v_y gives

$v_y = -\sqrt{2a_y(y - y_0)} = -\sqrt{2(-9.80\text{ m/s}^2)(-1.00\text{ m})} = -4.43\text{ m/s}$.

EVALUATE: The magnitude of the answer in part (c) is larger. $U_{1,\text{grav}}$ is the same for the stick as for a particle falling from a height of 1.00 m. For the stick $K = \frac{1}{2}I\omega_2^2 = \frac{1}{2}(\frac{1}{3}ML^2)(v/L)^2 = \frac{1}{6}Mv^2$. For the stick and for the particle, K_2 is the same but the same K gives a larger v for the end of the stick than for the particle. The reason is that all the other points along the stick are moving slower than the end opposite the axis.

9.74. **IDENTIFY:** The student accelerates downward and causes the wheel to turn. Newton's second law applies to the student and to the wheel. The acceleration is constant so the kinematics formulas apply.

SET UP: $\Sigma\tau = I\alpha$, $\Sigma\vec{F} = m\vec{a}$, $y - y_0 = v_{0y}t + \frac{1}{2}a_yt^2$, $v_y = v_{0y} + a_yt$.

EXECUTE: Apply $\Sigma\tau = I\alpha$ to the wheel: $TR = I\alpha = I(\alpha/R)$, so $T = I\alpha/R^2$.

Apply $\Sigma\vec{F} = m\vec{a}$ to the student: $mg - T = ma$, so $T = m(g - a)$.

Equating these two expressions for T and solving for the acceleration gives $a = \dfrac{mg}{m + I/R^2}$. Now apply kinematics for $y - y_0$ to the student, using $v_{0y} = 0$, and solve for t.

$t = \sqrt{\dfrac{2(y - y_0)}{a_y}} = \sqrt{\dfrac{2(y - y_0)(m + I/R^2)}{mg}}$. Putting in $y - y_0 = 12.0$ m, $m = 43.0$ kg, $I = 9.60\text{ kg}\cdot\text{m}^2$, and $R = 0.300$ m, we get $t = 2.92$ s.

Now use $v_y = v_{0y} + a_y t$ to get v_y, where $a = \dfrac{mg}{m + I/R^2}$. Putting in the numbers listed above, the result is $v_y = 8.22$ m/s.

EVALUATE: If the wheel were massless, her speed would simply be $v = \sqrt{2gy} = 15.3$ m/s, so the effect of the massive wheel reduces her speed by nearly half.

9.75. IDENTIFY: Mechanical energy is conserved since there is no friction.

SET UP: $K_1 + U_1 = K_2 + U_2$, $K = \frac{1}{2}I\omega^2$ (for rotational motion), $K = \frac{1}{2}mv^2$ (for linear motion), $I = \dfrac{1}{12}ML^2$ for a slender rod.

EXECUTE: Take the initial position with the rod horizontal, and the final position with the rod vertical. The heavier sphere will be at the bottom and the lighter one at the top. Call the gravitational potential energy zero with the rod horizontal, which makes the initial potential energy zero. The initial kinetic energy is also zero. Applying $K_1 + U_1 = K_2 + U_2$ and calling A and B the spheres gives $0 = K_A + K_B + K_{rod} + U_A + U_B + U_{rod}$. $U_{rod} = 0$ in the final position since its center of mass has not moved. Therefore $0 = \frac{1}{2}m_A v_A^2 + \frac{1}{2}m_B v_B^2 + \frac{1}{2}I\omega^2 + m_A g\dfrac{L}{2} - m_B g\dfrac{L}{2}$. We also know that $v_A = v_B = (L/2)\,\omega$. Calling v the speed of the spheres, we get

$0 = \frac{1}{2}m_A v^2 + \frac{1}{2}m_B v^2 + \frac{1}{2}(\frac{1}{12})(ML^2)(2v/L)^2 + m_A g\frac{L}{2} - m_B g\frac{L}{2}$ Putting in $m_A = 0.0200$ kg, $m_B = 0.0500$ kg, $M = 0.120$ kg, and $L = 800$ m, we get $v = 1.46$ m/s.

EVALUATE: As the rod turns, the heavier sphere loses potential energy but the lighter one gains potential energy.

9.76. IDENTIFY: Apply conservation of energy to the system of cylinder and rope.

SET UP: Taking the zero of gravitational potential energy to be at the axle, the initial potential energy is zero (the rope is wrapped in a circle with center on the axle).When the rope has unwound, its center of mass is a distance πR below the axle, since the length of the rope is $2\pi R$ and half this distance is the position of the center of the mass. Initially, every part of the rope is moving with speed $\omega_0 R$, and when the rope has unwound, and the cylinder has angular speed ω, the speed of the rope is ωR (the upper end of the rope has the same tangential speed at the edge of the cylinder). $I = (1/2)MR^2$ for a uniform cylinder.

EXECUTE: $K_1 = K_2 + U_2$. $\left(\dfrac{M}{4} + \dfrac{m}{2}\right)R^2\omega_0^2 = \left(\dfrac{M}{4} + \dfrac{m}{2}\right)R^2\omega^2 - mg\pi R$. Solving for ω gives

$\omega = \sqrt{\omega_0^2 + \dfrac{(4\pi mg/R)}{(M + 2m)}}$, and the speed of any part of the rope is $v = \omega R$.

EVALUATE: When $m \to 0$, $\omega \to \omega_0$, When $m >> M$, $\omega = \sqrt{\omega_0^2 + \dfrac{2\pi g}{R}}$ and $v = \sqrt{v_0^2 + 2\pi gR}$. This is the final speed when an object with initial speed v_0 descends a distance πR.

9.77. IDENTIFY: Apply conservation of energy to the system consisting of blocks A and B and the pulley.

SET UP: The system at points 1 and 2 of its motion is sketched in Figure 9.77.

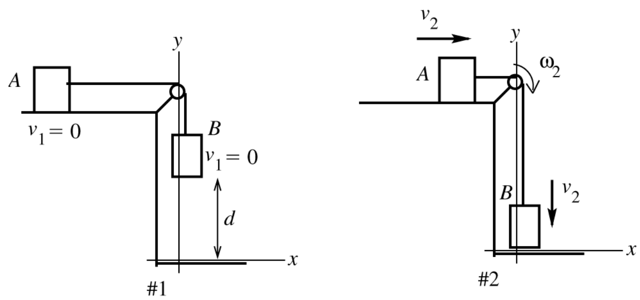


Figure 9.77

Use the work-energy relation $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$. Use coordinates where $+y$ is upward and where the origin is at the position of block *B* after it has descended. The tension in the rope does positive work on block *A* and negative work of the same magnitude on block *B*, so the net work done by the tension in the rope is zero. Both blocks have the same speed.

EXECUTE: Gravity does work on block *B* and kinetic friction does work on block *A*. Therefore $W_{\text{other}} = W_f = -\mu_k m_A g d.$

$K_1 = 0$ (system is released from rest)

$U_1 = m_B g y_{B1} = m_B g d;\; U_2 = m_B g y_{B2} = 0$

$K_2 = \frac{1}{2} m_A v_2^2 + \frac{1}{2} m_B v_2^2 + \frac{1}{2} I \omega_2^2.$

But $v(\text{blocks}) = R\omega(\text{pulley})$, so $\omega_2 = v_2/R$ and

$K_2 = \frac{1}{2}(m_A + m_B)v_2^2 + \frac{1}{2} I (v_2/R)^2 = \frac{1}{2}(m_A + m_B + I/R^2)v_2^2$

Putting all this into the work-energy relation gives

$m_B g d - \mu_k m_A g d = \frac{1}{2}(m_A + m_B + I/R^2)v_2^2$

$(m_A + m_B + I/R^2)v_2^2 = 2gd(m_B - \mu_k m_A)$

$$v_2 = \sqrt{\frac{2gd(m_B - \mu_k m_A)}{m_A + m_B + I/R^2}}$$

EVALUATE: If $m_B >> m_A$ and s I/R^2, then $v_2 = \sqrt{2gd}$; block *B* falls freely. If *I* is very large, v_2 is very small. Must have $m_B > \mu_k m_A$ for motion, so the weight of *B* will be larger than the friction force on *A*. I/R^2 has units of mass and is in a sense the "effective mass" of the pulley.

9.78. **IDENTIFY:** Apply conservation of energy to the system of two blocks and the pulley.

SET UP: Let the potential energy of each block be zero at its initial position. The kinetic energy of the system is the sum of the kinetic energies of each object. $v = R\omega$, where *v* is the common speed of the blocks and ω is the angular velocity of the pulley.

EXECUTE: The amount of gravitational potential energy which has become kinetic energy is $K = (4.00\text{ kg} - 2.00\text{ kg})(9.80\text{ m/s}^2)(5.00\text{ m}) = 98.0\text{ J}$. In terms of the common speed *v* of the blocks, the kinetic energy of the system is $K = \frac{1}{2}(m_1 + m_2)v^2 + \frac{1}{2} I \left(\frac{v}{R}\right)^2.$

$K = v^2 \frac{1}{2}\left(4.00\text{ kg} + 2.00\text{ kg} + \frac{(0.380\text{ kg}\cdot\text{m}^2)}{(0.160\text{ m})^2}\right) = v^2(10.422\text{ kg})$. Solving for *v* gives

$$v = \sqrt{\frac{98.0\text{ J}}{10.422\text{ kg}}} = 3.07\text{ m/s}.$$

EVALUATE: If the pulley is massless, $98.0\text{ J} = \frac{1}{2}(4.00\text{ kg} + 2.00\text{ kg})v^2$ and $v = 5.72\text{ m/s}$. The moment of inertia of the pulley reduces the final speed of the blocks.

9.79. **IDENTIFY:** $I = I_1 + I_2$. Apply conservation of energy to the system. The calculation is similar to Example 9.8.

SET UP: $\omega = \dfrac{v}{R_1}$ for part (b) and $\omega = \dfrac{v}{R_2}$ for part (c).

EXECUTE: **(a)** $I = \frac{1}{2}M_1R_1^2 + \frac{1}{2}M_2R_2^2 = \frac{1}{2}((0.80\text{ kg})(2.50\times10^{-2}\text{ m})^2 + (1.60\text{ kg})(5.00\times10^{-2}\text{ m})^2)$

$I = 2.25\times10^{-3}\text{ kg}\cdot\text{m}^2$.

(b) The method of Example 9.8 yields $v = \sqrt{\dfrac{2gh}{1+(I/mR_1^2)}}$.

$$v = \sqrt{\frac{2(9.80\text{ m/s}^2)(2.00\text{ m})}{(1+((2.25\times10^{-3}\text{ kg}\cdot\text{m}^2)/(1.50\text{ kg})(0.025\text{ m})^2))}} = 3.40\text{ m/s}.$$

(c) The same calculation, with R_2 instead of R_1 gives $v = 4.95\text{ m/s}$.

EVALUATE: The final speed of the block is greater when the string is wrapped around the larger disk. $v = R\omega$, so when $R = R_2$ the factor that relates v to ω is larger. For $R = R_2$ a larger fraction of the total kinetic energy resides with the block. The total kinetic energy is the same in both cases (equal to mgh), so when $R = R_2$ the kinetic energy and speed of the block are greater.

9.80. **IDENTIFY:** The potential energy of the falling block is transformed into kinetic energy of the block and kinetic energy of the turning wheel, but some of it is lost to the work by friction. Energy conservation applies, with the target variable being the angular velocity of the wheel when the block has fallen a given distance.

SET UP: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$, where $K = \frac{1}{2}mv^2$, $U = mgh$, and W_{other} is the work done by friction.

EXECUTE: Energy conservation gives $mgh + (-9.00\text{ J}) = \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2$. $v = R\omega$, so $\frac{1}{2}mv^2 = \frac{1}{2}mR^2\omega^2$ and $mgh + (-9.00\text{ J}) = \frac{1}{2}(mR^2 + I)\omega^2$. Solving for ω gives

$$\omega = \sqrt{\frac{2[mgh + (-9.00\text{ J})]}{mR^2 + I}} = \sqrt{\frac{2[(0.340\text{ kg})(9.8\text{ m/s}^2)(3.00\text{ m}) - 9.00\text{ J}]}{(0.340\text{ kg})(0.180\text{ m})^2 + 0.480\text{ kg}\cdot\text{m}^2}} = 2.01\text{ rad/s}.$$

EVALUATE: Friction does negative work because it opposes the turning of the wheel.

9.81. **IDENTIFY:** Apply conservation of energy to relate the height of the mass to the kinetic energy of the cylinder.

SET UP: First use $K(\text{cylinder}) = 480\text{ J}$ to find ω for the cylinder and v for the mass.

EXECUTE: $I = \frac{1}{2}MR^2 = \frac{1}{2}(10.0\text{ kg})(0.150\text{ m})^2 = 0.1125\text{ kg}\cdot\text{m}^2$. $K = \frac{1}{2}I\omega^2$ so $\omega = \sqrt{2K/I} = 92.38\text{ rad/s}$. $v = R\omega = 13.86\text{ m/s}$.

SET UP: Use conservation of energy $K_1 + U_1 = K_2 + U_2$ to solve for the distance the mass descends. Take $y = 0$ at lowest point of the mass, so $y_2 = 0$ and $y_1 = h$, the distance the mass descends.

EXECUTE: $K_1 = U_2 = 0$ so $U_1 = K_2$. $mgh = \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2$, where $m = 12.0\text{ kg}$. For the cylinder, $I = \frac{1}{2}MR^2$ and $\omega = v/R$, so $\frac{1}{2}I\omega^2 = \frac{1}{4}Mv^2$. Solving $mgh = \frac{1}{2}mv^2 + \frac{1}{4}Mv^2$ for h gives

$$h = \frac{v^2}{2g}\left(1 + \frac{M}{2m}\right) = 13.9\text{ m}.$$

EVALUATE: For the cylinder $K_{cyl} = \frac{1}{2}I\omega^2 = \frac{1}{2}(\frac{1}{2}MR^2)(v/R)^2 = \frac{1}{4}Mv^2$. $K_{mass} = \frac{1}{2}mv^2$, so $K_{mass} = (2m/M)K_{cyl} = [2(12.0 \text{ kg})/10.0 \text{ kg}](480 \text{ J}) = 1150 \text{ J}$. The mass has 1150 J of kinetic energy when the cylinder has 480 J of kinetic energy and at this point the system has total energy 1630 J since $U_2 = 0$. Initially the total energy of the system is $U_1 = mgy_1 = mgh = 1630$ J, so the total energy is shown to be conserved.

9.82. IDENTIFY: Energy conservation: Loss of U of box equals gain in K of system. Both the cylinder and pulley have kinetic energy of the form $K = \frac{1}{2}I\omega^2$.

$$m_{box}gh = \frac{1}{2}m_{box}v_{box}^2 + \frac{1}{2}I_{pulley}\omega_{pulley}^2 + \frac{1}{2}I_{cylinder}\omega_{cylinder}^2.$$

SET UP: $\omega_{pulley} = \dfrac{v_{box}}{r_{pulley}}$ and $\omega_{cylinder} = \dfrac{v_{box}}{r_{cylinder}}$.

Let B = box, P = pulley, and C = cylinder.

EXECUTE: $m_B gh = \frac{1}{2}m_B v_B^2 + \frac{1}{2}\left(\frac{1}{2}m_P r_P^2\right)\left(\dfrac{v_B}{r_P}\right)^2 + \frac{1}{2}\left(\frac{1}{2}m_C r_C^2\right)\left(\dfrac{v_B}{r_C}\right)^2$. $m_B gh = \dfrac{1}{2}m_B v_B^2 + \dfrac{1}{4}m_P v_B^2 + \dfrac{1}{4}m_C v_B^2$

and $v_B = \sqrt{\dfrac{m_B gh}{\frac{1}{2}m_B + \frac{1}{4}m_P + \frac{1}{4}m_C}} = \sqrt{\dfrac{(3.00 \text{ kg})(9.80 \text{ m/s}^2)(2.50 \text{ m})}{1.50 \text{ kg} + \frac{1}{4}(7.00 \text{ kg})}} = 4.76 \text{ m / s}.$

EVALUATE: If the box was disconnected from the rope and dropped from rest, after falling 2.50 m its speed would be $v = \sqrt{2g(2.50 \text{ m})} = 7.00$ m/s. Since in the problem some of the energy of the system goes into kinetic energy of the cylinder and of the pulley, the final speed of the box is less than this.

9.83. IDENTIFY: We know (or can calculate) the masses and geometric measurements of the various parts of the body. We can model them as familiar objects, such as uniform spheres, rods, and cylinders, and calculate their moments of inertia and kinetic energies.

SET UP: My total mass is $m = 90$ kg. I model my head as a uniform sphere of radius 8 cm. I model my trunk and legs as a uniform solid cylinder of radius 12 cm. I model my arms as slender rods of length 60 cm. $\omega = 72$ rev/min = 7.5 rad/s. For a solid uniform sphere, $I = 2/5\ MR^2$, for a solid cylinder, $I = \frac{1}{2}MR^2$, and for a rod rotated about one end $I = 1/3\ ML^2$.

EXECUTE: **(a)** Using the formulas indicated above, we have $I_{tot} = I_{head} + I_{trunk+legs} + I_{arms}$, which gives $I_{tot} = \frac{2}{5}(0.070m)(0.080 \text{ m})^2 + \frac{1}{2}(0.80m)(0.12 \text{ m})^2 + 2\left(\frac{1}{3}\right)(0.13m)(0.60 \text{ m})^2 = 3.3 \text{ kg}\cdot\text{m}^2$ where we have used $m = 90$ kg.

(b) $K_{rot} = \frac{1}{2}I\omega^2 = \frac{1}{2}(3.3 \text{ kg}\cdot\text{m}^2)(7.5 \text{ rad/s})^2 = 93$ J.

EVALUATE: According to these estimates about 85% of the total I is due to the outstretched arms. If the initial translational kinetic energy $\frac{1}{2}mv^2$ of the skater is converted to this rotational kinetic energy as he goes into a spin, his initial speed must be 1.4 m/s.

9.84. IDENTIFY: Apply the parallel-axis theorem to each side of the square.

SET UP: Each side has length a and mass $M/4$, and the moment of inertia of each side about an axis perpendicular to the side and through its center is $\frac{1}{12}\left(\frac{1}{4}Ma^2\right) = \frac{1}{48}Ma^2$.

EXECUTE: The moment of inertia of each side about the axis through the center of the square is, from the perpendicular axis theorem, $\dfrac{Ma^2}{48} + \dfrac{M}{4}\left(\dfrac{a}{2}\right)^2 = \dfrac{Ma^2}{12}$. The total moment of inertia is the sum of the contributions from the four sides, or $4\times\dfrac{Ma^2}{12} = \dfrac{Ma^2}{3}$.

EVALUATE: If all the mass of a side were at its center, a distance $a/2$ from the axis, we would have $I = 4\left(\frac{M}{4}\right)\left(\frac{a}{2}\right)^2 = \frac{1}{4}Ma^2$. If all the mass was divided equally among the four corners of the square, a distance $a/\sqrt{2}$ from the axis, we would have $I = 4\left(\frac{M}{4}\right)\left(\frac{a}{\sqrt{2}}\right)^2 = \frac{1}{2}Ma^2$. The actual I is between these two values.

9.85. IDENTIFY: The density depends on the distance from the center of the sphere, so it is a function of r. We need to integrate to find the mass and the moment of inertia.

SET UP: $M = \int dm = \int \rho dV$ and $I = \int dI$.

EXECUTE: **(a)** Divide the sphere into thin spherical shells of radius r and thickness dr. The volume of each shell is $dV = 4\pi r^2 dr$. $\rho(r) = a - br$, with $a = 3.00\times10^3\ \text{kg/m}^3$ and $b = 9.00\times10^3\ \text{kg/m}^4$.

Integrating gives $M = \int dm = \int \rho dV = \int_0^R (a - br)4\pi r^2 dr = \frac{4}{3}\pi R^3\left(a - \frac{3}{4}bR\right)$.

$$M = \frac{4}{3}\pi(0.200\ \text{m})^3\left(3.00\times10^3\ \text{kg/m}^3 - \frac{3}{4}(9.00\times10^3\ \text{kg/m}^4)(0.200\ \text{m})\right) = 55.3\ \text{kg}.$$

(b) The moment of inertia of each thin spherical shell is

$$dI = \frac{2}{3}r^2 dm = \frac{2}{3}r^2\rho dV = \frac{2}{3}r^2(a - br)4\pi r^2 dr = \frac{8\pi}{3}r^4(a - br)dr.$$

$$I = \int_0^R dI = \frac{8\pi}{3}\int_0^R r^4(a - br)dr = \frac{8\pi}{15}R^5\left(a - \frac{5b}{6}R\right).$$

$$I = \frac{8\pi}{15}(0.200\ \text{m})^5\left(3.00\times10^3\ \text{kg/m}^3 - \frac{5}{6}(9.00\times10^3\ \text{kg/m}^4)(0.200\ \text{m})\right) = 0.804\ \text{kg}\cdot\text{m}^2.$$

EVALUATE: We cannot use the formulas $M = \rho V$ and $I = \frac{1}{2}MR^2$ because this sphere is not uniform throughout. Its density increases toward the surface. For a uniform sphere with density $3.00\times10^3\ \text{kg/m}^3$, the mass is $\frac{4}{3}\pi R^3\rho = 100.5\ \text{kg}$. The mass of the sphere in this problem is less than this. For a uniform sphere with mass 55.3 kg and $R = 0.200$ m, $I = \frac{2}{5}MR^2 = 0.885\ \text{kg}\cdot\text{m}^2$. The moment of inertia for the sphere in this problem is less than this, since the density decreases with distance from the center of the sphere.

9.86. IDENTIFY: Write K in terms of the period T and take derivatives of both sides of this equation to relate dK/dt to dT/dt.

SET UP: $\omega = \frac{2\pi}{T}$ and $K = \frac{1}{2}I\omega^2$. The speed of light is $c = 3.00\times10^8$ m/s.

EXECUTE: **(a)** $K = \frac{2\pi^2 I}{T^2}$. $\frac{dK}{dt} = -\frac{4\pi^2 I}{T^3}\frac{dT}{dt}$. The rate of energy loss is $\frac{4\pi^2 I}{T^3}\frac{dT}{dt}$. Solving for the moment of inertia I in terms of the power P,

$$I = \frac{PT^3}{4\pi^2}\frac{1}{dT/dt} = \frac{(5\times10^{31}\ \text{W})(0.0331\ \text{s})^3}{4\pi^2}\frac{1\ \text{s}}{4.22\times10^{-13}\ \text{s}} = 1.09\times10^{38}\ \text{kg}\cdot\text{m}^2$$

(b) $R = \sqrt{\frac{5I}{2M}} = \sqrt{\frac{5(1.08\times10^{38}\ \text{kg}\cdot\text{m}^2)}{2(1.4)(1.99\times10^{30}\ \text{kg})}} = 9.9\times10^3\ \text{m}$, about 10 km.

(c) $v = \dfrac{2\pi R}{T} = \dfrac{2\pi(9.9\times10^3\,\text{m})}{(0.0331\text{ s})} = 1.9\times10^6\text{ m/s} = 6.3\times10^{-3}c.$

(d) $\rho = \dfrac{M}{V} = \dfrac{M}{(4\pi/3)R^3} = 6.9\times10^{17}\,\text{kg}/\text{m}^3$, which is much higher than the density of ordinary rock by 14 orders of magnitude, and is comparable to nuclear mass densities.

EVALUATE: I is huge because M is huge. A small rate of change in the period corresponds to a large release of energy.

9.87. **IDENTIFY:** The graph with the problem in the text shows that the angular acceleration increases linearly with time and is therefore not constant.

SET UP: $\omega_z = d\theta/dt$, $\alpha_z = d\omega_z/dt$.

EXECUTE: **(a)** Since the angular acceleration is not constant, Eq. (9.11) cannot be used, so we must use $\alpha_z = d\omega_z/dt$ and $\omega_z = d\theta/dt$ and integrate to find the angle. The graph passes through the origin and has a constant positive slope of 6/5 rad/s^3, so the equation for α_z is α_z = (1.2 rad/s^3)t. Using $\alpha_z = d\omega_z/dt$ gives $\omega_z = \omega_{0z} + \int_0^t \alpha_z dt = 0 + \int_0^t (1.2\text{ rad/s}^3)t dt = (0.60\text{ rad/s}^3)t^2$. Now we must use $\omega_z = d\theta/dt$ and integrate again to get the angle.

$\theta_2 - \theta_1 = \int_0^t \omega_z dt = \int_0^t (0.60\text{ rad/s}^3)t^2 dt = (0.20\text{ rad/s}^3)t^3$ = (0.20 rad/s^3)(5.0 s)^3 = 25 rad.

(b) The result of our first integration gives ω_z = (0.60 rad/s^3)(5.0 s)^2 = 15 rad/s.

(c) The result of our second integration gives 4π rad = (0.20 rad/s^3)t^3, so t = 3.98 s. Therefore ω_z = (0.60 rad/s^3)(3.98 s)^2 = 9.48 rad/s.

EVALUATE: When the constant-acceleration angular kinematics formulas do not apply, we must go back to basic definitions.

9.88. **IDENTIFY** and **SET UP:** The graph of a^2 versus $(\theta-\theta_0)^2$ is shown in Figure 9.88. It is a straight line with a positive slope. The angular acceleration is constant.

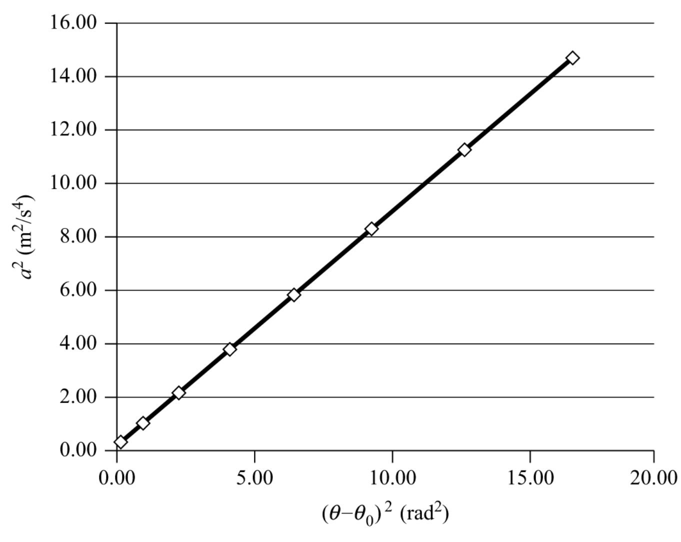

Figure 9.88

EXECUTE: **(a)** From graphing software, the slope is 0.921 m^2/s^4 and the y-intercept is 0.233 m^2/s^4.

(b) The resultant acceleration is $a^2 = a_{\tan}^2 + a_{\text{rad}}^2$. $a_{\tan} = r\alpha_z$ and $a_{\text{rad}} = r\omega_z^2$, where $\omega_z^2 = \omega_{z0}^2 + 2\alpha_z(\theta - \theta_0) = 0 + 2\alpha_z(\theta - \theta_0)$. Therefore the resultant acceleration is

$a^2 = (r\,\alpha_z)^2 + [2r\,\alpha_z(\theta - \theta_0)]^2$

$a^2 = 4r^2\alpha_z^2(\theta - \theta_0)^2 + (r\alpha_z)^2$.

From this result, we see that the slope of the graph is $4r^2\alpha_z^2$, so $4r^2\alpha_z^2 = 0.921\ \text{m}^2/\text{s}^4$. Solving for α_z gives $\alpha_z = \sqrt{\dfrac{0.921\ \text{m}^2/\text{s}^4}{4(0.800\ \text{m})^2}} = 0.600\ \text{rad/s}^2$.

(c) Using $\omega_z^2 = \omega_{z0}^2 + 2\alpha_z(\theta - \theta_0)$ gives $\omega_z^2 = 0 + 2(0.600\ \text{rad/s}^2)(3\pi/4\ \text{rad})$, $\omega_z = 1.6815$ rad/s. The speed is $v = r\,\omega_z = (0.800\ \text{m})(1.6815\ \text{rad/s}) = 1.35$ m/s.

(d) Call ϕ the angle between the linear velocity and the resultant acceleration. The resultant velocity is tangent to the circle, so $\tan\phi = \dfrac{a_{\text{rad}}}{a_{\tan}} = \dfrac{r\omega_z^2}{r\alpha_z} = \dfrac{\omega_z^2}{\alpha_z}$. It is also the case that $\omega_z^2 = 2\alpha_z\Delta\theta$, so

$\tan\phi = \dfrac{2\alpha_z\Delta\theta}{\alpha_z} = 2\Delta\theta = 2(\pi/2) = \pi$. Thus $\phi = \arctan \pi = 72.3°$.

EVALUATE: According to the work in parts (a) and (b), the *y*-intercept of the graph is $(r\alpha_z)^2$ and is equal to 0.233 m^2/s^4. Solving for α_z gives $\alpha_z = \sqrt{\dfrac{0.233\ \text{m}^2/\text{s}^4}{(0.800\ \text{m})^2}} = 0.60\ \text{rad/s}^2$, as we found in part (b).

9.89. IDENTIFY and SET UP: The equation of the graph in the text is $d = (165\ \text{cm/s}^2)t^2$. For constant acceleration, the second time derivative of the position (*d* in this case) is a constant.

EXECUTE: (a) $\dfrac{d(d)}{dt} = (330\ \text{cm/s}^2)t$ and $\dfrac{d^2(d)}{dt^2} = 330\ \text{cm/s}^2$, which is a constant. Therefore the acceleration of the metal block is a constant $330\ \text{cm/s}^2 = 3.30\ \text{m/s}^2$.

(b) $v = \dfrac{d(d)}{dt} = (330\ \text{cm/s}^2)t$. When $d = 1.50$ m = 150 cm, we have 150 cm = $(165\ \text{cm/s}^2)t^2$, which gives $t = 0.9535$ s. Thus $v = 330\ \text{cm/s}^2)(0.9535\ \text{s}) = 315\ \text{cm/s} = 3.15$ m/s.

(c) Energy conservation $K_1 + U_1 = K_2 + U_2$ gives $mgd = \tfrac{1}{2}I\omega^2 + \tfrac{1}{2}mv^2$. Using $\omega = v/r$, solving for *I* and putting in the numbers $m = 5.60$ kg, $d = 1.50$ m, $r = 0.178$ m, $v = 3.15$ m/s, we get $I = 0.348$ $\text{kg}\cdot\text{m}^2$.

(d) Newton's second law gives $mg - T = ma$, $T = m(g - a) = (5.60\ \text{kg})(9.80\ \text{m/s}^2 - 3.30\ \text{m/s}^2) = 36.4$ N.

EVALUATE: When dealing with non-uniform objects, such as this flywheel, we cannot use the standard moment of inertia formulas and must resort to other ways.

9.90. IDENTIFY: Apply $I = \int r^2\, dm$.

SET UP: Let *z* be the coordinate along the vertical axis. $r(z) = \dfrac{zR}{h}$. $dm = \pi\rho\dfrac{R^2z^2}{h^2}$ and

$$dI = \frac{\pi\rho}{2}\frac{R^4}{h^4}z^4\, dz.$$

EXECUTE: $I = \int dI = \dfrac{\pi\rho}{2}\dfrac{R^4}{h^4}\int_0^h z^4\, dz = \dfrac{\pi\rho}{10}\dfrac{R^4}{h^4}\left[z^5\right]_0^h = \dfrac{1}{10}\pi\rho R^4 h$. The volume of a right circular cone is $V = \tfrac{1}{3}\pi R^2 h$, the mass is $\tfrac{1}{3}\pi\rho R^2 h$ and so $I = \dfrac{3}{10}\left(\dfrac{\pi\rho R^2 h}{3}\right)R^2 = \dfrac{3}{10}MR^2$.

EVALUATE: For a uniform cylinder of radius R and for an axis through its center, $I = \frac{1}{2}MR^2$. I for the cone is less, as expected, since the cone is constructed from a series of parallel discs whose radii decrease from R to zero along the vertical axis of the cone.

9.91. **IDENTIFY:** Follow the steps outlined in the problem.

SET UP: $\omega_z = d\theta/dt$. $\alpha_z = d^2\omega_z/dt^2$.

EXECUTE: **(a)** $ds = r\,d\theta = r_0 d\theta + \beta\theta\, d\theta$ so $s(\theta) = r_0\theta + \frac{\beta}{2}\theta^2$. θ must be in radians.

(b) Setting $s = vt = r_0\theta + \frac{\beta}{2}\theta^2$ gives a quadratic in θ. The positive solution is

$$\theta(t) = \frac{1}{\beta}\left[\sqrt{r_0{}^2 + 2\beta vt} - r_0\right].$$

(The negative solution would be going backwards, to values of r smaller than r_0.)

(c) Differentiating, $\omega_z(t) = \dfrac{d\theta}{dt} = \dfrac{v}{\sqrt{r_0^2 + 2\beta vt}}$, $\alpha_z = \dfrac{d\omega_z}{dt} = -\dfrac{\beta v^2}{(r_0^2 + 2\beta vt)^{3/2}}$. The angular acceleration α_z is not constant.

(d) $r_0 = 25.0$ mm. θ must be measured in radians, so $\beta = (1.55\,\mu\text{m/rev})(1\text{ rev}/2\pi\text{ rad}) = 0.247\,\mu\text{m/rad}$. Using $\theta(t)$ from part (b), the total angle turned in $74.0\text{ min} = 4440\text{ s}$ is

$$\theta = \frac{1}{2.47\times10^{-7}\text{ m/rad}}\left(\sqrt{2(2.47\times10^{-7}\text{ m/rad})(1.25\text{ m/s})(4440\text{ s}) + (25.0\times10^{-3}\text{ m})^2} - 25.0\times10^{-3}\text{ m}\right)$$

$\theta = 1.337\times10^5$ rad, which is 2.13×10^4 rev.

(e) The graphs are sketched in Figure 9.91.

EVALUATE: ω_z must decrease as r increases, to keep $v = r\omega$ constant. For ω_z to decrease in time, α_z must be negative.

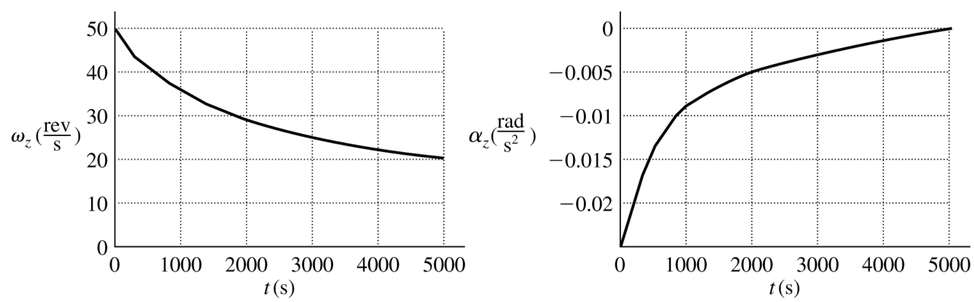

Figure 9.91

9.92. **IDENTIFY** and **SET UP:** For constant angular speed $\theta = \omega t$.

EXECUTE: **(a)** $\theta = \omega t$ = (14 rev/s)(2π rad/rev)(1/120 s) = 42°, which is choice (d).

EVALUATE: This is quite a large rotation in just one frame.

9.93. **IDENTIFY** and **SET UP:** The average angular acceleration is $\alpha_{\text{av}} = \dfrac{\omega - \omega_0}{t}$.

EXECUTE: **(a)** $\alpha_{\text{av}} = \dfrac{\omega - \omega_0}{t}$ = [8 rev/s – (–14 rev/s)]/(10 s) = (2.2 rev/s)(2π rad/rev) = 44π/10 rad/s^2 which is choice (d).

EVALUATE: This is nearly 14 rad/s^2.

9.94. **IDENTIFY and SET UP:** The rotational kinetic energy is $K = \frac{1}{2}I\omega^2$ and the kinetic energy due to running is $K = \frac{1}{2}mv^2$.

EXECUTE: Equating the two kinetic energies gives $\frac{1}{2}mv^2 = \frac{1}{2}I\omega^2$. Using $I = \frac{1}{2}mR^2$, we have $\frac{1}{2}(\frac{1}{2}mr^2)\omega^2 = \frac{1}{2}mv^2$, which gives $v = \dfrac{r\omega}{\sqrt{2}} = \dfrac{(0.05\text{ m})(14\text{ rev/s})(2\pi\text{ rad/rev})}{\sqrt{2}} = 3.11$ m/s, choice (c).

EVALUATE: This is about 3 times as fast as a human walks.

9.95. **IDENTIFY and SET UP:** $I = \frac{1}{2}mR^2$.

EXECUTE: **(a)** $I = \frac{1}{2}mR^2$, so if we double the radius but keep the mass fixed, the moment of inertia increases by a factor of 4, which is choice (d).

EVALUATE: The difference in length of the two eels plays no part in their moment of inertia if their mass is the same in both cases.

10

DYNAMICS OF ROTATIONAL MOTION

VP10.3.1. **IDENTIFY:** The force of the cable produces a torque on the cylinder, giving it an angular acceleration. We apply the rotational analog of Newton's second law.

SET UP: $\sum\tau_z = I\alpha_z$, $I = \frac{1}{2}MR^2$ for a solid cylinder, $a_{\tan} = r\alpha_z$ apply in this case.

EXECUTE: **(a)** $a_{\tan} = r\alpha_z$ gives $\alpha_z = a_{\tan}/R = (0.60\ \text{m/s}^2)/(0.060\ \text{m}) = 10\ \text{rad/s}^2$.

(b) Apply $\sum\tau_z = I\alpha_z$ to the cylinder. There is only one torque, so $\tau_z = I\alpha_z = \frac{1}{2}MR^2\alpha_z$.

$\tau_z = \frac{1}{2}(50\ \text{kg})(0.060\ \text{m})^2(10\ \text{rad/s}^2) = 0.90\ \text{N}\cdot\text{m}$.

(c) $\tau_z = FR \quad \rightarrow \quad F = \tau_z/R = (0.90\ \text{N}\cdot\text{m})/(0.060\ \text{m}) = 15\ \text{N}$.

EVALUATE: When using $\sum\tau_z = I\alpha_z$, α_z *must* be in radian measure.

VP10.3.2. **IDENTIFY:** Gravity pulls the block, causing tension in the cable. This tension produces a torque on the cylinder, giving it an angular acceleration. We apply the rotational analog of Newton's second law to the wheel and the linear form to the falling block.

SET UP: $\sum\tau_z = I\alpha_z$, $I = MR^2$ for a hollow cylinder, $a_{\tan} = r\alpha_z$, $\sum F_y = ma_y$ apply in this case. Call m the mass of the block and M the mass of the wheel.

EXECUTE: **(a)** Apply $\sum F_y = ma_y$ to the block. Since the block accelerates downward, it is best to call the y-axis positive downward. This gives $mg - T = ma_y$ (Eq. 1)

Now apply $\sum\tau_z = I\alpha_z$ to the wheel. $TR = MR^2\alpha_z$. Using $a_y = a_{\tan} = R\alpha_z$, the second equation becomes $T = MR(a_y/R) = Ma_y$ (Eq. 2)

Combining Eq. 1 and Eq. 2 gives $mg - Ma_y = ma_y$. Solving for a_y gives

$a_y = \dfrac{mg}{m+M} = \dfrac{g}{1+M/m}$.

(b) Eq. 2 gives $T = Ma_y = \dfrac{Mg}{1+M/m}$, which can also be written as $T = \dfrac{mg}{1+m/M}$.

EVALUATE: Careful! The torque on the wheel is *not* equal to mgR! It is the *tension* that turns the wheel, and $T \neq mg$. Look at our answers in some limiting cases. If $m >> M$, the ratio M/m is very small, so the acceleration approaches g. This is reasonable because the wheel has very little effect on the block, so the block is essentially in freefall. The tension approaches zero because M approaches zero. This is reasonable because the block is essentially in freefall. If $M >> m$, the acceleration approaches zero since the small m produces very little acceleration of the much heavier wheel. The tension approaches mg because $m/M << 1$, so the block is essentially just hanging with almost no acceleration.

VP10.3.3. **IDENTIFY:** Gravity pulls the block, causing tension in the cable. The torque on the cylinder is due to the tension in the cable. We apply the rotational analog of Newton's second law to the cylinder and the linear form to the block. We do not know the moment of inertia of the drum.

SET UP: $\sum\tau_z = I\alpha_z$, $a_{\tan} = r\alpha_z$, $\sum F_y = ma_y$ apply in this case. Call m the mass of the block.

EXECUTE: **(a)** Apply $\sum F_y = ma_y$ to the block. Since the block accelerates downward, it is best to call the y-axis positive downward. This gives $mg - T = ma$. Solving for T gives

$T = m(g - a)$ (Eq. 1)

(b) Applying $\sum\tau_z = I\alpha_z$ to the drum gives $TR = I\alpha_z$ (Eq. 2)

We also have $a_y = a_{\tan} = R\alpha_z$, which gives $\alpha_z = a_y/R$ (Eq. 3)

Combining Equations 1, 2, and 3 and solving for I gives $I = mR^2(g/a - 1)$.

EVALUATE: Check our result for $a \to g$, which gives $I \to 0$. This is reasonable because the block is then essentially in freefall, meaning that the drum had almost no effect on it. This would be the case of the drum's moment of inertia was very very small. You could also interpret our result for $a > g$ to understand its meaning in that case.

VP10.3.4. **IDENTIFY:** Gravity pulls the block, causing tension in the cable. The torque on the cylinder is due to the tension in the cable and the torque produced by the motor. We apply the rotational analog of Newton's second law to the cylinder and the linear form to the block.

SET UP: $\sum\tau_z = I\alpha_z$, $a_{\tan} = r\alpha_z$, $\sum F_y = ma_y$ apply in this case. Call m the mass of the block and M the mass of the cylinder. $I = \frac{1}{2}MR^2$ for a solid uniform cylinder.

EXECUTE: **(a)** Apply $\sum F_y = ma_y$ to the block. Since the block accelerates upward, it is best to call the y-axis positive upward. This gives $T - mg = ma$. Solving for T gives $T = m(g + a)$.

(b) $\tau_z = TR = mR(g + a)$.

(c) Apply $\sum\tau_z = I\alpha_z$ to the cylinder. The torque due to the motor must be opposite in direction to that of the tension and it must have a greater magnitude.

$\tau_{\text{motor}} + \tau_{\text{tension}} = I\alpha_z \quad \to \quad \tau_{\text{motor}} - TR = \left(\frac{1}{2}MR^2\right)\left(\frac{a}{R}\right)$. Using the tension from part (a) and solving for τ_{motor}, we get $\tau_{\text{motor}} = mR(g + a) +$ fc MRa.

EVALUATE: Check if our result is reasonable. If either m or M are large, the torque must be large to produce the given acceleration.

VP10.7.1. **IDENTIFY:** The cylinder is rotating and translating at the same time. The rotational analog of Newton's second law applies to its rotational motion, and the linear form applies to its center of mass motion.

SET UP: $\sum F_y = ma_y$ applies to the vertical motion and $\sum\tau_z = I\alpha_z$ applies to the rotational motion about the center of mass. For a solid hollow cylinder, $I = \frac{1}{2}M\left(R_1^2 + R_2^2\right)$ and $a = r\alpha$.

EXECUTE: **(a)** We want the acceleration, so we apply $\sum F_y = ma_y$: $Mg - T = Ma_y$ (Eq. 1)

Now apply $\sum\tau_z = I\alpha_z$. For this cylinder, $R_1 = R$ and $R_2 = R/2$, so $I = 5MR^2/4$. Using this result and $\alpha = a_y / R$, we have $TR = \frac{1}{2}\left(\frac{5R^2}{4}\right)\left(\frac{a_y}{R}\right)M$, so $T = \frac{5}{8}Ma_y$ (Eq. 2)

Combining Eq. 1 and Eq. 2 and solving for a_y gives $a_y = \frac{8}{13}g$.

(b) From Eq. 2, we have $T = \frac{5}{8}Ma_y = \frac{5}{8}M\left(\frac{8}{13}g\right) = \frac{5}{13}Mg$.

EVALUATE: Note the difference between the answer to this problem and Ex. 10.6. In both cases, the yo-yo has the same mass but a different distribution of that mass. The acceleration is less in this problem than in Example 10.6 because the moment of inertia is greater than in the example.

VP10.7.2. **IDENTIFY:** As the solid sphere rolls down a ramp its linear velocity and its angular velocity both increase. Newton's second law in both its linear and rotational forms applies.
SET UP: $\sum F_x = ma_x$ applies to the linear motion and $\sum \tau_z = I\alpha_z$ applies to the rotational motion about the center of mass. For a solid sphere $I = \frac{2}{3}MR^2$, and $a_x = R\alpha$ because the sphere does not slip. Take the x-axis along the surface of the ramp, pointing downward.
EXECUTE: Apply $\sum F_x = ma_x$. The friction force is up the ramp, so we get
$Mg \sin\beta - f = Ma_x$ (Eq. 1)
Apply $\sum \tau_z = I\alpha_z$, which gives $fR = \frac{2}{3}MR^2\ \alpha_z = \frac{2}{3}MR^2\ (a_x/R)$, which simplifies to
$f = \frac{2}{3}Ma_x$ (Eq. 2)
Combining Eq. 1 and Eq. 2 and solving for a_x gives $a_x = \frac{3}{5}g\sin\beta$.
(b) From Eq. 2 and the result from (a), we have $f = \frac{2}{3}Ma_x = \frac{2}{3}M\left(\frac{3}{5}g\sin\beta\right) = \frac{2}{5}Mg\sin\beta$.
(c) $\tau_z = fR = \frac{2}{5}MgR\sin\beta$.
EVALUATE: If there were no friction and the ball just slid down the incline, its acceleration would be $g\sin\beta$. But with rolling, friction is *up* the ramp, so it opposes the component of gravity down the ramp. Therefore the acceleration is *less* than $g\sin\beta$.

VP10.7.3. **IDENTIFY:** The yo-yo is rotating and translating at the same time. The rotational analog of Newton's second law applies to its rotational motion, and the linear form applies to its center of mass motion.
SET UP: $\sum F_y = ma_y$ applies to the vertical motion and $\sum \tau_z = I\alpha_z$ applies to the rotational motion about the center of mass. For a solid cylinder, $I = \frac{1}{2}MR^2$. We know that the tension in the string is 2/3 the weight of the yo-yo, and we want to find the acceleration of its center of mass and the angular acceleration about its center of mass. The only torque about the center of mass is due to the tension in the string.
EXECUTE: **(a)** We want the acceleration of the center of mass, so we apply $\sum F_y = ma_y$.
$Mg - T = Ma_y \rightarrow Mg - 2Mg/3 = Ma_y \rightarrow a_y = -g/3$. The magnitude is $g/3$ and the direction is downward.
(b) We want the angular acceleration about the center of mass, so we apply $\sum \tau_z = I\alpha_z$.
$TR = \frac{1}{2}MR^2\alpha_{\text{cm}} \rightarrow \alpha_{\text{cm}} = \frac{4g}{3R}$.
EVALUATE: Notice that a_{cm} is *not* equal to $R\alpha_{\text{cm}}$. The cylinder is turning and moving, but it is not rolling.

VP10.7.4. **IDENTIFY:** The cylinder is rotating and translating at the same time and is rolling without slipping. The rotational analog of Newton's second law applies to its rotational motion, and the linear form applies to its center of mass motion.
SET UP: $\sum F_x = ma_x$ applies to the center of mass motion and $\sum \tau_z = I\alpha_z$ applies to the rotational motion about the center of mass. For a solid cylinder, $I = \frac{1}{2}MR^2$, and for rolling without slipping $a_{\text{cm}} =$

$r\alpha_{cm}$. We want to find the friction force on the cylinder and the maximum angle of the ramp for which slipping will not occur. Call the *x*-axis along the surface of the ramp pointing downward.

EXECUTE: **(a)** We want the acceleration of the center of mass, so we apply $\sum F_x = ma_x$. The friction force *f* acts up the ramp to prevent sliding, so $Mg \sin\beta - f = Ma_x$ (Eq. 1)

Applying $\sum \tau_z = I\alpha_z$ about the center of mass of the cylinder gives $fR = \frac{1}{2}MR^2\alpha_{cm}$. For rolling we also have $a_{cm} = r\alpha_{cm}$, so this becomes $fR = \frac{1}{2}MR^2(a_{cm}/R)$, which gives $f = \frac{1}{2}Ma_{cm}$ (Eq. 2)

Putting Eq. 2 into Eq. 1 gives $f = \frac{Mg}{3}\sin\beta$.

(b) When the ramp is at the maximum angle β, the cylinder is just ready to slip, so f_s is at its maximum value of $\mu_s n$. Applying $\sum F_y = 0$ to the cylinder gives $n = Mg\cos\beta$. Combining this result with the answer to (a) gives $\frac{Mg}{3}\sin\beta = \mu_s Mg\cos\beta \rightarrow \tan\beta = 3\mu_s$, so

$\beta = \arctan(3\mu_s)$.

EVALUATE: Check a special case: If $\mu_s = 0$ (perfectly smooth ramp), then $\beta = 0$, which means that any elevation at all will cause slipping. This is a reasonable result for a perfectly smooth ramp.

VP10.12.1. **IDENTIFY:** The two-disk system does not experience any external torque, so its angular momentum is conserved.

SET UP: Angular momentum is $L = I\omega$, $I = \frac{1}{2}MR^2$ for a solid disk, and rotational kinetic energy is $K = \frac{1}{2}I\omega^2$.

EXECUTE: **(a)** Conservation of angular momentum tells us that $L_1 = L_2$, so $I_A\omega_A + I_B\omega_B = I_{A+B}\omega_2$. We know that $I_B = I_A/4$ and $\omega_B = \omega_A/2$, so this gives $I_A\omega_A + \frac{I_A}{4}\cdot\frac{\omega_A}{2} = \left(I_A + \frac{I_A}{4}\right)\omega_2$. Solving for ω_2 gives $\omega_2 = \frac{9}{10}\omega_A$.

(b) We want K_2/K_1. $K_1 = \frac{1}{2}I_A\omega_A^2 + \frac{1}{2}I_B\omega_B^2 = \frac{1}{2}I_A\omega_A^2 + \frac{1}{2}\left(\frac{I_A}{4}\right)\left(\frac{\omega_A}{2}\right)^2 = \frac{17}{32}I_A\omega_A^2$.

Using the result from (a) gives $K_2 = \frac{1}{2}I_{A+B}\omega^2 = \frac{1}{2}\left(I_A + \frac{I_A}{4}\right)\left(\frac{9}{10}\omega_A\right)^2 = \frac{405}{800}I_A\omega_A^2$.

The fraction of the initial rotational kinetic energy that remains is $\frac{K_2}{K_1} = \frac{\frac{405}{800}I_A\omega_A^2}{\frac{17}{32}I_A\omega_A^2} = \frac{81}{85} = 0.953$.

EVALUATE: The disks stick together so kinetic energy is lost, just as when objects collide in an inelastic collision. In this case, 95.3% of the kinetic energy remains, so only 4.7% is lost.

VP10.12.2. **IDENTIFY:** We follow exactly the same procedure as in VP10.12.1 *except* that the initial angular velocities are in *opposite* directions.

SET UP: The set up is the same as in VP10.12.1 except that $\omega_B = -\omega_A/2$

EXECUTE: **(a)** Conservation of angular momentum tells us that $L_1 = L_2$, so $I_A\omega_A + I_B\omega_B = I_{A+B}\omega_2$. We know that $I_B = I_A/4$ and $\omega_B = -\omega_A/2$, so this gives $I_A\omega_A - \frac{I_A}{4}\cdot\frac{\omega_A}{2} = \left(I_A + \frac{I_A}{4}\right)\omega_2$. Solving for ω_2 gives $\omega_2 = \frac{7}{10}\omega_A$.

(b) We want K_2/K_1. $K_1 = \frac{1}{2}I_A\omega_A^2 + \frac{1}{2}I_B\omega_B^2 = \frac{1}{2}I_A\omega_A^2 + \frac{1}{2}\left(\frac{I_A}{4}\right)\left(\frac{\omega_A}{2}\right)^2 = \frac{17}{32}I_A\omega_A^2$.

Using the result from (a) gives $K_2 = \frac{1}{2}I_{A+B}\omega^2 = \frac{1}{2}\left(I_A + \frac{I_A}{4}\right)\left(\frac{7}{10}\omega_A\right)^2 = \frac{49}{160}I_A\omega_A^2$.

The fraction of the initial rotational kinetic energy that remains is $\dfrac{K_2}{K_1} = \dfrac{\frac{49}{160}I_A\omega_A^2}{\frac{17}{32}I_A\omega_A^2} = \dfrac{49}{85} = 0.576.$

EVALUATE: The disks stick together so kinetic energy is lost, just as when objects collide in an inelastic collision. In this case, only 57.6% of the kinetic energy remains, so 42.4% is lost.

VP10.12.3. **IDENTIFY:** During the collision, the hinge exerts a force on the door. But if we look at the angular momentum about the hinge, the hinge exerts no torque, so the angular momentum of the bullet-door system is conserved about the hinge.

SET UP: About the hinge $L_{\text{bullet}} = mvd$, $L_{\text{door}} = I_{\text{door}}\,\omega$, and $I_{\text{door}} = \frac{1}{3}Md^2$. $K = \frac{1}{2}I\omega^2$ for rotation and $K = \frac{1}{2}mv^2$ for linear motion. Figure VP10.12.3 shows before and after sketches.

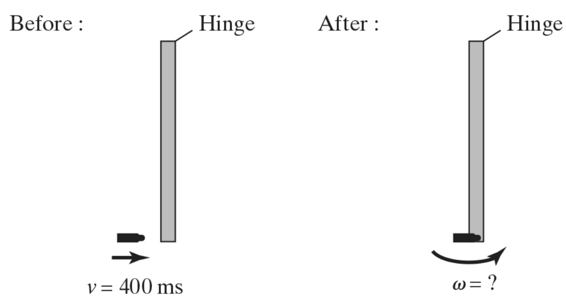

Figure VP10.12.3

EXECUTE: **(a)** We want the angular velocity ω just after the bullet hits the door, so use conservation of angular momentum about the hinge. $L_{\text{bullet}} + L_{\text{door}} = L_{\text{door + bullet}}$.

$mvd = (I_{\text{door}} + I_{\text{bullet}})\,\omega = \left(\frac{1}{3}Md^2 + md^2\right)\omega$

$$\omega = \frac{mv}{d\left(\frac{M}{3}+m\right)} = \frac{(0.0100\text{ kg})(400\text{ m/s})}{(1.00\text{ m})\left(\frac{15\text{ kg}}{3} + 0.0100\text{ kg}\right)} = 0.80\text{ rad/s.}$$

(b) $K_1 = K_{\text{bullet}} = \frac{1}{2}mv^2 = \frac{1}{2}(0.0100\text{ kg})(400\text{ m/s})^2 = 800\text{ J}$

$$K_2 = K_{\text{bullet}} + K_{\text{door}} = \frac{1}{2}\left(md^2\omega^2 + \frac{1}{3}Md^2\omega^2\right) = \left(m + \frac{M}{3}\right)\frac{(d\omega)^2}{2}$$

$$K_2 = \left(0.010\text{ kg} + \frac{15\text{ kg}}{3}\right)\frac{[(1.00\text{ m})(0.80\text{ rad/s})]^2}{2} = 1.6\text{ J}$$

$K_2/K_1 = (1.6\text{ J})/(800\text{ J}) = 0.0020 = 1/500$.

EVALUATE: This is a *very* inelastic collision. Only 0.20% of the original kinetic energy remained, so 99.8% was lost.

VP10.12.4. IDENTIFY: During the collision, the angular momentum of the clay-sphere system is conserved about the vertical shaft.

SET UP: About the shaft $L_{\text{clay}} = MvR$, $L_{\text{sphere}} = I_{\text{sphere}}\,\omega$, and $I_{\text{sphere}} = \frac{2}{3}MR^2$. $K = \frac{1}{2}I\omega^2$ for rotation and $K = \frac{1}{2}mv^2$ for linear motion.

EXECUTE: **(a)** Before: $L = MvR$. After: $L = M(v/2)R = \frac{1}{2}MvR$.

(b) The clay clay lost half of its angular momentum, so the sphere must have gained that amount by conservation of angular momentum. Therefore $L_{\text{sphere}} = \frac{1}{2}MvR = I_{\text{sphere}}\,\omega$. This gives $\frac{2}{3}MR^2\,\omega = \frac{1}{2}MvR$, so $\omega = \frac{3v}{4R}$.

(c) $K_1 = K_{\text{clay}} = \frac{1}{2}Mv^2$

$$K_2 = K_{\text{clay}} + K_{\text{sphere}} = \frac{1}{2}M(v/2)^2 + \frac{1}{2}I\omega^2 = \frac{1}{2}M\left(\frac{v}{2}\right)^2 + \frac{1}{2}\left(\frac{2}{3}MR^2\right)\left(\frac{3v}{4R}\right)^2 = \frac{5}{16}Mv^2$$

$$\frac{K_2}{K_1} = \frac{\frac{5}{16}Mv^2}{\frac{1}{2}Mv^2} = \frac{5}{8}.$$

EVALUATE: The system lost 3/8 of its kinetic energy during this collision, so it was *not* an elastic collision.

10.1. IDENTIFY: Use $\tau = Fl$ to calculate the magnitude of the torque and use the right-hand rule illustrated in Section 10.1 in the textbook to calculate the torque direction.

(a) SET UP: Consider Figure 10.1a.

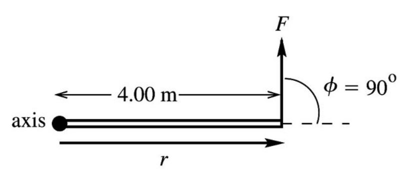

Figure 10.1a

EXECUTE: $\tau = Fl$

$l = r\sin\phi = (4.00\text{ m})\sin 90°$

$l = 4.00\text{ m}$

$\tau = (10.0\text{ N})(4.00\text{ m}) = 40.0\text{ N}\cdot\text{m}$

This force tends to produce a counterclockwise rotation about the axis; by the right-hand rule the vector $\vec{\tau}$ is directed out of the plane of the figure.

(b) SET UP: Consider Figure 10.1b.

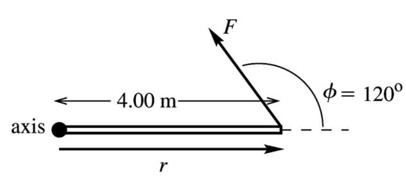

Figure 10.1b

EXECUTE: $\tau = Fl$

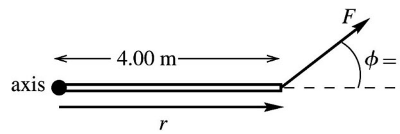
$l = r\sin\phi = (4.00\text{ m})\sin 120°$

$l = 3.464\text{ m}$

$\tau = (10.0\text{ N})(3.464\text{ m}) = 34.6\text{ N}\cdot\text{m}$

This force tends to produce a counterclockwise rotation about the axis; by the right-hand rule the vector $\vec{\tau}$ is directed out of the plane of the figure.

(c) SET UP: Consider Figure 10.1c.



EXECUTE: $\tau = Fl$

$l = r\sin\phi = (4.00\text{ m})\sin 30°$

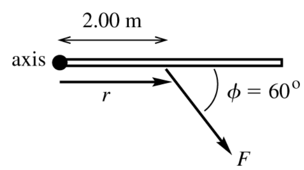
$l = 2.00\text{ m}$

$\tau = (10.0\text{ N})(2.00\text{ m}) = 20.0\text{ N}\cdot\text{m}$

Figure 10.1c

This force tends to produce a counterclockwise rotation about the axis; by the right-hand rule the vector $\vec{\tau}$ is directed out of the plane of the figure.

(d) SET UP: Consider Figure 10.1d.



EXECUTE: $\tau = Fl$

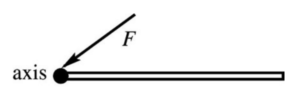
$l = r\sin\phi = (2.00\text{ m})\sin 60° = 1.732\text{ m}$

$\tau = (10.0\text{ N})(1.732\text{ m}) = 17.3\text{ N}\cdot\text{m}$

Figure 10.1d

This force tends to produce a clockwise rotation about the axis; by the right-hand rule the vector $\vec{\tau}$ is directed into the plane of the figure.

(e) SET UP: Consider Figure 10.1e.

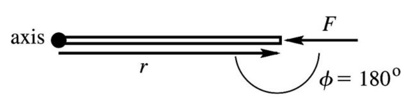


EXECUTE: $\tau = Fl$

$r = 0$ so $l = 0$ and $\tau = 0$

Figure 10.1e

(f) SET UP: Consider Figure 10.1f.



EXECUTE: $\tau = Fl$

$l = r\sin\phi$, $\phi = 180°$,

so $l = 0$ and $\tau = 0$

Figure 10.1f

EVALUATE: The torque is zero in parts (e) and (f) because the moment arm is zero; the line of action of the force passes through the axis.

10.2. **IDENTIFY:** $\tau = Fl$ with $l = r\sin\phi$. Add the two torques to calculate the net torque.

SET UP: Let counterclockwise torques be positive.

EXECUTE: $\tau_1 = -F_1 l_1 = -(8.00\text{ N})(5.00\text{ m}) = -40.0\text{ N}\cdot\text{m}$.

$\tau_2 = +F_2 l_2 = (12.0\text{ N})(2.00\text{ m})\sin 30.0° = +12.0\text{ N}\cdot\text{m}$. $\sum\tau = \tau_1 + \tau_2 = -28.0\text{ N}\cdot\text{m}$. The net torque is $28.0\text{ N}\cdot\text{m}$, clockwise.

EVALUATE: Even though $F_1 < F_2$, the magnitude of τ_1 is greater than the magnitude of τ_2, because F_1 has a larger moment arm.

10.3. **IDENTIFY** and **SET UP:** Use $\tau = Fl$ to calculate the magnitude of each torque and use the right-hand rule (Figure 10.4 in the textbook) to determine the direction. Consider Figure 10.3.

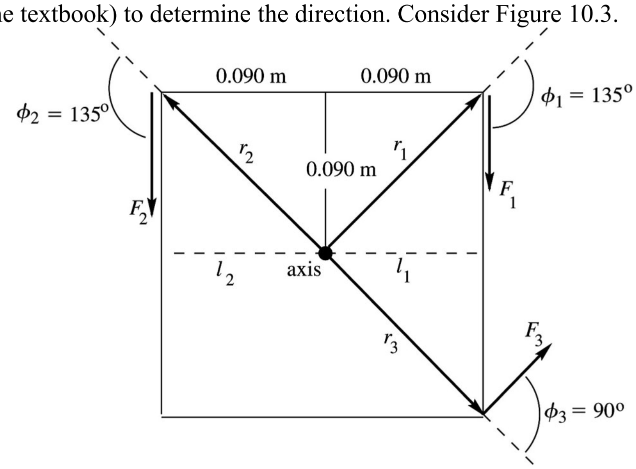


Figure 10.3

Let counterclockwise be the positive sense of rotation.

EXECUTE: $r_1 = r_2 = r_3 = \sqrt{(0.090\text{ m})^2 + (0.090\text{ m})^2} = 0.1273\text{ m}$

$\tau_1 = -F_1 l_1$

$l_1 = r_1 \sin\phi_1 = (0.1273\text{ m})\sin 135° = 0.0900\text{ m}$

$\tau_1 = -(18.0\text{ N})(0.0900\text{ m}) = -1.62\text{ N}\cdot\text{m}$

$\vec{\tau}_1$ is directed into paper

$\tau_2 = +F_2 l_2$

$l_2 = r_2 \sin\phi_2 = (0.1273\text{ m})\sin 135° = 0.0900\text{ m}$

$\tau_2 = +(26.0\text{ N})(0.0900\text{ m}) = +2.34\text{ N}\cdot\text{m}$

$\vec{\tau}_2$ is directed out of paper

$\tau_3 = +F_3 l_3$

$l_3 = r_3 \sin\phi_3 = (0.1273\text{ m})\sin 90° = 0.1273\text{ m}$

$\tau_3 = +(14.0\text{ N})(0.1273\text{ m}) = +1.78\text{ N}\cdot\text{m}$

$\vec{\tau}_3$ is directed out of paper

$\sum\tau = \tau_1 + \tau_2 + \tau_3 = -1.62\text{ N}\cdot\text{m} + 2.34\text{ N}\cdot\text{m} + 1.78\text{ N}\cdot\text{m} = 2.50\text{ N}\cdot\text{m}$

EVALUATE: The net torque is positive, which means it tends to produce a counterclockwise rotation; the vector torque is directed out of the plane of the paper. In summing the torques it is important to include + or − signs to show direction.

10.4. **IDENTIFY:** Use $\tau = Fl = rF\sin\phi$ to calculate the magnitude of each torque and use the right-hand rule to determine the direction of each torque. Add the torques to find the net torque.

SET UP: Let counterclockwise torques be positive. For the 11.9 N force (F_1), $r = 0$. For the 14.6 N force (F_2), $r = 0.350\text{ m}$ and $\phi = 40.0°$. For the 8.50 N force (F_3), $r = 0.350\text{ m}$ and $\phi = 90.0°$.

EXECUTE: $\tau_1 = 0$. $\tau_2 = -(14.6\text{ N})(0.350\text{ m})\sin 40.0° = -3.285\text{ N}\cdot\text{m}$.

$\tau_3 = +(8.50\text{ N})(0.350\text{ m})\sin 90.0° = +2.975\text{ N}\cdot\text{m}$. $\sum\tau = -3.285\text{ N}\cdot\text{m} + 2.975\text{ N}\cdot\text{m} = -0.31\text{ N}\cdot\text{m}$. The net torque is $0.31\text{ N}\cdot\text{m}$ and is clockwise.

EVALUATE: If we treat the torques as vectors, $\vec{\tau}_2$ is into the page and $\vec{\tau}_3$ is out of the page.

10.5. **IDENTIFY** and **SET UP:** Calculate the torque using Eq. (10.3) and also determine the direction of the torque using the right-hand rule.

(a) $\vec{r} = (-0.450\text{ m})\hat{i} + (0.150\text{ m})\hat{j}$; $\vec{F} = (-5.00\text{ N})\hat{i} + (4.00\text{ N})\hat{j}$. The sketch is given in Figure 10.5.

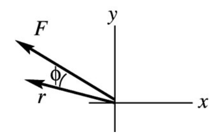

Figure 10.5

EXECUTE: **(b)** When the fingers of your right hand curl from the direction of $\vec{r}$ into the direction of $\vec{F}$ (through the smaller of the two angles, angle ϕ) your thumb points into the page (the direction of $\vec{\tau}$, the $-z$-direction).

(c) $\vec{\tau} = \vec{r} \times \vec{F} = [(-0.450\text{ m})\hat{i} + (0.150\text{ m})\hat{j}] \times [(-5.00\text{ N})\hat{i} + (4.00\text{ N})\hat{j}]$

$\vec{\tau} = +(2.25\text{ N}\cdot\text{m})\hat{i}\times\hat{i} - (1.80\text{ N}\cdot\text{m})\hat{i}\times\hat{j} - (0.750\text{ N}\cdot\text{m})\hat{j}\times\hat{i} + (0.600\text{ N}\cdot\text{m})\hat{j}\times\hat{j}$

$\hat{i}\times\hat{i} = \hat{j}\times\hat{j} = 0$

$\hat{i}\times\hat{j} = \hat{k}$, $\hat{j}\times\hat{i} = -\hat{k}$

Thus $\vec{\tau} = -(1.80\text{ N}\cdot\text{m})\hat{k} - (0.750\text{ N}\cdot\text{m})(-\hat{k}) = (-1.05\text{ N}\cdot\text{m})\hat{k}$.

EVALUATE: The calculation gives that $\vec{\tau}$ is in the $-z$-direction. This agrees with what we got from the right-hand rule.

10.6. **IDENTIFY:** Knowing the force on a bar and the point where it acts, we want to find the position vector for the point where the force acts and the torque the force exerts on the bar.

SET UP: The position vector is $\vec{r} = x\hat{i} + y\hat{j}$ and the torque is $\vec{\tau} = \vec{r} \times \vec{F}$.

EXECUTE: **(a)** Using $x = 3.00\text{ m}$ and $y = 4.00\text{ m}$, we have $\vec{r} = (3.00\text{ m})\hat{i} + (4.00\text{ m})\hat{j}$.

(b) $\vec{\tau} = \vec{r} \times \vec{F} = [(3.00\text{ m})\hat{i} + (4.00\text{ m})\hat{j}] \times [(7.00\text{ N})\hat{i} + (-3.00\text{ N})\hat{j}]$.

$\vec{\tau} = (-9.00\text{ N}\cdot\text{m})\hat{k} + (-28.0\text{ N}\cdot\text{m})(-\hat{k}) = (-37.0\text{ N}\cdot\text{m})\hat{k}$. The torque has magnitude $37.0\text{ N}\cdot\text{m}$ and is in the $-z$-direction.

EVALUATE: Applying the right-hand rule for the vector product to $\vec{r} \times \vec{F}$ shows that the torque must be in the $-z$-direction because it is perpendicular to both $\vec{r}$ and $\vec{F}$, which are both in the x-y plane.

10.7. **IDENTIFY:** Use $\tau = Fl = rF\sin\phi$ for the magnitude of the torque and the right-hand rule for the direction.

SET UP: In part (a), $r = 0.250\text{ m}$ and $\phi = 37°$.

EXECUTE: **(a)** $\tau = (17.0\text{ N})(0.250\text{ m})\sin 37° = 2.56\text{ N}\cdot\text{m}$. The torque is counterclockwise.

(b) The torque is maximum when $\phi = 90°$ and the force is perpendicular to the wrench. This maximum torque is $(17.0\text{ N})(0.250\text{ m}) = 4.25\text{ N}\cdot\text{m}$.

EVALUATE: If the force is directed along the handle then the torque is zero. The torque increases as the angle between the force and the handle increases.

10.8. **IDENTIFY:** The constant force produces a torque which gives a constant angular acceleration to the disk and a linear acceleration to points on the disk.

SET UP: $\sum\tau_z = I\alpha_z$ applies to the disk, $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$ because the angular acceleration is constant. The acceleration components of the rim are $a_{\text{tan}} = r\alpha$ and $a_{\text{rad}} = r\omega^2$, and the magnitude of the acceleration is $a = \sqrt{a_{\text{tan}}^2 + a_{\text{rad}}^2}$.

EXECUTE: **(a)** $\sum \tau_z = I\alpha_z$ gives $Fr = I\alpha_z$. For a uniform disk,

$I = \frac{1}{2}MR^2 = \frac{1}{2}(40.0\ \text{kg})(0.200\ \text{m})^2 = 0.800\ \text{kg}\cdot\text{m}^2.$ $\alpha_z = \dfrac{Fr}{I} = \dfrac{(30.0\ \text{N})(0.200\ \text{m})}{0.800\ \text{kg}\cdot\text{m}^2} = 7.50\ \text{rad/s}^2.$

$\theta - \theta_0 = 0.200\ \text{rev} = 1.257\ \text{rad}.$ $\omega_{0z} = 0,$ so $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$ gives

$\omega_z = \sqrt{2(7.50\ \text{rad/s}^2)(1.257\ \text{rad})} = 4.342\ \text{rad/s}.$ $v = r\omega = (0.200\ \text{m})(4.342\ \text{rad/s}) = 0.868\ \text{m/s}.$

(b) $a_{\text{tan}} = r\alpha = (0.200\ \text{m})(7.50\ \text{rad/s}^2) = 1.50\ \text{m/s}^2.$ $a_{\text{rad}} = r\omega^2 = (0.200\ \text{m})(4.342\ \text{rad/s})^2 = 3.771\ \text{m/s}^2.$

$a = \sqrt{a_{\text{tan}}^2 + a_{\text{rad}}^2} = 4.06\ \text{m/s}^2.$

EVALUATE: The net acceleration is neither toward the center nor tangent to the disk.

10.9. **IDENTIFY:** Apply $\sum \tau_z = I\alpha_z$.

SET UP: $\omega_{0z} = 0.$ $\omega_z = (400\ \text{rev/min})\left(\dfrac{2\pi\ \text{rad/rev}}{60\ \text{s/min}}\right) = 41.9\ \text{rad/s}$

EXECUTE: $\tau_z = I\alpha_z = I\dfrac{\omega_z - \omega_{0z}}{t} = (1.60\ \text{kg}\cdot\text{m}^2)\dfrac{41.9\ \text{rad/s}}{8.00\ \text{s}} = 8.38\ \text{N}\cdot\text{m}.$

EVALUATE: In $\tau_z = I\alpha_z$, α_z must be in rad/s^2.

10.10. **IDENTIFY:** Apply $\sum \tau_z = I\alpha_z$ to the wheel. The acceleration a of a point on the cord and the angular acceleration α of the wheel are related by $a = R\alpha$.

SET UP: Let the direction of rotation of the wheel be positive. The wheel has the shape of a disk and $I = \frac{1}{2}MR^2$. The free-body diagram for the wheel is sketched in Figure 10.10a for a horizontal pull and in Figure 10.10b for a vertical pull. P is the pull on the cord and F is the force exerted on the wheel by the axle.

EXECUTE: **(a)** $\alpha_z = \dfrac{\tau_z}{I} = \dfrac{(40.0\ \text{N})(0.250\ \text{m})}{\frac{1}{2}(9.20\ \text{kg})(0.250\ \text{m})^2} = 34.8\ \text{rad/s}^2.$

$a = R\alpha = (0.250\ \text{m})(34.8\ \text{rad/s}^2) = 8.70\ \text{m/s}^2.$

(b) $F_x = -P,$ $F_y = Mg.$ $F = \sqrt{P^2 + (Mg)^2} = \sqrt{(40.0\ \text{N})^2 + ([9.20\ \text{kg}][9.80\ \text{m/s}^2])^2} = 98.6\ \text{N}.$

$\tan\phi = \dfrac{|F_y|}{|F_x|} = \dfrac{Mg}{P} = \dfrac{(9.20\ \text{kg})(9.80\ \text{m/s}^2)}{40.0\ \text{N}}$ and $\phi = 66.1°.$ The force exerted by the axle has magnitude 98.6 N and is directed at $66.1°$ above the horizontal, away from the direction of the pull on the cord.

(c) The pull exerts the same torque as in part (a), so the answers to part (a) don't change. In part (b), $F + P = Mg$ and $F = Mg - P = (9.20\ \text{kg})(9.80\ \text{m/s}^2) - 40.0\ \text{N} = 50.2\ \text{N}.$ The force exerted by the axle has magnitude 50.2 N and is upward.

EVALUATE: The weight of the wheel and the force exerted by the axle produce no torque because they act at the axle.

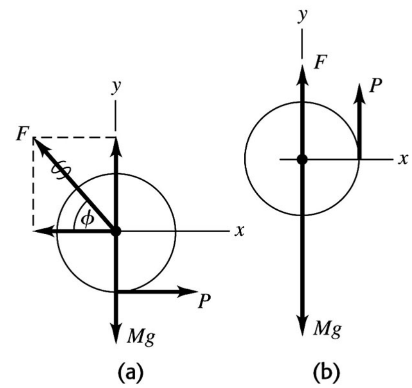

Figure 10.10

10.11. **IDENTIFY:** Use $\sum \tau_z = I\alpha_z$ to calculate α. Use a constant angular acceleration kinematic equation to relate α_z, ω_z, and t.

SET UP: For a solid uniform sphere and an axis through its center, $I = \frac{2}{5}MR^2$. Let the direction the sphere is spinning be the positive sense of rotation. The moment arm for the friction force is $l = 0.0150\text{ m}$ and the torque due to this force is negative.

EXECUTE: **(a)** $\alpha_z = \dfrac{\tau_z}{I} = \dfrac{-(0.0200\text{ N})(0.0150\text{ m})}{\frac{2}{5}(0.225\text{ kg})(0.0150\text{ m})^2} = -14.8\text{ rad/s}^2$

(b) $\omega_z - \omega_{0z} = -22.5\text{ rad/s}$. $\omega_z = \omega_{0z} + \alpha_z t$ gives $t = \dfrac{\omega_z - \omega_{0z}}{\alpha_z} = \dfrac{-22.5\text{ rad/s}}{-14.8\text{ rad/s}^2} = 1.52\text{ s}$.

EVALUATE: The fact that α_z is negative means its direction is opposite to the direction of spin. The negative α_z causes ω_z to decrease.

10.12. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$ to the stone and $\sum \tau_z = I\alpha_z$ to the pulley. Use a constant acceleration equation to find a for the stone.

SET UP: For the motion of the stone take $+y$ to be downward. The pulley has $I = \frac{1}{2}MR^2$. $a = R\alpha$.

EXECUTE: **(a)** $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $12.6\text{ m} = \frac{1}{2}a_y(3.00\text{ s})^2$ and $a_y = 2.80\text{ m/s}^2$.

Then $\sum F_y = ma_y$ applied to the stone gives $mg - T = ma$.

$\sum \tau_z = I\alpha_z$ applied to the pulley gives $TR = \frac{1}{2}MR^2\alpha = \frac{1}{2}MR^2(a/R)$. $T = \frac{1}{2}Ma$.

Combining these two equations to eliminate T gives

$$m = \frac{M}{2}\left(\frac{a}{g-a}\right) = \left(\frac{10.0\text{ kg}}{2}\right)\left(\frac{2.80\text{ m/s}^2}{9.80\text{ m/s}^2 - 2.80\text{ m/s}^2}\right) = 2.00\text{ kg}.$$

(b) $T = \frac{1}{2}Ma = \frac{1}{2}(10.0\text{ kg})(2.80\text{ m/s}^2) = 14.0\text{ N}$

EVALUATE: The tension in the wire is less than the weight $mg = 19.6\text{ N}$ of the stone, because the stone has a downward acceleration.

10.13. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$ to each book and apply $\sum \tau_z = I\alpha_z$ to the pulley. Use a constant acceleration equation to find the common acceleration of the books.

SET UP: $m_1 = 2.00\text{ kg}$, $m_2 = 3.00\text{ kg}$. Let T_1 be the tension in the part of the cord attached to m_1 and T_2 be the tension in the part of the cord attached to m_2. Let the $+x$-direction be in the direction of the acceleration of each book. $a = R\alpha$.

EXECUTE: **(a)** $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives $a_x = \dfrac{2(x - x_0)}{t^2} = \dfrac{2(1.20 \text{ m})}{(0.800 \text{ s})^2} = 3.75 \text{ m/s}^2$. $a_1 = 3.75 \text{ m/s}^2$ so $T_1 = m_1 a_1 = 7.50 \text{ N}$ and $T_2 = m_2(g - a_1) = 18.2 \text{ N}$.

(b) The torque on the pulley is $(T_2 - T_1)R = 0.803 \text{ N} \cdot \text{m}$, and the angular acceleration is $\alpha = a_1/R = 50 \text{ rad/s}^2$, so $I = \tau/\alpha = 0.016 \text{ kg} \cdot \text{m}^2$.

EVALUATE: The tensions in the two parts of the cord must be different, so there will be a net torque on the pulley.

10.14. **IDENTIFY:** Apply $\sum F_y = ma_y$ to the bucket, with $+y$ downward. Apply $\sum \tau_z = I\alpha_z$ to the cylinder, with the direction the cylinder rotates positive.

SET UP: The free-body diagram for the bucket is given in Figure 10.14a and the free-body diagram for the cylinder is given in Figure 10.14b. $I = \frac{1}{2}MR^2$. $a(\text{bucket}) = R\alpha(\text{cylinder})$

EXECUTE: **(a)** For the bucket, $mg - T = ma$. For the cylinder, $\sum \tau_z = I\alpha_z$ gives $TR = \frac{1}{2}MR^2\alpha$. $\alpha = a/R$ then gives $T = \frac{1}{2}Ma$. Combining these two equations gives $mg - \frac{1}{2}Ma = ma$ and

$$a = \frac{mg}{m + M/2} = \left(\frac{15.0 \text{ kg}}{15.0 \text{ kg} + 6.0 \text{ kg}}\right)(9.80 \text{ m/s}^2) = 7.00 \text{ m/s}^2.$$

$T = m(g - a) = (15.0 \text{ kg})(9.80 \text{ m/s}^2 - 7.00 \text{ m/s}^2) = 42.0 \text{ N}$.

(b) $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives $v_y = \sqrt{2(7.00 \text{ m/s}^2)(10.0 \text{ m})} = 11.8 \text{ m/s}$.

(c) $a_y = 7.00 \text{ m/s}^2$, $v_{0y} = 0$, $y - y_0 = 10.0 \text{ m}$. $y - y_0 = v_{0y}t + \frac{1}{2}\alpha_y t^2$ gives

$$t = \sqrt{\frac{2(y - y_0)}{a_y}} = \sqrt{\frac{2(10.0 \text{ m})}{7.00 \text{ m/s}^2}} = 1.69 \text{ s}$$

(d) $\sum F_y = ma_y$ applied to the cylinder gives $n - T - Mg = 0$ and

$n = T + mg = 42.0 \text{ N} + (12.0 \text{ kg})(9.80 \text{ m/s}^2) = 160 \text{ N}$.

EVALUATE: The tension in the rope is less than the weight of the bucket, because the bucket has a downward acceleration. If the rope were cut, so the bucket would be in free fall, the bucket would strike the water in $t = \sqrt{\dfrac{2(10.0 \text{ m})}{9.80 \text{ m/s}^2}} = 1.43 \text{ s}$ and would have a final speed of 14.0 m/s. The presence of the cylinder slows the fall of the bucket.

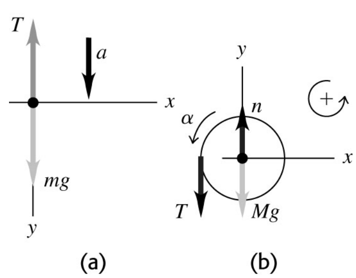

Figure 10.14

10.15. **IDENTIFY:** The constant force produces a torque which gives a constant angular acceleration to the wheel.

SET UP: $\omega_z = \omega_{0z} + \alpha_z t$ because the angular acceleration is constant, and $\sum \tau_z = I\alpha_z$ applies to the wheel.

Execute: $\omega_{0z} = 0$ and $\omega_z = 12.0 \text{ rev/s} = 75.40 \text{ rad/s}$. $\omega_z = \omega_{0z} + \alpha_z t$, so

$\alpha_z = \dfrac{\omega_z - \omega_{0z}}{t} = \dfrac{75.40 \text{ rad/s}}{2.00 \text{ s}} = 37.70 \text{ rad/s}^2$. $\sum \tau_z = I\alpha_z$ gives

$I = \dfrac{Fr}{\alpha_z} = \dfrac{(80.0 \text{ N})(0.120 \text{ m})}{37.70 \text{ rad/s}^2} = 0.255 \text{ kg} \cdot \text{m}^2$.

Evaluate: The units of the answer are the proper ones for moment of inertia.

10.16. Identify: Apply $\sum \vec{F} = m\vec{a}$ to each box and $\sum \tau_z = I\alpha_z$ to the pulley. The magnitude a of the acceleration of each box is related to the magnitude of the angular acceleration α of the pulley by $a = R\alpha$.

Set Up: The free-body diagrams for each object are shown in Figure 10.16. For the pulley, $R = 0.250$ m and $I = \frac{1}{2}MR^2$. T_1 and T_2 are the tensions in the wire on either side of the pulley. $m_1 = 12.0$ kg, $m_2 = 5.00$ kg and $M = 2.00$ kg. $\vec{F}$ is the force that the axle exerts on the pulley. For the pulley, let clockwise rotation be positive.

Execute: (a) $\sum F_x = ma_x$ for the 12.0 kg box gives $T_1 = m_1 a$. $\sum F_y = ma_y$ for the 5.00 kg weight gives $m_2 g - T_2 = m_2 a$. $\sum \tau_z = I\alpha_z$ for the pulley gives $(T_2 - T_1)R = (\frac{1}{2}MR^2)\alpha$. $a = R\alpha$ and $T_2 - T_1 = \frac{1}{2}Ma$. Adding these three equations gives $m_2 g = (m_1 + m_2 + \frac{1}{2}M)a$ and

$a = \left(\dfrac{m_2}{m_1 + m_2 + \frac{1}{2}M}\right) g = \left(\dfrac{5.00 \text{ kg}}{12.0 \text{ kg} + 5.00 \text{ kg} + 1.00 \text{ kg}}\right)(9.80 \text{ m/s}^2) = 2.72 \text{ m/s}^2$. Then

$T_1 = m_1 a = (12.0 \text{ kg})(2.72 \text{ m/s}^2) = 32.6$ N. $m_2 g - T_2 = m_2 a$ gives

$T_2 = m_2(g - a) = (5.00 \text{ kg})(9.80 \text{ m/s}^2 - 2.72 \text{ m/s}^2) = 35.4$ N. The tension to the left of the pulley is 32.6 N and below the pulley it is 35.4 N.

(b) $a = 2.72 \text{ m/s}^2$

(c) For the pulley, $\sum F_x = ma_x$ gives $F_x = T_1 = 32.6$ N and $\sum F_y = ma_y$ gives

$F_y = Mg + T_2 = (2.00 \text{ kg})(9.80 \text{ m/s}^2) + 35.4 \text{ N} = 55.0$ N.

Evaluate: The equation $m_2 g = (m_1 + m_2 + \frac{1}{2}M)a$ says that the external force $m_2 g$ must accelerate all three objects.

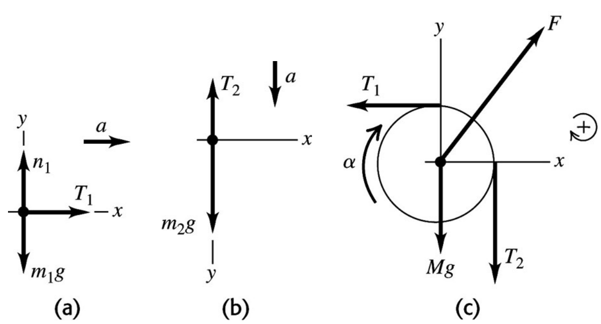

Figure 10.16

10.17. Identify: The rotational form of Newton's second law applies to the cylinder. Interpretation of graphical data is necessary.

Set Up: Since $\theta - \theta_0$ is proportional to t^2, the equation $\theta - \theta_0 = \omega_{0z} t + \dfrac{1}{2}\alpha_z t^2$ applies to the rotational motion. Since the rotation starts from rest, $\omega_{0z} = 0$, so we have $\theta - \theta_0 = \dfrac{1}{2}\alpha_z t^2$. Therefore a graph of

$\theta-\theta_0$ versus t^2 should be a straight line having slope $\frac{1}{2}\alpha_z$. Our target variable is the moment of inertia of the cylinder. Once we know α_z, we can apply $\sum\tau_z = I\alpha_z$ to find I.

EXECUTE: Use the slope of the graph to find α_z. As we discussed above, slope = $\frac{1}{2}\alpha_z$, so α_z = 2(slope) = 2(16.0 rad/s^2) = 32.0 rad/s^2. Now use $\sum\tau_z = I\alpha_z$ to find I. $FR = I\alpha_z$, so

$I = \dfrac{FR}{\alpha_z} = \dfrac{(3.00\text{ N})(0.140\text{ m})}{32.0\text{ rad/s}^2} = 0.0131\ \text{kg}\cdot\text{m}^2$.

EVALUATE: Using the slope to find α_z is more accurate than using individual data points because individual measurements vary, but finding the slope essentially "averages out" the data points.

10.18. IDENTIFY: The spheres have kinetic energy due to the motion of their center of mass and the rotation about the center of mass.

SET UP: $K_{\text{total}} = \frac{1}{2}mv_{\text{cm}}^2 + \frac{1}{2}I\omega^2$, $I = \frac{2}{5}MR^2$ for a solid sphere, and $v_{\text{cm}} = r\omega$ when there is no slipping. The work done on each sphere is equal to its loss of kinetic energy. The work is the target variable.

EXECUTE: $W_A = \frac{1}{2}mv_{\text{cm}}^2 + \frac{1}{2}I\omega^2 = \frac{1}{2}mv_{cm}^2 + \frac{1}{2}\left(\frac{2}{5}mR^2\right)\omega^2 = \frac{1}{2}mv_{cm}^2 + \frac{1}{2}\left(\frac{2}{5}mR^2\right)\left(\frac{v_{\text{cm}}}{R}\right)^2$.

$W_A = \frac{7}{10}mv_{\text{cm}}^2 = \frac{7}{10}(5.00\text{ kg})(4.00\text{ m/s})^2 = 56.0$ J. A similar calculation for sphere B, except using $I = \frac{2}{3}MR^2$, gives $W_B = \frac{5}{6}mv_{\text{cm}}^2 = \frac{5}{6}(5.00\text{ kg})(4.00\text{ m/s})^2 = 66.7$ J.

EVALUATE: Sphere B requires more work because it has a larger moment of inertia than A. Even though both spheres have the same size, mass, and linear speed, B's mass is farther from the rotation axis so its moment of inertia is greater than that of A.

10.19. IDENTIFY: Since there is rolling without slipping, $v_{\text{cm}} = R\omega$. The kinetic energy is given by $K_{\text{tot}} = K_{\text{cm}} + K_{\text{rot}}$ where $K_{\text{cm}} = \frac{1}{2}Mv_{\text{cm}}^2$ and $K_{\text{rot}} = \frac{1}{2}I_{\text{cm}}\omega^2$. The velocity of any point on the rim of the hoop is the vector sum of the tangential velocity of the rim and the velocity of the center of mass of the hoop.

SET UP: $\omega = 2.60$ rad/s and $R = 0.600$ m. For a hoop rotating about an axis at its center, $I = MR^2$.

EXECUTE: **(a)** $v_{\text{cm}} = R\omega = (0.600\text{ m})(2.60\text{ rad/s}) = 1.56$ m/s.

(b) $K = \frac{1}{2}Mv_{\text{cm}}^2 + \frac{1}{2}I\omega^2 = \frac{1}{2}Mv_{\text{cm}}^2 + \frac{1}{2}(MR^2)(v_{\text{cm}}/R^2) = Mv_{\text{cm}}^2 = (2.20\text{ kg})(1.56\text{ m/s})^2 = 5.35$ J

(c) (i) $v = 2v_{\text{cm}} = 3.12$ m/s. $\vec{v}$ is to the right. (ii) $v = 0$

(iii) $v = \sqrt{v_{\text{cm}}^2 + v_{\tan}^2} = \sqrt{v_{\text{cm}}^2 + (R\omega)^2} = \sqrt{2}v_{\text{cm}} = 2.21$ m/s. $\vec{v}$ at this point is at $45°$ below the horizontal.

(d) To someone moving to the right at $v = v_{\text{cm}}$, the hoop appears to rotate about a stationary axis at its center. (i) $v = R\omega = 1.56$ m/s, to the right. (ii) $v = 1.56$ m/s, to the left. (iii) $v = 1.56$ m/s, downward.

EVALUATE: For the special case of a hoop, the total kinetic energy is equally divided between the motion of the center of mass and the rotation about the axis through the center of mass. In the rest frame of the ground, different points on the hoop have different speed.

10.20. IDENTIFY: Newton's second law applies to the sphere rolling down the incline.

SET UP: From Example 10.7, we have $f_s = \frac{2}{7}Mg\sin\beta$. For maximum static friction, $f_s = \mu_s n$. The target variable is μ_s.

EXECUTE: (a) Balancing forces perpendicular to the surface of the incline gives $n = Mg\cos\beta$. Using this in the result from Example 10.7 gives $\mu_s Mg\cos\beta = \frac{2}{7}Mg\sin\beta$. Solving for μ_s we get $\mu_s = \frac{2}{7}\tan\beta$.

(b) As $\beta \to 0°$, $\mu_s \to 0$. As $\beta \to 90°$, $\mu_s \to \infty$.

EVALUATE: The results in part (a) are reasonable. As $\beta \to 0°$, the ball will roll on a smooth horizontal surface. If it is already moving and rotating, it will continue to do so. If it is not already rotating, it will not start to do so. As $\beta \to 90°$, $\mu_s \to \infty$. As $\beta \to 0°$, the normal force gets smaller and smaller, so we would need a larger and larger value of μ_s to prevent slipping.

10.21. IDENTIFY: Apply $K = K_{cm} + K_{rot}$.

SET UP: For an object that is rolling without slipping, $v_{cm} = R\omega$.

EXECUTE: The fraction of the total kinetic energy that is rotational is

$$\frac{(1/2)I_{cm}\omega^2}{(1/2)Mv_{cm}^2 + (1/2)I_{cm}\omega^2} = \frac{1}{1 + (M/I_{cm})v_{cm}^2/\omega^2} = \frac{1}{1 + (MR^2/I_{cm})}$$

(a) $I_{cm} = (1/2)MR^2$, so the above ratio is 1/3.

(b) $I_{cm} = (2/5)MR^2$ so the above ratio is 2/7.

(c) $I_{cm} = (2/3)MR^2$ so the ratio is 2/5.

(d) $I_{cm} = (5/8)MR^2$ so the ratio is 5/13.

EVALUATE: The moment of inertia of each object takes the form $I = \beta MR^2$. The ratio of rotational kinetic energy to total kinetic energy can be written as $\frac{1}{1+1/\beta} = \frac{\beta}{1+\beta}$. The ratio increases as β increases.

10.22. IDENTIFY: Only gravity does work, so $W_{other} = 0$ and conservation of energy gives $K_1 + U_1 = K_2 + U_2$. $K_2 = \frac{1}{2}Mv_{cm}^2 + \frac{1}{2}I_{cm}\omega^2$.

SET UP: Let $y_2 = 0$, so $U_2 = 0$ and $y_1 = 0.750$ m. The hoop is released from rest so $K_1 = 0$. $v_{cm} = R\omega$. For a hoop with an axis at its center, $I_{cm} = MR^2$.

EXECUTE: (a) Conservation of energy gives $U_1 = K_2$. $K_2 = \frac{1}{2}MR^2\omega^2 + \frac{1}{2}(MR^2)\omega^2 = MR^2\omega^2$, so $MR^2\omega^2 = Mgy_1$. $\omega = \frac{\sqrt{gy_1}}{R} = \frac{\sqrt{(9.80\text{ m/s}^2)(0.750\text{ m})}}{0.0800\text{ m}} = 33.9\text{ rad/s}$.

(b) $v = R\omega = (0.0800\text{ m})(33.9\text{ rad/s}) = 2.71\text{ m/s}$

EVALUATE: An object released from rest and falling in free fall for 0.750 m attains a speed of $\sqrt{2g(0.750\text{ m})} = 3.83\text{ m/s}$. The final speed of the hoop is less than this because some of its energy is in kinetic energy of rotation. Or, equivalently, the upward tension causes the magnitude of the net force of the hoop to be less than its weight.

10.23. IDENTIFY: Apply $\sum \vec{F}_{ext} = m\vec{a}_{cm}$ and $\sum \tau_z = I_{cm}\alpha_z$ to the motion of the ball.

(a) SET UP: The free-body diagram is given in Figure 10.23a.

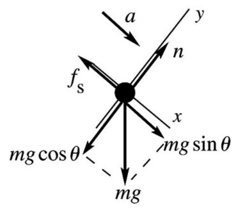

Figure 10.23a

EXECUTE: $\sum F_y = ma_y$

$n = mg\cos\theta$ and $f_s = \mu_s mg\cos\theta$

$\sum F_x = ma_x$

$mg\sin\theta - \mu_s mg\cos\theta = ma$

$g(\sin\theta - \mu_s\cos\theta) = a$ (Eq. 1)

SET UP: Consider Figure 10.23b.

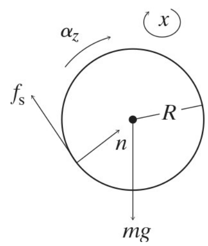

Figure 10.23b

The normal force n is directed through the center of the ball and mg acts at the center of the ball, so neither of them produces a torque about the center.

EXECUTE: $\sum\tau = \tau_f = \mu_s mg(\cos\theta)R$; $I = \frac{2}{5}mR^2$

$\sum\tau_z = I_{cm}\alpha_z$ gives $\mu_s\, mg(\cos\theta)R = \frac{2}{5}mR^2\alpha$

No slipping means $\alpha = a/R$, so $\mu_s g\cos\theta = \frac{2}{5}a$ (Eq. 2)

We have two equations in the two unknowns a and μ_s. Solving gives $a = \frac{5}{7}g\sin\theta$ and

$\mu_s = \frac{2}{7}\tan\theta = \frac{2}{7}\tan 65.0° = 0.613.$

(b) Repeat the calculation of part (a), but now $I = \frac{2}{3}mR^2$. $a = \frac{3}{5}g\sin\theta$ and

$\mu_s = \frac{2}{5}\tan\theta = \frac{2}{5}\tan 65.0° = 0.858$

The value of μ_s calculated in part (a) is not large enough to prevent slipping for the hollow ball.

(c) EVALUATE: There is no slipping at the point of contact. More friction is required for a hollow ball since for a given m and R it has a larger I and more torque is needed to provide the same α. Note that the required μ_s is independent of the mass or radius of the ball and only depends on how that mass is distributed.

10.24. IDENTIFY: Apply $\sum\vec{F} = m\vec{a}$ to the translational motion of the center of mass and $\sum\tau_z = I\alpha_z$ to the rotation about the center of mass.

SET UP: Let $+x$ be down the incline and let the shell be turning in the positive direction. The free-body diagram for the shell is given in Figure 10.24. From Table 9.2, $I_{cm} = \frac{2}{3}mR^2$.

EXECUTE: **(a)** $\sum F_x = ma_x$ gives $mg\sin\beta - f = ma_{cm}$. $\sum\tau_z = I\alpha_z$ gives $fR = \left(\frac{2}{3}mR^2\right)\alpha$. With $\alpha = a_{cm}/R$ this becomes $f = \frac{2}{3}ma_{cm}$. Combining the equations gives $mg\sin\beta - \frac{2}{3}ma_{cm} = ma_{cm}$ and

$a_{cm} = \frac{3g\sin\beta}{5} = \frac{3(9.80\text{ m/s}^2)(\sin 38.0°)}{5} = 3.62\text{ m/s}^2$. $f = \frac{2}{3}ma_{cm} = \frac{2}{3}(2.00\text{ kg})(3.62\text{ m/s}^2) = 4.83\text{ N}$.

The friction is static since there is no slipping at the point of contact. $n = mg\cos\beta = 15.45\text{ N}$.

$\mu_s = \frac{f}{n} = \frac{4.83\text{ N}}{15.45\text{ N}} = 0.313.$

(b) The acceleration is independent of m and doesn't change. The friction force is proportional to m so will double; $f = 9.66$ N. The normal force will also double, so the minimum μ_s required for no slipping wouldn't change.

EVALUATE: If there is no friction and the object slides without rolling, the acceleration is $g\sin\beta$. Friction and rolling without slipping reduce a to 0.60 times this value.

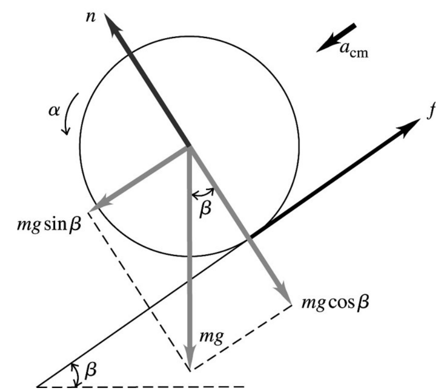

Figure 10.24

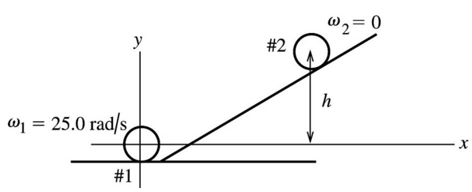
10.25. IDENTIFY: Apply conservation of energy to the motion of the wheel.

SET UP: The wheel at points 1 and 2 of its motion is shown in Figure 10.25.



Take $y = 0$ at the center of the wheel when it is at the bottom of the hill.

Figure 10.25

The wheel has both translational and rotational motion so its kinetic energy is $K = \frac{1}{2}I_{cm}\omega^2 + \frac{1}{2}Mv_{cm}^2$.

EXECUTE: $K_1 + U_1 + W_{other} = K_2 + U_2$

$W_{other} = W_{fric} = -2600$ J (the friction work is negative)

$K_1 = \frac{1}{2}I\omega_1^2 + \frac{1}{2}Mv_1^2$; $v = R\omega$ and $I = 0.800MR^2$ so

$K_1 = \frac{1}{2}(0.800)MR^2\omega_1^2 + \frac{1}{2}MR^2\omega_1^2 = 0.900MR^2\omega_1^2$

$K_2 = 0$, $U_1 = 0$, $U_2 = Mgh$

Thus $0.900MR^2\omega_1^2 + W_{fric} = Mgh$

$M = w/g = 392\text{ N}/(9.80\text{ m/s}^2) = 40.0$ kg

$$h = \frac{0.900MR^2\omega_1^2 + W_{fric}}{Mg}$$

$$h = \frac{(0.900)(40.0\text{ kg})(0.600\text{ m})^2(25.0\text{ rad/s})^2 - 2600\text{ J}}{(40.0\text{ kg})(9.80\text{ m/s}^2)} = 14.0\text{ m}.$$

EVALUATE: Friction does negative work and reduces h.

10.26. **IDENTIFY:** Apply conservation of energy to the motion of the marble.

SET UP: $K = \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2$, with $I = \frac{2}{5}MR^2$. $v_{cm} = R\omega$ for no slipping.

Let $y = 0$ at the bottom of the bowl. The marble at its initial and final locations is sketched in Figure 10.26.

EXECUTE: **(a)** Motion from the release point to the bottom of the bowl: $mgh = \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2$.

$mgh = \frac{1}{2}mv^2 + \frac{1}{2}\left(\frac{2}{5}mR^2\right)\left(\frac{v}{R}\right)^2$ and $v = \sqrt{\frac{10}{7}gh}$.

Motion along the smooth side: The rotational kinetic energy does not change, since there is no friction torque on the marble, $\frac{1}{2}mv^2 + K_{rot} = mgh' + K_{rot}$. $h' = \frac{v^2}{2g} = \frac{\frac{10}{7}gh}{2g} = \frac{5}{7}h$

(b) $mgh = mgh'$ so $h' = h$.

EVALUATE: **(c)** With friction on both halves, all the initial potential energy gets converted back to potential energy. Without friction on the right half some of the energy is still in rotational kinetic energy when the marble is at its maximum height.

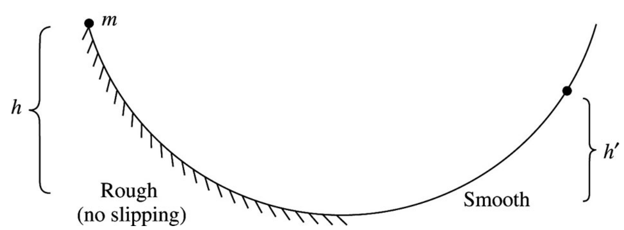


Figure 10.26

10.27. **IDENTIFY:** We want to investigate the kinetic energy of a bowling ball as it rolls down the bowling lane.

SET UP: $K_{total} = \frac{1}{2}mv_{cm}^2 + \frac{1}{2}I\omega^2$, $I = \frac{2}{5}MR^2$ for a solid sphere, and $v_{cm} = r\omega$ when there is no slipping. Estimate: It takes 5.0 s to travel the 60 ft.

EXECUTE: **(a)** The target variable is the rotation rate of the ball. v_{cm} = (60 ft)/(5.0 s) = 12 ft/s. With no slipping $v_{cm} = r\omega$, so $\omega = \frac{v_{cm}}{R} = \frac{12 \text{ ft/s}}{\left(\frac{8.5}{2}\right)\left(\frac{1}{12}\right)\text{ft}}$ = 34 rad/s = 5.4 rev/s.

(b) We want to find out what fraction of the ball's kinetic energy is rotational.

$K_{tot} = \frac{1}{2}mv_{cm}^2 + \frac{1}{2}I\omega^2 = \frac{1}{2}mv_{cm}^2 + \frac{1}{2}\left(\frac{2}{5}mR^2\right)\omega^2 = \frac{1}{2}mv_{cm}^2 + \frac{1}{2}\left(\frac{2}{5}mR^2\right)\left(\frac{v_{cm}}{R}\right)^2$, which gives

$K_{tot} = \frac{7}{10}mv_{cm}^2 = \frac{7}{10}\left(\frac{12 \text{ lb}}{32.2 \text{ ft/s}^2}\right)(12 \text{ ft/s})^2 = 37.6 \text{ ft}\cdot\text{lb}$. The fraction that is rotational is

$\frac{K_{rot}}{K_{tot}} = \frac{\frac{1}{2}I\omega^2}{\frac{7}{10}mv_{cm}^2} = \frac{\frac{1}{2}\left(\frac{2}{5}mR^2\right)\left(\frac{v_{cm}}{R}\right)^2}{\frac{7}{10}mv_{cm}^2} = \frac{2}{7}$. Therefore 2/7 of the kinetic energy is rotational.

EVALUATE: The distribution of the kinetic between rotational and translational forms depends only on the *geometry* of the ball, not on its mass or size. If the ball were hollow, its moment of inertia would be different which would give a different result for the fraction we just found.

10.28. **IDENTIFY:** We want to compare the kinetic energy of two rolling balls.

SET UP: $K_{\text{tot}} = \frac{1}{2}mv_{\text{cm}}^2 + \frac{1}{2}I\omega^2$, $I = \frac{2}{5}MR^2$ for a solid sphere, and $v_{\text{cm}} = r\omega$ when there is no slipping. We know the kinetic energy of ball 2 is 27.0 J, and our target variable is the kinetic energy of ball 1.

EXECUTE: $K_{\text{tot}} = \frac{1}{2}mv_{\text{cm}}^2 + \frac{1}{2}I\omega^2 = \frac{1}{2}mv_{cm}^2 + \frac{1}{2}\left(\frac{2}{5}mR^2\right)\omega^2 = \frac{1}{2}mv_{cm}^2 + \frac{1}{2}\left(\frac{2}{5}mR^2\right)\left(\frac{v_{\text{cm}}}{R}\right)^2$, which gives $K_1 = \frac{7}{10}m_1v_1^2$. We get a similar result for ball 2: $K_2 = \frac{7}{10}m_2v_2^2$. Taking the ratio gives

$$\frac{K_1}{K_2} = \frac{\frac{7}{10}m_1v_1^2}{\frac{7}{10}m_2v_2^2} = \left(\frac{m_1}{m_2}\right)\left(\frac{v_1}{v_2}\right)^2 = \left(\frac{\frac{1}{2}m_2}{m_2}\right)\left(\frac{\frac{1}{3}v_2}{v_2}\right)^2 = \frac{1}{18}.$$ So $K_1 = K_2/18 = (27.0\text{ J})/18 = 1.50$ J.

EVALUATE: The result does *not* depend on the relative size of the balls since R cancels out.

10.29. **IDENTIFY:** As the cylinder falls, its potential energy is transformed into both translational and rotational kinetic energy. Its mechanical energy is conserved.

SET UP: The hollow cylinder has $I = \frac{1}{2}m(R_a^2 + R_b^2)$, where $R_a = 0.200$ m and $R_b = 0.350$ m. Use coordinates where $+y$ is upward and $y = 0$ at the initial position of the cylinder. Then $y_1 = 0$ and $y_2 = -d$, where d is the distance it has fallen. $v_{\text{cm}} = R\omega$. $K_{\text{cm}} = \frac{1}{2}Mv_{\text{cm}}^2$ and $\omega_{0z} = 10.47$ rad/s,

EXECUTE: **(a)** Conservation of energy gives $K_1 + U_1 = K_2 + U_2$. $K_1 = 0$, $U_1 = 0$. $0 = U_2 + K_2$ and $0 = -mgd + \frac{1}{2}mv_{\text{cm}}^2 + \frac{1}{2}I_{\text{cm}}\omega^2$. $\frac{1}{2}I\omega^2 = \frac{1}{2}\left[\frac{1}{2}m(R_a^2 + R_b^2)\right](v_{\text{cm}}/R_b)^2 = \frac{1}{4}m\left[1 + (R_a/R_b)^2\right]v_{\text{cm}}^2$, so

$\frac{1}{2}\left\{1 + \frac{1}{2}\left[1 + (R_a/R_b)^2\right]\right\}v_{\text{cm}}^2 = gd$ and

$$d = \frac{\left\{1 + \frac{1}{2}\left[1 + (R_a/R_b)^2\right]\right\}v_{\text{cm}}^2}{2g} = \frac{(1 + 0.663)(6.66\text{ m/s})^2}{2(9.80\text{ m/s}^2)} = 3.76\text{ m}.$$

(b) $K_2 = \frac{1}{2}mv_{\text{cm}}^2$ since there is no rotation. So $mgd = \frac{1}{2}mv_{\text{cm}}^2$ which gives

$v_{\text{cm}} = \sqrt{2gd} = \sqrt{2(9.80\text{ m/s}^2)(3.76\text{ m})} = 8.58$ m/s.

(c) In part (a) the cylinder has rotational as well as translational kinetic energy and therefore less translational speed at a given kinetic energy. The kinetic energy comes from a decrease in gravitational potential energy and that is the same, so in (a) the translational speed is less.

EVALUATE: If part (a) were repeated for a solid cylinder, $R_a = 0$ and $d = 3.39$ m. For a thin-walled hollow cylinder, $R_a = R_b$ and $d = 4.52$ cm. Note that all of these answers are independent of the mass m of the cylinder.

10.30. **IDENTIFY:** Apply $\sum\tau_z = I\alpha_z$ and $\sum\vec{F} = m\vec{a}$ to the motion of the bowling ball.

SET UP: $a_{\text{cm}} = R\alpha$. $f_s = \mu_s n$. Let $+x$ be directed down the incline.

EXECUTE: **(a)** The free-body diagram is sketched in Figure 10.30.

The angular speed of the ball must decrease, and so the torque is provided by a friction force that acts up the hill.

(b) The friction force results in an angular acceleration, given by $I\alpha = fR$. $\sum\vec{F} = m\vec{a}$ applied to the motion of the center of mass gives $mg\sin\beta - f = ma_{\text{cm}}$, and the acceleration and angular acceleration are related by $a_{\text{cm}} = R\alpha$.

Combining, $mg\sin\beta = ma_{\text{cm}}\left(1+\dfrac{I}{mR^2}\right) = ma_{\text{cm}}(7/5).$ $a_{\text{cm}} = (5/7)g\sin\beta.$

(c) From either of the above relations between f and a_{cm}, $f = \dfrac{2}{5}ma_{\text{cm}} = \dfrac{2}{7}mg\sin\beta \le \mu_s n = \mu_s mg\cos\beta.$

$\mu_s \ge (2/7)\tan\beta.$

EVALUATE: If $\mu_s = 0$, $a_{\text{cm}} = mg\sin\beta.$ a_{cm} is less when friction is present. The ball rolls farther uphill when friction is present, because the friction removes the rotational kinetic energy and converts it to gravitational potential energy. In the absence of friction the ball retains the rotational kinetic energy that is has initially.

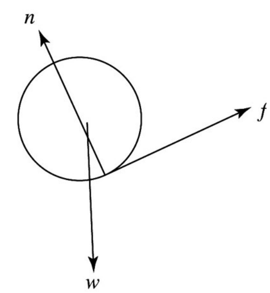

Figure 10.30

10.31. **IDENTIFY:** As the ball rolls up the hill, its kinetic energy (translational and rotational) is transformed into gravitational potential energy. Since there is no slipping, its mechanical energy is conserved.

SET UP: The ball has moment of inertia $I_{\text{cm}} = \frac{2}{3}mR^2$. Rolling without slipping means $v_{\text{cm}} = R\omega$. Use coordinates where $+y$ is upward and $y = 0$ at the bottom of the hill, so $y_1 = 0$ and $y_2 = h = 5.00$ m. The ball's kinetic energy is $K = \frac{1}{2}mv_{\text{cm}}^2 + \frac{1}{2}I_{\text{cm}}\omega^2$ and its potential energy is $U = mgh.$

EXECUTE: **(a)** Conservation of energy gives $K_1 + U_1 = K_2 + U_2$. $U_1 = 0$, $K_2 = 0$ (the ball stops).

Therefore $K_1 = U_2$ and $\frac{1}{2}mv_{\text{cm}}^2 + \frac{1}{2}I_{\text{cm}}\omega^2 = mgh.$ $\frac{1}{2}I_{\text{cm}}\omega^2 = \frac{1}{2}(\frac{2}{3}mR^2)\left(\dfrac{v_{\text{cm}}}{R}\right)^2 = \frac{1}{3}mv_{\text{cm}}^2$, so

$\frac{5}{6}mv_{\text{cm}}^2 = mgh.$ Therefore $v_{\text{cm}} = \sqrt{\dfrac{6gh}{5}} = \sqrt{\dfrac{6(9.80\text{ m/s}^2)(5.00\text{ m})}{5}} = 7.67$ m/s and

$\omega = \dfrac{v_{\text{cm}}}{R} = \dfrac{7.67\text{ m/s}}{0.113\text{ m}} = 67.9$ rad/s.

(b) $K_{\text{rot}} = \frac{1}{2}I\omega^2 = \frac{1}{3}mv_{\text{cm}}^2 = \frac{1}{3}(0.426\text{ kg})(7.67\text{ m/s})^2 = 8.35$ J.

EVALUATE: Its translational kinetic energy at the base of the hill is $\frac{1}{2}mv_{\text{cm}}^2 = \frac{3}{2}K_{\text{rot}} = 12.52$ J. Its total kinetic energy is 20.9 J, which equals its final potential energy:

$mgh = (0.426\text{ kg})(9.80\text{ m/s}^2)(5.00\text{ m}) = 20.9$ J.

10.32. **IDENTIFY:** Apply $P = \tau\omega$ and $W = \tau\Delta\theta.$

SET UP: P must be in watts, $\Delta\theta$ must be in radians, and ω must be in rad/s. 1 rev $= 2\pi$ rad. 1 hp $= 746$ W. π rad/s $= 30$ rev/min.

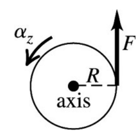
EXECUTE: **(a)** $\tau = \dfrac{P}{\omega} = \dfrac{(175\text{ hp})(746\text{ W/hp})}{(2400\text{ rev/min})\left(\dfrac{\pi\ \text{rad/s}}{30\text{ rev/min}}\right)} = 519\text{ N}\cdot\text{m}.$

(b) $W = \tau\Delta\theta = (519\ \text{N}\cdot\text{m})(2\pi\ \text{rad}) = 3260\ \text{J}$

EVALUATE: $\omega = 40$ rev/s, so the time for one revolution is 0.025 s. $P = 1.306\times 10^5$ W, so in one revolution, $W = Pt = 3260$ J, which agrees with our result.

10.33. **(a) IDENTIFY:** Use $\sum\tau_z = I\alpha_z$ to find α_z and then use a constant angular acceleration equation to find ω_z.

SET UP: The free-body diagram is given in Figure 10.33.



EXECUTE: Apply $\sum\tau_z = I\alpha_z$ to find the angular acceleration:

$FR = I\alpha_z$

$$\alpha_z = \frac{FR}{I} = \frac{(18.0\ \text{N})(2.40\ \text{m})}{2100\ \text{kg}\cdot\text{m}^2} = 0.02057\ \text{rad/s}^2$$

Figure 10.33

SET UP: Use the constant α_z kinematic equations to find ω_z.

$\omega_z = ?$; ω_{0z} (initially at rest); $\alpha_z = 0.02057\ \text{rad/s}^2$; $t = 15.0$ s

EXECUTE: $\omega_z = \omega_{0z} + \alpha_z t = 0 + (0.02057\ \text{rad/s}^2)(15.0\ \text{s}) = 0.309\ \text{rad/s}$

(b) IDENTIFY and **SET UP:** Calculate the work from $W = \tau_z\Delta\theta$, using a constant angular acceleration equation to calculate $\theta - \theta_0$, or use the work-energy theorem. We will do it both ways.

EXECUTE: (1) $W = \tau_z\Delta\theta$

$\Delta\theta = \theta - \theta_0 = \omega_{0z}t + \frac{1}{2}\alpha_z t^2 = 0 + \frac{1}{2}(0.02057\ \text{rad/s}^2)(15.0\ \text{s})^2 = 2.314\ \text{rad}$

$\tau_z = FR = (18.0\ \text{N})(2.40\ \text{m}) = 43.2\ \text{N}\cdot\text{m}$

Then $W = \tau_z\Delta\theta = (43.2\ \text{N}\cdot\text{m})(2.314\ \text{rad}) = 100\ \text{J}$.

or

(2) $W_{\text{tot}} = K_2 - K_1$

$W_{\text{tot}} = W$, the work done by the child

$K_1 = 0$; $K_2 = \frac{1}{2}I\omega^2 = \frac{1}{2}(2100\ \text{kg}\cdot\text{m}^2)(0.309\ \text{rad/s})^2 = 100\ \text{J}$

Thus $W = 100$ J, the same as before.

EVALUATE: Either method yields the same result for W.

(c) IDENTIFY and **SET UP:** Use $P_{\text{av}} = \dfrac{\Delta W}{\Delta t}$ to calculate P_{av}.

EXECUTE: $P_{\text{av}} = \dfrac{\Delta W}{\Delta t} = \dfrac{100\ \text{J}}{15.0\ \text{s}} = 6.67\ \text{W}$.

EVALUATE: Work is in joules, power is in watts.

10.34. **IDENTIFY:** The power output of the motor is related to the torque it produces and to its angular velocity by $P = \tau_z\omega_z$, where ω_z must be in rad/s.

SET UP: The work output of the motor in 60.0 s is $\frac{2}{3}(9.00\ \text{kJ}) = 6.00\ \text{kJ}$, so $P = \dfrac{6.00\ \text{kJ}}{60.0\ \text{s}} = 100\ \text{W}$.

$\omega_z = 2500\ \text{rev/min} = 262\ \text{rad/s}$.

EXECUTE: $\tau_z = \dfrac{P}{\omega_z} = \dfrac{100\ \text{W}}{262\ \text{rad/s}} = 0.382\ \text{N}\cdot\text{m}$.

EVALUATE: For a constant power output, the torque developed decreases when the rotation speed of the motor increases.

10.35. **IDENTIFY:** Apply $\sum \tau_z = I\alpha_z$ and constant angular acceleration equations to the motion of the wheel.

SET UP: 1 rev $= 2\pi$ rad. π rad/s $= 30$ rev/min.

EXECUTE: **(a)** $\tau_z = I\alpha_z = I\dfrac{\omega_z - \omega_{0z}}{t}$.

$$\tau_z = \frac{\left[(1/2)(2.80\text{ kg})(0.100\text{ m})^2\right](1200\text{ rev/min})\left(\dfrac{\pi}{30}\dfrac{\text{rad/s}}{\text{rev/min}}\right)}{2.5\text{ s}} = 0.704\text{ N}\cdot\text{m}.$$

(b) $\omega_{\text{av}}\Delta t = \dfrac{(600\text{ rev/min})(2.5\text{ s})}{60\text{ s/min}} = 25.0\text{ rev} = 157\text{ rad}.$

(c) $W = \tau\Delta\theta = (0.704\text{ N}\cdot\text{m})(157\text{ rad}) = 111\text{ J}.$

(d) $K = \frac{1}{2}I\omega^2 = \frac{1}{2}\left[(1/2)(2.80\text{ kg})(0.100\text{ m})^2\right]\left[(1200\text{ rev/min})\left(\dfrac{\pi}{30}\dfrac{\text{rad/s}}{\text{rev/min}}\right)\right]^2 = 111\text{ J}.$

the same as in part (c).

EVALUATE: The agreement between the results of parts (c) and (d) illustrates the work-energy theorem.

10.36. **IDENTIFY:** Apply $\sum \tau_z = I\alpha_z$ to the motion of the propeller and then use constant acceleration equations to analyze the motion. $W = \tau\Delta\theta$.

SET UP: $I = \frac{1}{12}mL^2 = \frac{1}{12}(117\text{ kg})(2.08\text{ m})^2 = 42.2\text{ kg}\cdot\text{m}^2.$

EXECUTE: **(a)** $\alpha = \dfrac{\tau}{I} = \dfrac{1950\text{ N}\cdot\text{m}}{42.2\text{ kg}\cdot\text{m}^2} = 46.2\text{ rad/s}^2.$

(b) $\omega_z^2 = \omega_{0z}^2 + 2\alpha_z(\theta - \theta_0)$ gives $\omega = \sqrt{2\alpha\theta} = \sqrt{2(46.2\text{ rad/s}^2)(5.0\text{ rev})(2\pi\text{ rad/rev})} = 53.9\text{ rad/s}.$

(c) $W = \tau\theta = (1950\text{ N}\cdot\text{m})(5.00\text{ rev})(2\pi\text{ rad/rev}) = 6.13\times10^4\text{ J}.$

(d) $t = \dfrac{\omega_z - \omega_{0z}}{\alpha_z} = \dfrac{53.9\text{ rad/s}}{46.2\text{ rad/s}^2} = 1.17\text{ s}.$ $P_{\text{av}} = \dfrac{W}{\Delta t} = \dfrac{6.13\times10^4\text{ J}}{1.17\text{ s}} = 52.5\text{ kW}.$

(e) $P = \tau\omega = (1950\text{ N}\cdot\text{m})(53.9\text{ rad/s}) = 105\text{ kW}.$

EVALUATE: $P = \tau\omega$. τ is constant and ω is linear in t, so P_{av} is half the instantaneous power at the end of the 5.00 revolutions. We could also calculate W from $W = \Delta K = \frac{1}{2}I\omega^2 = \frac{1}{2}(42.2\text{ kg}\cdot\text{m}^2)(53.9\text{ rad/s})^2 = 6.13\times10^4\text{ J}.$

10.37. **(a) IDENTIFY:** Use $L = mvr\sin\phi$.

SET UP: Consider Figure 10.37.

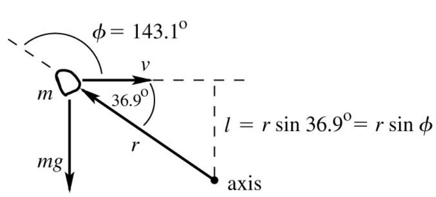


Figure 10.37

EXECUTE: $L = mvr\sin\phi =$ $(2.00\text{ kg})(12.0\text{ m/s})(8.00\text{ m})\sin 143.1°$

$L = 115\text{ kg}\cdot\text{m}^2/\text{s}$

To find the direction of $\vec{L}$ apply the right-hand rule by turning $\vec{r}$ into the direction of $\vec{v}$ by pushing on it with the fingers of your right hand. Your thumb points into the page, in the direction of $\vec{L}$.

(b) IDENTIFY and **SET UP:** By $\vec{\tau} = \dfrac{d\vec{L}}{dt}$ the rate of change of the angular momentum of the rock equals the torque of the net force acting on it.

EXECUTE: $\tau = mg(8.00\text{ m})\cos 36.9° = 125\text{ kg}\cdot\text{m}^2/\text{s}^2$

To find the direction of $\vec{\boldsymbol{\tau}}$ and hence of $d\vec{\boldsymbol{L}}/dt$, apply the right-hand rule by turning $\vec{\boldsymbol{r}}$ into the direction of the gravity force by pushing on it with the fingers of your right hand. Your thumb points out of the page, in the direction of $d\vec{\boldsymbol{L}}/dt$.

EVALUATE: $\vec{\boldsymbol{L}}$ and $d\vec{\boldsymbol{L}}/dt$ are in opposite directions, so L is decreasing. The gravity force is accelerating the rock downward, toward the axis. Its horizontal velocity is constant but the distance l is decreasing and hence L is decreasing.

10.38. **IDENTIFY:** $L = I\omega$ and $I = I_{\text{disk}} + I_{\text{woman}}$.

SET UP: $\omega = 0.80\text{ rev/s} = 5.026\text{ rad/s}$. $I_{\text{disk}} = \frac{1}{2}m_{\text{disk}}R^2$ and $I_{\text{woman}} = m_{\text{woman}}R^2$.

EXECUTE: $I = (55\text{ kg} + 50.0\text{ kg})(4.0\text{ m})^2 = 1680\text{ kg}\cdot\text{m}^2$.

$L = (1680\text{ kg}\cdot\text{m}^2)(5.026\text{ rad/s}) = 8.4\times10^3\text{ kg}\cdot\text{m}^2/\text{s}$.

EVALUATE: The disk and the woman have similar values of I, even though the disk has twice the mass.

10.39. **IDENTIFY** and **SET UP:** Use $L = I\omega$.

EXECUTE: The second hand makes 1 revolution in 1 minute, so
$\omega = (1.00\text{ rev/min})(2\pi\text{ rad/1 rev})(1\text{ min/60 s}) = 0.1047\text{ rad/s}$.

For a slender rod, with the axis about one end,
$I = \frac{1}{3}ML^2 = \frac{1}{3}(6.00\times10^{-3}\text{ kg})(0.150\text{ m})^2 = 4.50\times10^{-5}\text{ kg}\cdot\text{m}^2$.

Then $L = I\omega = (4.50\times10^{-5}\text{ kg}\cdot\text{m}^2)(0.1047\text{ rad/s}) = 4.71\times10^{-6}\text{ kg}\cdot\text{m}^2/\text{s}$.

EVALUATE: $\vec{\boldsymbol{L}}$ is clockwise.

10.40. **IDENTIFY:** $L_z = I\omega_z$

SET UP: For a particle of mass m moving in a circular path at a distance r from the axis, $I = mr^2$ and $v = r\omega$. For a uniform sphere of mass M and radius R and an axis through its center, $I = \frac{2}{5}MR^2$. The earth has mass $m_{\text{E}} = 5.97\times10^{24}\text{ kg}$, radius $R_{\text{E}} = 6.37\times10^6\text{ m}$ and orbit radius $r = 1.50\times10^{11}\text{ m}$. The earth completes one rotation on its axis in $24\text{ h} = 86{,}400\text{ s}$ and one orbit in $1\text{ y} = 3.156\times10^7\text{ s}$.

EXECUTE: **(a)**

$$L_z = I\omega_z = mr^2\omega_z = (5.97\times10^{24}\text{ kg})(1.50\times10^{11}\text{ m})^2\left(\frac{2\pi\text{ rad}}{3.156\times10^7\text{ s}}\right) = 2.67\times10^{40}\text{ kg}\cdot\text{m}^2/\text{s}.$$

The radius of the earth is much less than its orbit radius, so it is very reasonable to model it as a particle for this calculation.

(b) $L_z = I\omega_z = (\frac{2}{5}MR^2)\omega = \frac{2}{5}(5.97\times10^{24}\text{ kg})(6.38\times10^6\text{ m})^2\left(\frac{2\pi\text{ rad}}{86{,}400\text{ s}}\right) = 7.07\times10^{33}\text{ kg}\cdot\text{m}^2/\text{s}$

EVALUATE: The angular momentum associated with each of these motions is very large.

10.41. **IDENTIFY:** $\omega_z = d\theta/dt$. $L_z = I\omega_z$ and $\tau_z = dL_z/dt$.

SET UP: For a hollow, thin-walled sphere rolling about an axis through its center, $I = \frac{2}{3}MR^2$. $R = 0.240\text{ m}$.

EXECUTE: **(a)** $A = 1.50\text{ rad/s}^2$ and $B = 1.10\text{ rad/s}^4$, so that $\theta(t)$ will have units of radians.

(b) (i) $\omega_z = \dfrac{d\theta}{dt} = 2At + 4Bt^3$. At $t = 3.00\text{ s}$,

$\omega_z = 2(1.50\text{ rad/s}^2)(3.00\text{ s}) + 4(1.10\text{ rad/s}^4)(3.00\text{ s})^3 = 128\text{ rad/s}$.

$L_z = (\frac{2}{3}MR^2)\omega_z = \frac{2}{3}(12.0\text{ kg})(0.240\text{ m})^2(128\text{ rad/s}) = 59.0\text{ kg}\cdot\text{m}^2/\text{s}$.

(ii) $\tau_z = \dfrac{dL_z}{dt} = I\dfrac{d\omega_z}{dt} = I(2A + 12Bt^2)$ and

$\tau_z = \frac{2}{3}(12.0\text{ kg})(0.240\text{ m})^2\left[2(1.50\text{ rad/s}^2) + 12(1.10\text{ rad/s}^4)(3.00\text{ s})^2\right] = 56.1\text{ N}\cdot\text{m}.$

EVALUATE: The angular speed of rotation is increasing. This increase is due to an acceleration α_z that is produced by the torque on the sphere. When I is constant, as it is here, $\tau_z = dL_z/dt = Id\omega_z/dt = I\alpha_z$.

10.42. IDENTIFY and SET UP: $\vec{L}$ is conserved if there is no net external torque.
Use conservation of angular momentum to find ω at the new radius and use $K = \frac{1}{2}I\omega^2$ to find the change in kinetic energy, which is equal to the work done on the block.

EXECUTE: **(a)** Yes, angular momentum is conserved. The moment arm for the tension in the cord is zero so this force exerts no torque and there is no net torque on the block.

(b) $L_1 = L_2$ so $I_1\omega_1 = I_2\omega_2$. Block treated as a point mass, so $I = mr^2$, where r is the distance of the block from the hole.

$mr_1^2\omega_1 = mr_2^2\omega_2$

$$\omega_2 = \left(\frac{r_1}{r_2}\right)^2\omega_1 = \left(\frac{0.300\text{ m}}{0.150\text{ m}}\right)^2(2.85\text{ rad/s}) = 11.4\text{ rad/s}$$

(c) $K_1 = \frac{1}{2}I_1\omega_1^2 = \frac{1}{2}mr_1^2\omega_1^2 = \frac{1}{2}mv_1^2$

$v_1 = r_1\omega_1 = (0.300\text{ m})(2.85\text{ rad/s}) = 0.855\text{ m/s}$

$K_1 = \frac{1}{2}mv_1^2 = \frac{1}{2}(0.0250\text{ kg})(0.855\text{ m/s})^2 = 0.00914\text{ J}$

$K_2 = \frac{1}{2}mv_2^2$

$v_2 = r_2\omega_2 = (0.150\text{ m})(11.4\text{ rad/s}) = 1.71\text{ m/s}$

$K_2 = \frac{1}{2}mv_2^2 = \frac{1}{2}(0.0250\text{ kg})(1.71\text{ m/s}^2)^2 = 0.03655\text{ J}$

$\Delta K = K_2 - K_1 = 0.03655\text{ J} - 0.00914\text{ J} = 0.0274\text{ J} = 27.4\text{ mJ}.$

(d) $W_{\text{tot}} = \Delta K$

But $W_{\text{tot}} = W$, the work done by the tension in the cord, so $W = 0.0274$ J.

EVALUATE: Smaller r means smaller I. $L = I\omega$ is constant so ω increases and K increases. The work done by the tension is positive since it is directed inward and the block moves inward, toward the hole.

10.43. IDENTIFY: Apply conservation of angular momentum.

SET UP: For a uniform sphere and an axis through its center, $I = \frac{2}{5}MR^2$.

EXECUTE: The moment of inertia is proportional to the square of the radius, and so the angular velocity will be proportional to the inverse of the square of the radius, and the final angular velocity is

$$\omega_2 = \omega_1\left(\frac{R_1}{R_2}\right)^2 = \left(\frac{2\pi\text{ rad}}{(30\text{ d})(86{,}400\text{ s/d})}\right)\left(\frac{7.0\times10^5\text{ km}}{16\text{ km}}\right)^2 = 4.6\times10^3\text{ rad/s}.$$

EVALUATE: $K = \frac{1}{2}I\omega^2 = \frac{1}{2}L\omega$. L is constant and ω increases by a large factor, so there is a large increase in the rotational kinetic energy of the star. This energy comes from potential energy associated with the gravity force within the star.

10.44. IDENTIFY and SET UP: Apply conservation of angular momentum to the diver.

SET UP: The number of revolutions she makes in a certain time is proportional to her angular velocity. The ratio of her untucked to tucked angular velocity is $(3.6\text{ kg}\cdot\text{m}^2)/(18\text{ kg}\cdot\text{m}^2)$.

EXECUTE: If she had not tucked, she would have made $(2\text{ rev})(3.6\text{ kg}\cdot\text{m}^2)/(18\text{ kg}\cdot\text{m}^2) = 0.40\text{ rev}$ in the last 1.0 s, so she would have made $(0.40\text{ rev})(1.5/1.0) = 0.60\text{ rev}$ in the total 1.5 s.

EVALUATE: Untucked she rotates slower and completes fewer revolutions.

10.45. **IDENTIFY:** Apply conservation of angular momentum to the motion of the skater.

SET UP: For a thin-walled hollow cylinder $I = mR^2$. For a slender rod rotating about an axis through its center, $I = \frac{1}{12}ml^2$.

EXECUTE: $L_\text{i} = L_\text{f}$ so $I_\text{i}\omega_\text{i} = I_\text{f}\omega_\text{f}$.

$I_\text{i} = 0.40\text{ kg}\cdot\text{m}^2 + \frac{1}{12}(8.0\text{ kg})(1.8\text{ m})^2 = 2.56\text{ kg}\cdot\text{m}^2.$

$I_\text{f} = 0.40\text{ kg}\cdot\text{m}^2 + (8.0\text{ kg})(0.25\text{ m})^2 = 0.90\text{ kg}\cdot\text{m}^2.$

$$\omega_\text{f} = \left(\frac{I_\text{i}}{I_\text{f}}\right)\omega_\text{i} = \left(\frac{2.56\text{ kg}\cdot\text{m}^2}{0.90\text{ kg}\cdot\text{m}^2}\right)(0.40\text{ rev/s}) = 1.14\text{ rev/s}.$$

EVALUATE: $K = \frac{1}{2}I\omega^2 = \frac{1}{2}L\omega.$ ω increases and L is constant, so K increases. The increase in kinetic energy comes from the work done by the skater when he pulls in his hands.

10.46. **IDENTIFY:** Apply conservation of angular momentum to the collision.

SET UP: Let the width of the door be l. The initial angular momentum of the mud is $mv(l/2)$, since it strikes the door at its center. For the axis at the hinge, $I_\text{door} = \frac{1}{3}Ml^2$ and $I_\text{mud} = m(l/2)^2$.

EXECUTE: $\omega = \dfrac{L}{I} = \dfrac{mv(l/2)}{(1/3)Ml^2 + m(l/2)^2}.$

$$\omega = \frac{(0.500\text{ kg})(12.0\text{ m/s})(0.500\text{ m})}{(1/3)(40.0\text{ kg})(1.00\text{ m})^2 + (0.500\text{ kg})(0.500\text{ m})^2} = 0.223\text{ rad/s}.$$

Ignoring the mass of the mud in the denominator of the above expression gives $\omega = 0.225\text{ rad/s}$, so the mass of the mud in the moment of inertia does affect the third significant figure.

EVALUATE: Angular momentum is conserved but there is a large decrease in the kinetic energy of the system.

10.47. **IDENTIFY** and **SET UP:** There is no net external torque about the rotation axis so the angular momentum $L = I\omega$ is conserved.

EXECUTE: **(a)** $L_1 = L_2$ gives $I_1\omega_1 = I_2\omega_2$, so $\omega_2 = (I_1/I_2)\omega_1$

$I_1 = I_\text{tt} = \frac{1}{2}MR^2 = \frac{1}{2}(120\text{ kg})(2.00\text{ m})^2 = 240\text{ kg}\cdot\text{m}^2$

$I_2 = I_\text{tt} + I_\text{p} = 240\text{ kg}\cdot\text{m}^2 + mR^2 = 240\text{ kg}\cdot\text{m}^2 + (70\text{ kg})(2.00\text{ m})^2 = 520\text{ kg}\cdot\text{m}^2$

$\omega_2 = (I_1/I_2)\omega_1 = (240\text{ kg}\cdot\text{m}^2/520\text{ kg}\cdot\text{m}^2)(3.00\text{ rad/s}) = 1.38\text{ rad/s}$

(b) $K_1 = \frac{1}{2}I_1\omega_1^2 = \frac{1}{2}(240\text{ kg}\cdot\text{m}^2)(3.00\text{ rad/s})^2 = 1080\text{ J}$

$K_2 = \frac{1}{2}I_2\omega_2^2 = \frac{1}{2}(520\text{ kg}\cdot\text{m}^2)(1.38\text{ rad/s})^2 = 495\text{ J}$

EVALUATE: The kinetic energy decreases because of the negative work done on the turntable and the parachutist by the friction force between these two objects.
The angular speed decreases because I increases when the parachutist is added to the system.

10.48. **IDENTIFY:** Apply conservation of angular momentum to the system of earth plus asteroid.

SET UP: Take the axis to be the earth's rotation axis. The asteroid may be treated as a point mass and it has zero angular momentum before the collision, since it is headed toward the center of the earth. For the earth, $L_z = I\omega_z$ and $I = \frac{2}{5}MR^2$, where M is the mass of the earth and R is its radius. The length of a day is $T = \dfrac{2\pi\text{ rad}}{\omega}$, where ω is the earth's angular rotation rate.

EXECUTE: Conservation of angular momentum applied to the collision between the earth and asteroid gives $\frac{2}{5}MR^2\omega_1 = (mR^2 + \frac{2}{5}MR^2)\omega_2$ and $m = \frac{2}{5}M\left(\frac{\omega_1 - \omega_2}{\omega_2}\right)$. $T_2 = 1.250T_1$ gives $\frac{1}{\omega_2} = \frac{1.250}{\omega_1}$ and

$\omega_1 = 1.250\omega_2$. $\frac{\omega_1 - \omega_2}{\omega_2} = 0.250$. $m = \frac{2}{5}(0.250)M = 0.100M$.

EVALUATE: If the asteroid hit the surface of the earth tangentially it could have some angular momentum with respect to the earth's rotation axis, and could either speed up or slow down the earth's rotation rate.

10.49. **(a) IDENTIFY** and **SET UP:** Apply conservation of angular momentum $\vec{L}$, with the axis at the nail. Let object A be the bug and object B be the bar. Initially, all objects are at rest and $L_1 = 0$. Just after the bug jumps, it has angular momentum in one direction of rotation and the bar is rotating with angular velocity ω_B in the opposite direction.

EXECUTE: $L_2 = m_A v_A r - I_B\omega_B$ where $r = 1.00\text{ m}$ and $I_B = \frac{1}{3}m_B r^2$

$L_1 = L_2$ gives $m_A v_A r = \frac{1}{3}m_B r^2\omega_B$

$$\omega_B = \frac{3m_A v_A}{m_B r} = 0.120\text{ rad/s}$$

(b) $K_1 = 0$;

$K_2 = \frac{1}{2}m_A v_A^2 + \frac{1}{2}I_B\omega_B^2 = \frac{1}{2}(0.0100\text{ kg})(0.200\text{ m/s})^2 + \frac{1}{2}(\frac{1}{3}(0.0500\text{ kg})(1.00\text{ m})^2)(0.120\text{ rad/s})^2 = 3.2\times10^{-4}\text{ J}.$

(c) The increase in kinetic energy comes from work done by the bug when it pushes against the bar in order to jump.

EVALUATE: There is no external torque applied to the system and the total angular momentum of the system is constant. There are internal forces, forces the bug and bar exert on each other. The forces exert torques and change the angular momentum of the bug and the bar, but these changes are equal in magnitude and opposite in direction. These internal forces do positive work on the two objects and the kinetic energy of each object and of the system increases.

10.50. **IDENTIFY:** As the bug moves outward, it increases the moment of inertia of the rod-bug system. The angular momentum of this system is conserved because no unbalanced external torques act on it.

SET UP: The moment of inertia of the rod is $I = \frac{1}{3}ML^2$, and conservation of angular momentum gives $I_1\omega_1 = I_2\omega_2$.

EXECUTE: **(a)** $I = \frac{1}{3}ML^2$ gives $M = \frac{3I}{L^2} = \frac{3(3.00\times10^{-3}\text{ kg}\cdot\text{m}^2)}{(0.500\text{ m})^2} = 0.0360\text{ kg}.$

(b) $L_1 = L_2$, so $I_1\omega_1 = I_2\omega_2$. $\omega_2 = \frac{v}{r} = \frac{0.160\text{ m/s}}{0.500\text{ m}} = 0.320\text{ rad/s}$, so

$(3.00\times10^{-3}\text{ kg}\cdot\text{m}^2)(0.400\text{ rad/s}) = (3.00\times10^{-3}\text{ kg}\cdot\text{m}^2 + m_{\text{bug}}(0.500\text{ m})^2)(0.320\text{ rad/s}).$

$$m_{\text{bug}} = \frac{(3.00\times10^{-3}\text{ kg}\cdot\text{m}^2)(0.400\text{ rad/s} - 0.320\text{ rad/s})}{(0.320\text{ rad/s})(0.500\text{ m})^2} = 3.00\times10^{-3}\text{ kg}.$$

EVALUATE: This is a 3.00 mg bug, which is not unreasonable.

10.51. **IDENTIFY:** Energy is conserved as the cylinder rolls down the incline without slipping.

SET UP: The total energy of the cylinder is $K_{\text{tot}} = \frac{1}{2}mv_{\text{cm}}^2 + \frac{1}{2}I\omega^2$, $I_{\text{cyl}} = \frac{1}{2}MR^2$. As the cylinder rolls down the incline, gravitational potential energy is transformed into kinetic energy, so we use $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$. Our target variable is the acceleration due to gravity on the planet.

EXECUTE: Energy conservation gives $mgh = \frac{1}{2}mv_{cm}^2 + \frac{1}{2}I\omega^2$, which, for a solid cylinder, gives $mgh = \frac{1}{2}mv_{cm}^2 + \frac{1}{2}\left(\frac{1}{2}mR^2\right)\left(\frac{v_{cm}}{R}\right)^2$. Solving for v_{cm}^2 gives $v_{cm}^2 = \left(\frac{4}{3}g\right)h.$ The graph of v_{cm}^2 versus h should be a straight line having slope equal to $4g/3$. Thus $g = \frac{3}{4}(\text{slope}) = \frac{3}{4}(6.42\text{ m/s}^2) = 4.82\text{ m/s}^2$.

EVALUATE: On this planet, g is about half of what it is on the earth.

10.52. **IDENTIFY:** If we take the raven and the gate as a system, the torque about the pivot is zero, so the angular momentum of the system about the pivot is conserved.

SET UP: The system before and after the collision is sketched in Figure 10.52. The gate has $I = \frac{1}{3}ML^2$. Take counterclockwise torques to be positive.

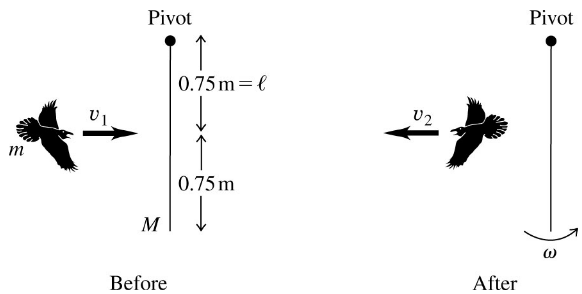

Figure 10.52

EXECUTE: **(a)** The gravity forces exert no torque at the moment of collision and angular momentum is conserved. $L_1 = L_2$. $mv_1 l = -mv_2 l + I_{gate}\omega$ with $l = L/2$.

$$\omega = \frac{m(v_1 + v_2)l}{\frac{1}{3}ML^2} = \frac{3m(v_1 + v_2)}{2ML} = \frac{3(1.1\text{ kg})(5.0\text{ m/s} + 2.0\text{ m/s})}{2(4.5\text{ kg})(1.5\text{ m})} = 1.71\text{ rad/s}.$$

(b) Linear momentum is not conserved; there is an external force exerted by the pivot. But the force on the pivot has zero torque. There is no external torque and angular momentum is conserved.

EVALUATE: $K_1 = \frac{1}{2}(1.1\text{ kg})(5.0\text{ m/s})^2 = 13.8\text{ J}$.

$K_2 = \frac{1}{2}(1.1\text{ kg})(2.0\text{ m/s})^2 + \frac{1}{2}(\frac{1}{3}[4.5\text{ kg}][1.5\text{ m/s}]^2)(1.71\text{ rad/s})^2 = 7.1\text{ J}$. This is an inelastic collision and $K_2 < K_1$.

10.53. **IDENTIFY:** When the teenager throws the rock, it causes the wooden disk to spin. Because no external torques act on the system due to the throw, the angular momentum of the system is conserved.

SET UP: $L = I\omega$ for a rotating object, and $L = mvr$ for a small object. $I_{disk} = \frac{1}{2}MR^2$. The target variable is the angular speed of the disk just after the rock is thrown.

EXECUTE: The initial angular momentum is zero since nothing is turning. Conservation of angular momentum tells us that $L_1 = L_2$, so $0 = L_{teen} + L_{disk} + L_{rock}$. The rock's motion is opposite to that of the teen and disk. This gives us $0 = mR^2\omega + \frac{1}{2}MR^2\omega - m_{rock}vR$. Solving for ω gives $\omega = \frac{m_{rock}v}{R\left(m + \frac{M}{2}\right)}$.

EVALUATE: Check some special cases. If $m_{rock} \to 0$, then $\omega \to 0$, which means that throwing the very light rock had no effect on the disk. If m or M are very large, $\omega \to 0$, which means that the teen or the disk were too massive to be moved by the light rock. If the teen and the rock are both much more massive than the disk, then $\omega \rightarrow v/R$, which means that the teen and rock have the same speed but in opposite directions.

10.54. **IDENTIFY:** The bullet collides with (and embeds itself in) the wooden disk, causing the disk and bullet to rotate. The angular momentum of the system is conserved because the collision did not cause any external torques on it.

SET UP: $L = I\omega$ for a rotating object, and $L = mvr$ for a small object. $I_{\text{disk}} = \frac{1}{2}MR^2$. The target variable is the speed of the bullet just before it hit the disk.

EXECUTE: Angular momentum conservation tells us that $L_{\text{bullet}} = L_{\text{bullet+disk}}$. Calling m the bullet mass and M the disk mass gives $mvR = (I_b + I_d)\omega = \left(mR^2 + \frac{1}{2}MR^2\right)\omega$. Solving for v gives

$$v = R\omega\left(1+\frac{M}{2m}\right) = (0.600\text{ m})(4.00\text{ rad/s})\left(1+\frac{1.60\text{ kg}}{0.0400\text{ kg}}\right) = 98.4\text{ m/s}.$$

EVALUATE: Our result tells us that if m is small, v will need to be large to give the disk angular speed. If m is large, v can be small to give the disk angular speed.

10.55. **IDENTIFY:** An external torque will cause precession of the telescope.

SET UP: $I = MR^2$, with $R = 2.5\times10^{-2}$ m. 1.0×10^{-6} degree $= 1.745\times10^{-8}$ rad.

$\omega = 19{,}200$ rpm $= 2.01\times10^3$ rad/s. $t = 5.0$ h $= 1.8\times10^4$ s.

EXECUTE: $\Omega = \dfrac{\Delta\phi}{\Delta t} = \dfrac{1.745\times10^{-8}\text{ rad}}{1.8\times10^4\text{ s}} = 9.694\times10^{-13}$ rad/s. $\Omega = \dfrac{\tau}{I\omega}$ so $\tau = \Omega I\omega = \Omega MR^2\omega$. Putting in the numbers gives

$\tau = (9.694\times10^{-13}\text{ rad/s})(2.0\text{ kg})(2.5\times10^{-2}\text{ m})^2(2.01\times10^3\text{ rad/s}) = 2.4\times10^{-12}\text{ N}\cdot\text{m}.$

EVALUATE: The external torque must be very small for this degree of stability.

10.56. **IDENTIFY:** The precession angular speed is related to the acceleration due to gravity by $\Omega = \dfrac{mgr}{I\omega}$, with $w = mg$.

SET UP: $\Omega_E = 0.50$ rad/s, $g_E = g$ and $g_M = 0.165g$. For the gyroscope, m, r, I, and ω are the same on the moon as on the earth.

EXECUTE: $\Omega = \dfrac{mgr}{I\omega}$. $\dfrac{\Omega}{g} = \dfrac{mr}{I\omega} =$ constant, so $\dfrac{\Omega_E}{g_E} = \dfrac{\Omega_M}{g_M}$.

$$\Omega_M = \Omega_E\left(\frac{g_M}{g_E}\right) = 0.165\Omega_E = (0.165)(0.50\text{ rad/s}) = 0.0825\text{ rad/s}.$$

EVALUATE: In the limit that $g \rightarrow 0$ the precession rate $\rightarrow 0$.

10.57. **IDENTIFY:** As you pedal your bike, you turn a large sprocket which then turns a smaller sprocket on the wheel, and this causes the wheel to turn. Fig. 10.57 illustrates this arrangement.

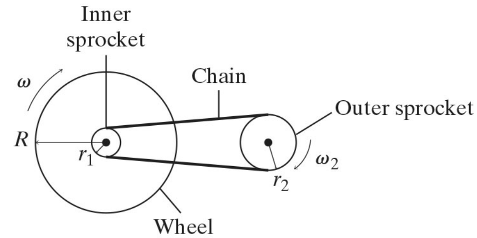

Figure 10.57

SET UP: Estimates: Bicycle wheel is 30 in. in diameter, large sprocket is 8.0 in. in diameter, and small sprocket is 4.0 in. in diameter. This means that in Fig. 10.57, $R = 15$ in., $r_1 = 2.0$ in., and $r_2 = 4.0$ in. We assume that the bike's wheel does not slip on the pavement, so $v_{cm} = R\omega$. The target variable is the angular speed of the large sprocket while the bike is traveling at 30 mph.

EXECUTE: <u>Wheel</u>: $v_{cm} = R\omega = 30$ mph $= 44$ ft/s, so $\omega = (44\text{ ft/s})/(15/12\text{ ft}) = 35.2$ rad/s.

<u>Inner sprocket</u>: It turns at the same angular speed as the wheel, so its speed is $v_1 = r_1\omega$.

<u>Outer sprocket</u>: It is connected by a chain to the inner sprocket, so its tangential speed is the same as that of the inner sprocket, which means that $v_1 = v_2$ and $v_2 = r_2\omega_2$. Equating these two speeds gives $r_1\omega = r_2\omega_2$, so $\omega_2 = \frac{r_1}{r_2}\omega = \frac{2.0\text{ in.}}{4.0\text{ in.}}(35.2\text{ rad/s}) = 17.6$ rad/s. Converting to rpm gives

$$\omega_2 = \left(17.6\frac{\text{rad}}{\text{s}}\right)\left(\frac{60\text{ s}}{1\text{ min}}\right)\left(\frac{1\text{ rev}}{2\pi\text{ rad}}\right) = 170\text{ rev/min}.$$

EVALUATE: By contrast, the bike's wheel turns at $\omega = 35$ rad/s $= 330$ rpm.

10.58. **IDENTIFY:** Apply $\sum\tau_z = I\alpha_z$ and constant acceleration equations to the motion of the grindstone.

SET UP: Let the direction of rotation of the grindstone be positive. The friction force is $f = \mu_k n$ and produces torque fR. $\omega = (120\text{rev/min})\left(\frac{2\pi\text{ rad}}{1\text{ rev}}\right)\left(\frac{1\text{ min}}{60\text{ s}}\right) = 4\pi$ rad/s. $I = \frac{1}{2}MR^2 = 1.69\text{ kg}\cdot\text{m}^2$.

EXECUTE: **(a)** The net torque must be

$$\tau = I\alpha = I\frac{\omega_z - \omega_{0z}}{t} = (1.69\text{ kg}\cdot\text{m}^2)\frac{4\pi\text{ rad/s}}{9.00\text{ s}} = 2.36\text{ N}\cdot\text{m}.$$

This torque must be the sum of the applied force FR and the opposing frictional torques τ_f at the axle and $fR = \mu_k nR$ due to the knife. $F = \frac{1}{R}(\tau + \tau_f + \mu_k nR)$.

$$F = \frac{1}{0.500\text{ m}}\left[(2.36\text{ N}\cdot\text{m}) + (6.50\text{ N}\cdot\text{m}) + (0.60)(160\text{ N})(0.260\text{ m})\right] = 67.6\text{ N}.$$

(b) To maintain a constant angular velocity, the net torque τ is zero, and the force F' is

$$F' = \frac{1}{0.500\text{ m}}(6.50\text{ N}\cdot\text{m} + 24.96\text{ N}\cdot\text{m}) = 62.9\text{ N}.$$

(c) The time t needed to come to a stop is found by taking the magnitudes in $\vec{\tau} = \frac{d\vec{\boldsymbol{L}}}{dt}$, with $\tau = \tau_f$ constant; $t = \frac{L}{\tau_f} = \frac{\omega I}{\tau_f} = \frac{(4\pi\text{ rad/s})(1.69\text{ kg}\cdot\text{m}^2)}{6.50\text{ N}\cdot\text{m}} = 3.27$ s.

EVALUATE: The time for a given change in ω is proportional to α, which is in turn proportional to the net torque, so the time in part (c) can also be found as $t = (9.00\text{ s})\frac{2.36\text{ N}\cdot\text{m}}{6.50\text{ N}\cdot\text{m}}$.

10.59. **IDENTIFY:** Use the kinematic information to solve for the angular acceleration of the grindstone. Assume that the grindstone is rotating counterclockwise and let that be the positive sense of rotation. Then apply $\sum\tau_z = I\alpha_z$ to calculate the friction force and use $f_k = \mu_k n$ to calculate μ_k.

SET UP: $\omega_{0z} = 850\text{ rev/min}(2\pi\text{ rad/1 rev})(1\text{ min/60 s}) = 89.0\text{ rad/s}$

$t = 7.50$ s; $\omega_z = 0$ (comes to rest); $\alpha_z = ?$

EXECUTE: $\omega_z = \omega_{0z} + \alpha_z t$

$$\alpha_z = \frac{0 - 89.0\text{ rad/s}}{7.50\text{ s}} = -11.9\text{ rad/s}^2$$

SET UP: Apply $\sum\tau_z = I\alpha_z$ to the grindstone. The free-body diagram is given in Figure 10.59.

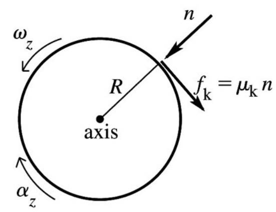

Figure 10.59

The normal force has zero moment arm for rotation about an axis at the center of the grindstone, and therefore zero torque. The only torque on the grindstone is that due to the friction force f_k exerted by the ax; for this force the moment arm is $l = R$ and the torque is negative.

EXECUTE: $\sum\tau_z = -f_k R = -\mu_k nR$

$I = \frac{1}{2}MR^2$ (solid disk, axis through center)

Thus $\sum\tau_z = I\alpha_z$ gives $-\mu_k nR = (\frac{1}{2}MR^2)\alpha_z$

$$\mu_k = -\frac{MR\alpha_z}{2n} = -\frac{(50.0\text{ kg})(0.260\text{ m})(-11.9\text{ rad/s}^2)}{2(160\text{ N})} = 0.483$$

EVALUATE: The friction torque is clockwise and slows down the counterclockwise rotation of the grindstone.

10.60. IDENTIFY: This problem involves moving blocks and a turning pulley, so we need to use Newton's second law in its linear and rotational forms. The constant-acceleration formulas also apply.

SET UP: Apply $\sum F_x = ma_x$ and $\sum F_y = ma_y$ to the blocks and $\sum\tau_z = I\alpha_z$ to the pulley. We also apply $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ to block B. The target variables are the tension in the rope on both sides of the pulley and the moment of inertia of the pulley.

EXECUTE: **(a)** First use $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ to find the acceleration of the blocks, giving $\Delta y = \frac{1}{2}at^2$. $a = 2(1.80\text{ m})/(2.00\text{ s})^2 = 0.900\text{ m/s}^2$. Now apply $\sum F_y = ma_y$ to block B. Choose $+y$ downward since that is the direction of the acceleration. This gives $m_B g - T_B = m_B a$, and solving for T_B gives

$T_B = m_B(g-a) = (6.00\text{ kg})(9.80\text{ m/s}^2 - 0.900\text{ m/s}^2) = 53.4\text{ N}$.

(b) Apply $\sum F_x = ma_x$ to block A: $T_A = m_A a = (2.50\text{ kg})(0.900\text{ m/s}^2) = 2.25\text{ N}$.

(c) Apply $\sum\tau_z = I\alpha_z$ to the pulley. It is important to realize that the tensions on the pulley are *not* the same because the pulley has mass. The acceleration of the blocks is the same as the tangential acceleration of the rope on the pulley, so $\alpha_z = a/R$, where R is the pulley radius. Therefore we get

$T_B R - T_A R = I(a/R)$, so $I = \frac{R^2}{a}(T_B - T_A) = \frac{(0.0800\text{ m})^2}{0.900\text{ m/s}^2}(53.4\text{ N} - 2.25\text{ N}) = 0.364\text{ kg}\cdot\text{m}^2$.

EVALUATE: We found that $T_B > T_A$ which is reasonable since their torques are what give the pulley its angular acceleration causing it to turn in a direction that allows B to go downward.

10.61. IDENTIFY: Use $\sum\tau_z = I\alpha_z$ to find the angular acceleration just after the ball falls off and use conservation of energy to find the angular velocity of the bar as it swings through the vertical position.

SET UP: The axis of rotation is at the axle. For this axis the bar has $I = \frac{1}{12}m_{\text{bar}}L^2$, where $m_{\text{bar}} = 3.80\text{ kg}$ and $L = 0.800\text{ m}$. Energy conservation gives $K_1 + U_1 = K_2 + U_2$. The gravitational potential energy of the bar doesn't change. Let $mg(\sin 36.9° - \mu_k\cos 36.9°) - T = ma$ so $y_2 = -L/2$.

EXECUTE: **(a)** $\tau_z = m_{\text{ball}}g(L/2)$ and $I = I_{\text{ball}} + I_{\text{bar}} = \frac{1}{12}m_{\text{bar}}L^2 + m_{\text{ball}}(L/2)^2$. $\sum\tau_z = I\alpha_z$ gives

$$\alpha_z = \frac{m_{\text{ball}}g(L/2)}{\frac{1}{12}m_{\text{bar}}L^2 + m_{\text{ball}}(L/2)^2} = \frac{2g}{L}\left(\frac{m_{\text{ball}}}{m_{\text{ball}} + m_{\text{bar}}/3}\right) \text{ and}$$

$$\alpha_z = \frac{2(9.80\text{ m/s}^2)}{0.800\text{ m}}\left(\frac{2.50\text{ kg}}{2.50\text{ kg} + [3.80\text{ kg}]/3}\right) = 16.3\text{ rad/s}^2.$$

(b) As the bar rotates, the moment arm for the weight of the ball decreases and the angular acceleration of the bar decreases.

(c) $K_1 + U_1 = K_2 + U_2$. $0 = K_2 + U_2$. $\frac{1}{2}(I_{\text{bar}} + I_{\text{ball}})\omega^2 = -m_{\text{ball}}g(-L/2)$.

$$\omega = \sqrt{\frac{m_{\text{ball}}gL}{m_{\text{ball}}L^2/4 + m_{\text{bar}}L^2/12}} = \sqrt{\frac{g}{L}\left(\frac{4m_{\text{ball}}}{m_{\text{ball}} + m_{\text{bar}}/3}\right)} = \sqrt{\frac{9.80\text{ m/s}^2}{0.800\text{ m}}\left(\frac{4(2.50\text{ kg})}{2.50\text{ kg} + (3.80\text{ kg})/3}\right)}$$

$\omega = 5.70$ rad/s.

EVALUATE: As the bar swings through the vertical, the linear speed of the ball that is still attached to the bar is $v = (0.400\text{ m})(5.70\text{ rad/s}) = 2.28\text{ m/s}$. A point mass in free-fall acquires a speed of 2.80 m/s after falling 0.400 m; the ball on the bar acquires a speed less than this.

10.62. **IDENTIFY:** A solid sphere rolls up a ramp without slipping. Newton's second law in its linear and angular forms applies to the sphere.

SET UP: Apply $\sum\tau_z = I\alpha_z$ and $\sum F_x = ma_x$ to the sphere. Choose the x-axis to be parallel to the surface of the ramp with $+x$ down the ramp since that is the direction of the acceleration. $I_{\text{sphere}} = \frac{2}{5}MR^2$. Our target variables are the linear acceleration of the sphere and the friction force on it.

EXECUTE: **(a)** $\sum F_x = ma_x$: $mg\sin\beta - f = ma_{\text{cm}}$ (Eq. 1)

$\sum\tau_z = I\alpha_z$: $fR = \frac{2}{5}mR^2\alpha$. There is no slipping, so $\alpha = a_{\text{cm}}/R$, which gives $fR = \frac{2}{5}mR^2\left(\frac{a_{\text{cm}}}{R}\right)$.

Solving for f gives $f = \frac{2}{5}ma_{\text{cm}}$ (Eq. 2)

Combining Eq. 1 and Eq. 2 gives $mg\sin\beta - \frac{2}{5}ma_{\text{cm}} = ma_{\text{cm}}$, from which we get $a_{\text{cm}} = \frac{5}{7}g\sin\beta$. This is the same result as in Example 10.7.

(b) Eq. 2 gives $f = \frac{2}{5}ma_{\text{cm}} = \frac{2}{5}m\left(\frac{5}{7}g\sin\beta\right) = \frac{2}{7}mg\sin\beta$. This is the same as required to prevent the sphere to slip while rolling down the ramp.

EVALUATE: Whether rolling up the ramp or down the ramp, friction is up the ramp and gravity has a component down the ramp, so we get the same answers in Example 10.7.

10.63. **IDENTIFY:** Blocks A and B have linear acceleration and therefore obey the linear form of Newton's second law $\sum F_y = ma_y$. The wheel C has angular acceleration, so it obeys the rotational form of Newton's second law $\sum\tau_z = I\alpha_z$.

SET UP: A accelerates downward, B accelerates upward and the wheel turns clockwise. Apply $\sum F_y = ma_y$ to blocks A and B. Let $+y$ be downward for A and $+y$ be upward for B. Apply $\sum\tau_z = I\alpha_z$ to the wheel, with the clockwise sense of rotation positive. Each block has the same magnitude of acceleration, a, and $a = R\alpha$. Call the T_A the tension in the cord between C and A and T_B the tension between C and B.

EXECUTE: For A, $\sum F_y = ma_y$ gives $m_A g - T_A = m_A a$. For B, $\sum F_y = ma_y$ gives $T_B - m_B g = m_B a$. For the wheel, $\sum \tau_z = I\alpha_z$ gives $T_A R - T_B R = I\alpha = I(a/R)w$ and $T_A - T_B = \left(\frac{I}{R^2}\right)a$. Adding these three equations gives $(m_A - m_B)g = \left(m_A + m_B + \frac{I}{R^2}\right)a$. Solving for a, we have

$$a = \left(\frac{m_A - m_B}{m_A + m_B + I/R^2}\right)g = \left(\frac{4.00\text{ kg} - 2.00\text{ kg}}{4.00\text{ kg} + 2.00\text{ kg} + (0.220\text{ kg}\cdot\text{m}^2)/(0.120\text{ m})^2}\right)(9.80\text{ m/s}^2) = 0.921\text{ m/s}^2.$$

$$\alpha = \frac{a}{R} = \frac{0.921\text{ m/s}^2}{0.120\text{ m}} = 7.68\text{ rad/s}^2.$$

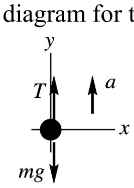
$$T_A = m_A(g - a) = (4.00\text{ kg})(9.80\text{ m/s}^2 - 0.921\text{ m/s}^2) = 35.5\text{ N}.$$

$$T_B = m_B(g + a) = (2.00\text{ kg})(9.80\text{ m/s}^2 + 0.921\text{ m/s}^2) = 21.4\text{ N}.$$

EVALUATE: The tensions must be different in order to produce a torque that accelerates the wheel when the blocks accelerate.

10.64. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$ to the crate and $\sum \tau_z = I\alpha_z$ to the cylinder. The motions are connected by $a(\text{crate}) = R\alpha(\text{cylinder})$.

SET UP: The force diagram for the crate is given in Figure 10.64a.

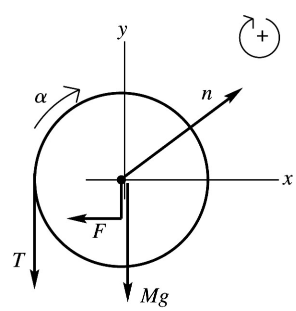


EXECUTE: Applying $\sum F_y = ma_y$ gives $T - mg = ma$. Solving for T gives

$$T = m(g + a) = (50\text{ kg})(9.80\text{ m/s}^2 + 1.40\text{ m/s}^2) = 5$$

Figure 10.64a

SET UP: The force diagram for the cylinder is given in Figure 10.64b.



EXECUTE: $\sum \tau_z = I\alpha_z$ gives $Fl - TR = I\alpha_z$, where $l = 0.12$ m and $R = 0.25$ m. $a = R\alpha$ so $\alpha_z = a/R$. Therefore $Fl = TR + Ia/R$.

Figure 10.64b

$$F = T\left(\frac{R}{l}\right) + \frac{Ia}{Rl} = (560\text{ N})\left(\frac{0.25\text{ m}}{0.12\text{ m}}\right) + \frac{(2.9\text{ kg}\cdot\text{m}^2)(1.40\text{ m/s}^2)}{(0.25\text{ m})(0.12\text{ m})} = 1300\text{ N}.$$

EVALUATE: The tension in the rope is greater than the weight of the crate since the crate accelerates upward. If F were applied to the rim of the cylinder ($l = 0.25$ m), it would have the value $F = 625$ N. This is greater than T because it must accelerate the cylinder as well as the crate. And F is larger than this because it is applied closer to the axis than R so has a smaller moment arm and must be larger to give the same torque.

10.65. IDENTIFY: A hollow sphere and a solid sphere roll up a ramp without slipping starting with the same speed at the base. Energy conservation applies to both of them.

SET UP: We use $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$, with $K_2 = 0$, $U_1 = 0$, $U_2 = mgh$, and $W_{\text{other}} = 0$. The total kinetic energy is $K_{\text{tot}} = \frac{1}{2}mv_{\text{cm}}^2 + \frac{1}{2}I\omega^2$, where $I_{\text{solid}} = \frac{2}{5}MR^2$ and $I_{\text{hollow}} = \frac{2}{3}MR^2$. We want to know which sphere reaches the greater height on the ramp.

EXECUTE: Apply energy conservation to each sphere to find h in each case.

<u>Solid sphere</u>: $mgh_{\text{s}} = \frac{1}{2}mv_{\text{cm}}^2 + \frac{1}{2}\left(\frac{2}{5}mR^2\right)\left(\frac{v_{\text{cm}}}{R}\right)^2$, so $h_{\text{s}} = \frac{7}{10}\frac{v_{\text{cm}}^2}{g} = 0.700\frac{v_{\text{cm}}^2}{g}$.

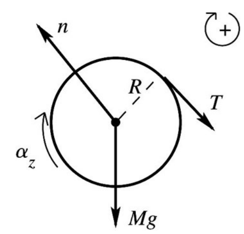
<u>Hollow sphere</u>: $mgh_{\text{H}} = \frac{1}{2}mv_{\text{cm}}^2 + \frac{1}{2}\left(\frac{2}{3}mR^2\right)\left(\frac{v_{\text{cm}}}{R}\right)^2$, so $h_{\text{H}} = \frac{5}{6}\frac{v_{\text{cm}}^2}{g} = 0.833\frac{v_{\text{cm}}^2}{g}$.

The hollow sphere reaches a greater height than the solid sphere.

EVALUATE: Even though the two spheres have the same size, mass, linear speed, and angular speed at the bottom of the ramp, they do not have the same kinetic energy because the hollow sphere has a greater moment of inertia. Therefore the hollow sphere goes higher up the ramp.

10.66. IDENTIFY: Apply $\sum\tau_z = I\alpha_z$ to the flywheel and $\sum\vec{F} = m\vec{a}$ to the block. The target variables are the tension in the string and the acceleration of the block.

(a) SET UP: Apply $\sum\tau_z = I\alpha_z$ to the rotation of the flywheel about the axis. The free-body diagram for the flywheel is given in Figure 10.66a.



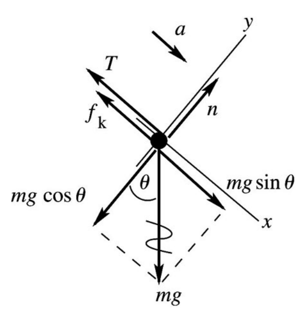
EXECUTE: The forces n and Mg act at the axis so have zero torque.

$\sum\tau_z = TR$

$TR = I\alpha_z$

Figure 10.66a

SET UP: Apply $\sum\vec{F} = m\vec{a}$ to the translational motion of the block. The free-body diagram for the block is given in Figure 10.66b.



EXECUTE: $\Sigma F_y = ma_y$

$n - mg\cos 36.9° = 0$

$n = mg\cos 36.9°$

$f_{\text{k}} = \mu_{\text{k}}n = \mu_{\text{k}}mg\cos 36.9°$

Figure 10.66b

$\sum F_x = ma_x$

$mg\sin 36.9° - T - \mu_{\text{k}}mg\cos 36.9° = ma$

$mg(\sin 36.9° - \mu_{\text{k}}\cos 36.9°) - T = ma$

But we also know that $a_{\text{block}} = R\alpha_{\text{wheel}}$, so $\alpha = a/R$. Using this in the $\sum\tau_z = I\alpha_z$ equation gives $TR = Ia/R$ and $T = (I/R^2)a$. Use this to replace T in the $\sum F_x = ma_x$ equation:

$$mg(\sin 36.9° - \mu_k \cos 36.9°) - (I/R^2)a = ma$$

$$a = \frac{mg(\sin 36.9° - \mu_k \cos 36.9°)}{m + I/R^2}$$

$$a = \frac{(5.00\text{ kg})(9.80\text{ m/s}^2)[\sin 36.9° - (0.25)\cos 36.9°]}{5.00\text{ kg} + 0.500\text{ kg}\cdot\text{m}^2/(0.200\text{ m})^2} = 1.12\text{ m/s}^2.$$

(b) $T = \dfrac{0.500\text{ kg}\cdot\text{m}^2}{(0.200\text{ m})^2}(1.12\text{ m/s}^2) = 14.0\text{ N}$

EVALUATE: If the string is cut the block will slide down the incline with $a = g\sin 36.9° - \mu_k g\cos 36.9° = 3.92\text{ m/s}^2$. The actual acceleration is less than this because $mg\sin 36.9°$ must also accelerate the flywheel. $mg\sin 36.9° - f_k = 19.6$ N. T is less than this; there must be more force on the block directed down the incline than up the incline since the block accelerates down the incline.

10.67. **IDENTIFY:** A force produces a torque on a wheel, giving it an angular acceleration. But the force is not constant, so the angular acceleration is not constant.

SET UP: The force is $F = kt$, where $k = 5.00$ N/s. Our target variable is the magnitude of the force at the instant the wheel has turned through 8.00 rev (which is 16.0π rad). We can apply $\sum\tau_z = I\alpha_z$ to the wheel but we cannot use the constant-acceleration equations. We must return to the basic definitions $\omega_z = d\theta/dt$ and $\alpha_z = d\omega_z/dt$ and integrate.

EXECUTE: First apply $\sum\tau_z = I\alpha_z$ to get α_z, calling R the wheel radius. $FR = ktR = I\alpha_z$, so $\alpha_z = Rkt/I = Bt$, where $B = Rk/I$. Since α_z is a function of time, we must integrate to get the angle turned through $\Delta\theta$. $\omega_z = \int \alpha_z dt = \int Bt\,dt = \dfrac{Bt^2}{2}$, where we have used $\omega_z = 0$ at $t = 0$. Now integrate ω_z to find $\Delta\theta$. $\Delta\theta = \int \omega dt = \int \dfrac{Bt^2}{2} dt = \dfrac{Bt^3}{6}$, so $t = \left(\dfrac{6\Delta\theta}{B}\right)^{1/3}$. The force at this time is

$$F = kt = k\left(\frac{6\Delta\theta}{B}\right)^{1/3} = k\left(\frac{96\pi I}{kR}\right)^{1/3} = (5.00\text{ N/s})\left[\frac{96\pi(2.50\text{ kg}\cdot\text{m}^2)}{(5.00\text{ N/s})(0.0600\text{ m})}\right]^{1/3} = 68.0\text{ N}.$$

EVALUATE: When the acceleration (linear or angular) is not constant, we have little choice but to return to basic definitions and use calculus.

10.68. **IDENTIFY:** Apply both $\sum\vec{F} = m\vec{a}$ and $\sum\tau_z = I\alpha_z$ to the motion of the roller. Rolling without slipping means $a_{\text{cm}} = R\alpha$. Target variables are a_{cm} and f.

SET UP: The free-body diagram for the roller is given in Figure 10.68.

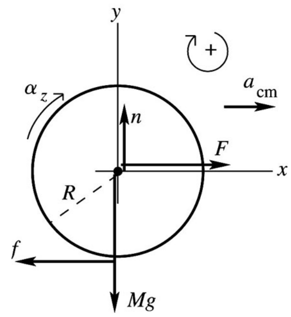


Figure 10.68

EXECUTE: Apply $\sum \vec{F} = m\vec{a}$ to the translational motion of the center of mass:

$\sum F_x = ma_x$

$F - f = Ma_{\text{cm}}$

Apply $\sum \tau_z = I\alpha_z$ to the rotation about the center of mass:

$\sum \tau_z = fR$

thin-walled hollow cylinder: $I = MR^2$

Then $\sum \tau_z = I\alpha_z$ implies $fR = MR^2\alpha.$

But $\alpha_{\text{cm}} = R\alpha,$ so $f = Ma_{\text{cm}}.$

Using this in the $\sum F_x = ma_x$ equation gives $F - Ma_{\text{cm}} = Ma_{\text{cm}}.$

$a_{\text{cm}} = F/2M,$ and then $f = Ma_{\text{cm}} = M(F/2M) = F/2.$

EVALUATE: If the surface were frictionless the object would slide without rolling and the acceleration would be $a_{\text{cm}} = F/M$. The acceleration is less when the object rolls.

10.69. **IDENTIFY:** Apply $\sum \vec{F} = m\vec{a}$ to each object and apply $\sum \tau_z = I\alpha_z$ to the pulley.

SET UP: Call the 75.0 N weight *A* and the 125 N weight *B*. Let T_A and T_B be the tensions in the cord to the left and to the right of the pulley. For the pulley, $I = \frac{1}{2}MR^2,$ where $Mg = 80.0\text{ N}$ and $R = 0.300\text{ m}.$ The 125 N weight accelerates downward with acceleration *a*, the 75.0 N weight accelerates upward with acceleration *a* and the pulley rotates clockwise with angular acceleration α, where $a = R\alpha.$

EXECUTE: $\sum \vec{F} = m\vec{a}$ applied to the 75.0 N weight gives $T_A - w_A = m_A a.$ $\sum \vec{F} = m\vec{a}$ applied to the 125.0 N weight gives $w_B - T_B = m_B a.$ $\sum \tau_z = I\alpha_z$ applied to the pulley gives $(T_B - T_A)R = (\frac{1}{2}MR^2)\alpha_z$ and $T_B - T_A = \frac{1}{2}Ma.$ Combining these three equations gives $w_B - w_A = (m_A + m_B + M/2)a$ and

$$a = \left(\frac{w_B - w_A}{w_A + w_B + w_{\text{pulley}}/2}\right)g = \left(\frac{125\text{ N} - 75.0\text{ N}}{75.0\text{ N} + 125\text{ N} + 40.0\text{ N}}\right)g = 0.2083g.$$

$T_A = w_A(1 + a/g) = 1.2083w_A = 90.62\text{ N}.$ $T_B = w_B(1 - a/g) = 0.792w_B = 98.96\text{ N}.$ $\sum \vec{F} = m\vec{a}$ applied to the pulley gives that the force *F* applied by the hook to the pulley is $F = T_A + T_B + w_{\text{pulley}} = 270\text{ N}.$ The force the ceiling applies to the hook is 270 N.

EVALUATE: The force the hook exerts on the pulley is less than the total weight of the system, since the net effect of the motion of the system is a downward acceleration of mass.

10.70. **IDENTIFY:** Dropping the object on the rotating turntable slows down the turntable and speeds up the object, but it does not change the total angular momentum of the object-turntable system.

SET UP: Angular momentum is conserved, so $L_{\text{table}} = L_{\text{table+object}}$, where $L = I\omega$. Our target variable is the moment of inertia *I* of the table.

EXECUTE: Using so $L_{\text{table}} = L_{\text{table+object}}$ gives $I\omega = \left(I + I_{object}\right)\omega_f = \left(I + mR^2\right)\omega_f$. Now solve for $\dfrac{\omega - \omega_f}{\omega_f}$, which gives $\dfrac{\omega - \omega_f}{\omega_f} = \left(\dfrac{R^2}{I}\right)m$. From this we see that a graph of $\dfrac{\omega - \omega_f}{\omega_f}$ versus m should give a straight line having slope equal to R^2/I. Thus $I = \dfrac{R^2}{\text{slope}} = \dfrac{(3.00\text{ m})^2}{0.250\text{ kg}^{-1}} = 36.0\text{ kg}\cdot\text{m}^2$.

EVALUATE: It would be quite difficult to measure directly the moment of a large heavy turntable, especially if it was not uniform throughout. But the measurements described here would be fairly easy to make.

10.71. IDENTIFY: Apply $\sum \vec{F}_{\text{ext}} = m\vec{a}_{\text{cm}}$ to the motion of the center of mass and apply $\sum \tau_z = I_{\text{cm}}\alpha_z$ to the rotation about the center of mass.

SET UP: $I = 2(\tfrac{1}{2}mR^2) = mR^2$. The moment arm for T is b.

EXECUTE: The tension is related to the acceleration of the yo-yo by $(2m)g - T = (2m)a$, and to the angular acceleration by $Tb = I\alpha = I\dfrac{a}{b}$. Dividing the second equation by b and adding to the first to eliminate T yields $a = g\dfrac{2m}{(2m + I/b^2)} = g\dfrac{2}{2 + (R/b)^2}$, $\alpha = g\dfrac{2}{2b + R^2/b}$. The tension is found by substitution into either of the two equations:

$$T = (2m)(g - a) = (2mg)\left(1 - \frac{2}{2 + (R/b)^2}\right) = 2mg\frac{(R/b)^2}{2 + (R/b)^2} = \frac{2mg}{(2(b/R)^2 + 1)}.$$

EVALUATE: $a \to 0$ when $b \to 0$. As $b \to R$, $a \to 2g/3$.

10.72. IDENTIFY: Apply conservation of energy to the motion of the shell, to find its linear speed v at points A and B. Apply $\sum \vec{F} = m\vec{a}$ to the circular motion of the shell in the circular part of the track to find the normal force exerted by the track at each point. Since $r << R$ the shell can be treated as a point mass moving in a circle of radius R when applying $\sum \vec{F} = m\vec{a}$. But as the shell rolls along the track, it has both translational and rotational kinetic energy.

SET UP: $K_1 + U_1 = K_2 + U_2$. Let 1 be at the starting point and take $y = 0$ to be at the bottom of the track, so $y_1 = h_0$. $K = \tfrac{1}{2}mv^2 + \tfrac{1}{2}I\omega^2$. $I = \tfrac{2}{3}mr^2$ and $\omega = v/r$, so $K = \tfrac{5}{6}mv^2$. During the circular motion, $a_{\text{rad}} = v^2/R$.

EXECUTE: **(a)** $\sum \vec{F} = m\vec{a}$ at point A gives $n + mg = m\dfrac{v^2}{R}$. The minimum speed for the shell not to fall off the track is when $n \to 0$ and $v^2 = gR$. Let point 2 be A, so $y_2 = 2R$ and $v_2^2 = gR$. Then $K_1 + U_1 = K_2 + U_2$ gives $mgh_0 = 2mgR + \tfrac{5}{6}m(gR)$. $h_0 = (2 + \tfrac{5}{6})R = \tfrac{17}{6}R$.

(b) Let point 2 be B, so $y_2 = R$. Then $K_1 + U_1 = K_2 + U_2$ gives $mgh_0 = mgR + \tfrac{5}{6}mv_2^2$. With $h = \tfrac{17}{6}R$ this gives $v^2 = \tfrac{11}{5}gR$. Then $\sum \vec{F} = m\vec{a}$ at B gives $n = m\dfrac{v^2}{R} = \tfrac{11}{5}mg$.

(c) Now $K = \tfrac{1}{2}mv^2$ instead of $\tfrac{5}{6}mv^2$. The shell would be moving faster at A than with friction and would still make the complete loop.

(d) In part (c): $mgh_0 = mg(2R) + \frac{1}{2}mv^2$. $h_0 = \frac{17}{6}R$ gives $v^2 = \frac{5}{3}gR$. $\sum \vec{F} = m\vec{a}$ at point A gives $mg + n = m\dfrac{v^2}{R}$ and $n = m\left(\dfrac{v^2}{R} - g\right) = \frac{2}{3}mg$. In part (a), $n = 0$, since at this point gravity alone supplies the net downward force that is required for the circular motion.

EVALUATE: The normal force at A is greater when friction is absent because the speed of the shell at A is greater when friction is absent than when there is rolling without slipping.

10.73. **IDENTIFY:** As it rolls down the rough slope, the basketball gains rotational kinetic energy as well as translational kinetic energy. But as it moves up the smooth slope, its rotational kinetic energy does not change since there is no friction.

SET UP: $I_{cm} = \frac{2}{3}mR^2$. When it rolls without slipping, $v_{cm} = R\omega$. When there is no friction the angular speed of rotation is constant. Take $+y$ upward and let $y = 0$ in the valley.

EXECUTE: **(a)** Find the speed v_{cm} in the level valley: $K_1 + U_1 = K_2 + U_2$. $y_1 = H_0$, $y_2 = 0$. $K_1 = 0$, $U_2 = 0$. Therefore, $U_1 = K_2$. $mgH_0 = \frac{1}{2}mv_{cm}^2 + \frac{1}{2}I_{cm}\omega^2$. $\frac{1}{2}I_{cm}\omega^2 = \frac{1}{2}(\frac{2}{3}mR^2)\left(\dfrac{v_{cm}}{R}\right)^2 = \frac{1}{3}mv_{cm}^2$, so $mgH_0 = \frac{5}{6}mv_{cm}^2$ and $v_{cm}^2 = \dfrac{6gH_0}{5}$. Find the height H it goes up the other side. Its rotational kinetic energy stays constant as it rolls on the frictionless surface. $\frac{1}{2}mv_{cm}^2 + \frac{1}{2}I_{cm}\omega^2 = \frac{1}{2}I_{cm}\omega^2 + mgH$.

$H = \dfrac{v_{cm}^2}{2g} = \frac{3}{5}H_0$.

(b) Some of the initial potential energy has been converted into rotational kinetic energy so there is less potential energy at the second height H than at the first height H_0.

EVALUATE: Mechanical energy is conserved throughout this motion. But the initial gravitational potential energy on the rough slope is not all transformed into potential energy on the smooth slope because some of that energy remains as rotational kinetic energy at the highest point on the smooth slope.

10.74. **IDENTIFY:** Apply conservation of energy to the motion of the ball as it rolls up the hill. After the ball leaves the edge of the cliff it moves in projectile motion and constant acceleration equations can be used.

(a) SET UP: Use conservation of energy to find the speed v_2 of the ball just before it leaves the top of the cliff. Let point 1 be at the bottom of the hill and point 2 be at the top of the hill. Take $y = 0$ at the bottom of the hill, so $y_1 = 0$ and $y_2 = 28.0$ m.

EXECUTE: $K_1 + U_1 = K_2 + U_2$

$\frac{1}{2}mv_1^2 + \frac{1}{2}I\omega_1^2 = mgy_2 + \frac{1}{2}mv_2^2 + \frac{1}{2}I\omega_2^2$

Rolling without slipping means $\omega = v/r$ and $\frac{1}{2}I\omega^2 = \frac{1}{2}(\frac{2}{5}mr^2)(v/r)^2 = \frac{1}{5}mv^2$.

$\frac{7}{10}mv_1^2 = mgy_2 + \frac{7}{10}mv_2^2$

$v_2 = \sqrt{v_1^2 - \frac{10}{7}gy_2} = 15.26$ m/s

SET UP: Consider the projectile motion of the ball, from just after it leaves the top of the cliff until just before it lands. Take $+y$ to be downward. Use the vertical motion to find the time in the air:

$v_{0y} = 0$, $a_y = 9.80$ m/s^2, $y - y_0 = 28.0$ m, $t = ?$

EXECUTE: $y - y_0 = v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = 2.39$ s

During this time the ball travels horizontally

$x - x_0 = v_{0x}t = (15.26 \text{ m/s})(2.39 \text{ s}) = 36.5$ m.

Just before it lands, $v_y = v_{0y} + a_y t = 23.4$ m/s and $v_x = v_{0x} = 15.3$ m/s

$v = \sqrt{v_x^2 + v_y^2} = 28.0$ m/s

(b) EVALUATE: At the bottom of the hill, $\omega = v/r = (25.0 \text{ m/s})/r$. The rotation rate doesn't change while the ball is in the air, after it leaves the top of the cliff, so just before it lands $\omega = (15.3 \text{ m/s})/r$. The total kinetic energy is the same at the bottom of the hill and just before it lands, but just before it lands less of this energy is rotational kinetic energy, so the translational kinetic energy is greater.

10.75. IDENTIFY: Apply conservation of energy to the motion of the boulder.

SET UP: $K = \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2$ and $v = R\omega$ when there is rolling without slipping. $I = \frac{2}{5}mR^2$.

EXECUTE: Break into two parts, the rough and smooth sections.

Rough: $mgh_1 = \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2$. $mgh_1 = \frac{1}{2}mv^2 + \frac{1}{2}\left(\frac{2}{5}mR^2\right)\left(\frac{v}{R}\right)^2$. $v^2 = \frac{10}{7}gh_1$.

Smooth: Rotational kinetic energy does not change. $mgh_2 + \frac{1}{2}mv^2 + K_{\text{rot}} = \frac{1}{2}mv_{\text{Bottom}}^2 + K_{\text{rot}}$.

$$gh_2 + \frac{1}{2}\left(\frac{10}{7}gh_1\right) = \frac{1}{2}v_{\text{Bottom}}^2.\ v_{\text{Bottom}} = \sqrt{\frac{10}{7}gh_1 + 2gh_2} = \sqrt{\frac{10}{7}(9.80 \text{ m/s}^2)(25 \text{ m}) + 2(9.80 \text{ m/s}^2)(25 \text{ m})} = 29.0 \text{ m/s}.$$

EVALUATE: If all the hill was rough enough to cause rolling without slipping,

$v_{\text{Bottom}} = \sqrt{\frac{10}{7}g(50 \text{ m})} = 26.5$ m/s. A smaller fraction of the initial gravitational potential energy goes into translational kinetic energy of the center of mass than if part of the hill is smooth. If the entire hill is smooth and the boulder slides without slipping, $v_{\text{Bottom}} = \sqrt{2g(50 \text{ m})} = 31.3$ m/s. In this case all the initial gravitational potential energy goes into the kinetic energy of the translational motion.

10.76. IDENTIFY: Apply Newton's second law in its linear and rotational form to the cylinder. The cylinder does not slip on the surface of the ramp.

SET UP: $\sum \vec{F}_{\text{ext}} = M\vec{a}_{\text{cm}}$, $\Sigma\tau_z = I\alpha_z$, $I = \frac{1}{2}mR^2$, and $a_{\text{cm}} = R\alpha$ for no slipping. Take the x-axis parallel to the surface of the ramp; call up the ramp positive since that is the direction in which the cylinders must accelerate. Take the y-axis perpendicular to the surface. For uniform acceleration $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$.

EXECUTE: (a) The forces balance in the y-direction, so the normal force n is $n = mg\cos\theta$. In the x-direction, $\Sigma F_x = ma_x$ gives

$F - f_s - mg\sin\theta = ma$.

Now apply $\Sigma\tau_z = I\alpha_z$.

$f_s R = (\frac{1}{2}mR^2)(a/R)$, which gives $a = 2f_s/m$. Putting this result into the previous result gives

$F - f_s - mg\sin\theta = m(2f_s/m) = 2f_s$.

Solving for F gives

$F = 3f_s + mg\sin\theta = 3\mu_s n + mg\sin\theta = 3\mu_s mg\cos\theta + mg\sin\theta = mg(3\mu_s\cos\theta + \sin\theta)$

$F = (460 \text{ kg})(9.80 \text{ m/s}^2)[3(0.120)\cos 37° + \sin 37°] = 4010$ N.

(b) From part (a) we have
$a = 2f_s/m = (2\mu_s mg\cos\theta)/m = 2\mu_s g\cos\theta$.
Linear kinematics using $x - x_0 = v_{0x}t + \frac{1}{2}a_x t^2$ gives

$$t = \sqrt{\frac{2(x-x_0)}{a}} = \sqrt{\frac{2(x-x_0)}{2\mu_s g\cos\theta}} = \sqrt{\frac{6.00\text{ m}}{(0.120)(9.80\text{ m/s}^2)\cos 37°}} = 2.53\text{ s}.$$

EVALUATE: Just lifting the 460-kg vertically would require a force of $mg = 4510$ N, so we don't do very much better by rolling them up the slope since friction opposes the linear motion.

10.77. IDENTIFY: Apply conservation of energy to the motion of the wheel.

SET UP: $K = \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2$. No slipping means that $\omega = v/R$. Uniform density means $m_r = \lambda 2\pi R$ and $m_s = \lambda R$, where m_r is the mass of the rim and m_s is the mass of each spoke. For the wheel, $I = I_{\text{rim}} + I_{\text{spokes}}$. For each spoke, $I = \frac{1}{3}m_s R^2$.

EXECUTE: **(a)** $mgh = \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2$. $I = I_{\text{rim}} + I_{\text{spokes}} = m_r R^2 + 6(\frac{1}{3}m_s R^2)$

Also, $m = m_r + m_s = 2\pi R\lambda + 6R\lambda = 2R\lambda(\pi + 3)$. Substituting into the conservation of energy equation gives $2R\lambda(\pi+3)gh = \frac{1}{2}(2R\lambda)(\pi+3)(R\omega)^2 + \frac{1}{2}\left[2\pi R\lambda R^2 + 6(\frac{1}{3}\lambda RR^2)\right]\omega^2$.

$$\omega = \sqrt{\frac{(\pi+3)gh}{R^2(\pi+2)}} = \sqrt{\frac{(\pi+3)(9.80\text{ m/s}^2)(58.0\text{ m})}{(0.210\text{ m})^2(\pi+2)}} = 124\text{ rad/s} \quad \text{and } v = R\omega = 26.0\text{ m/s}$$

(b) Doubling the density would have no effect because it does not appear in the answer. ω is inversely proportional to R so doubling the diameter would double the radius which would reduce ω by half, but $v = R\omega$ would be unchanged.

EVALUATE: Changing the masses of the rim and spokes by different amounts would alter the speed v at the bottom of the hill.

10.78. IDENTIFY: The rings and the rod exert forces on each other, but there is no net force or torque on the system, and so the angular momentum will be constant.

SET UP: For the rod, $I = \frac{1}{12}ML^2$. For each ring, $I = mr^2$, where r is their distance from the axis.

EXECUTE: **(a)** As the rings slide toward the ends, the moment of inertia changes, and the final angular velocity is given by $\omega_2 = \omega_1\frac{I_1}{I_2} = \omega_1\left[\frac{\frac{1}{12}ML^2 + 2mr_1^2}{\frac{1}{12}ML^2 + 2mr_2^2}\right] = \omega_1\left(\frac{5.00\times10^{-4}\text{ kg}\cdot\text{m}^2}{2.00\times10^{-3}\text{ kg}\cdot\text{m}^2}\right) = \frac{\omega_1}{4}$, so

$\omega_2 = 12.0$ rev/min.

(b) The forces and torques that the rings and the rod exert on each other will vanish, but the common angular velocity will be the same, 12.0 rev/min.

EVALUATE: Note that conversion from rev/min to rad/s was not necessary. The angular velocity of the rod decreases as the rings move away from the rotation axis.

10.79. IDENTIFY: Use conservation of energy to relate the speed of the block to the distance it has descended. Then use a constant acceleration equation to relate these quantities to the acceleration.

SET UP: For the cylinder, $I = \frac{1}{2}M(2R)^2$, and for the pulley, $I = \frac{1}{2}MR^2$.

EXECUTE: Doing this problem using kinematics involves four unknowns (six, counting the two angular accelerations), while using energy considerations simplifies the calculations greatly. If the block and the cylinder both have speed v, the pulley has angular velocity v/R and the cylinder has angular velocity $v/2R$, the total kinetic energy is

$$K = \frac{1}{2}\left[Mv^2 + \frac{M(2R)^2}{2}(v/2R)^2 + \frac{MR^2}{2}(v/R)^2 + Mv^2\right] = \frac{3}{2}Mv^2.$$

This kinetic energy must be the work done by gravity; if the hanging mass descends a distance y, $K = Mgy$, or $v^2 = (2/3)gy$. For constant acceleration, $v^2 = 2ay$, and comparison of the two expressions gives $a = g/3$.

EVALUATE: If the pulley were massless and the cylinder slid without rolling, $Mg = 2Ma$ and $a = g/2$. The rotation of the objects reduces the acceleration of the block.

10.80. **IDENTIFY:** Apply conservation of energy to the motion of the first ball before the collision and to the motion of the second ball after the collision. Apply conservation of angular momentum to the collision between the first ball and the bar.

SET UP: The speed of the ball just before it hits the bar is $v = \sqrt{2gy} = 15.34\text{ m/s}$. Use conservation of angular momentum to find the angular velocity ω of the bar just after the collision. Take the axis at the center of the bar.

EXECUTE: $L_1 = mvr = (5.00\text{ kg})(15.34\text{ m/s})(2.00\text{ m}) = 153.4\text{ kg}\cdot\text{m}^2/\text{s}$

Immediately after the collision the bar and both balls are rotating together.

$L_2 = I_{\text{tot}}\omega$

$I_{\text{tot}} = \frac{1}{12}Ml^2 + 2mr^2 = \frac{1}{12}(8.00\text{ kg})(4.00\text{ m})^2 + 2(5.00\text{ kg})(2.00\text{ m})^2 = 50.67\text{ kg}\cdot\text{m}^2$

$L_2 = L_1 = 153.4\text{ kg}\cdot\text{m}^2/\text{s}$

$\omega = L_2/I_{\text{tot}} = 3.027\text{ rad/s}$

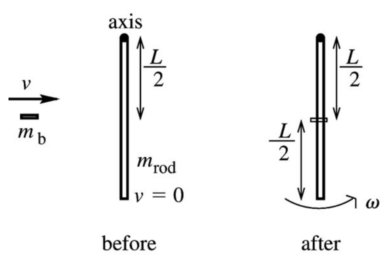
Just after the collision the second ball has linear speed $v = r\omega = (2.00\text{ m})(3.027\text{ rad/s}) = 6.055\text{ m/s}$ and is moving upward. $\frac{1}{2}mv^2 = mgy$ gives $y = 1.87\text{ m}$ for the height the second ball goes.

EVALUATE: Mechanical energy is lost in the inelastic collision and some of the final energy is in the rotation of the bar with the first ball stuck to it. As a result, the second ball does not reach the height from which the first ball was dropped.

10.81. **IDENTIFY:** Apply conservation of angular momentum to the collision. Linear momentum is not conserved because of the force applied to the rod at the axis. But since this external force acts at the axis, it produces no torque and angular momentum is conserved.

SET UP: The system before and after the collision is sketched in Figure 10.81.

EXECUTE: **(a)** $m_b = \frac{1}{4}m_{\text{rod}}$



EXECUTE: $L_1 = m_b vr = \frac{1}{4}m_{\text{rod}}v(L/2)$

$L_1 = \frac{1}{8}m_{\text{rod}}vL$

$L_2 = (I_{\text{rod}} + I_b)\omega$

$I_{\text{rod}} = \frac{1}{3}m_{\text{rod}}L^2$

$I_b = m_b r^2 = \frac{1}{4}m_{\text{rod}}(L/2)^2$

$I_b = \frac{1}{16}m_{\text{rod}}L^2$

Figure 10.81

Thus $L_1 = L_2$ gives $\frac{1}{8}m_{\text{rod}}vL = (\frac{1}{3}m_{\text{rod}}L^2 + \frac{1}{16}m_{\text{rod}}L^2)\omega$

$\frac{1}{8}v = \frac{19}{48}L\omega$

$\omega = \frac{6}{19}v/L$

(b) $K_1 = \frac{1}{2}mv^2 = \frac{1}{8}m_{\text{rod}}v^2$

$K_2 = \frac{1}{2}I\omega^2 = \frac{1}{2}(I_{\text{rod}} + I_{\text{b}})\omega^2 = \frac{1}{2}(\frac{1}{3}m_{\text{rod}}L^2 + \frac{1}{16}m_{\text{rod}}L^2)(6v/19L)^2$

$K_2 = \frac{1}{2}(\frac{19}{48})(\frac{6}{19})^2 m_{\text{rod}}v^2 = \frac{3}{152}m_{\text{rod}}v^2$

Then $\dfrac{K_2}{K_1} = \dfrac{\frac{3}{152}m_{\text{rod}}v^2}{\frac{1}{8}m_{\text{rod}}v^2} = 3/19.$

EVALUATE: The collision is inelastic and $K_2 < K_1$.

10.82. **IDENTIFY:** As you walk toward the center of the turntable, the angular momentum of the system (you plus turntable) is conserved. By getting closer to the center, you are decreasing the moment of inertia of the system. Newton's second law applies to you, and static friction provides the centripetal force on you.

SET UP: $I_0\omega_0 = I_2\omega_2$, $I = mr^2$ for a point mass, $a_{\text{rad}} = r\omega^2$, $f_{\text{s}}^{\max} = \mu_{\text{s}}n$, and $\Sigma\vec{F} = m\vec{a}$.

EXECUTE: At the closest distance, the friction force is

$f_{\text{s}} = \mu_{\text{s}}n = \mu_{\text{s}}mg$

Newton's second law gives

$f_{\text{s}} = ma = mr\omega^2$

Combining these two equations gives

$\mu_{\text{s}}mg = mr\omega^2$

Conservation of angular momentum gives $\omega = \dfrac{I_0}{I}\omega_0 = \left(\dfrac{I_{\text{t}} + mr_0^2}{I_{\text{t}} + mr^2}\right)\omega_0$. Solving the earlier equation for μ_{s} and using the previous result gives $\mu_{\text{s}} = \dfrac{\omega^2 r}{g} = \left(\dfrac{I_{\text{t}} + mr_0^2}{I_{\text{t}} + mr^2}\right)^2 \dfrac{\omega_0^2 r}{g}$. Putting in $m = 70.0$ kg, $r = 3.00$ m, and $I_{\text{t}} = 1200\ \text{kg}\cdot\text{m}^2$, and using $\omega_0 = 2\pi/(8.0\ \text{s})$, we get $\mu_{\text{s}} = 0.780$.

EVALUATE: This coefficient of static friction is physically reasonable.

10.83. **IDENTIFY:** As the disks are connected, their angular momentum is conserved, but some of their initial kinetic energy is converted to thermal energy. The 2400 J of thermal energy is equal to the loss of rotational kinetic energy.

SET UP: $I_1\omega_1 = I_2\omega_2$, $K = \frac{1}{2}I\omega^2$.

EXECUTE: Angular momentum conservation gives $I_A\omega_A = (I_A + I_B)\omega \rightarrow \omega = \dfrac{I_A\omega_A}{I_A + I_B}$. The loss of kinetic energy is $\Delta K = K_1 - K_2 = \frac{1}{2}I_A\omega_0^2 - \frac{1}{2}(I_A + I_B)\omega^2$. Combining these two equations gives $\Delta K = \dfrac{I_A\omega_0^2}{2}\left(1 - \dfrac{I_A}{I_A + I_B}\right)$. The loss of kinetic energy should be no more than 2400 J, so $\dfrac{I_A\omega_0^2}{2}\left(1 - \dfrac{I_A}{I_A + I_B}\right) \le 2400\ \text{J}$. The quantity $\dfrac{I_A\omega_0^2}{2}$ is the kinetic energy of A, K_A. Therefore we can solve the inequality for K_A, giving $K_A \le (2400\ \text{J})\left(\dfrac{I_A + I_B}{I_B}\right)$. Since $I_A = I_B/3$, the maximum kinetic energy of A is 3200 J.

EVALUATE: This situation is the rotational analog to a collision in which one object is initially at rest and they stick together. As in that situation, the momentum (angular in this case) is conserved but the kinetic energy is not.

10.84. **IDENTIFY:** This is a collision in which one object is initially stationary and they stick together. The rod is pivoted at one end, so it can only rotate after it is struck. The puck has angular momentum, some of which is transferred to the rod, but the angular momentum of the puck-rod system is conserved.

SET UP: The initial angular momentum of the puck is mvr, the final angular momentum of the rod is $I\omega$, and $I_{rod} = \frac{1}{3}ML^2$.

EXECUTE: After the collision, $\omega = 2\pi/T$, where $T = 0.736$ s, $r = L$, and $I = I_{rod} + I_{puck}$. Conservation of angular momentum gives $mvr = (\frac{1}{3}ML^2 + mL^2)\omega$. Solving for v gives $v = \dfrac{(\frac{1}{3}ML^2 + mL^2)\left(\frac{2\pi}{T}\right)}{mL}$. Putting in $m = 0.163$ kg, $M = 0.800$ kg, $L = 2.00$ m, $T = 0.736$ s gives $v = 45.0$ m/s.

EVALUATE: This situation is the rotational analog to a collision in which one object is initially at rest and they stick together. As in that situation, the momentum (angular in this case) is conserved but the kinetic energy is not.

10.85. **IDENTIFY:** Apply conservation of angular momentum to the collision between the bird and the bar and apply conservation of energy to the motion of the bar after the collision.

SET UP: For conservation of angular momentum take the axis at the hinge. For this axis the initial angular momentum of the bird is $m_{bird}(0.500\text{ m})v$, where $m_{bird} = 0.500$ kg and $v = 2.25$ m/s. For this axis the moment of inertia is $I = \frac{1}{3}m_{bar}L^2 = \frac{1}{3}(1.50\text{ kg})(0.750\text{ m})^2 = 0.281\text{ kg}\cdot\text{m}^2$. For conservation of energy, the gravitational potential energy of the bar is $U = m_{bar}gy_{cm}$, where y_{cm} is the height of the center of the bar. Take $y_{cm,1} = 0$, so $y_{cm,2} = -0.375$ m.

EXECUTE: **(a)** $L_1 = L_2$ gives $m_{bird}(0.500\text{ m})v = (\frac{1}{3}m_{bar}L^2)\omega$.

$$\omega = \frac{3m_{bird}(0.500\text{ m})v}{m_{bar}L^2} = \frac{3(0.500\text{ kg})(0.500\text{ m})(2.25\text{ m/s})}{(1.50\text{ kg})(0.750\text{ m})^2} = 2.00\text{ rad/s}.$$

(b) $U_1 + K_1 = U_2 + K_2$ applied to the motion of the bar after the collision gives

$$\tfrac{1}{2}I\omega_1^2 = m_{bar}g(-0.375\text{ m}) + \tfrac{1}{2}I\omega_2^2. \quad \omega_2 = \sqrt{\omega_1^2 + \frac{2}{I}m_{bar}g(0.375\text{ m})}.$$

$$\omega_2 = \sqrt{(2.00\text{ rad/s})^2 + \frac{2}{0.281\text{ kg}\cdot\text{m}^2}(1.50\text{ kg})(9.80\text{ m/s}^2)(0.375\text{ m})} = 6.58\text{ rad/s}.$$

EVALUATE: Mechanical energy is not conserved in the collision. The kinetic energy of the bar just after the collision is less than the kinetic energy of the bird just before the collision.

10.86. **IDENTIFY:** Angular momentum is conserved, since the tension in the string is in the radial direction and therefore produces no torque. Apply $\sum\vec{F} = m\vec{a}$ to the block, with $a = a_{rad} = v^2/r$.

SET UP: The block's angular momentum with respect to the hole is $L = mvr$.

EXECUTE: The tension is related to the block's mass and speed, and the radius of the circle, by $T = m\dfrac{v^2}{r}$. $T = mv^2\dfrac{1}{r} = \dfrac{m^2v^2}{m}\dfrac{r^2}{r^3} = \dfrac{(mvr)^2}{mr^3} = \dfrac{L^2}{mr^3}$. The radius at which the string breaks is

$$r^3 = \frac{L^2}{mT_{max}} = \frac{(mv_1r_1)^2}{mT_{max}} = \frac{[(0.130\text{ kg})(4.00\text{ m/s})(0.800\text{ m})]^2}{(0.130\text{ kg})(30.0\text{ N})},$$ from which $r = 0.354$ m.

EVALUATE: Just before the string breaks, the speed of the rock is $(4.00\text{ m/s})\left(\dfrac{0.800\text{ m}}{0.354\text{ m}}\right) = 9.04$ m/s.

We can verify that using $T = mv^2/R$ that $v = 9.04$ m/s and $r = 0.354$ m do give $T = 30.0$ N.

10.87. **IDENTIFY:** Apply conservation of momentum to the system of the runner and turntable.
SET UP: Let the positive sense of rotation be the direction the turntable is rotating initially.
EXECUTE: The initial angular momentum is $I\omega_1 - mRv_1,$ with the minus sign indicating that runner's motion is opposite the motion of the part of the turntable under his feet. The final angular momentum is $\omega_2(I+mR^2),$ so $\omega_2 = \dfrac{I\omega_1 - mRv_1}{I+mR^2}.$

$$\omega_2 = \frac{(80\text{ kg}\cdot\text{m}^2)(0.200\text{ rad/s}) - (55.0\text{ kg})(3.00\text{ m})(2.8\text{ m/s})}{(80\text{ kg}\cdot\text{m}^2) + (55.0\text{ kg})(3.00\text{ m})^2} = -0.776\text{ rad/s}.$$

EVALUATE: The minus sign indicates that the turntable has reversed its direction of motion. This happened because the man had the larger magnitude of angular momentum initially.

10.88. **IDENTIFY:** We use the power and angular velocity to calculate the torque.
SET UP: $P = \tau\omega,$ 1 hp = 746 W.
EXECUTE: **(a)** First make the necessary conversions: $1\text{ ft}\cdot\text{lb} = (0.3048\text{ m})(4.448\text{ N}) = 1.356\text{ N}\cdot\text{m}$
1 rpm = 1 rev/min = (2π rad)/(60 s) = 0.1047 rad/s.
Solve for torque and use the above conversions:
$\tau = P/\omega$ = [(285 hp)/(5300 rpm)]{(746 W/hp)/[(0.1047 rad/s)/rpm]} = 383 N·m = 283 ft·lb.
As we can see, 283 ft·lb is less than the maximum 305 ft·lb.
(b) $P = \tau\omega$ = (305 ft·lb) (3900 rpm)(1.356 N·m / ft·lb) [(0.1047 rad/s)/rpm] = 169 kW = 226 hp.
The power of 226 hp is smaller than the maximum of 285 hp.
(c) Make the following conversions:
$\text{hp} = \tau(\text{ft}\cdot\text{lb})\omega(\text{rpm})\left(\dfrac{1.356\text{ N}\cdot\text{m}}{1\text{ ft}\cdot\text{lb}}\right)\left(\dfrac{0.1047\text{ rad/s}}{1\text{ rpm}}\right)\left(\dfrac{1\text{ hp}}{746\text{ W}}\right) = 1.9031\times10^{-4}\ \tau(\text{ft}\cdot\text{lb})\omega(\text{rpm}),$ so $1/c$ = 1.9031×10^{-4}, which gives c = 5254.
(d) From (c), $P = \tau\omega$ gives 580 hp = τ(6000 rpm)/5254, so τ = 508 ft·lb.
EVALUATE: Torque, power, and angular velocity are often expressed in diverse units, so conversions are frequently necessary.

10.89. **IDENTIFY:** All the objects have the same mass and start from rest at the same height h. They roll without slipping, so their mechanical energy is conserved. Newton's second law, in its linear and rotational forms, applies to each object. Since the objects have different mass distributions, they will take different times to reach the bottom of the ramp.
SET UP: $K_1 + U_1 = K_2 + U_2,\ \ \sum\vec{F}_{\text{ext}} = M\vec{a}_{\text{cm}},\ \ \Sigma\tau = I\alpha,\ \ K_{\text{tot}} = K_{\text{cm}} + K_{\text{rot}},\ \ K_{\text{cm}} = \tfrac{1}{2}Mv_{\text{cm}}^2,$ $K_{\text{rot}} = \tfrac{1}{2}I_{\text{cm}}\omega^2.$
EXECUTE: **(a)** We can express the moment of inertia of a round object as $I = cmR^2$, where c depends on the shape and mass distribution. Energy conservation gives $K_1 + U_1 = K_2 + U_2,$ so
$mgh = \tfrac{1}{2}mv^2 + \tfrac{1}{2}I\omega^2 = \tfrac{1}{2}mv^2 + \tfrac{1}{2}cmR^2\omega^2 = \tfrac{1}{2}mv^2 + \tfrac{1}{2}cmR^2\left(\dfrac{v}{R}\right)^2 = \tfrac{1}{2}v^2(1+c).$ Solving for v^2 gives $v^2 = \dfrac{2gh}{1+c}.$ This v is the speed at the bottom of the ramp. The object with the greatest speed v will also have the greatest average speed down the ramp and will therefore take the shortest time to reach the bottom. Thus the object with the smallest c will have the greatest v and therefore the shortest time in the bar graph shown with the problem. For a solid cylinder, $I = \tfrac{1}{2}mR^2$ so c = ½, for a hollow cylinder, $I = mR^2$, so c = 1, and likewise we get c = 2/5 for a solid sphere and c = 2/3 for a hollow sphere. The smallest value of c is 2/5 for a solid sphere, so that object must take the shortest time, which makes it

object *A*. The largest value of c is 1 for a hollow cylinder, so that object takes the longest time, which makes it object *D*. The hollow sphere has a larger c than the solid cylinder, so it takes longer than the solid cylinder, so *C* must be the hollow sphere and *B* the solid cylinder. Summarizing these results, we have

A: solid sphere, $c = 2/5$

B: solid cylinder, $c = 1/2$

C: hollow sphere, $c = 2/3$

D: hollow cylinder, $c = 1$

(b) All the objects start from rest at the same initial height and roll without slipping, so they all have the same kinetic energy at the bottom of the ramp.

(c) Using $K_{\text{rot}} = \frac{1}{2}I_{\text{cm}}\omega^2$, we have $K_{\text{rot}} = ½\,(cmR^2)(v/R)^2 = ½\,mcv^2$. Using our result for v^2 from (a) gives

$K_{\text{rot}} = \frac{1}{2}mc\left(\frac{2gh}{1+c}\right) = mgh\left(\frac{1}{1+\frac{1}{c}}\right)$. From this result, we see that the object with the largest c has the largest rotational kinetic energy because the denominator in the parentheses is the smallest. Therefore the hollow cylinder, with $c = 1$, has the largest rotational kinetic energy.

(d) Apply Newton's second law. Perpendicular to the ramp surface, we get $n = mg\cos\theta$ for the normal force. Parallel to the surface, with down the ramp as positive, we get $mg\sin\theta - f_s = ma$. Taking torques about the center of the rolling object gives $fR = I\alpha = (mcR^2)(a/R)$, which gives $f_s = mca$, so $ma = f_s/c$. Putting this into the previous equation gives $mg\sin\theta - f_s = f_s/c$, which can be written as $mg\sin\theta = f_s(1 + 1/c)$. We want the minimum coefficient of friction to prevent slipping, so $f_s = \mu_s n = \mu_s mg\cos\theta$. Putting this into the previous equation gives $mg\sin\theta = (\mu_s mg\cos\theta)(1 + 1/c)$.

Solving for μ_s gives $\mu_s = \dfrac{\tan\theta}{1+\frac{1}{c}}$. We want μ_s such that none of the objects will slip, so we must find the maximum μ_s. That will occur when c has its largest value since that will make the denominator smallest, and that is for the hollow cylinder for which $c = 1$. This gives $\mu_s = (\tan 35.0°)/2 = 0.350$.

EVALUATE: As a check, part (a) could be solved using Newton's second law, as we did in part (d). As a check in part (d), find μ_s for the solid sphere which has the smallest value of c. This gives

$\mu_s = \dfrac{\tan 35.0°}{1+\frac{1}{2/5}} = \dfrac{\tan 35.0°}{3.5} = 0.200$. This is less than the 0.350 we found in (d), so a coefficient of friction of 0.350 is more than enough to prevent slipping of the solid sphere.

10.90. **IDENTIFY:** The work done by the force F is equal to the kinetic energy gained by the flywheel. This work is the area under the curve in a F-versus-d graph.

SET UP: $W = Fd$, $K = \frac{1}{2}I\omega^2$, $v = r\omega$.

EXECUTE: **(a)** The pull is constant, so the linear and angular accelerations are constant. Therefore $v = 2v_{\text{av}} = 2(d/t)$, so $\omega = v/R = 2d/tR$. The work done is equal to the kinetic energy of the flywheel, so

$Fd = \frac{1}{2}I\omega^2 = \frac{1}{2}I\left(\frac{2d}{tR}\right)^2$. Solving for I gives

$I = Ft^2R^2/2d = (25.0\text{ N})(2.00\text{ s})^2(0.166\text{ m})^2/[2(8.35\text{ m})] = 0.165\ \text{kg}\cdot\text{m}^2$.

(b) The kinetic energy gained is equal to the work done which is equal to the area under the curve on the F-d graph. This gives

$K = (60.0\text{ N})(3.00\text{ m}) + ½\,(60.0\text{ N})(3.00\text{ m}) = 270\text{ J}$.

(c) $K = \frac{1}{2}I\omega^2$ so $\omega = \sqrt{\frac{2K}{I}} = \sqrt{\frac{2(270\text{ J})}{0.165\text{ kg}\cdot\text{m}^2}} = 57.2$ rad/s. Converting to rpm gives

(57.2 rad/s)[(60 s)/(1 min)][(1 rev)/(2π rad)] = 546 rpm.

EVALUATE: In this case, we could have deduced the equation for *F* as a function of *d* from the graph and integrated to find the work. But for a more complicated *F*-*d* dependence, that would have been impossible, but we could still estimate the area quite accurately from the graph.

10.91. IDENTIFY: The answer to part (a) can be taken from the solution to Problem 10.86. The work-energy theorem says $W = \Delta K$.

SET UP: Problem 10.86 uses conservation of angular momentum to show that $r_1 v_1 = r_2 v_2$.

EXECUTE: **(a)** $T = m v_1^2 r_1^2 / r^3$.

(b) $\vec{T}$ and $d\vec{r}$ are always antiparallel. $\vec{T}\cdot d\vec{r} = -T dr$.

$$W = -\int_{r_1}^{r_2} T\,dr = m v_1^2 r_1^2 \int_{r_2}^{r_1} \frac{dr}{r^3} = \frac{m v_1^2}{2} r_1^2 \left[\frac{1}{r_2^2} - \frac{1}{r_1^2}\right].$$

(c) $v_2 = v_1(r_1/r_2)$, so $\Delta K = \frac{1}{2}m(v_2^2 - v_1^2) = \frac{m v_1^2}{2}\left[(r_1/r_2)^2 - 1\right]$, which is equal to the work found in part (b).

EVALUATE: The work done by *T* is positive, since $\vec{T}$ is toward the hole in the surface and the block moves toward the hole. Positive work means the kinetic energy of the object increases.

10.92. IDENTIFY: Apply $\sum \vec{F}_{\text{ext}} = m\vec{a}_{\text{cm}}$ and $\sum \tau_z = I_{\text{cm}}\alpha_z$ to the motion of the cylinder. Use constant acceleration equations to relate a_x to the distance the object travels. Use the work-energy theorem to find the work done by friction.

SET UP: The cylinder has $I_{\text{cm}} = \frac{1}{2}MR^2$.

EXECUTE: **(a)** The free-body diagram is sketched in Figure 10.92. The friction force is $f = \mu_k n = \mu_k Mg$, so $a = \mu_k g$. The magnitude of the angular acceleration is $\frac{fR}{I} = \frac{\mu_k MgR}{(1/2)MR^2} = \frac{2\mu_k g}{R}$.

(b) Setting $v = at = \omega R = (\omega_0 - \alpha t)R$ and solving for *t* gives $t = \frac{R\omega_0}{a + R\alpha} = \frac{R\omega_0}{\mu_k g + 2\mu_k g} = \frac{R\omega_0}{3\mu_k g}$,

and $d = \frac{1}{2}at^2 = \frac{1}{2}(\mu_k g)\left(\frac{R\omega_0}{3\mu_k g}\right)^2 = \frac{R^2\omega_0^2}{18\mu_k g}$.

(c) The final kinetic energy is $(3/4)Mv^2 = (3/4)M(at)^2$, so the change in kinetic energy is

$$\Delta K = \frac{3}{4}M\left(\mu_k g \frac{R\omega_0}{3\mu_k g}\right)^2 - \frac{1}{4}MR^2\omega_0^2 = -\frac{1}{6}MR^2\omega_0^2.$$

EVALUATE: The fraction of the initial kinetic energy that is removed by friction work is $\frac{\frac{1}{6}MR\omega_0^2}{\frac{1}{4}MR\omega_0^2} = \frac{2}{3}$.

This fraction is independent of the initial angular speed ω_0.

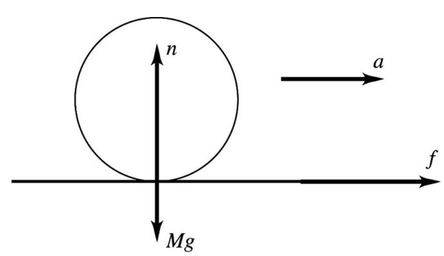


Figure 10.92

10.93. **IDENTIFY:** The vertical forces must sum to zero. Apply $\Omega = \dfrac{\tau_z}{L_z} = \dfrac{wr}{I\omega}$.

SET UP: Denote the upward forces that the hands exert as F_L and F_R. $\tau = (F_L - F_R)r$, where $r = 0.200$ m.

EXECUTE: The conditions that F_L and F_R must satisfy are $F_L + F_R = w$ and $F_L - F_R = \Omega \dfrac{I\omega}{r}$, where the second equation is $\tau = \Omega L$, divided by r. These two equations can be solved for the forces by first adding and then subtracting, yielding $F_L = \frac{1}{2}\left(w + \Omega \dfrac{I\omega}{r}\right)$ and $F_R = \frac{1}{2}\left(w - \Omega \dfrac{I\omega}{r}\right)$. Using the values

$w = mg = (8.00 \text{ kg})(9.80 \text{ m/s}^2) = 78.4 \text{ N}$ and

$\dfrac{I\omega}{r} = \dfrac{(8.00 \text{ kg})(0.325 \text{ m})^2(5.00 \text{ rev/s} \times 2\pi \text{ rad/rev})}{(0.200 \text{ m})} = 132.7 \text{ kg} \cdot \text{m/s}$ gives

$F_L = 39.2 \text{ N} + \Omega(66.4 \text{ N} \cdot \text{s})$, $F_R = 39.2 \text{ N} - \Omega(66.4 \text{ N} \cdot \text{s})$.

(a) $\Omega = 0, F_L = F_R = 39.2$ N.

(b) $\Omega = 0.05 \text{ rev/s} = 0.314 \text{ rad/s}, F_L = 60.0 \text{ N}, F_R = 18.4$ N.

(c) $\Omega = 0.3 \text{ rev/s} = 1.89 \text{ rad/s}, F_L = 165 \text{ N}, F_R = -86.2$ N, with the minus sign indicating a downward force.

(d) $F_R = 0$ gives $\Omega = \dfrac{39.2 \text{ N}}{66.4 \text{ N} \cdot \text{s}} = 0.590$ rad/s, which is 0.0940 rev/s.

EVALUATE: The larger the precession rate Ω, the greater the torque on the wheel and the greater the difference between the forces exerted by the two hands.

10.94. **IDENTIFY:** The rotational form of Newton's second law applies.
SET UP: $\Sigma\tau = I\alpha$ and $\omega_z = \omega_{0z} + \alpha_z t$.
EXECUTE: $\Sigma\tau = I\alpha = \Delta\omega/\Delta t$, where $I = I_{\text{person}} + I_0$. Solving for I_{person} gives $I_{\text{person}} = \tau/\alpha - I_0$.

$I_{\text{person}} = \dfrac{2.5 \text{ N} \times \text{m}}{\left(\dfrac{1.0 \text{ rad/s}}{3.0 \text{ s}}\right)} - 1.5 \text{ kg} \times \text{m}^2 = 6.0 \text{ kg} \times \text{m}^2$, which is choice (b).

EVALUATE: The moment of inertia of the turntable is considerably less than that of the person, which is a good thing. If the moment of inertia of the table were much greater than that of the person, the person's body would have a small effect on the angular acceleration of the table, making it hard to get an accurate measurement.

10.95. **IDENTIFY** and **SET UP:** Moment of inertia depends on the distribution of mass.
EXECUTE: Extending her legs increases the person's moment of inertia to increase. With a constant torque on the turntable, this would decrease her angular acceleration, which is choice (c).
EVALUATE: The person being studied should be told to lie still during the procedure.

10.96. **IDENTIFY** and **SET UP:** The torque is the product of the force times the lever arm, and $\Sigma\tau = I\alpha$.
EXECUTE: Doubling the lever arm with a constant force doubles the torque, which then doubles the angular acceleration, so choice (b) is correct.
EVALUATE: Doubling the diameter of the pulley would also allow the tension to be decreased by a factor of 2 and still keep the same original angular acceleration.

10.97. **IDENTIFY** and **SET UP:** The parallel-axis theorem, $I = I_{\text{cm}} + md^2$, applies to the person.
EXECUTE: The measured moment of inertia would be I, but this would be greater than I_{cm}, so the measured value would be too large, choice (a).
EVALUATE: Care is essential to position the person properly on the turntable.

11

EQUILIBRIUM AND ELASTICITY

VP11.1.1. **IDENTIFY:** We are dealing with center of gravity. If the center of gravity of the mass-plank system moves beyond the right-hand support point, the plank will tip over.

SET UP: $x_{cg} = \dfrac{m_1x_1 + m_2x_2 + m_3x_3 + \cdots}{m_1 + m_2 + m_3 + \cdots}$. Call the origin the right-hand support point. The center of mass of the system is at that point, so $x_{cm} = 0$. Call m the unknown mass.

EXECUTE: Applying the center of gravity formula $x_{cg} = \dfrac{m_1x_1 + m_2x_2}{m_1 + m_2}$ gives

$$0 = \frac{(40.0\text{ kg})(-1.00\text{ m}) + (3.00\text{ m})\,m}{40.0\text{ kg} + m} \quad \rightarrow \quad m = 13.3\text{ kg}.$$

EVALUATE: The added mass of 13.3 kg is much less than the 40.0-kg mass of the plank because this added mass is much farther from the pivot point than the center of mass is.

VP11.1.2. **IDENTIFY:** We are dealing with center of gravity. If the center of gravity of the two-ball system is at the bowling ball, the system will balance.

SET UP: $x_{cg} = \dfrac{m_1x_1 + m_2x_2}{m_1 + m_2}$. Call the origin the center of the bowling ball and call d the distance between the centers of the two balls.

EXECUTE: With our choice of origin, $x_{cm} = 0.216$ m, so we have

$$0.216\text{ m} = \frac{(7.26\text{ kg})(0) + (0.145\text{ kg})d}{7.26\text{ kg} + 0.145\text{ kg}} \quad \rightarrow \quad d = 11.0\text{ m}.$$

EVALUATE: To check, we can balance torques about the surface of the bowling ball with the rod horizontal. Call M the mass of the bowling ball and R its radius and m the mass of the baseball. This gives $MgR - mg(d - R) = 0 \quad \rightarrow \quad d = R(M + m)/m = 11.0$ m, which agrees with our result.

VP11.1.3. **IDENTIFY:** For balance, the center of gravity of the system of three objects and the rod must be at the support point.

SET UP: Call the center of the rod the origin and call x the distance of the support point from the center of the rod; this is also the distance of the center of gravity from the center. We treat the bar as a point-mass of m located at its center.

EXECUTE: $x_{cg} = \dfrac{m_1x_1 + m_2x_2 + m_3x_3 + \cdots}{m_1 + m_2 + m_3 + \cdots} = \dfrac{m(-L/2) + 2m(0) + 2m(L/2)}{5m} = \dfrac{L}{10}$. The support point should be a distance $L/10$ to the right of the center of the bar, which is the location of the center of gravity of the system.

EVALUATE: To check, substitute the calculated answer back into the center-of-mass formula but using a different origin and use it to calculate the location of the center of mass. For example, using the left end of the bar as the origin, we have $x_{cg} = \dfrac{2m(L/2)+2m(L)}{5m}$ = 6*L*/10, which is *L*/10 to the right of the center of the bar, as we just found.

VP11.1.4. **IDENTIFY:** We know where the center of gravity of the loaded plane should be, and we want to find out how much mass we can have in the baggage compartment.

SET UP: Use $x_{cg} = \dfrac{m_1x_1 + m_2x_2 + m_3x_3 + \cdots}{m_1 + m_2 + m_3 + \cdots}$. Let the *x*-axis point horizontally to the right with the nose of the plane on the left end and the origin at the center of gravity of the *loaded* plane. With this choice, $x_{cm} = 0$.

EXECUTE: Let *M* be the maximum mass in the baggage compartment.

$$0 = \frac{-(1170\text{ kg})(2.76\text{ m} - 2.58\text{ m}) - (75.0\text{ kg})(2.76\text{ m} - 2.67\text{ m}) + M(4.30\text{ m} - 2.76\text{ m})}{m_{\text{total}}}$$

M = 141 kg.

EVALUATE: Choosing the origin at the center of gravity of the loaded plane makes the algebra rather simple compared to other choices because we do not have to deal with m_{total} in the denominator. Since m_{total} includes *M*, we would have more work (and more chances for error) with other choices of the origin. It helps to plan ahead!

VP11.4.1. **IDENTIFY:** The truck is in equilibrium, so the torques on it must balance.

SET UP: Apply $\sum \tau_z = 0$. Take torques about the rear wheel. Call *d* the wheelbase and *w* the weight of the truck. See Fig. VP11.4.1.

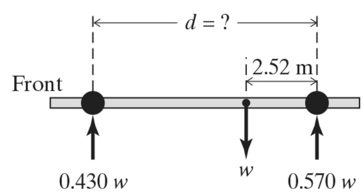

Figure VP11.4.1

EXECUTE: $\sum \tau_z = 0$ gives $(0.430\,w)d = (2.52\text{ m})w \;\rightarrow\; d = 5.86\text{ m}$.

EVALUATE: To check, calculate the center of gravity of the truck. This gives $(0.570\,w)(2.52\text{ m}) - (0.430\,w)(5.86\text{ m} - 2.52\text{ m}) = 0$, as it should since the truck is in equilibrium.

VP11.4.2. **IDENTIFY:** The plane is in equilibrium, so the torques on it must balance.

SET UP: Apply $\sum \tau_z = 0$. Take torques about the nose wheel. Call *F* the force due to the main wheel and *w* the weight of the plane.

EXECUTE: $\sum \tau_z = 0$ gives $-w(2.58\text{ m} - 0.800\text{ m}) + F(3.02\text{ m} - 0.800\text{ m}) = 0$, so $F = 0.802w$. The main wheel supports 80.2% of the weight of the plane, so the nose wheels must support 19.8% of the weight.

EVALUATE: To check, calculate torques about another point.

VP11.4.3. **IDENTIFY:** The sign is in equilibrium, so the forces and torques on the rod must balance.

SET UP: Apply $\sum \tau_z = 0$, $\sum F_x = 0$, and $\sum F_y = 0$.

EXECUTE: **(a)** Apply $\sum \tau_z = 0$ about the right end of the rod, giving

$F_{\text{hinge-}y} L + F_{\text{hinge-}x}(0) + T(0) + w(0) = 0 \;\rightarrow\; F_{\text{hinge-}y} = 0$.

(b) $\sum F_y = 0$ gives $F_{\text{hinge-}y} + T\sin\theta - w = 0 \;\rightarrow\; 0 + T\sin\theta - w = 0 \;\rightarrow\; T = w/\sin\theta$.

(c) $\sum F_x = 0$ gives $F_{\text{hinge-}x} - T\cos\theta = 0$. Using *T* from part (b) gives

$F_{\text{hinge-}x} = \left(\dfrac{w}{\sin\theta}\right)\cos\theta = w/\tan\theta.$

EVALUATE: Our result in (c) says that if θ is small, the hinge exerts a large horizontal force on the rod. This is reasonable because the cable pulls nearly horizontally against the rod which causes it to push very hard against the hinge.

VP11.4.4. **IDENTIFY:** The sign is in equilibrium, so the forces and torques on the rod must balance.

SET UP: Apply $\sum\tau_z = 0$, $\sum F_x = 0$, and $\sum F_y = 0$. The rod now also has weight w.

EXECUTE: **(a)** Apply $\sum\tau_z = 0$ about the right end of the rod, giving

$F_{\text{hinge-}y}L + F_{\text{hinge-}x}(0) + wL/2 + T(0) + w(0) = 0 \quad \rightarrow \quad F_{\text{hinge-}y} = w/2.$

(b) $\sum F_y = 0$ gives $F_{\text{hinge-}y} + T\sin\theta - w/2 - w = 0 \quad \rightarrow \quad T\sin\theta - 3w/2 = 0$

so $T = \dfrac{3w}{2\sin\theta}$.

(c) $\sum F_x = 0$ gives $F_{\text{hinge-}x} - T\cos\theta = 0$. Using T from part (b) gives

$F_{\text{hinge-}x} = \left(\dfrac{3w}{2\sin\theta}\right)\cos\theta = \dfrac{3w}{2\tan\theta}.$

EVALUATE: Our result in (c) says that if θ is small, the hinge exerts a large horizontal force on the rod. This is reasonable because the cable pulls nearly horizontally against the rod, which causes it to push very hard against the hinge. We also find that if the rod weighs as much as the sign, the tension and hinge force each are 1.5 times as great as before.

VP11.7.1. **IDENTIFY:** This problem involves elasticity, tensile stress, tensile stress, and Young's modulus.

SET UP: Young's modulus is $Y = \dfrac{\text{Tensile stress}}{\text{Tensile strain}}$, tensile strain = $\dfrac{\Delta\ell}{\ell_0}$, tensile stress = $\dfrac{F_\perp}{A}$.

EXECUTE: **(a)** Tensile stress = Y (tensile strain). $\dfrac{\Delta\ell}{\ell_0} = \dfrac{5.0\times10^{-3}\ell_0}{\ell_0} = 5.0\times10^{-3}$, so

tensile stress = $(11\times10^{10}\text{ Pa})(5.0\times10^{-3}) = 5.5\times10^{8}$ Pa.

(b) Tensile stress = $\dfrac{F_\perp}{A}$, where $A = \pi r^2$. Therefore $F_\perp$ = (tensile strain)(πr^2) so

$F_\perp = (5.5\times10^{8}\text{ Pa})(\pi)(4.5\times10^{-3}\text{ m})^2 = 3.5\times10^{4}$ N.

EVALUATE: The pressure is much less than atmospheric pressure, but the force is about 7600 lb, which is very large. But a wire 4.5 mm in radius is quite thick compared to ordinary electrical copper wires.

VP11.7.2. **IDENTIFY:** This problem involves elasticity, compressive stress and compressive strain, and Young's modulus.

SET UP: Young's modulus is $Y = \dfrac{\text{Compressive stress}}{\text{Compressive strain}}$, compressive strain = $\dfrac{\Delta\ell}{\ell_0}$, compressive stress = $\dfrac{F_\perp}{A}$. From Table 11.1, $Y = 7.0\times10^{10}$ Pa for aluminum.

EXECUTE: **(a)** We want the compressive strain. $Y = \dfrac{\text{Compressive stress}}{\text{Compressive strain}}$ tells us that compressive strain = $\dfrac{\text{Compressive stress}}{Y} = \dfrac{F_\perp}{AY} = \dfrac{3.2\times10^{4}\text{ N}}{\pi(0.025\text{ m})^2(7.0\times10^{10}\text{ Pa})} = 2.3\times10^{-4}$.

(b) Compressive strain = $\dfrac{\Delta\ell}{\ell_0} \quad \rightarrow \quad \Delta\ell = \ell_0 \times$ compressive strain, which gives

$\Delta\ell = (82\text{ cm})(2.3\times10^{-4}) = 1.9\times10^{-2}\text{ cm} = 0.19$ mm.

EVALUATE: Note that an 82-cm cylinder compresses only 0.19 mm under a force of 32,000 N, which is about 7200 lb. So fractional changes in length are normally quite small.

VP11.7.3. **IDENTIFY:** The increase in pressure compresses the sphere. Using the bulk modulus we can find the change in volume.

SET UP: Bulk modulus is $B = -\dfrac{\Delta p}{\Delta V / V_0}$. To find the *decrease* in volume, we can neglect the minus sign. From Table 11.1, $B = 4.1\times10^{10}$ Pa for lead, and from Table 11.2, $B = 1/k = 2.7\times10^{10}$ Pa for mercury.

EXECUTE: The decrease in volume is $\Delta V = \dfrac{V_0\Delta p}{B}$.

(a) Lead: $\Delta V = \dfrac{V_0\Delta p}{B} = \dfrac{\frac{4}{3}\pi(0.012\text{ m})^3(2.5\times10^7\text{ Pa})}{4.1\times10\text{ Pa}} = 4.4\times10^{-9}\text{ m}^3.$

(b) Mercury: Table 11.2 gives compressibility (k), so we use $B = 1/k$ to find $B = 2.7\times10^{10}$ Pa. Using the same formula as in (a), but with a different B, gives $\Delta V = 6.7\times10^{-9}\text{ m}^3$.

EVALUATE: If we divide the equations for ΔV, we get $\Delta V_M = \Delta V_L(B_L/B_M)$ $\Delta V_M = (4.4\times10^{-9}\text{ m}^3)(4.1/2.7) = 6.7\times10^{-9}\text{ m}^3$, which agrees with our result. Also note that since $B_L \approx 1.5\,B_M$, we would expect ΔV_M to be about 1.5 times as great as ΔV_L (since ΔV is *inversely* proportional to B), which is what we find.

VP11.7.4. **IDENTIFY:** The shear forces distort the cube by a small distance x.

SET UP: The shear modulus is $S = \dfrac{F_{\parallel}h}{Ax}$, so $x = \dfrac{F_{\parallel}h}{AS}$. For brass $S = 3.5\times10^{10}$ Pa from Table 11.1.

EXECUTE: $x = \dfrac{(4.2\times10^4\text{ N})(0.025\text{ m})}{(0.025\text{ m})^2(3.5\times10^{10}\text{ Pa})} = 4.8\times10^{-5}\text{ m}.$

EVALUATE: The length of a side of this cube is 2.5 cm, but the shear displacement is only 4.8×10^{-3} cm, which is 4.8 thousandths of a centimeter. Shear displacements are typically very small.

11.1. **IDENTIFY:** Use $x_{\text{cm}} = \dfrac{m_1x_1 + m_2x_2 + m_3x_3 + \ldots}{m_1 + m_2 + m_3 + \ldots}$ to calculate x_{cm}. The center of gravity of the bar is at its center and it can be treated as a point mass at that point.

SET UP: Use coordinates with the origin at the left end of the bar and the $+x$-axis along the bar. $m_1 = 0.120$ kg, $m_2 = 0.055$ kg, $m_3 = 0.110$ kg.

EXECUTE: $x_{\text{cm}} = \dfrac{m_1x_1 + m_2x_2 + m_3x_3}{m_1 + m_2 + m_3} = \dfrac{(0.120\text{ kg})(0.250\text{ m}) + 0 + (0.110\text{ kg})(0.500\text{ m})}{0.120\text{ kg} + 0.055\text{ kg} + 0.110\text{ kg}} = 0.298\text{ m}.$ The fulcrum should be placed 29.8 cm to the right of the left-hand end.

EVALUATE: The mass at the right-hand end is greater than the mass at the left-hand end. So the center of gravity is to the right of the center of the bar.

11.2. **IDENTIFY:** Use $x_{\text{cm}} = \dfrac{m_1x_1 + m_2x_2 + m_3x_3 + \ldots}{m_1 + m_2 + m_3 + \ldots}$ to calculate x_{cm} of the composite object.

SET UP: Use coordinates where the origin is at the original center of gravity of the object and $+x$ is to the right. With the 1.50 kg mass added, $x_{\text{cm}} = -2.20$ cm, $m_1 = 5.00$ kg and $m_2 = 1.50$ kg. $x_1 = 0$.

EXECUTE: $x_{\text{cm}} = \dfrac{m_2x_2}{m_1 + m_2}$. $x_2 = \left(\dfrac{m_1 + m_2}{m_2}\right)x_{\text{cm}} = \left(\dfrac{5.00\text{ kg} + 1.50\text{ kg}}{1.50\text{ kg}}\right)(-2.20\text{ cm}) = -9.53\text{ cm}.$

The additional mass should be attached 9.53 cm to the left of the original center of gravity.

EVALUATE: The new center of gravity is somewhere between the added mass and the original center of gravity.

11.3. IDENTIFY: Treat the rod and clamp as point masses. The center of gravity of the rod is at its midpoint, and we know the location of the center of gravity of the rod-clamp system.

SET UP: $x_{\text{cm}} = \dfrac{m_1 x_1 + m_2 x_2}{m_1 + m_2}$.

EXECUTE: $1.20 \text{ m} = \dfrac{(1.80 \text{ kg})(1.00 \text{ m}) + (2.40 \text{ kg})x_2}{1.80 \text{ kg} + 2.40 \text{ kg}}$.

$$x_2 = \frac{(1.20 \text{ m})(1.80 \text{ kg} + 2.40 \text{ kg}) - (1.80 \text{ kg})(1.00 \text{ m})}{2.40 \text{ kg}} = 1.35 \text{ m}$$

EVALUATE: The clamp is to the right of the center of gravity of the system, so the center of gravity of the system lies between that of the rod and the clamp, which is reasonable.

11.4. IDENTIFY: This problem involves center of gravity and torque.

SET UP: Refer to Fig. 11.9(b) in the textbook. The equation $x_{\text{cg}} = \dfrac{m_1 x_1 + m_2 x_2 + m_3 x_3 + \cdots}{m_1 + m_2 + m_3 + \cdots}$ gives the location of the center of gravity, and torque is equal to the force times the lever arm. In the center of gravity formula, we should use the masses of the objects. However since mass is $m = w/g$, we do not have to divide each weight by g since the g will cancel out because it occurs in each term in the numerator and denominator.

EXECUTE: **(a)** $x_{\text{cg}} = \dfrac{(180 \text{ N})(1.5 \text{ m}) + (800 \text{ N})(1.0 \text{ m})}{180 \text{ N} + 800 \text{ N}}$ = 1.1 m to the right of the foot of the ladder.

(b) $\tau = (980 \text{ N})(1.1 \text{ m}) = 1070 \text{ N} \cdot \text{m}$.

EVALUATE: **(c)** In the text the torque is $\tau = (180 \text{ N})(1.5 \text{ m}) + (800 \text{ N})(1.0 \text{ m}) = 1070 \text{ N} \cdot \text{m}$. Our answer in (b) agrees with the text answer.

11.5. IDENTIFY: We need to calculate the center of gravity of a compound object consisting of two spheres and a steel rod. The center of gravity of each of them is at their midpoint since they are all uniform.

SET UP: Use $x_{\text{cg}} = \dfrac{m_1 x_1 + m_2 x_2 + m_3 x_3}{m_1 + m_2 + m_3}$ with the origin at the center of the rod. Let the 0.900-kg sphere be on the left end of the rod and the 0380-kg sphere on the right end.

EXECUTE: $x_{\text{cg}} = \dfrac{m_1 x_1 + m_2 x_2 + m_3 x_3}{m_1 + m_2 + m_3} = \dfrac{(0.900 \text{ kg})(-28.0 \text{ m}) + (0.300 \text{ kg})(0 \text{ m}) + (0.380 \text{ kg})(26.0 \text{ cm})}{0.900 \text{ kg} + 0.300 \text{ kg} + 0.380 \text{ kg}}$

$= -9.70$ cm. So the center of gravity is 9.70 cm from the center of the rod toward the 0.900-kg sphere.

EVALUATE: The center of gravity is toward the heavier sphere, which is reasonable.

11.6. IDENTIFY: Apply the first and second conditions for equilibrium to the trap door.

SET UP: For $\sum \tau_z = 0$ take the axis at the hinge. Then the torque due to the applied force must balance the torque due to the weight of the door.

EXECUTE: **(a)** The force is applied at the center of gravity, so the applied force must have the same magnitude as the weight of the door, or 300 N. In this case the hinge exerts no force.

(b) With respect to the hinges, the moment arm of the applied force is twice the distance to the center of mass, so the force has half the magnitude of the weight, or 150 N.

The hinges supply an upward force of $300 \text{ N} - 150 \text{ N} = 150 \text{ N}$.

EVALUATE: Less force must be applied when it is applied farther from the hinges.

11.7. IDENTIFY: Apply $\sum \tau_z = 0$ to the ladder.

SET UP: Take the axis to be at point A. The free-body diagram for the ladder is given in Figure 11.7. The torque due to F must balance the torque due to the weight of the ladder.

EXECUTE: $F(8.0 \text{ m})\sin 40° = (3400 \text{ N})(10.0 \text{ m})$, so $F = 6.6$ kN.

EVALUATE: The force required is greater than the weight of the ladder, because the moment arm for F is less than the moment arm for w.

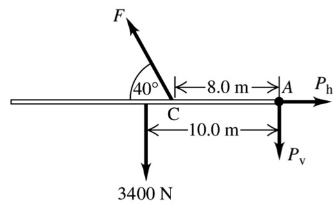

Figure 11.7

11.8. **IDENTIFY:** Apply the first and second conditions of equilibrium to the board.
SET UP: The free-body diagram for the board is given in Figure 11.8. Since the board is uniform its center of gravity is 1.50 m from each end. Apply $\sum F_y = 0$, with $+y$ upward. Apply $\sum \tau_z = 0$ with the axis at the end where the first person applies a force and with counterclockwise torques positive.
EXECUTE: $\sum F_y = 0$ gives $F_1 + F_2 - w = 0$ and $F_2 = w - F_1 = 160\text{ N} - 60\text{ N} = 100\text{ N}$. $\sum \tau_z = 0$ gives $F_2 x - w(1.50\text{ m}) = 0$ and $x = \left(\dfrac{w}{F_2}\right)(1.50\text{ m}) = \left(\dfrac{160\text{ N}}{100\text{ N}}\right)(1.50\text{ m}) = 2.40\text{ m}$. The other person lifts with a force of 100 N at a point 2.40 m from the end where the other person lifts.
EVALUATE: By considering the axis at the center of gravity we can see that a larger force is applied by the person who pushes closer to the center of gravity.

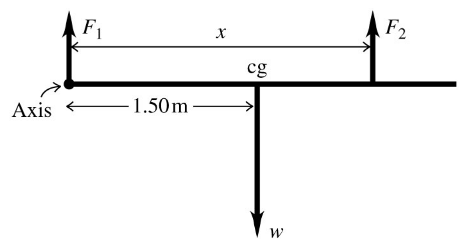

Figure 11.8

11.9. **IDENTIFY:** Apply $\sum F_y = 0$ and $\sum \tau_z = 0$ to the board.
SET UP: Let $+y$ be upward. Let x be the distance of the center of gravity of the motor from the end of the board where the 400 N force is applied.
EXECUTE: **(a)** If the board is taken to be massless, the weight of the motor is the sum of the applied forces, 1000 N. The motor is a distance $\dfrac{(2.00\text{ m})(600\text{ N})}{(1000\text{ N})} = 1.20\text{ m}$ from the end where the 400 N force is applied, and so is 0.800 m from the end where the 600 N force is applied.
(b) The weight of the motor is $400\text{ N} + 600\text{ N} - 200\text{ N} = 800\text{ N}$. Applying $\sum \tau_z = 0$ with the axis at the end of the board where the 400 N acts gives $(600\text{ N})(2.00\text{ m}) = (200\text{ N})(1.00\text{ m}) + (800\text{ N})x$ and $x = 1.25\text{ m}$. The center of gravity of the motor is 0.75 m from the end of the board where the 600 N force is applied.
EVALUATE: The motor is closest to the end of the board where the larger force is applied.

11.10. **IDENTIFY:** Apply the first and second conditions of equilibrium to the shelf.
SET UP: The free-body diagram for the shelf is given in Figure 11.10. Take the axis at the left-hand end of the shelf and let counterclockwise torque be positive. The center of gravity of the uniform shelf is at its center.
EXECUTE: **(a)** $\sum \tau_z = 0$ gives $-w_t(0.200\text{ m}) - w_s(0.300\text{ m}) + T_2(0.400\text{ m}) = 0$.

$$T_2 = \frac{(25.0\text{ N})(0.200\text{ m}) + (50.0\text{ N})(0.300\text{ m})}{0.400\text{ m}} = 50.0\text{ N}$$

$\sum F_y = 0$ gives $T_1 + T_2 - w_t - w_s = 0$ and $T_1 = 25.0$ N. The tension in the left-hand wire is 25.0 N and the tension in the right-hand wire is 50.0 N.

EVALUATE: We can verify that $\sum \tau_z = 0$ is zero for any axis, for example for an axis at the right-hand end of the shelf.

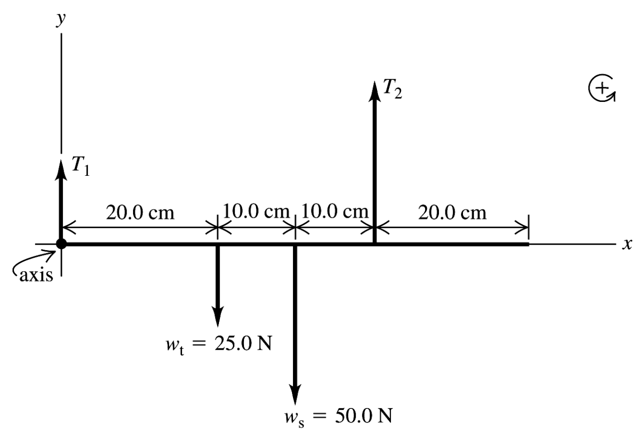

Figure 11.10

11.11. **IDENTIFY:** Apply the conditions for equilibrium to the bar. Set each tension equal to its maximum value.

SET UP: Let cable *A* be at the left-hand end. Take the axis to be at the left-hand end of the bar and *x* be the distance of the weight *w* from this end. The free-body diagram for the bar is given in Figure 11.11.

EXECUTE: **(a)** $\sum F_y = 0$ gives $T_A + T_B - w - w_{\text{bar}} = 0$ and

$w = T_A + T_B - w_{\text{bar}} = 500.0\ \text{N} + 400.0\ \text{N} - 350.0\ \text{N} = 550\ \text{N}.$

(b) $\sum \tau_z = 0$ gives $T_B(1.50\ \text{m}) - wx - w_{\text{bar}}(0.750\ \text{m}) = 0.$

$x = \dfrac{T_B(1.50\ \text{m}) - w_{\text{bar}}(0.750\ \text{m})}{w} = \dfrac{(400.0\ \text{N})(1.50\ \text{m}) - (350\ \text{N})(0.750\ \text{m})}{550\ \text{N}} = 0.614\ \text{m}.$ The weight should be placed 0.614 m from the left-hand end of the bar (cable *A*).

EVALUATE: If the weight is moved to the left, T_A exceeds 500.0 N and if it is moved to the right T_B exceeds 400.0 N.

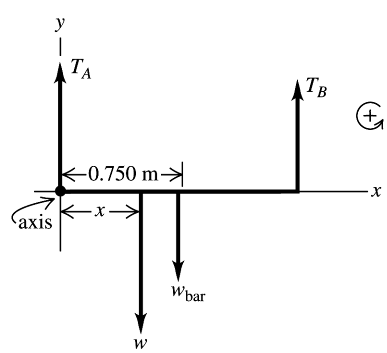

Figure 11.11

11.12. **IDENTIFY:** Apply the first and second conditions for equilibrium to the ladder.

SET UP: Let n_2 be the upward normal force exerted by the ground and let n_1 be the horizontal normal force exerted by the wall. The maximum possible static friction force that can be exerted by the ground is $\mu_s n_2$.

EXECUTE: **(a)** Since the wall is frictionless, the only vertical forces are the weights of the man and the ladder, and the normal force n_2. For the vertical forces to balance,

$n_2 = w_1 + w_m = 160\text{ N} + 740\text{ N} = 900\text{ N}$, and the maximum frictional force is

$\mu_s n_2 = (0.40)(900\text{ N}) = 360\text{ N}$.

(b) Note that the ladder makes contact with the wall at a height of 4.0 m above the ground. Balancing torques about the point of contact with the ground,

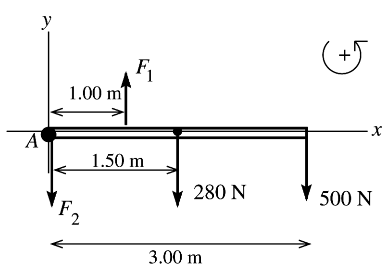
$(4.0\text{ m})n_1 = (1.5\text{ m})(160\text{ N}) + (1.0\text{ m})(3/5)(740\text{ N}) = 684\text{ N}\cdot\text{m}$, so $n_1 = 171.0\text{ N}$. This horizontal force must be balanced by the friction force, which must then be 170 N to two figures.

(c) Setting the friction force, and hence n_1, equal to the maximum of 360 N and solving for the distance x along the ladder, $(4.0\text{ m})(360\text{ N}) = (1.50\text{ m})(160\text{ N}) + x(3/5)(740\text{ N})$, so $x = 2.7\text{ m}$.

EVALUATE: The normal force exerted by the ground doesn't change as the man climbs up the ladder. But the normal force exerted by the wall and the friction force exerted by the ground both increase as he moves up the ladder.

11.13. **IDENTIFY:** The system of the person and diving board is at rest so the two conditions of equilibrium apply.

(a) SET UP: The free-body diagram for the diving board is given in Figure 11.13. Take the origin of coordinates at the left-hand end of the board (point A).



$\vec{F}_1$ is the force applied at the support point and $\vec{F}_2$ is the force at the end that is held down.

Figure 11.13

EXECUTE: $\sum\tau_A = 0$ gives $+F_1(1.0\text{ m}) - (500\text{ N})(3.00\text{ m}) - (280\text{ N})(1.50\text{ m}) = 0$

$$F_1 = \frac{(500\text{ N})(3.00\text{ m}) + (280\text{ N})(1.50\text{ m})}{1.00\text{ m}} = 1920\text{ N}$$

(b) $\sum F_y = ma_y$

$F_1 - F_2 - 280\text{ N} - 500\text{ N} = 0$

$F_2 = F_1 - 280\text{ N} - 500\text{ N} = 1920\text{ N} - 280\text{ N} - 500\text{ N} = 1140\text{ N}$

EVALUATE: We can check our answers by calculating the net torque about some point and checking that $\sum\tau_z = 0$ for that point also. Net torque about the right-hand end of the board:

$(1140\text{ N})(3.00\text{ m}) + (280\text{ N})(1.50\text{ m}) - (1920\text{ N})(2.00\text{ m}) = 3420\text{ N}\cdot\text{m} + 420\text{ N}\cdot\text{m} - 3840\text{ N}\cdot\text{m} = 0$, which checks.

11.14. **IDENTIFY:** Apply the first and second conditions of equilibrium to the beam.

SET UP: The boy exerts a downward force on the beam that is equal to his weight.

EXECUTE: **(a)** The graphs are given in Figure 11.14.

(b) $x = 6.25$ m when $F_A = 0$, which is 1.25 m beyond point B.

(c) Take torques about the right end. When the beam is just balanced, $F_A = 0$, so $F_B = 900$ N.

The distance that point B must be from the right end is then $\dfrac{(300\text{ N})(4.50\text{ m})}{(900\text{ N})} = 1.50$ m.

EVALUATE: When the beam is on the verge of tipping it starts to lift off the support A and the normal force F_A exerted by the support goes to zero.

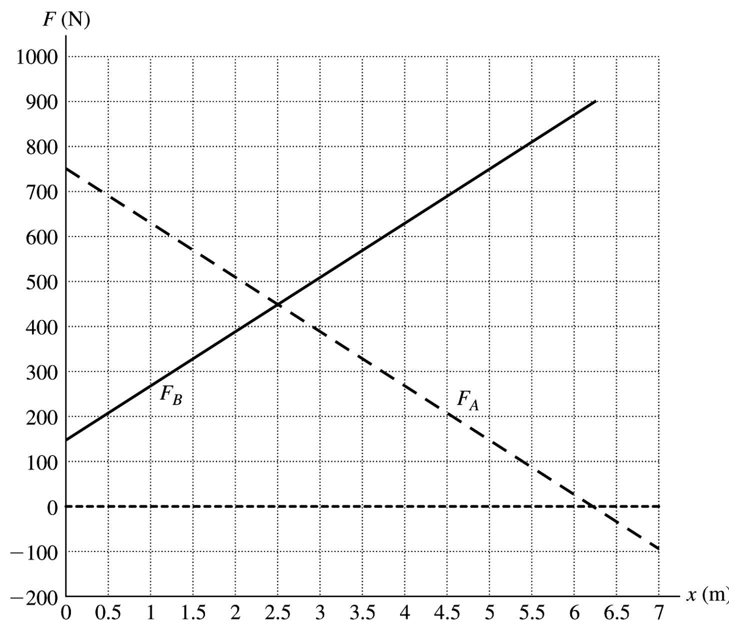


Figure 11.14

11.15. IDENTIFY: Apply the first and second conditions of equilibrium to the strut.

(a) SET UP: The free-body diagram for the strut is given in Figure 11.15a. Take the origin of coordinates at the hinge (point A) and $+y$ upward. Let F_h and F_v be the horizontal and vertical components of the force $\vec{F}$ exerted on the strut by the pivot. The tension in the vertical cable is the weight w of the suspended object. The weight w of the strut can be taken to act at the center of the strut. Let L be the length of the strut.

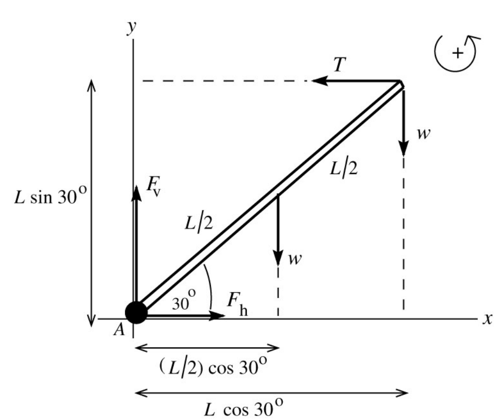

Figure 11.15a

EXECUTE:

$\sum F_y = ma_y$

$F_v - w - w = 0$

$F_v = 2w$

Sum torques about point A. The pivot force has zero moment arm for this axis and so doesn't enter into the torque equation.

$\tau_A = 0$

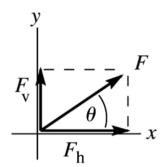
$TL\sin 30.0° - w((L/2)\cos 30.0°) - w(L\cos 30.0°) = 0$

$T\sin 30.0° - (3w/2)\cos 30.0° = 0$

$T = \dfrac{3w\cos 30.0°}{2\sin 30.0°} = 2.60w$

Then $\sum F_x = ma_x$ implies $T - F_\text{h} = 0$ and $F_\text{h} = 2.60w$.

We now have the components of $\vec{F}$ so can find its magnitude and direction (Figure 11.15b).



$F = \sqrt{F_\text{h}^2 + F_\text{v}^2}$

$F = \sqrt{(2.60w)^2 + (2.00w)^2}$

$F = 3.28w$

$\tan\theta = \dfrac{F_\text{v}}{F_\text{h}} = \dfrac{2.00w}{2.60w}$

$\theta = 37.6°$

Figure 11.15b

(b) SET UP: The free-body diagram for the strut is given in Figure 11.15c.

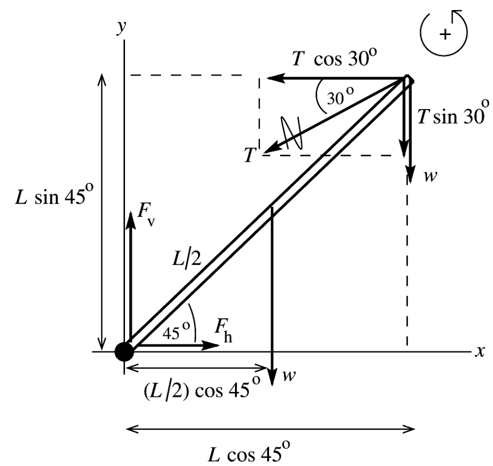


Figure 11.15c

The tension T has been replaced by its x and y components. The torque due to T equals the sum of the torques of its components, and the latter are easier to calculate.

EXECUTE: $\sum\tau_A = 0 + (T\cos 30.0°)(L\sin 45.0°) - (T\sin 30.0°)(L\cos 45.0°) -$

$$w[(L/2)\cos 45.0°] - w(L\cos 45.0°) = 0$$

The length L divides out of the equation. The equation can also be simplified by noting that $\sin 45.0° = \cos 45.0°$.

Then $T(\cos 30.0° - \sin 30.0°) = 3w/2$.

$T = \dfrac{3w}{2(\cos 30.0° - \sin 30.0°)} = 4.10w$

$\sum F_x = ma_x$

$F_h - T\cos 30.0° = 0$

$F_h = T\cos 30.0° = (4.10w)(\cos 30.0°) = 3.55w$

$\sum F_y = ma_y$

$F_v - w - w - T\sin 30.0° = 0$

$F_v = 2w + (4.10w)\sin 30.0° = 4.05w$

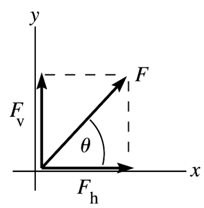

Figure 11.15d

From Figure 11.15d,

$F = \sqrt{F_h^2 + F_v^2}$

$F = \sqrt{(3.55w)^2 + (4.05w)^2} = 5.39w$

$\tan\theta = \dfrac{F_v}{F_h} = \dfrac{4.05w}{3.55w}$

$\theta = 48.8°$

EVALUATE: In each case the force exerted by the pivot does not act along the strut. Consider the net torque about the upper end of the strut. If the pivot force acted along the strut, it would have zero torque about this point. The two forces acting at this point also have zero torque and there would be one nonzero torque, due to the weight of the strut. The net torque about this point would then not be zero, violating the second condition of equilibrium.

11.16. IDENTIFY: Apply the first and second conditions of equilibrium to the beam.

SET UP: The free-body diagram for the beam is given in Figure 11.16. H_v and H_h are the vertical and horizontal components of the force exerted on the beam at the wall (by the hinge). Since the beam is uniform, its center of gravity is 2.00 m from each end. The angle θ has $\cos\theta = 0.800$ and $\sin\theta = 0.600$. The tension *T* has been replaced by its *x*- and *y*-components.

EXECUTE: **(a)** H_v, H_h and $T_x = T\cos\theta$ all produce zero torque. $\sum\tau_z = 0$ gives $-w(2.00\text{ m}) - w_{load}(4.00\text{ m}) + T\sin\theta(4.00\text{ m}) = 0$ and

$T = \dfrac{(190\text{ N})(2.00\text{ m}) + (300\text{ N})(4.00\text{ m})}{(4.00\text{ m})(0.600)} = 658.3\text{ N}$, which rounds to 658 N.

(b) $\sum F_x = 0$ gives $H_h - T\cos\theta = 0$ and $H_h = (658.3\text{ N})(0.800) = 527\text{ N}$. $\sum F_y = 0$ gives $H_v - w - w_{load} + T\sin\theta = 0$ and $H_v = w + w_{load} - T\sin\theta = 190\text{ N} + 300\text{ N} - (658\text{ N})(0.600) = 95\text{ N}$.

EVALUATE: For an axis at the right-hand end of the beam, only *w* and H_v produce torque. The torque due to *w* is counterclockwise so the torque due to H_v must be clockwise. To produce a clockwise torque, H_v must be upward, in agreement with our result from $\sum F_y = 0$.

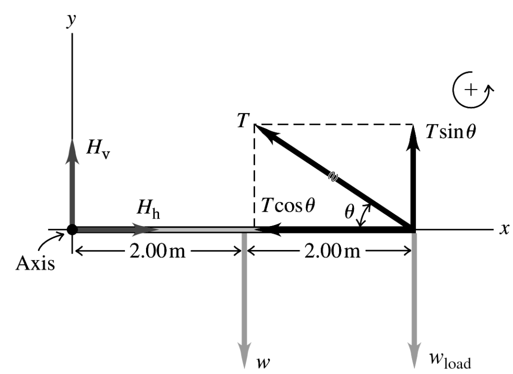

Figure 11.16

11.17. **IDENTIFY:** The boom is at rest, so the forces and torques on it must each balance.
SET UP: $\sum\tau = 0,\ \sum F_x = 0,\ \sum F_y = 0.$ The free-body is shown in Figure 11.17. Call L the length of the boom.

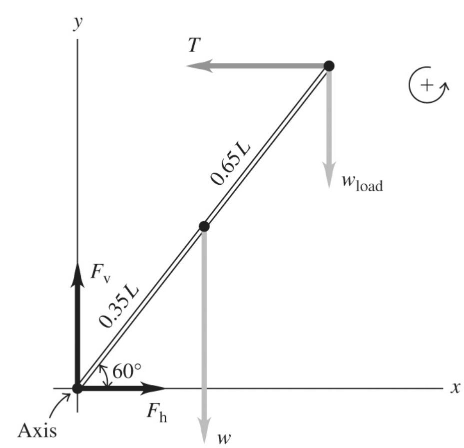

Figure 11.17

EXECUTE: **(a)** $\sum\tau = 0$ gives $T(L\sin 60.0°) - w_{load}(L\cos 60.0°) - w(0.35L\cos 60.0°) = 0$ and

$$T = \frac{w_{load}\cos 60.0° + w(0.35\cos 60.0°)}{\sin 60.0°} = \frac{(5000\text{ N})\cos 60.0° + (2600\text{ N})(0.35\cos 60.0°)}{\sin 60.0°} = 3.41\times 10^3\text{ N}.$$

(b) $\sum F_x = 0$ gives $F_h - T = 0$ and $F_h = 3410$ N.

$\sum F_y = 0$ gives $F_v - w - w_{load} = 0$ and $F_v = 5000\text{ N} + 2600\text{ N} = 7600\text{ N}$

EVALUATE: The bottom of the boom is the best point about which to take torques because only one unknown (the tension) appears in our equation. Using the top (or the center of mass) would give a torque equation with two (or three) unknowns.

11.18. **IDENTIFY:** The wheelbarrow is normally either held at rest or is moving with uniform velocity. Therefore the forces and torques on it must both balance.
SET UP: Estimate: The maximum upward force is 75 lb. Apply $\sum F_y = 0$ and $\sum\tau_z = 0$. Our target variables are the maximum weight of dirt we can life and the force the ground exerts on the wheels with that load in the wheelbarrow. Start with a free-body diagram of the wheelbarrow as shown in Fig. 11.18. Call F the upward force we exert (75 lb), w_{wb} the weight of the wheelbarrow (80.0 N = 18.0 lb), w_d the weight of the load of dirt, and F_{grd} the upward force the ground exerts on the front wheel.

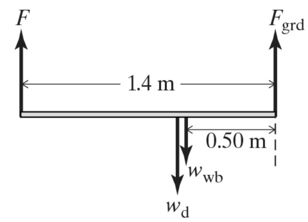

Figure 11.18

EXECUTE: **(a)** Apply $\sum \tau_z = 0$ about the point where the wheel is in contact with the ground. Using the notation in Fig 11.18 gives $-F(1.4\text{ m}) + (w_{wb} + w_d)(0.50\text{ m}) = 0$. Putting in the numbers and solving for w_d gives $w_d = \dfrac{(75\text{ lb})(1.4) - (18.0\text{ lb})(0.50)}{0.50} = 190\text{ lb}$.

(b) Now apply $\sum F_y = 0$: $F + F_{grd} - w_{wb} - w_d = 0$, which gives $F_{grd} =$ 18.0 lb + 190 lb – 75 lb = 130 lb.

EVALUATE: You can lift such a heavy load of dirt with only 75 lb because of your long lever arm compared to that of the dirt.

11.19. **IDENTIFY:** The beam is at rest so the forces and torques on it must each balance.

SET UP: $\sum \tau = 0$, $\sum F_x = 0$, $\sum F_y = 0$. The distance along the beam from the hinge to where the cable is attached is 3.0 m. The angle ϕ that the cable makes with the beam is given by $\sin\phi = \dfrac{4.0\text{ m}}{5.0\text{ m}}$, so $\phi = 53.1°$. The center of gravity of the beam is 4.5 m from the hinge. Use coordinates with $+y$ upward and $+x$ to the right. Take the pivot at the hinge and let counterclockwise torque be positive. Express the hinge force as components H_v and H_h. Assume H_v is downward and that H_h is to the right. If one of these components is actually in the opposite direction we will get a negative value for it. Set the tension in the cable equal to its maximum possible value, $T = 1.00$ kN.

EXECUTE: **(a)** The free-body diagram is shown in Figure 11.19, with $\vec{T}$ resolved into its x- and y-components.

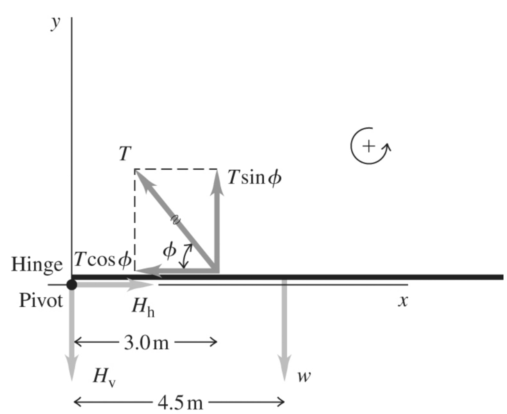

Figure 11.19

(b) $\sum \tau = 0$ gives $(T\sin\phi)(3.0\text{ m}) - w(4.5\text{ m}) = 0$

$$w = \frac{(T\sin\phi)(3.00\text{ m})}{4.50\text{ m}} = \frac{(1000\text{ N})(\sin 53.1°)(3.00\text{ m})}{4.50\text{ m}} = 533\text{ N}$$

(c) $\sum F_x = 0$ gives $H_h - T\cos\phi = 0$ and $H_h = (1.00\text{ kN})(\cos 53.1°) = 600\text{ N}$

$\sum F_y = 0$ gives $T\sin\phi - \text{H}_v - w = 0$ and $H_v = (1.00\text{ kN})(\sin 53.1°) - 533\text{ N} = 267\text{ N}$.

EVALUATE: $T\cos\phi$, H_v and H_h all have zero moment arms for a pivot at the hinge and therefore produce zero torque. If we consider a pivot at the point where the cable is attached we can see that H_v must be downward to produce a torque that opposes the torque due to *w*.

11.20. IDENTIFY: Apply the conditions for equilibrium to the crane.

SET UP: The free-body diagram for the crane is sketched in Figure 11.20. F_h and F_v are the components of the force exerted by the axle. $\vec{T}$ pulls to the left so F_h is to the right. $\vec{T}$ also pulls downward and the two weights are downward, so F_v is upward.

EXECUTE: **(a)** $\sum\tau_z = 0$ gives $T[(13\text{ m})\sin 25°] - w_c[(7.0\text{ m})\cos 55°] - w_b[(16.0\text{ m})\cos 55°] = 0$.

$$T = \frac{(11{,}000\text{ N})[(16.0\text{ m})\cos 55°] + (15{,}000\text{ N})[(7.0\text{ m})\cos 55°]}{(13.0\text{ m})\sin 25°} = 2.93\times10^4\text{ N}.$$

(b) $\sum F_x = 0$ gives $F_h - T\cos 30° = 0$ and $F_h = 2.54\times10^4$ N.

$\sum F_y = 0$ gives $F_v - T\sin 30° - w_c - w_b = 0$ and $F_v = 4.06\times10^4$ N.

EVALUATE: $\tan\theta = \dfrac{F_v}{F_h} = \dfrac{4.06\times10^4\text{ N}}{2.54\times10^4\text{ N}}$ and $\theta = 58°$. The force exerted by the axle is not directed along the crane.

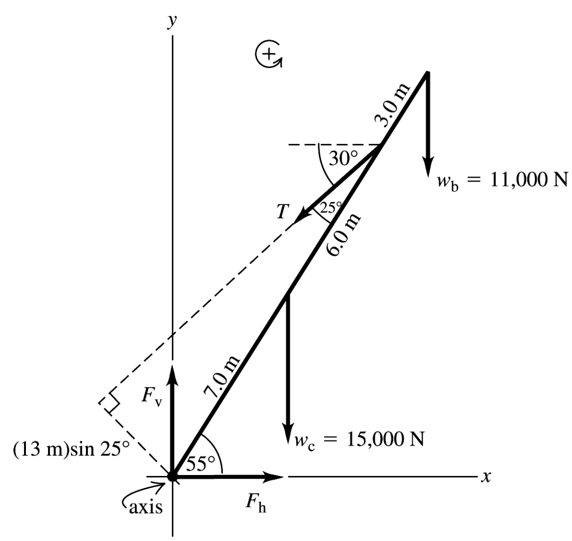

Figure 11.20

11.21. IDENTIFY: Apply the first and second conditions of equilibrium to the rod.

SET UP: The force diagram for the rod is given in Figure 11.21.

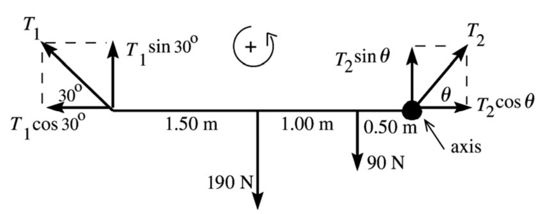

Figure 11.21

EXECUTE: $\sum\tau_z = 0$, axis at right end of rod, counterclockwise torque is positive

$(190\ \text{N})(1.50\ \text{m}) + (90\ \text{N})(0.50\ \text{m}) - (T_1 \sin 30.0°)(3.00\ \text{m}) = 0$

$$T_1 = \frac{285\ \text{N}\cdot\text{m} + 45\ \text{N}\cdot\text{m}}{1.50\ \text{m}} = 220\ \text{N}$$

$\sum F_x = ma_x$

$T_2 \cos\theta - T_1 \cos 30° = 0$ and $T_2 \cos\theta = (220\ \text{N})(\cos 30°) = 190.5\ \text{N}$

$\sum F_y = ma_y$

$T_1 \sin 30° + T_2 \sin\theta - 190\ \text{N} - 90\ \text{N} = 0$

$T_2 \sin\theta = 280\ \text{N} - (220\ \text{N})\sin 30° = 170\ \text{N}$

Then $\dfrac{T_2 \sin\theta}{T_2 \cos\theta} = \dfrac{170\ \text{N}}{190.5\ \text{N}}$ gives $\tan\theta = 0.89239$ and $\theta = 41.7°$

And $T_2 = \dfrac{170\ \text{N}}{\sin 41.7°} = 255\ \text{N}.$

EVALUATE: The monkey is closer to the right rope than to the left one, so the tension is larger in the right rope. The horizontal components of the tensions must be equal in magnitude and opposite in direction. Since $T_2 > T_1$, the rope on the right must be at a greater angle above the horizontal to have the same horizontal component as the tension in the other rope.

11.22. IDENTIFY: Apply the first and second conditions for equilibrium to the beam.

SET UP: The free-body diagram for the beam is given in Figure 11.22.

EXECUTE: The cable is given as perpendicular to the beam, so the tension is found by taking torques about the pivot point; $T(3.00\ \text{m}) = (1.40\ \text{kN})(2.00\ \text{m})\cos 25.0° + (5.00\ \text{kN})(4.50\ \text{m})\cos 25.0°$, and $T = 7.64\ \text{kN}$. The vertical component of the force exerted on the beam by the pivot is the net weight minus the upward component of T, $6.00\ \text{kN} - T\cos 25.0° = -0.53\ \text{kN}$. The vertical component is downward. The horizontal force is $T\sin 25.0° = 3.23\ \text{kN}$.

EVALUATE: The vertical component of the tension is nearly the same magnitude as the total weight of the object and the vertical component of the force exerted by the pivot is much less than its horizontal component.

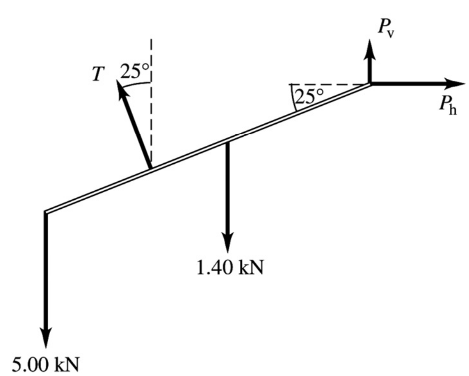

Figure 11.22

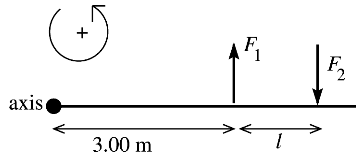
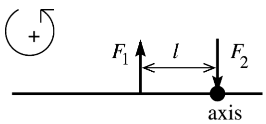
11.23. (a) IDENTIFY and SET UP: Use $\tau = Fl$ to calculate the torque (magnitude and direction) for each force and add the torques as vectors. See Figure 11.23a.



EXECUTE:
$\tau_1 = F_1 l_1 = +(8.00\text{ N})(3.00\text{ m})$
$\tau_1 = +24.0\text{ N}\cdot\text{m}$
$\tau_2 = -F_2 l_2 = -(8.00\text{ N})(l + 3.00\text{ m})$
$\tau_2 = -24.0\text{ N}\cdot\text{m} - (8.00\text{ N})l$

Figure 11.23a

$\sum \tau_z = \tau_1 + \tau_2 = +24.0\text{ N}\cdot\text{m} - 24.0\text{ N}\cdot\text{m} - (8.00\text{ N})l = -(8.00\text{ N})l$
Want l that makes $\sum \tau_z = -6.40\text{ N}\cdot\text{m}$ (net torque must be clockwise)
$-(8.00\text{ N})l = -6.40\text{ N}\cdot\text{m}$
$l = (6.40\text{ N}\cdot\text{m})/8.00\text{ N} = 0.800\text{ m}$
(b) $|\tau_2| > |\tau_1|$ since F_2 has a larger moment arm; the net torque is clockwise.
(c) See Figure 11.23b.



$\tau_1 = -F_1 l_1 = -(8.00\text{ N})l$
$\tau_2 = 0$ since $\vec{F}_2$ is at the axis

Figure 11.23b

$\sum \tau_z = -6.40\text{ N}\cdot\text{m}$ gives $-(8.00\text{ N})l = -6.40\text{ N}\cdot\text{m}$
$l = 0.800\text{ m}$, same as in part (a).
EVALUATE: The force couple gives the same magnitude of torque for the pivot at any point.

11.24. **IDENTIFY:** The person is in equilibrium, so the torques on him must balance. The target variable is the force exerted by the deltoid muscle.
SET UP: The free-body diagram for the arm is given in Figure 11.24. Take the pivot at the shoulder joint and let counterclockwise torques be positive. Use coordinates as shown. Let F be the force exerted by the deltoid muscle. There are also the weight of the arm and forces at the shoulder joint, but none of these forces produce any torque when the arm is in this position. The forces F and T have been replaced by their x- and y-components. $\sum \tau_z = 0$.

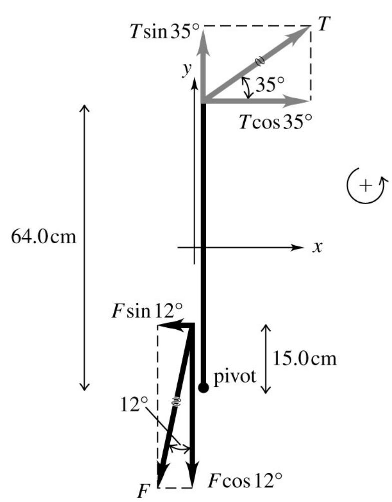


Figure 11.24

EXECUTE: $\sum \tau_z = 0$ gives $(F \sin 12.0°)(15.0 \text{ cm}) - (T \cos 35°)(64.0 \text{ cm}) = 0.$

$$F = \frac{(36.0 \text{ N})(\cos 35°)(64.0 \text{ cm})}{(\sin 12.0°)(15.0 \text{ cm})} = 605 \text{ N}.$$

EVALUATE: The force exerted by the deltoid muscle is much larger than the tension in the cable because the deltoid muscle makes a small angle (only 12.0°) with the humerus.

11.25. **IDENTIFY:** This problem involves the use of torques and graphical interpretation.

SET UP: In order to interpret the graph, apply $\sum \tau_z = 0$ to the rod and solve for the tension T in terms of the angle θ. Take torques about the hinge and call L the length of the rod. The mass of the rod is the target variable.

EXECUTE: $\sum \tau_z = 0$: $TL \sin\theta - mg\frac{L}{2}\cos\theta$, which gives $T = \frac{mg}{2}\frac{\cos\theta}{\sin\theta} = \left(\frac{mg}{2}\right)\cot\theta$. From this we see that a graph of T versus $\cot\theta$ should be a straight line having slope $mg/2$. Using the given slope we have $m = \frac{2(\text{slope})}{g} = \frac{2(30.0 \text{ N})}{9.80 \text{ m/s}^2} = 6.12$ kg.

EVALUATE: A situation like this might occur if you had a very heavy rod that could not easily be removed to weigh it, but could be pivoted about the hinge. The tension could be measured using a strain gauge.

11.26. **IDENTIFY:** Use $Y = \frac{l_0 F_\perp}{A\Delta l}$.

SET UP: $A = 50.0 \text{ cm}^2 = 50.0 \times 10^{-4} \text{ m}^2$.

EXECUTE: Relaxed: $Y = \frac{(0.200 \text{ m})(25.0 \text{ N})}{(50.0 \times 10^{-4} \text{ m}^2)(3.0 \times 10^{-2} \text{ m})} = 3.33 \times 10^4$ Pa.

Maximum tension: $Y = \frac{(0.200 \text{ m})(500 \text{ N})}{(50.0 \times 10^{-4} \text{ m}^2)(3.0 \times 10^{-2} \text{ m})} = 6.67 \times 10^5$ Pa.

EVALUATE: The muscle tissue is much more difficult to stretch when it is under maximum tension.

11.27. **IDENTIFY and SET UP:** Apply $Y = \frac{l_0 F_\perp}{A\Delta l}$ and solve for A and then use $A = \pi r^2$ to get the radius and $d = 2r$ to calculate the diameter.

EXECUTE: $Y = \frac{l_0 F_\perp}{A\Delta l}$ so $A = \frac{l_0 F_\perp}{Y\Delta l}$ (A is the cross-section area of the wire)

For steel, $Y = 2.0 \times 10^{11}$ Pa (Table 11.1)

Thus $A = \frac{(2.00 \text{ m})(700 \text{ N})}{(2.0 \times 10^{11} \text{ Pa})(0.25 \times 10^{-2} \text{ m})} = 2.8 \times 10^{-6} \text{ m}^2$.

$A = \pi r^2$, so $r = \sqrt{A/\pi} = \sqrt{2.8 \times 10^{-6} \text{ m}^2/\pi} = 9.44 \times 10^{-4}$ m

$d = 2r = 1.9 \times 10^{-3} \text{ m} = 1.9$ mm.

EVALUATE: Steel wire of this diameter doesn't stretch much; $\Delta l/l_0 = 0.12\%$.

11.28. **IDENTIFY:** Apply $Y = \frac{l_0 F_\perp}{A\Delta l}$.

SET UP: From Table 11.1, for steel, $Y = 2.0 \times 10^{11}$ Pa and for copper, $Y = 1.1 \times 10^{11}$ Pa. $A = \pi(d^2/4) = 1.77 \times 10^{-4} \text{ m}^2$. $F_\perp = 4000$ N for each rod.

EXECUTE: **(a)** The strain is $\frac{\Delta l}{l_0} = \frac{F}{YA}$. For steel $\frac{\Delta l}{l_0} = \frac{(4000 \text{ N})}{(2.0 \times 10^{11} \text{ Pa})(1.77 \times 10^{-4} \text{ m}^2)} = 1.1 \times 10^{-4}$.

Similarly, the strain for copper is 2.1×10^{-4}.

(b) Steel: $(1.1\times10^{-4})(0.750\text{ m}) = 8.3\times10^{-5}\text{ m}$. Copper: $(2.1\times10^{-4})(0.750\text{ m}) = 1.6\times10^{-4}\text{ m}$.

EVALUATE: Copper has a smaller Y and therefore a greater elongation.

11.29. IDENTIFY: Apply $Y = \dfrac{l_0F_\perp}{A\Delta l}$.

SET UP: $A = 0.50\text{ cm}^2 = 0.50\times10^{-4}\text{ m}^2$

EXECUTE: $Y = \dfrac{(4.00\text{ m})(5000\text{ N})}{(0.50\times10^{-4}\text{ m}^2)(0.20\times10^{-2}\text{ m})} = 2.0\times10^{11}\text{ Pa}$

EVALUATE: Our result is the same as that given for steel in Table 11.1.

11.30. IDENTIFY: Apply $Y = \dfrac{l_0F_\perp}{A\Delta l}$.

SET UP: $A = \pi r^2 = \pi(3.5\times10^{-3}\text{ m})^2 = 3.85\times10^{-5}\text{ m}^2$. The force applied to the end of the rope is the weight of the climber: $F_\perp = (65.0\text{ kg})(9.80\text{ m/s}^2) = 637\text{ N}$.

EXECUTE: $Y = \dfrac{(45.0\text{ m})(637\text{ N})}{(3.85\times10^{-5}\text{ m}^2)(1.10\text{ m})} = 6.77\times10^{8}\text{ Pa}$

EVALUATE: Our result is a lot smaller than the values given in Table 11.1. An object made of rope material is much easier to stretch than if the object were made of metal.

11.31. IDENTIFY: The increased pressure compresses the lead sphere, so we are dealing with bulk stress and strain.

SET UP: The bulk modulus is $B = -\dfrac{\Delta p}{\Delta V / V_0}$, and for lead it is $B = 4.1\times10^{10}$ Pa. The volume compresses by 0.50%, so $\Delta V = -0.0050V_0$. The target variable is the pressure increase that causes this amount of compression.

EXECUTE: Solve $-\dfrac{\Delta p}{\Delta V / V_0}$ for Δp : $\Delta p = -B\left(\dfrac{\Delta V}{V_0}\right) = -\left(4.1\times10^{10}\text{ Pa}\right)\left(\dfrac{-0.0050V_0}{V_0}\right) = 2.05\times10^{8}\text{ Pa} = 2.0\times10^{3}$ atm. The pressure is 2000 atmospheres above atmospheric pressure.

EVALUATE: This is a very large pressure, but it would take a large pressure to compress a lead sphere.

11.32. IDENTIFY: Apply $\text{stress} = \dfrac{F_\perp}{A}$, $\text{strain} = \dfrac{\text{stress}}{Y}$, $Y = \dfrac{l_0F_\perp}{A\Delta l}$.

SET UP: The cross-sectional area of the post is $A = \pi r^2 = \pi(0.125\text{ m})^2 = 0.0491\text{ m}^2$. The force applied to the end of the post is $F_\perp = (8000\text{ kg})(9.80\text{ m/s}^2) = 7.84\times10^4\text{ N}$. The Young's modulus of steel is $Y = 2.0\times10^{11}\text{ Pa}$.

EXECUTE: **(a)** $\text{stress} = \dfrac{F_\perp}{A} = -\dfrac{7.84\times10^4\text{ N}}{0.0491\text{ m}^2} = -1.60\times10^6\text{ Pa}$. The minus sign indicates that the stress is compressive.

(b) $\text{strain} = \dfrac{\text{stress}}{Y} = -\dfrac{1.60\times10^6\text{ Pa}}{2.0\times10^{11}\text{ Pa}} = -8.0\times10^{-6}$. The minus sign indicates that the length decreases.

(c) $\Delta l = l_0(\text{strain}) = (2.50\text{ m})(-8.0\times10^{-6}) = -2.0\times10^{-5}\text{ m}$

EVALUATE: The fractional change in length of the post is very small.

11.33. IDENTIFY: The amount of compression depends on the bulk modulus of the bone.

SET UP: $\dfrac{\Delta V}{V_0} = -\dfrac{\Delta p}{B}$ and $1\text{ atm} = 1.01\times10^5\text{ Pa}$.

EXECUTE: **(a)** $\Delta p = -B\dfrac{\Delta V}{V_0} = -(15\times10^9\ \text{Pa})(-0.0010) = 1.5\times10^7\ \text{Pa} = 150\ \text{atm}.$

(b) The depth for a pressure increase of $1.5\times10^7\ \text{Pa}$ is 1.5 km.

EVALUATE: An extremely large pressure increase is needed for just a 0.10% bone compression, so pressure changes do not appreciably affect the bones. Unprotected dives do not approach a depth of 1.5 km, so bone compression is not a concern for divers.

11.34. **IDENTIFY:** Apply $\dfrac{\Delta V}{V_0} = -\dfrac{\Delta p}{B}.$

SET UP: $\Delta V = -\dfrac{V_0 \Delta p}{B}.$ Δp is positive when the pressure increases.

EXECUTE: **(a)** The volume would increase slightly.
(b) The volume change would be twice as great.
(c) The volume change is inversely proportional to the bulk modulus for a given pressure change, so the volume change of the lead ingot would be four times that of the gold.

EVALUATE: For lead, $B = 4.1\times10^{10}\ \text{Pa},$ so $\Delta p/B$ is very small and the fractional change in volume is very small.

11.35. **IDENTIFY** and **SET UP:** Use $\dfrac{\Delta V}{V_0} = -\dfrac{\Delta p}{B}$ and $k = 1/B$ to calculate B and k.

EXECUTE: $B = -\dfrac{\Delta p}{\Delta V/V_0} = -\dfrac{(3.6\times10^6\ \text{Pa})(600\ \text{cm}^3)}{(-0.45\ \text{cm}^3)} = +4.8\times10^9\ \text{Pa}$

$k = 1/B = 1/4.8\times10^9\ \text{Pa} = 2.1\times10^{-10}\ \text{Pa}^{-1}$

EVALUATE: k is the same as for glycerine (Table 11.2).

11.36. **IDENTIFY:** Apply $\dfrac{\Delta V}{V_0} = -\dfrac{\Delta p}{B}.$ Density $= m/V.$

SET UP: At the surface the pressure is $1.0\times10^5\ \text{Pa},$ so $\Delta p = 1.16\times10^8\ \text{Pa}.$ $V_0 = 1.00\ \text{m}^3.$ At the surface $1.00\ \text{m}^3$ of water has mass $1.03\times10^3\ \text{kg}.$

EXECUTE: **(a)** $B = -\dfrac{(\Delta p)V_0}{\Delta V}$ gives $\Delta V = -\dfrac{(\Delta p)V_0}{B} = -\dfrac{(1.16\times10^8\ \text{Pa})(1.00\ \text{m}^3)}{2.2\times10^9\ \text{Pa}} = -0.0527\ \text{m}^3$

(b) At this depth $1.03\times10^3\ \text{kg}$ of seawater has volume $V_0 + \Delta V = 0.9473\ \text{m}^3.$ The density is $\dfrac{1.03\times10^3\ \text{kg}}{0.9473\ \text{m}^3} = 1.09\times10^3\ \text{kg/m}^3.$

EVALUATE: The density is increased because the volume is compressed due to the increased pressure.

11.37. **IDENTIFY:** Apply $S = \dfrac{F_\parallel}{A}\dfrac{h}{x}.$

SET UP: $F_\parallel = 9.0\times10^5\ \text{N}.$ $A = (0.100\ \text{m})(0.500\times10^{-2}\ \text{m}).$ $h = 0.100\ \text{m}.$ From Table 11.1, $S = 7.5\times10^{10}\ \text{Pa}$ for steel.

EXECUTE: **(a)** Shear strain $= \dfrac{F_\parallel}{AS} = \dfrac{(9\times10^5\ \text{N})}{[(0.100\ \text{m})(0.500\times10^{-2}\ \text{m})][7.5\times10^{10}\ \text{Pa}]} = 2.4\times10^{-2}.$

(b) Since shear strain $= x/h,$ $x = (\text{Shear strain})\cdot h = (0.024)(0.100\ \text{m}) = 2.4\times10^{-3}\ \text{m}.$

EVALUATE: This very large force produces a small displacement; $x/h = 2.4\%.$

11.38. **IDENTIFY:** The force components parallel to the face of the cube produce a shear which can deform the cube.

SET UP: $S = \dfrac{F_\parallel}{A\phi}$, where $\phi = x/h$. $F_\parallel$ is the component of the force tangent to the surface, so $F_\parallel = (1375\ \text{N})\cos 8.50° = 1360\ \text{N}$. ϕ must be in radians, $\phi = 1.24° = 0.0216$ rad.

EXECUTE: $S = \dfrac{1360\ \text{N}}{(0.0925\ \text{m})^2(0.0216\ \text{rad})} = 7.36\times 10^6\ \text{Pa}$.

EVALUATE: The shear modulus of this material is much less than the values for metals given in Table 11.1 in the text.

11.39. **IDENTIFY:** The problem involves the stretching of metal wires, so it makes use of tensile stress and strain and Young's modulus.

SET UP: The steel and aluminum wires have the same fractional change in length. We use $Y = \dfrac{F_\perp}{A}\dfrac{\ell_0}{\Delta\ell}$. We know that $\dfrac{\Delta\ell}{\ell_0}$ is the same for both wires, $r_{\text{al}} = 2r_{\text{st}}$, and $A = \pi r^2$. Table 11.1 gives us the values of Y for both metals. Our target variable is the tension T_{al} in the aluminum wire in terms of the tension T_{st} in the steel wire. Since $\dfrac{\Delta\ell}{\ell_0}$ is the same for both wires, we can equate this expression for both wires and solve for T_{al}.

EXECUTE: <u>Steel</u>: $\dfrac{\Delta\ell}{\ell_0} = \dfrac{T_{\text{st}}}{Y_{\text{st}}\pi r_{\text{st}}^2}$. <u>Aluminum</u>: $\dfrac{T_{\text{al}}}{Y_{\text{al}}\pi r_{\text{al}}^2}$. Equating gives $\dfrac{T_{\text{st}}}{Y_{\text{st}}\pi r_{\text{st}}^2} = \dfrac{T_{\text{al}}}{Y_{\text{al}}\pi r_{\text{al}}^2}$. Using the fact that $r_{\text{al}} = 2r_{\text{st}}$ and $A = \pi r^2$, we have $T_{\text{al}} = \dfrac{Y_{\text{al}}}{Y_{\text{st}}}\left(\dfrac{r_{\text{al}}}{r_{\text{st}}}\right)^2 T_{\text{st}} = \dfrac{7.0\times 10^{10}\ \text{Pa}}{20\times 10^{10}\ \text{Pa}}\left(\dfrac{2r_{\text{st}}}{r_{\text{st}}}\right)^2 T_{\text{st}} = 1.4T_{\text{st}}$.

EVALUATE: Although aluminum has a smaller Young's modulus than does steel, the aluminum wire is twice as thick and hence has 4 times the area as the steel wire, so it can support more tension than the steel for the same fractional stretch.

11.40. **IDENTIFY:** The applied force stretches the wire, so are dealing with tensile stress and strain and Young's modulus.

SET UP: Since we graph $\dfrac{\Delta\ell}{\ell_0}$ versus $F_\perp$, we need to discover a relationship between these quantities so we can interpret the slope of the graph. We start with $Y = \dfrac{F_\perp}{A}\dfrac{\ell_0}{\Delta\ell}$. Our target variable is Y for the metal of the wire.

EXECUTE: Solve $\dfrac{F_\perp}{A}\dfrac{\ell_0}{\Delta\ell}$ for $\dfrac{\Delta\ell}{\ell_0}$ in terms of $F_\perp$, which gives $\dfrac{\Delta\ell}{\ell_0} = \dfrac{1}{AY}F_\perp$. Therefore a graph of $\dfrac{\Delta\ell}{\ell_0}$ versus $F_\perp$ should be a straight line having slope $\dfrac{1}{AY}$. Thus $Y = \dfrac{1}{A(\text{slope})}$, which gives

$$Y = \frac{1}{(8.00\times 10^{-6}\ \text{m}^2)(8.00\times 10^{-7}\ \text{N}^{-1})} = 1.6\times 10^{11}\ \text{Pa}.$$

EVALUATE: From Table 11.1, we see that this value is about the same as Y for steel, nickel, iron, and copper, so it is a reasonable result.

11.41. **IDENTIFY:** We are dealing with compression due to increased pressure, so we must use bulk stress and strain and the bulk modulus B.

SET UP: Since we are dealing with liquids, we will need to use Table 11.2. It gives the compressibility k, which is $1/B$, so $k = -\frac{\Delta V / V_0}{\Delta p}$. We know that $\Delta V / V_0$ will be negative (for a compression) when Δp is positive, so we can neglect the minus signs. We also know that $\Delta V / V_0$ is the same for both liquids. The target variable is the pressure increase Δp_{a} in the alcohol.

EXECUTE: Equating $\Delta V / V_0$ for both liquids gives $k_{\text{a}}\Delta p_{\text{a}} = k_{\text{g}}\Delta p_{\text{g}} = k_{\text{g}}\Delta p_1$. Solving for Δp_{a} gives

$$\Delta p_{\text{a}} = \frac{k_{\text{g}}}{k_{\text{a}}}\Delta p_1 = \frac{21\times 10^{-11}\ \text{Pa}^{-1}}{110\times 10^{-11}\ \text{Pa}^{-1}}\Delta p_1 = 0.19\Delta p_1.$$

EVALUATE: Since $k_{\text{a}} \approx 5k_{\text{g}}$, alcohol is 5 times more compressible than glycerin, so it takes only about 1/5 the pressure increase to produce the same compression as for glycerin. This is a reasonable result.

11.42. **IDENTIFY:** The breaking stress of the wire is the value of $F_\perp/A$ at which the wire breaks.

SET UP: From Table 11.3, the breaking stress of brass is 4.7×10^8 Pa. The area A of the wire is related to its diameter by $A = \pi d^2/4$.

EXECUTE: $A = \frac{350\ \text{N}}{4.7\times 10^8\ \text{Pa}} = 7.45\times 10^{-7}\ \text{m}^2$, so $d = \sqrt{4A/\pi} = 0.97$ mm.

EVALUATE: The maximum force a wire can withstand without breaking is proportional to the square of its diameter.

11.43. **IDENTIFY** and **SET UP:** Use $\text{stress} = \frac{F_\perp}{A}$.

EXECUTE: $\text{Tensile stress} = \frac{F_\perp}{A} = \frac{F_\perp}{\pi r^2} = \frac{90.8\ \text{N}}{\pi(0.92\times 10^{-3}\ \text{m})^2} = 3.41\times 10^7\ \text{Pa}$

EVALUATE: A modest force produces a very large stress because the cross-sectional area is small.

11.44. **IDENTIFY:** The elastic limit is a value of the stress, $F_\perp/A$. Apply $\sum \vec{F} = m\vec{a}$ to the elevator in order to find the tension in the cable.

SET UP: $\frac{F_\perp}{A} = \frac{1}{3}(2.40\times 10^8\ \text{Pa}) = 0.80\times 10^8\ \text{Pa}$. The free-body diagram for the elevator is given in Figure 11.44. $F_\perp$ is the tension in the cable.

EXECUTE: $F_\perp = A(0.80\times 10^8\ \text{Pa}) = (3.00\times 10^{-4}\ \text{m}^2)(0.80\times 10^8\ \text{Pa}) = 2.40\times 10^4\ \text{N}$. $\sum F_y = ma_y$ applied to the elevator gives $F_\perp - mg = ma$ and $a = \frac{F_\perp}{m} - g = \frac{2.40\times 10^4\ \text{N}}{1200\ \text{kg}} - 9.80\ \text{m/s}^2 = 10.2\ \text{m/s}^2$

EVALUATE: The tension in the cable is about twice the weight of the elevator.

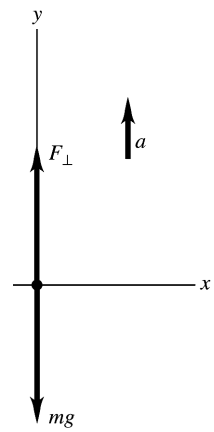

Figure 11.44

11.45. **IDENTIFY:** To pull out the nail, you exert a torque on the handle which in turn produces a torque on the nail.

SET UP: Estimate: $F_2 = 25$ lb in Fig. 11.45 in the text. Use $\sum \tau_z = 0$ about contact point A in the figure. The target variable is the force the hammer exerts on the nail (F_1 in the figure).

EXECUTE: Using the figure in the text, applying $\sum \tau_z = 0$ to the hammer gives $F_2(0.300 \text{ m}) - F_1(\sin 60°)(0.080 \text{ m}) = 0.$ Using $F_2 = 25$ lb and solving for F_1 gives $F_1 = 110$ lb. Note that in the figure $\vec{F}_1$ is the force on the nail, but by Newton's third law, the force on the hammer is equal and opposite to this force.

EVALUATE: The long handle allows the force on the nail to be about 4 times your force. A longer handle would increase this factor even more.

11.46. **IDENTIFY:** Apply the first and second conditions of equilibrium to the door.

SET UP: The free-body diagram for the door is given in Figure 11.46. Let $\vec{H}_1$ and $\vec{H}_2$ be the forces exerted by the upper and lower hinges. Take the origin of coordinates at the bottom hinge (point A) and $+y$ upward.

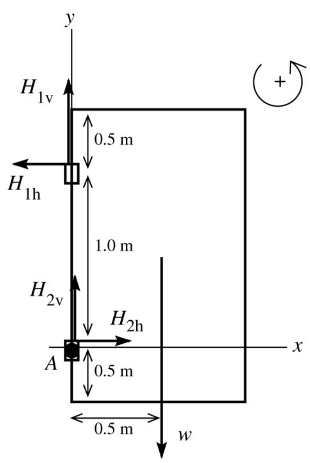

Figure 11.46

EXECUTE:
We are given that
$H_{1v} = H_{2v} = w/2 = 165$ N.
$\sum F_x = ma_x$
$H_{2h} - H_{1h} = 0$
$H_{1h} = H_{2h}$
The horizontal components of the hinge forces are equal in magnitude and opposite in direction.

Sum torques about point A. H_{1v}, H_{2v}, and H_{2h} all have zero moment arm and hence zero torque about an axis at this point. Thus $\sum \tau_A = 0$ gives $H_{1h}(1.00 \text{ m}) - w(0.50 \text{ m}) = 0$

$$H_{1h} = w\left(\frac{0.50\text{ m}}{1.00\text{ m}}\right) = \tfrac{1}{2}(330\text{ N}) = 165\text{ N}.$$

The horizontal component of each hinge force is 165 N.

EVALUATE: The horizontal components of the force exerted by each hinge are the only horizontal forces so must be equal in magnitude and opposite in direction. With an axis at A, the torque due to the horizontal force exerted by the upper hinge must be counterclockwise to oppose the clockwise torque exerted by the weight of the door. So, the horizontal force exerted by the upper hinge must be to the left. You can also verify that the net torque is also zero if the axis is at the upper hinge.

11.47. **IDENTIFY:** The center of gravity of the combined object must be at the fulcrum. Use $x_{\text{cm}} = \dfrac{m_1x_1 + m_2x_2 + m_3x_3 + \dots}{m_1 + m_2 + m_3 + \dots}$ to calculate x_{cm}.

SET UP: The center of gravity of the sand is at the middle of the box. Use coordinates with the origin at the fulcrum and $+x$ to the right. Let $m_1 = 25.0$ kg, so $x_1 = 0.500$ m. Let $m_2 = m_{\text{sand}}$, so $x_2 = -0.625$ m. $x_{\text{cm}} = 0$.

EXECUTE: $x_{\text{cm}} = \dfrac{m_1x_1 + m_2x_2}{m_1 + m_2} = 0$ and $m_2 = -m_1\dfrac{x_1}{x_2} = -(25.0\text{ kg})\left(\dfrac{0.500\text{ m}}{-0.625\text{ m}}\right) = 20.0\text{ kg}.$

EVALUATE: The mass of sand required is less than the mass of the plank since the center of the box is farther from the fulcrum than the center of gravity of the plank is.

11.48. **IDENTIFY:** Apply $\sum\tau_z = 0$ to the bridge.

SET UP: Let the axis of rotation be at the left end of the bridge and let counterclockwise torques be positive.

EXECUTE: If Lancelot were at the end of the bridge, the tension in the cable would be (from taking torques about the hinge of the bridge) obtained from

$T(12.0\text{ m}) = (600\text{ kg})(9.80\text{ m/s}^2)(12.0\text{ m}) + (200\text{ kg})(9.80\text{ m/s}^2)(6.0\text{ m})$, so $T = 6860$ N.

This exceeds the maximum tension that the cable can have, so Lancelot is going into the drink. To find the distance x Lancelot can ride, replace the 12.0 m multiplying Lancelot's weight by x and the tension T by $T_{\text{max}} = 5.80\times10^3$ N and solve for x;

$$x = \frac{(5.80\times10^3\text{ N})(12.0\text{ m}) - (200\text{ kg})(9.80\text{ m/s}^2)(6.0\text{ m})}{(600\text{ kg})(9.80\text{ m/s}^2)} = 9.84\text{ m}.$$

EVALUATE: Before Lancelot goes onto the bridge, the tension in the supporting cable is $T = \dfrac{(6.0\text{ m})(200\text{ kg})(9.80\text{ m/s}^2)}{12.0\text{ m}} = 980$ N, well below the breaking strength of the cable. As he moves along the bridge, the increase in tension is proportional to x, the distance he has moved along the bridge.

11.49. **IDENTIFY:** Apply the conditions of equilibrium to the climber. For the minimum coefficient of friction the static friction force has the value $f_s = \mu_s n$.

SET UP: The free-body diagram for the climber is given in Figure 11.49. f_s and n are the vertical and horizontal components of the force exerted by the cliff face on the climber. The moment arm for the force T is $(1.4\text{ m})\cos10°$.

EXECUTE: **(a)** $\sum\tau_z = 0$ gives $T(1.4\text{ m})\cos10° - w(1.1\text{ m})\cos35.0° = 0$.

$$T = \frac{(1.1\text{ m})\cos35.0°}{(1.4\text{ m})\cos10°}(82.0\text{ kg})(9.80\text{ m/s}^2) = 525\text{ N}$$

(b) $\sum F_x = 0$ gives $n = T\sin 25.0° = 222\ \text{N}$. $\sum F_y = 0$ gives $f_s + T\cos 25° - w = 0$ and $f_s = (82.0\ \text{kg})(9.80\ \text{m/s}^2) - (525\ \text{N})\cos 25° = 328\ \text{N}$.

(c) $\mu_s = \dfrac{f_s}{n} = \dfrac{328\ \text{N}}{222\ \text{N}} = 1.48$

EVALUATE: To achieve this large value of μ_s the climber must wear special rough-soled shoes.

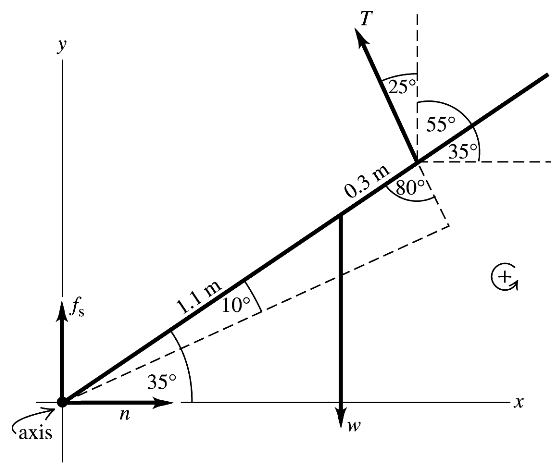

Figure 11.49

11.50. **IDENTIFY:** The beam is at rest, so the forces and torques on it must balance.

SET UP: The weight of the beam acts 4.0 m from each end. Take the pivot at the hinge and let counterclockwise torques be positive. Represent the force exerted by the hinge by its horizontal and vertical components, H_h and H_v. $\sum F_x = 0$, $\sum F_y = 0$ and $\sum \tau_z = 0$.

EXECUTE: **(a)** The free-body diagram for the beam is given in Figure 11.50a.

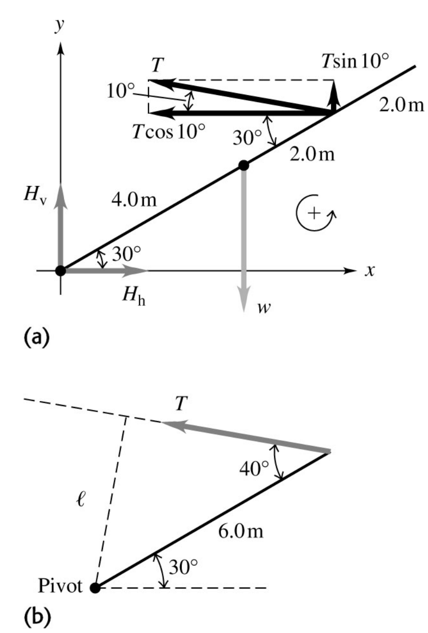

Figure 11.50

(b) The moment arm for T is sketched in Figure 11.50b and is equal to $(6.0\text{ m})\sin 40.0°$. $\sum\tau_z = 0$ gives $T(6.0\text{ m})(\sin 40.0°) - w(4.0\text{ m})(\cos 30.0°) = 0$.

$$T = \frac{(1150\text{ kg})(9.80\text{ m/s}^2)(4.0\text{ m})(\cos 30.0°)}{(6.0\text{ m})(\sin 40.0°)} = 1.01\times 10^4\text{ N}.$$

(c) $\sum F_x = 0$ gives $H_\text{h} - T\cos 10.0° = 0$ and $H_\text{h} = T\cos 10.0° = 9.97\times 10^3$ N.

EVALUATE: The tension is less than the weight of the beam because it has a larger moment arm than the weight force has.

11.51. **IDENTIFY:** In each case, to achieve balance the center of gravity of the system must be at the fulcrum. Use $x_\text{cm} = \dfrac{m_1x_1 + m_2x_2 + m_3x_3 + \dots}{m_1 + m_2 + m_3 + \dots}$ to locate x_cm, with m_i replaced by w_i.

SET UP: Let the origin be at the left-hand end of the rod and take the $+x$-axis to lie along the rod. Let $w_1 = 255$ N (the rod) so $x_1 = 1.00$ m, let $w_2 = 225$ N so $x_2 = 2.00$ m and let $w_3 = W$. In part (a) $x_3 = 0.500$ m and in part (b) $x_3 = 0.750$ m.

EXECUTE: **(a)** $x_\text{cm} = 1.25$ m. $x_\text{cm} = \dfrac{w_1x_1 + w_2x_2 + w_3x_3}{w_1 + w_2 + w_3}$ gives $w_3 = \dfrac{(w_1 + w_2)x_\text{cm} - w_1x_1 - w_2x_2}{x_3 - x_\text{cm}}$ and

$$W = \frac{(480\text{ N})(1.25\text{ m}) - (255\text{ N})(1.00\text{ m}) - (225\text{ N})(2.00\text{ m})}{0.500\text{ m} - 1.25\text{ m}} = 140\text{ N}.$$

(b) Now $w_3 = W = 140$ N and $x_3 = 0.750$ m.

$$x_\text{cm} = \frac{(255\text{ N})(1.00\text{ m}) + (225\text{ N})(2.00\text{ m}) + (140\text{ N})(0.750\text{ m})}{255\text{ N} + 225\text{ N} + 140\text{ N}} = 1.31\text{ m}.$$ W must be moved $1.31\text{ m} - 1.25\text{ m} = 6\text{ cm}$ to the right.

EVALUATE: Moving W to the right means x_cm for the system moves to the right.

11.52. **IDENTIFY:** Apply $\sum\tau_z = 0$ to the hammer.

SET UP: Take the axis of rotation to be at point A.

EXECUTE: The force $\vec{F}_1$ is directed along the length of the nail, and so has a moment arm of $(0.080\text{ m})\sin 60°$. The moment arm of $\vec{F}_2$ is 0.300 m, so

$$F_2 = F_1\frac{(0.0800\text{ m})\sin 60°}{(0.300\text{ m})} = (400\text{ N})(0.231) = 92.4\text{ N}.$$

EVALUATE: The force F_2 that must be applied to the hammer handle is much less than the force that the hammer applies to the nail, because of the large difference in the lengths of the moment arms.

11.53. **IDENTIFY:** Apply the conditions of equilibrium to the horizontal beam. Since the two wires are symmetrically placed on either side of the middle of the sign, their tensions are equal and are each equal to $T_\text{w} = mg/2 = 137$ N.

SET UP: The free-body diagram for the beam is given in Figure 11.53. F_v and F_h are the vertical and horizontal forces exerted by the hinge on the beam. Since the cable is 2.00 m long and the beam is 1.50 m long, $\cos\theta = \dfrac{1.50\text{ m}}{2.00\text{ m}}$ and $\theta = 41.4°$. The tension T_c in the cable has been replaced by its horizontal and vertical components.

EXECUTE: **(a)** $\sum\tau_z = 0$ gives $T_\text{c}(\sin 41.4°)(1.50\text{ m}) - w_\text{beam}(0.750\text{ m}) - T_\text{w}(1.50\text{ m}) - T_\text{w}(0.60\text{ m}) = 0$.

$$T_\text{c} = \frac{(16.0\text{ kg})(9.80\text{ m/s}^2)(0.750\text{ m}) + (137\text{ N})(1.50\text{ m} + 0.60\text{ m})}{(1.50\text{ m})(\sin 41.4°)} = 408.6\text{ N},$$ which rounds to 409 N.

(b) $\sum F_y = 0$ gives $F_v + T_c \sin 41.4° - w_{beam} - 2T_w = 0$ and

$F_v = 2T_w + w_{beam} - T_c \sin 41.4° = 2(137 \text{ N}) + (16.0 \text{ kg})(9.80 \text{ m/s}^2) - (408.6 \text{ N})(\sin 41.4°) = 161 \text{ N}$. The hinge must be able to supply a vertical force of 161 N.

EVALUATE: The force from the two wires could be replaced by the weight of the sign acting at a point 0.60 m to the left of the right-hand edge of the sign.

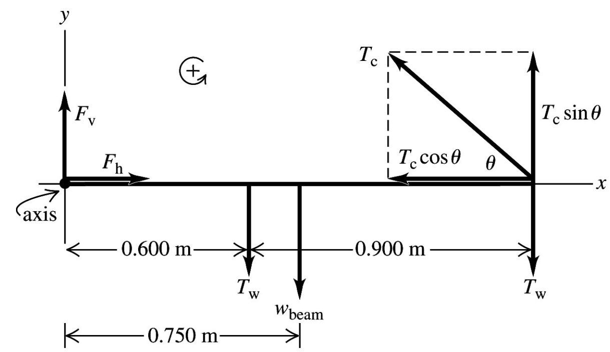

Figure 11.53

11.54. **IDENTIFY:** Apply the first and second conditions of equilibrium to the bar.

SET UP: The free-body diagram for the bar is given in Figure 11.54. n is the normal force exerted on the bar by the surface. There is no friction force at this surface. H_h and H_v are the components of the force exerted on the bar by the hinge. The components of the force of the bar on the hinge will be equal in magnitude and opposite in direction.

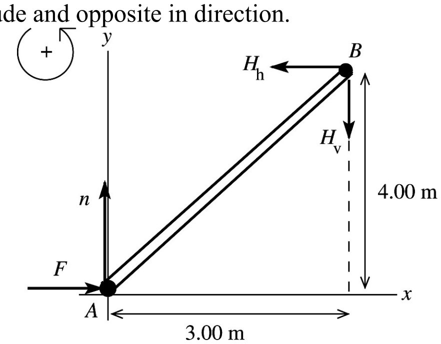

Figure 11.54

EXECUTE:

$\sum F_x = ma_x$

$F = H_h = 220 \text{ N}$

$\sum F_y = ma_y$

$n - H_v = 0$

$H_v = n$, but we don't know either of these forces.

$\sum \tau_B = 0$ gives $F(4.00 \text{ m}) - n(3.00 \text{ m}) = 0$.

$n = (4.00 \text{ m}/3.00 \text{ m})F = \frac{4}{3}(220 \text{ N}) = 293 \text{ N}$ and then $H_v = 293 \text{ N}$.

Force of bar on hinge:
horizontal component 220 N, to right
vertical component 293 N, upward

EVALUATE: $H_h/H_v = 220/293 = 0.75 = 3.00/4.00$, so the force the hinge exerts on the bar is directed along the bar. $\vec{n}$ and $\vec{F}$ have zero torque about point A, so the line of action of the hinge force $\vec{H}$ must pass through this point also if the net torque is to be zero.

11.55. **IDENTIFY:** We want to locate the center of mass of the leg-cast system. We can treat each segment of the leg and cast as a point-mass located at its center of mass.

SET UP: The force diagram for the leg is given in Figure 11.55. The weight of each piece acts at the center of mass of that piece. The mass of the upper leg is $m_{ul} = (0.215)(37 \text{ kg}) = 7.955 \text{ kg}$. The mass of the lower leg is $m_{ll} = (0.140)(37\text{ kg}) = 5.18\text{ kg}$. Use the coordinates shown, with the origin at the hip and the x-axis along the leg, and use $x_{cm} = \dfrac{x_{ul}m_{ul} + x_{ll}m_{ll} + x_{cast}m_{cast}}{m_{ul} + m_{ll} + m_{cast}}$.

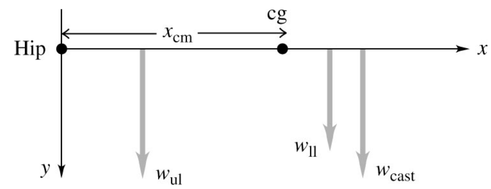

Figure 11.55

EXECUTE: Using $x_{cm} = \dfrac{x_{ul}m_{ul} + x_{ll}m_{ll} + x_{cast}m_{cast}}{m_{ul} + m_{ll} + m_{cast}}$, we have

$$x_{cm} = \frac{(18.0\text{ cm})(7.955\text{ kg}) + (69.0\text{ cm})(5.18\text{ kg}) + (78.0\text{ cm})(5.50\text{ kg})}{7.955\text{ kg} + 5.18\text{ kg} + 5.50\text{ kg}} = 49.9\text{ cm}$$

EVALUATE: The strap is attached to the left of the center of mass of the cast, but it is still supported by the rigid cast since the cast extends beyond its center of mass.

11.56. **IDENTIFY:** Apply the first and second conditions for equilibrium to the bridge.
SET UP: Find torques about the hinge. Use L as the length of the bridge and w_T and w_B for the weights of the truck and the raised section of the bridge. Take $+y$ to be upward and $+x$ to be to the right.
EXECUTE: **(a)** $TL\sin 70° = w_T(\tfrac{3}{4}L)\cos 30° + w_B(\tfrac{1}{2}L)\cos 30°$, so

$$T = \frac{(\tfrac{3}{4}m_T + \tfrac{1}{2}m_B)(9.80\text{ m/s}^2)\cos 30°}{\sin 70°} = 2.84\times 10^5\text{ N}.$$

(b) Horizontal: $T\cos(70° - 30°) = 2.18\times 10^5\text{ N}$ (to the right).

Vertical: $w_T + w_B - T\sin 40° = 2.88\times 10^5\text{ N}$ (upward).

EVALUATE: If ϕ is the angle of the hinge force above the horizontal,

$\tan\phi = \dfrac{2.88\times 10^5\text{ N}}{2.18\times 10^5\text{ N}}$ and $\phi = 52.9°$. The hinge force is not directed along the bridge.

11.57. **IDENTIFY:** The rod is suspended at rest, so the forces and torques on it must balance. Once the wire breaks, it rotates downward about the hinge, so we can use energy conservation.
SET UP: While the rod is at rest, we use $\sum\tau_z = 0$. After the wire breaks, we apply energy conservation $U_1 + K_1 + W_{other} = U_2 + K_2$ with $I = \dfrac{1}{3}ML^2$, $K_1 = 0$, $U_2 = 0$, and $W_{other} = 0$ because the hinge is frictionless. Our target variables are the angle the wire makes with the horizontal and its angular speed after the wire breaks. Begin with a free-body diagram of the rod, as in Fig. 11.57.

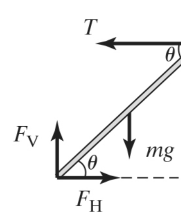

Figure 11.57

EXECUTE: **(a)** $\sum \tau_z = 0$: $TL\sin\theta - mg\dfrac{L}{2}\cos\theta = 0$, which gives $\theta = \arctan\left(\dfrac{mg}{2T}\right)$.

(b) Calling $y = 0$ at the level when the rod is horizontal, $U_1 + K_1 + W_{\text{other}} = U_2 + K_2$ gives

$mg\dfrac{L}{2}\sin\theta = \dfrac{1}{2}\left(\dfrac{1}{3}mL^2\right)\omega^2$, from which we get $\omega = \sqrt{\dfrac{3g\sin\theta}{L}}$.

EVALUATE: Check is some special cases: If θ is large, ω is large, which is reasonable because a large θ means that the center of gravity of the rod would be higher than for a small θ. If $\theta = 0$, $\omega = 0$, which is reasonable since the rod started from rest horizontally.

11.58. **IDENTIFY:** The arm is stationary, so the forces and torques must each balance.

SET UP: $\sum\tau = 0$, $\sum F_x = 0$, $\sum F_y = 0$. Let the forearm be at an angle ϕ below the horizontal. Take the pivot at the elbow joint and let counterclockwise torques be positive. Let $+y$ be upward and let $+x$ be to the right. Each forearm has mass $m_{\text{arm}} = \frac{1}{2}(0.0600)(72\text{ kg}) = 2.16\text{ kg}$. The weight held in each hand is $w = mg$, with $m = 7.50\text{ kg}$. $\vec{T}$ is the force the biceps muscle exerts on the forearm. $\vec{E}$ is the force exerted by the elbow and has components E_v and E_h.

EXECUTE: **(a)** The free-body diagram is shown in Figure 11.58.

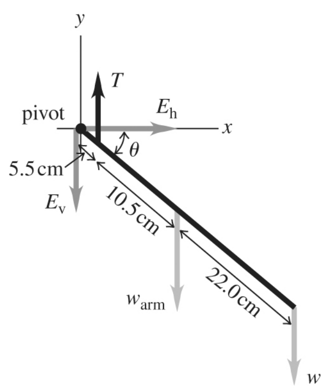

Figure 11.58

(b) $\sum\tau = 0$ gives $T(5.5\text{ cm})(\cos\theta) - w_{\text{arm}}(16.0\text{ cm})(\cos\theta) - w(38.0\text{ cm})(\cos\theta) = 0$

$$T = \frac{16.0w_{\text{arm}} + 38.0w}{5.5} = \frac{16.0(2.16\text{ kg})(9.80\text{ m/s}^2) + 38.0(7.50\text{ kg})(9.80\text{ m/s}^2)}{5.5} = 569\text{ N}$$

(c) $\sum F_x = 0$ gives $E_\text{h} = 0$. $\sum F_y = 0$ gives $T - E_\text{v} - w_{\text{arm}} - w = 0$, so

$$E_\text{v} = T - w_{\text{arm}} - w = 569\text{ N} - (2.16\text{ kg})(9.80\text{ m/s}^2) - (7.50\text{ kg})(9.80\text{ m/s}^2) = 474\text{ N}$$

Since we calculate E_v to be positive, we correctly assumed that it was downward when we drew the free-body diagram.

(d) The weight and the pull of the biceps are both always vertical in this situation, so the factor $\cos\theta$ divides out of the $\sum\tau = 0$ equation in part (b). Therefore the force T stays the same as she raises her arm.

EVALUATE: The biceps force must be much greater than the weight of the forearm and the weight in her hand because it has such a small lever arm compared to those two forces.

11.59. **IDENTIFY:** The rod is held in position, so the forces and torques on it must balance.

SET UP: Start with a free-body diagram of the rod, as in Fig. 11.59. Apply $\sum\tau_z = 0$, $\sum F_x = 0$, and $\sum F_y = 0$. The target variable is the angle β in the figure.

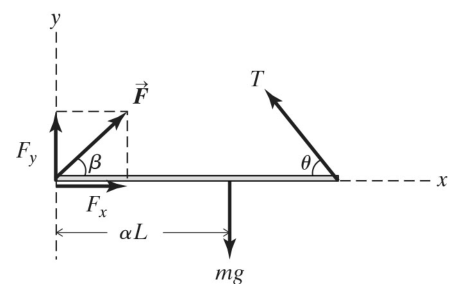

Figure 11.59

EXECUTE: **(a)** If we can find the components F_x and F_y of the hinge force $\vec{F}$, we can use them to find β. Taking torques about the right end of the rod gives $F_y L = mg(L - \alpha L) = mgL(1-\alpha)$, which gives

$F_y = mg(1-\alpha)$ (Eq. 1)

$\sum F_x = 0$: $F_x = T\cos\theta$ (Eq. 2)

$\sum\tau_z = 0$ about the hinge: $TL\sin\theta = mg\alpha L$ (Eq. 3)

Dividing Eq. 3 by Eq. 2 gives $\dfrac{TL\sin\theta}{T\cos\theta} = \dfrac{mg\alpha L}{F_x}$, which gives $F_x = \dfrac{mg\alpha}{\tan\theta}$. Now use this result and Eq. 1 to find β. $\tan\beta = \dfrac{F_y}{F_x} = \dfrac{mg(1-\alpha)}{\dfrac{mg\alpha}{\tan\theta}} = \left(\dfrac{1}{\alpha} - 1\right)\tan\theta$, so $\beta = \arctan\left(\dfrac{1}{\alpha} - 1\right)$.

(b) If $\beta = \theta$ we get $\tan\beta = \left(\dfrac{1}{\alpha} - 1\right)\tan\theta = \tan\theta$, so $\alpha = ½$.

(c) If $\alpha = 1$, we get $\tan\beta = \left(\dfrac{1}{\alpha} - 1\right)\tan\theta = 0$, so $\beta = 0$.

EVALUATE: In part (c), if $\beta = 0$ then $F_y = 0$, so all the weight of m is supported by T_y. Taking torques about the hinge gives $TL\sin\theta - mgL = 0$, so $T\sin\theta = mg$, which agrees with our answer with $\beta = 0$.

11.60. **IDENTIFY:** The rod is held fixed so it is in equilibrium. Therefore the forces and torques on it must balance.

SET UP: Apply $\sum\tau_z = 0$, $\sum F_x = 0$, and $\sum F_y = 0$. The target variable is the friction force f at the wall and the maximum angle θ for which slipping will not occur. Fig. 11.60 shows a free-body diagram of the rod.

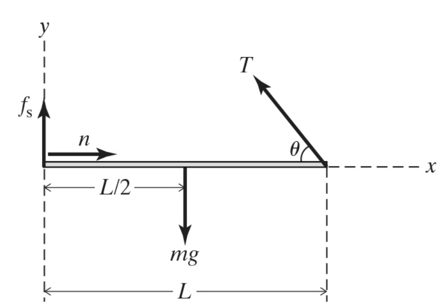

Figure 11.60

EXECUTE: **(a)** Using $\sum\tau_z = 0$ about the right end gives $fL = mg\dfrac{L}{2}$, so $f = \dfrac{mg}{2}$.

(b) $\sum F_x = 0$: $n = T\cos\theta$

$\sum F_y = 0$: $T\sin\theta + f = mg$. Using $f = \dfrac{mg}{2}$ and simplifying gives $T\sin\theta = mg - f = mg - \dfrac{mg}{2} = \dfrac{mg}{2}$,

so $T = \dfrac{mg}{2\sin\theta}$. Using this result, we find n to be $n = T\cos\theta = \left(\dfrac{mg}{2\sin\theta}\right)\cos\theta = \dfrac{mg}{2\tan\theta}$. At the maximum angle θ the rod is just ready to slip, so static friction is at its maximum value of $f_{\max} = \mu_s n$.

Combining this with our results that $f = \dfrac{mg}{2}$ and $n = \dfrac{mg}{2\tan\theta}$, we have $f = \dfrac{mg}{2} = \mu_s n = \dfrac{\mu_s mg}{2\tan\theta}$, which gives $\tan\theta = \mu_s$, so $\theta = \arctan\mu_s$.

EVALUATE: Check in some special cases. As $\theta \to 90°$, $\tan\theta \to \infty$ so $\mu_s \to \infty$. This is reasonable because the normal force $n = \dfrac{mg}{2\tan\theta} \to 0$, so we would need an extremely large μ_s (that is, an extremely rough wall) to hold up the rod. As $\theta \to 0$, $T = \dfrac{mg}{2\sin\theta} \to \infty$. This means that the normal force would get extremely large, so we would need a very small coefficient of friction to hold up the rod. Our results are reasonable.

11.61. **IDENTIFY:** Apply $\sum\tau_z = 0$ to the beam.

SET UP: The free-body diagram for the beam is given in Figure 11.61.

EXECUTE: $\sum\tau_z = 0$, axis at hinge, gives $T(6.0\text{ m})(\sin 40°) - (6490\text{ N})(3.75\text{ m})(\cos 30°) = 0$ and $T = 5500\text{ N}$.

EVALUATE: The tension in the cable is less than the weight of the beam. $T\sin 40°$ is the component of T that is perpendicular to the beam.

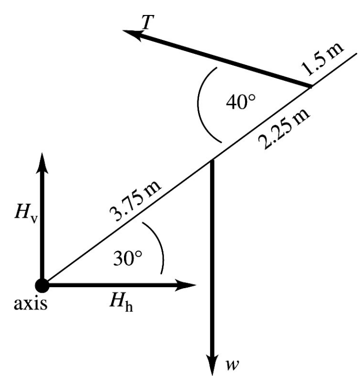

Figure 11.61

11.62. **IDENTIFY:** Apply the first and second conditions of equilibrium to the drawbridge.

SET UP: The free-body diagram for the drawbridge is given in Figure 11.62. H_v and H_h are the components of the force the hinge exerts on the bridge. In part (c), apply $\sum\tau_z = I\alpha$ to the rotating bridge and in part (d) apply energy conservation to the bridge.

EXECUTE: **(a)** $\sum\tau_z = 0$ with the axis at the hinge gives $-w(7.0\text{ m})(\cos 37°) + T(3.5\text{ m})(\sin 37°) = 0$ and $T = 2w\dfrac{\cos 37°}{\sin 37°} = 2\dfrac{(45{,}000\text{ N})}{\tan 37°} = 1.19\times 10^5\text{ N}$.

(b) $\sum F_x = 0$ gives $H_h = T = 1.19\times 10^5\text{ N}$. $\sum F_y = 0$ gives $H_v = w = 4.50\times 10^4\text{ N}$.

$H=\sqrt{H_h^2+H_v^2}=1.27\times10^5$ N. $\tan\theta=\dfrac{H_v}{H_h}$ and $\theta=20.7°$. The hinge force has magnitude 1.27×10^5 N and is directed at 20.7° above the horizontal.

(c) We can treat the bridge as a uniform bar rotating around one end, so $I=1/3\,mL^2$. $\sum\tau_z=I\alpha_z$ gives $mg(L/2)\cos37°=1/3\ mL^2\alpha$. Solving for α gives $\alpha=\dfrac{3g\cos37°}{2L}=\dfrac{3(9.80\text{ m/s}^2)\cos37°}{2(14.0\text{ m})}=0.839\text{ rad/s}^2$.

(d) Energy conservation gives $U_1=K_2$, giving $mgh=1/2\ I\omega^2=(1/2)(1/3\ mL^2)\omega^2$. Trigonometry gives $h=L/2\ \sin37°$. Canceling *m*, the energy conservation equation gives $g(L/2)\sin37°=(1/6)L^2\omega^2$. Solving for ω gives $\omega=\sqrt{\dfrac{3g\sin37°}{L}}=\sqrt{\dfrac{3(9.80\text{ m/s}^2)\sin37°}{14.0\text{ m}}}=1.12$ rad/s.

EVALUATE: The hinge force is not directed along the bridge. If it were, it would have zero torque for an axis at the center of gravity of the bridge and for that axis the tension in the cable would produce a single, unbalanced torque.

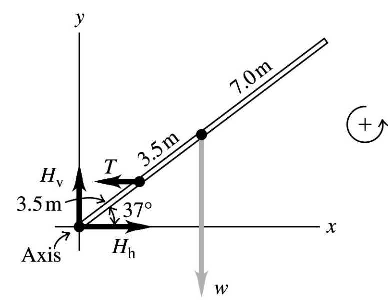

Figure 11.62

11.63. IDENTIFY: The amount the tendon stretches depends on Young's modulus for the tendon material. The foot is in rotational equilibrium, so the torques on it balance.

SET UP: $Y=\dfrac{F_T/A}{\Delta l/l_0}$. The foot is in rotational equilibrium, so $\sum\tau_z=0$.

EXECUTE: (a) The free-body diagram for the foot is given in Figure 11.63. *T* is the tension in the tendon and *A* is the force exerted on the foot by the ankle. $n=(75\text{ kg})g$, the weight of the person.

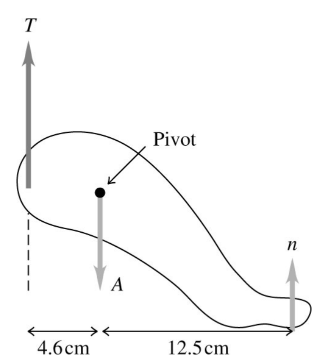

Figure 11.63

(b) Apply $\sum\tau_z=0$, letting counterclockwise torques be positive and with the pivot at the ankle: $T(4.6\text{ cm})-n(12.5\text{ cm})=0$. $T=\left(\dfrac{12.5\text{ cm}}{4.6\text{ cm}}\right)(75\text{ kg})(9.80\text{ m/s}^2)=2000$ N, which is 2.72 times his weight.

(c) The foot pulls downward on the tendon with a force of 2000 N.

$$\Delta l = \left(\frac{F_\text{T}}{YA}\right) l_0 = \frac{2000\text{ N}}{(1470\times 10^6\text{ Pa})(78\times 10^{-6}\text{ m}^2)}(25\text{ cm}) = 4.4\text{ mm}.$$

EVALUATE: The tension is quite large, but the Achilles tendon stretches about 4.4 mm, which is only about 1/6 of an inch, so it must be a strong tendon.

11.64 **IDENTIFY:** Apply $\sum \tau_z = 0$ to the beam.

SET UP: The center of mass of the beam is 1.0 m from the suspension point.

EXECUTE: **(a)** Taking torques about the suspension point,
$w(4.00\text{ m})\sin 30° + (140.0\text{ N})(1.00\text{ m})\sin 30° = (100\text{ N})(2.00\text{ m})\sin 30°.$

The common factor of $\sin 30°$ divides out, from which $w = 15.0$ N.

(b) In this case, a common factor of $\sin 45°$ would be factored out, and the result would be the same.

EVALUATE: All the forces are vertical, so the moments are all horizontal and all contain the factor $\sin\theta$, where θ is the angle the beam makes with the horizontal.

11.65. **IDENTIFY:** The rod is held in place, so the torques on it must balance. The added weight of the object causes the wire to stretch slightly, so we need to use tensile stress and strain.

SET UP: We use $\sum \tau_z = 0$ and $Y = \dfrac{F_\perp}{A}\dfrac{\ell_0}{\Delta\ell}$. The target variable is the distance the aluminum wire stretches due to the added weight.

EXECUTE: **(a)** A little trigonometry gives cos 30.0° = (1.20 m)/L_wire, so L_wire = 1.39 m.

(b) Fig. 11.65 shows a free-body diagram of the rod with the object attached. The stretching of the wire is due to the *increase* in tension due to the addition of the 90.0-kg object. Therefore in Fig. 11.65 we do not use the weight *mg* of the rod when computing the torque about the hinge.

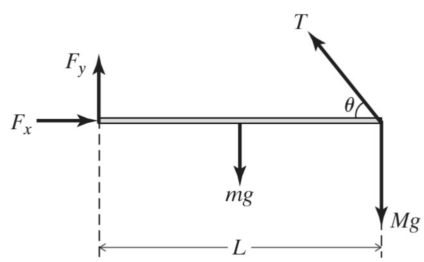

Figure 11.65

$\sum \tau_z = 0:\ TL\sin\theta = MgL \quad\rightarrow\quad T = \dfrac{mg}{\sin\theta} = \dfrac{(90.0\text{ kg})(9.80\text{ m/s}^2)}{\sin 30.0°} = 1764\text{ N}.$ Now use Young's modulus for aluminum (from Table 11.1) to find the increase in the length of the wire. Solving

$Y = \dfrac{F_\perp}{A}\dfrac{\ell_0}{\Delta\ell}$ for $\Delta\ell$ gives $\Delta\ell = \dfrac{F_\perp \ell_0}{AY} = \dfrac{F_\perp \ell_0}{\pi r^2 Y} = \dfrac{(1764\text{ N})(1.39\text{ m})}{\pi(0.00250\text{ m})^2(7.0\times 10^{10}\text{ Pa})} = 1.8\times 10^{-3}\text{ m} = 1.8\text{ mm}.$

EVALUATE: Since $\Delta\ell << \ell_0$ we are justified in treating the rod as being horizontal after object is added. Our result is reasonable since most materials stretch very little under ordinary circumstances.

11.66. **IDENTIFY:** Apply $\sum \vec{F} = 0$ to each object, including the point where *D*, *C*, and *B* are joined. Apply $\sum \tau_z = 0$ to the rod.

SET UP: To find T_C and T_D, use a coordinate system with axes parallel to the cords.

EXECUTE: *A* and *B* are straightforward, the tensions being the weights suspended:
$T_A = (0.0360\text{ kg})(9.80\text{ m/s}^2) = 0.353\text{ N}$ and $T_B = (0.0240\text{ kg} + 0.0360\text{ kg})(9.80\text{ m/s}^2) = 0.588\text{ N}.$

Applying $\sum F_x = 0$ and $\sum F_y = 0$ to the point where the cords are joined, $T_C = T_B \cos 36.9° = 0.470$ N and $T_D = T_B \cos 53.1° = 0.353$ N. To find T_E, take torques about the point where string F is attached. $T_E(1.00 \text{ m}) = T_D \sin 36.9°(0.800 \text{ m}) + T_C \sin 53.1°(0.200 \text{ m}) + (0.120 \text{ kg})(9.80 \text{ m/s}^2)(0.500 \text{ m})$ and $T_E = 0.833$ N.

T_F may be found similarly, or from the fact that $T_E + T_F$ must be the total weight of the ornament. $(0.180\text{kg})(9.80\text{m/s}^2) = 1.76$ N, from which $T_F = 0.931$ N.

EVALUATE: The vertical line through the spheres is closer to *F* than to *E*, so we expect $T_F > T_E$, and this is indeed the case.

11.67. IDENTIFY: The torques must balance since the person is not rotating.

SET UP: Figure 11.67a shows the distances and angles. $\theta + \phi = 90°$. $\theta = 56.3°$ and $\phi = 33.7°$. The distances x_1 and x_2 are $x_1 = (90 \text{ cm})\cos\theta = 50.0$ cm and $x_2 = (135 \text{ cm})\cos\phi = 112$ cm. The free-body diagram for the person is given in Figure 11.67b. $w_1 = 277$ N is the weight of his feet and legs, and $w_t = 473$ N is the weight of his trunk. n_f and f_f are the total normal and friction forces exerted on his feet and n_h and f_h are those forces on his hands. The free-body diagram for his legs is given in Figure 11.67c. *F* is the force exerted on his legs by his hip joints. For balance, $\sum \tau_z = 0$.

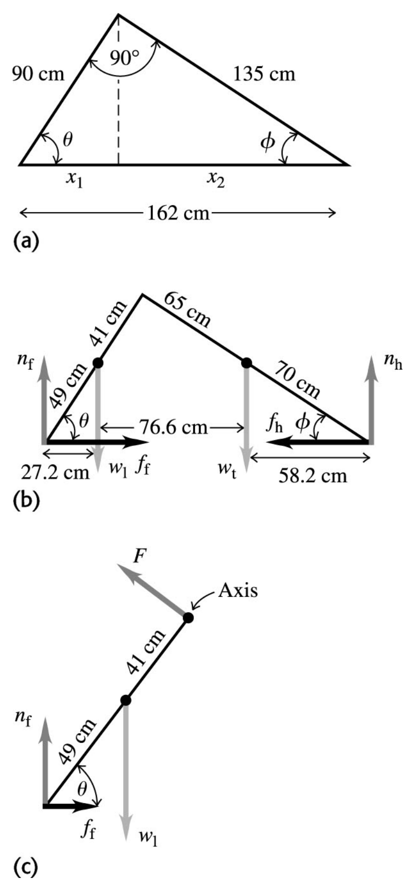

Figure 11.67

EXECUTE: **(a)** Consider the force diagram of Figure 11.67b. $\sum \tau_z = 0$ with the pivot at his feet and counterclockwise torques positive gives $n_h(162 \text{ cm}) - (277 \text{ N})(27.2 \text{ cm}) - (473 \text{ N})(103.8 \text{ cm}) = 0$.

$n_{\text{h}} = 350\text{ N},$ so there is a normal force of 175 N at each hand. $n_{\text{f}} + n_{\text{h}} - w_{\text{l}} - w_{\text{t}} = 0$ so $n_{\text{f}} = w_{\text{l}} + w_{\text{t}} - n_{\text{h}} = 750\text{ N} - 350\text{ N} = 400\text{ N},$ so there is a normal force of 200 N at each foot.

(b) Consider the force diagram of Figure 11.67c. $\sum \tau_z = 0$ with the pivot at his hips and counterclockwise torques positive gives $f_{\text{f}}(74.9\text{ cm}) + w_{\text{l}}(22.8\text{ cm}) - n_{\text{f}}(50.0\text{ cm}) = 0.$

$f_{\text{f}} = \dfrac{(400\text{ N})(50.0\text{ cm}) - (277\text{ N})(22.8\text{ cm})}{74.9\text{ cm}} = 182.7\text{ N}.$ There is a friction force of 91 N at each foot.

$\sum F_x = 0$ in Figure 11.67b gives $f_{\text{h}} = f_{\text{f}},$ so there is a friction force of 91 N at each hand.

EVALUATE: In this position the normal forces at his feet and at his hands don't differ very much.

11.68. IDENTIFY: The ball is going in a circle, so it obeys Newton's second law. Since the brass wire stretches slightly, we must use Young's modulus and stress and strain.

SET UP: We know the fractional change in the wire's length. The target variable is the speed of the ball at the bottom of its circular path. Apply $\sum F = m\dfrac{v^2}{R}$ and then use $Y = \dfrac{F_\perp}{A}\dfrac{\ell_0}{\Delta\ell}.$

EXECUTE: At the lowest point, the ball's acceleration is upward. The fractional change in length of the wire is only 2.0×10^{-5}, so we can use ℓ_0 for the radius of the circle. $\sum F = m\dfrac{v^2}{R}$ gives $T - mg = \dfrac{mv^2}{\ell_0},$ so $T = mg + \dfrac{mv^2}{\ell_0}.$ Now use $Y = \dfrac{F_\perp}{A}\dfrac{\ell_0}{\Delta\ell},$ where $F_\perp$ is the tension in the wire. Doing so gives

$Y = \dfrac{mg + \dfrac{mv^2}{\ell_0}}{A\left(\dfrac{\Delta\ell}{\ell_0}\right)}.$ Solving for v gives $v = \sqrt{\dfrac{\ell_0}{m}\left[YA\left(\dfrac{\Delta\ell}{\ell_0}\right) - mg\right]}.$ Using $\dfrac{\Delta\ell}{\ell_0} = 2.0\times10^{-5},$ $\ell_0 = 1.40$ m, A = 6.00 mm^2 = 6.00×10^{-6} m^2, m = 0.0800 kg, and $Y = 9.0\times10^{10}$ Pa for brass (from Table 11.1 in the text), we have v = 13.2 m/s.

EVALUATE: A speed of 13.2 m/s is about 30 mph, yet this speed would only produce a fractional length change of 0.000020. The fractional length change would be even less at the top since the ball is moving slower up there than at the bottom.

11.69. IDENTIFY: Apply the equilibrium conditions to the crate. When the crate is on the verge of tipping it touches the floor only at its lower left-hand corner and the normal force acts at this point. The minimum coefficient of static friction is given by the equation $f_{\text{s}} = \mu_{\text{s}} n.$

SET UP: The free-body diagram for the crate when it is ready to tip is given in Figure 11.69.

EXECUTE: **(a)** $\sum \tau_z = 0$ gives $P(1.50\text{ m})\sin 53.0° - w(1.10\text{ m}) = 0.$

$$P = w\left(\frac{1.10\text{ m}}{[1.50\text{ m}][\sin 53.0°]}\right) = 1.15\times10^3\text{ N}$$

(b) $\sum F_y = 0$ gives $n - w - P\cos 53.0° = 0.$

$$n = w + P\cos 53.0° = 1250\text{ N} + (1.15\times10^3\text{ N})\cos 53° = 1.94\times10^3\text{ N}$$

(c) $\sum F_y = 0$ gives $f_{\text{s}} = P\sin 53.0° = (1.15\times10^3\text{ N})\sin 53.0° = 918\text{ N}.$

(d) $\mu_{\text{s}} = \dfrac{f_{\text{s}}}{n} = \dfrac{918\text{ N}}{1.94\times10^3\text{ N}} = 0.473$

EVALUATE: The normal force is greater than the weight because P has a downward component.

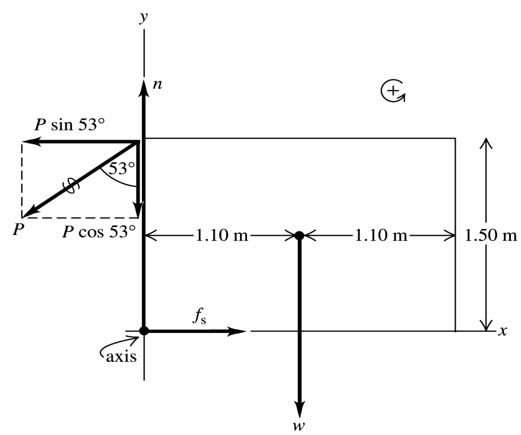

Figure 11.69

11.70. **IDENTIFY:** Apply $\sum \tau_z = 0$ to the meterstick.

SET UP: The wall exerts an upward static friction force *f* and a horizontal normal force *n* on the stick. Denote the length of the stick by *l*. $f = \mu_s n$.

EXECUTE: **(a)** Taking torques about the right end of the stick, the friction force is half the weight of the stick, $f = w/2$. Taking torques about the point where the cord is attached to the wall (the tension in the cord and the friction force exert no torque about this point), and noting that the moment arm of the normal force is $l \tan\theta$, $n \tan\theta = w/2$. Then, $(f/n) = \tan\theta < 0.40$, so $\theta < \arctan(0.40) = 22°$.

(b) Taking torques as in part (a), $fl = w\dfrac{l}{2} + w(l - x)$ and $nl \tan\theta = w\dfrac{l}{2} + wx$. In terms of the coefficient of friction μ_s, $\mu_s > \dfrac{f}{n} = \dfrac{l/2 + (l - x)}{l/2 + x}\tan\theta = \dfrac{3l - 2x}{l + 2x}\tan\theta$. Solving for *x*, $x > \dfrac{l}{2}\dfrac{3\tan\theta - \mu_s}{\mu_s + \tan\theta} = 30.2$ cm.

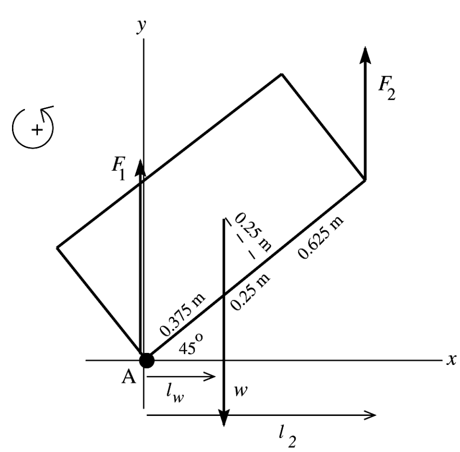
(c) In the above expression, setting $x = 10$ cm and $l = 100$ cm and solving for μ_s gives

$$\mu_s > \frac{(3 - 20/l)\tan\theta}{1 + 20/l} = 0.625.$$

EVALUATE: For $\theta = 15°$ and without the block suspended from the stick, a value of $\mu_s \geq 0.268$ is required to prevent slipping. Hanging the block from the stick increases the value of μ_s that is required.

11.71. **IDENTIFY:** Apply the first and second conditions of equilibrium to the crate.

SET UP: The free-body diagram for the crate is given in Figure 11.71.



$l_w = (0.375 \text{ m})\cos 45°$

$l_2 = (1.25 \text{ m})\cos 45°$

Let $\vec{F}_1$ and $\vec{F}_2$ be the vertical forces exerted by you and your friend. Take the origin at the lower left-hand corner of the crate (point A).

Figure 11.71

EXECUTE: $\sum F_y = ma_y$ gives $F_1 + F_2 - w = 0$

$F_1 + F_2 = w = (200\text{ kg})(9.80\text{ m/s}^2) = 1960\text{ N}$

$\sum \tau_A = 0$ gives $F_2 l_2 - w l_w = 0$

$$F_2 = w\left(\frac{l_w}{l_2}\right) = 1960\text{ N}\left(\frac{0.375\text{ m}\cos 45^\circ}{1.25\text{ m}\cos 45^\circ}\right) = 590\text{ N}$$

Then $F_1 = w - F_2 = 1960\text{ N} - 590\text{ N} = 1370\text{ N}.$

EVALUATE: The person below (you) applies a force of 1370 N. The person above (your friend) applies a force of 590 N. It is better to be the person above. As the sketch shows, the moment arm for $\vec{F}_1$ is less than for $\vec{F}_2$, so must have $F_1 > F_2$ to compensate.

11.72. **IDENTIFY:** The beam is at rest, so the forces and torques on it must all balance.

SET UP: The cables could point inward toward each other or outward away from each other. We shall assume they point away from each other. Call *d* the distance of the center of gravity from the left end, call *w* the weight of the beam, and call *T* the tension in the right-hand cable. $\Sigma F_x = 0$, $\Sigma F_y = 0$, $\sum \tau_z = 0$.

EXECUTE: $\Sigma F_x = 0$ gives (620 N)(sin30.0°) – *T*(sin50.0°) = 0, so *T* = 404.68 N.

$\Sigma F_y = 0$ gives (620 N)(cos30.0°) + (404.68 N)(cos50.0°) – *w* = 0, so *w* = 797 N.

Taking torques about the left end, $\sum \tau_z = 0$ gives (404.68 N)(cos50.0°)(4.00 m) – (797 N)*d* = 0, so *d* = 1.31 m from the left end of the beam, or 2.69 m from the right end.

EVALUATE: The center of gravity is closer to the cable having the greater tension. The answer would be no different if we assumed that the cables pointed inward toward each other.

11.73. **IDENTIFY:** Apply $\sum \tau_z = 0$ to the forearm.

SET UP: The free-body diagram for the forearm is given in Figure 11.10 in the textbook.

EXECUTE: **(a)** $\sum \tau_z = 0$, axis at elbow gives

$$wL - (T\sin\theta)D = 0.\ \sin\theta = \frac{h}{\sqrt{h^2 + D^2}} \text{ so } w = T\frac{hD}{L\sqrt{h^2 + D^2}}.$$

$$w_{\max} = T_{\max}\frac{hD}{L\sqrt{h^2 + D^2}}.$$

(b) $\dfrac{dw_{\max}}{dD} = \dfrac{T_{\max}h}{L\sqrt{h^2 + D^2}}\left(1 - \dfrac{D^2}{h^2 + D^2}\right)$; the derivative is positive.

EVALUATE: **(c)** The result of part (b) shows that $w_{\max}$ increases when *D* increases, since the derivative is positive. $w_{\max}$ is larger for a chimp since *D* is larger.

11.72. **IDENTIFY:** Apply $\sum \tau_z = 0$ to the wheel.

SET UP: Take torques about the upper corner of the curb.

EXECUTE: The force $\vec{F}$ acts at a perpendicular distance $R - h$ and the weight acts at a perpendicular distance $\sqrt{R^2 - (R-h)^2} = \sqrt{2Rh - h^2}$. Setting the torques equal for the minimum necessary force,

$$F = mg\frac{\sqrt{2Rh - h^2}}{R - h}.$$

(b) The torque due to gravity is the same, but the force $\vec{F}$ acts at a perpendicular distance $2R - h$, so the minimum force is $(mg)\sqrt{2Rh - h^2}/(2R - h)$.

EVALUATE: **(c)** Less force is required when the force is applied at the top of the wheel, since in this case $\vec{F}$ has a larger moment arm.

11.75. IDENTIFY: Apply the first and second conditions of equilibrium to the gate.

SET UP: The free-body diagram for the gate is given in Figure 11.75.

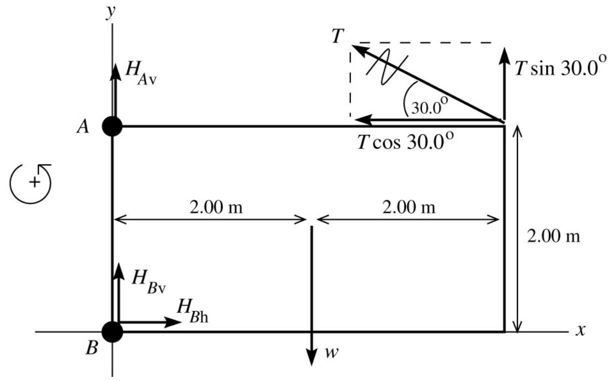


Figure 11.75

Use coordinates with the origin at B. Let $\vec{H}_A$ and $\vec{H}_B$ be the forces exerted by the hinges at A and B. The problem states that $\vec{H}_A$ has no horizontal component. Replace the tension $\vec{T}$ by its horizontal and vertical components.

EXECUTE: (a) $\sum \tau_B = 0$ gives $+(T\sin 30.0^{\circ})(4.00\text{ m}) + (T\cos 30.0^{\circ})(2.00\text{ m}) - w(2.00\text{ m}) = 0$

$T(2\sin 30.0^{\circ} + \cos 30.0^{\circ}) = w$

$$T = \frac{w}{2\sin 30.0^{\circ} + \cos 30.0^{\circ}} = \frac{700\text{ N}}{2\sin 30.0^{\circ} + \cos 30.0^{\circ}} = 375\text{ N}.$$

(b) $\sum F_x = ma_x$ says $H_{Bh} - T\cos 30.0^{\circ} = 0$

$H_{Bh} = T\cos 30.0^{\circ} = (375\text{ N})\cos 30.0^{\circ} = 325\text{ N}.$

(c) $\sum F_y = ma_y$ says $H_{Av} + H_{Bv} + T\sin 30.0^{\circ} - w = 0$

$H_{Av} + H_{Bv} = w - T\sin 30.0^{\circ} = 700\text{ N} - (375\text{ N})\sin 30.0^{\circ} = 512\text{ N}.$

EVALUATE: T has a horizontal component to the left so H_{Bh} must be to the right, as these are the only two horizontal forces. Note that we cannot determine H_{Av} and H_{Bv} separately, only their sum.

11.76. IDENTIFY: Use $x_{cm} = \dfrac{m_1x_1 + m_2x_2 + m_3x_3 + \ldots}{m_1 + m_2 + m_3 + \ldots}$ to locate the x-coordinate of the center of gravity of the block combinations.

SET UP: The center of mass and the center of gravity are the same point. For two identical blocks, the center of gravity is midway between the center of the two blocks.

EXECUTE: (a) The center of gravity of the top block can be as far out as the edge of the lower block. The center of gravity of this combination is then $3L/4$ to the left of the right edge of the upper block, so the overhang is $3L/4$.

(b) Take the two-block combination from part (a), and place it on top of the third block such that the overhang of $3L/4$ is from the right edge of the third block; that is, the center of gravity of the first two blocks is above the right edge of the third block. The center of mass of the three-block combination, measured from the right end of the bottom block, is $-L/6$ and so the largest possible overhang is $(3L/4) + (L/6) = 11L/12$. Similarly, placing this three-block combination with its center of gravity over the right edge of the fourth block allows an extra overhang of $L/8$, for a total of $25L/24$.

(c) As the result of part (b) shows, with only four blocks, the overhang can be larger than the length of a single block.

EVALUATE: The sequence of maximum overhangs is $\dfrac{18L}{24}, \dfrac{22L}{24}, \dfrac{25L}{24}, \ldots$. The increase of overhang when one more block is added is decreasing.

11.77. **IDENTIFY:** Apply the first and second conditions of equilibrium, first to both marbles considered as a composite object and then to the bottom marble.

(a) SET UP: The forces on each marble are shown in Figure 11.77.

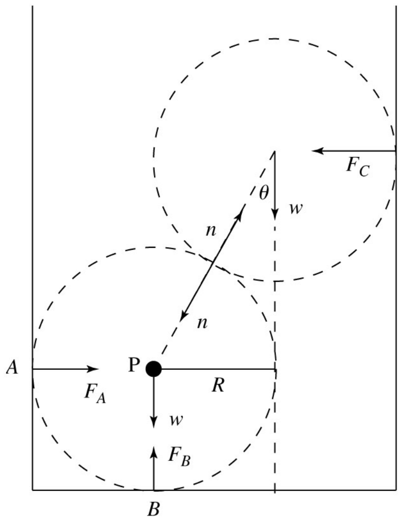

Figure 11.77

EXECUTE:

$F_B = 2w = 1.47$ N

$\sin\theta = R/2R$ so $\theta = 30°$

$\sum\tau_z = 0$, axis at P

$F_C(2R\cos\theta) - wR = 0$

$$F_C = \frac{mg}{2\cos 30°} = 0.424 \text{ N}$$

$F_A = F_C = 0.424$ N

(b) Consider the forces on the bottom marble. The horizontal forces must sum to zero, so $F_A = n\sin\theta$.

$$n = \frac{F_A}{\sin 30°} = 0.848 \text{ N}$$

Could use instead that the vertical forces sum to zero

$F_B - mg - n\cos\theta = 0$

$$n = \frac{F_B - mg}{\cos 30°} = 0.848 \text{ N, which checks.}$$

EVALUATE: If we consider each marble separately, the line of action of every force passes through the center of the marble so there is clearly no torque about that point for each marble. We can use the results we obtained to show that $\sum F_x = 0$ and $\sum F_y = 0$ for the top marble.

11.78. **IDENTIFY:** Apply $\sum\tau_z = 0$ to the right-hand beam.

SET UP: Use the hinge as the axis of rotation and take counterclockwise rotation as positive. If F_{wire} is the tension in each wire and $w = 260$ N is the weight of each beam, $2F_{\text{wire}} - 2w = 0$ and $F_{\text{wire}} = w$. Let L be the length of each beam.

EXECUTE: **(a)** $\sum\tau_z = 0$ gives $F_{\text{wire}}L\sin\frac{\theta}{2} - F_c\frac{L}{2}\cos\frac{\theta}{2} - w\frac{L}{2}\sin\frac{\theta}{2} = 0$, where θ is the angle between the beams and F_c is the force exerted by the cross bar. The length drops out, and all other quantities except F_c are known, so $F_c = \dfrac{F_{\text{wire}}\sin(\theta/2) - \frac{1}{2}w\sin(\theta/2)}{\frac{1}{2}\cos(\theta/2)} = (2F_{\text{wire}} - w)\tan\dfrac{\theta}{2}$. Therefore

$$F_c = (260 \text{ N})\tan\frac{53°}{2} = 130 \text{ N}.$$

(b) The crossbar is under compression, as can be seen by imagining the behavior of the two beams if the crossbar were removed. It is the crossbar that holds them apart.

(c) The upward pull of the wire on each beam is balanced by the downward pull of gravity, due to the symmetry of the arrangement. The hinge therefore exerts no vertical force. It must, however, balance the outward push of the crossbar. The hinge exerts a force 130 N horizontally to the left for the right-hand beam and 130 N to the right for the left-hand beam. Again, it's instructive to visualize what the beams would do if the hinge were removed.

EVALUATE: The force exerted on each beam increases as θ increases and exceeds the weight of the beam for $\theta \geq 90°$.

11.79. **IDENTIFY:** Apply the first and second conditions of equilibrium to the bale.

(a) SET UP: Find the angle where the bale starts to tip. When it starts to tip only the lower left-hand corner of the bale makes contact with the conveyor belt. Therefore the line of action of the normal force n passes through the left-hand edge of the bale. Consider $\Sigma\tau_z = 0$ with point A at the lower left-hand corner. Then $\tau_n = 0$ and $\tau_f = 0$, so it must be that $\tau_{mg} = 0$ also. This means that the line of action of the gravity must pass through point A. Thus the free-body diagram must be as shown in Figure 11.79a.

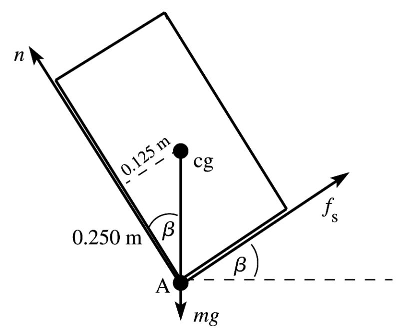

Figure 11.79a

EXECUTE: $\tan\beta = \dfrac{0.125\text{ m}}{0.250\text{ m}}$

$\beta = 27°$, angle where tips

SET UP: At the angle where the bale is ready to slip down the incline f_s has its maximum possible value, $f_s = \mu_s n$. The free-body diagram for the bale, with the origin of coordinates at the cg is given in Figure 11.79b.

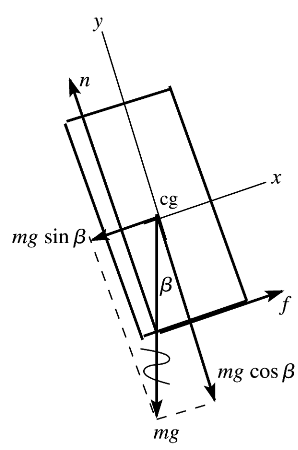

Figure 11.79b

EXECUTE:

$\sum F_y = ma_y$

$n - mg\cos\beta = 0$

$n = mg\cos\beta$

$f_s = \mu_s mg\cos\beta$

(f_s has maximum value when bale ready to slip)

$\sum F_x = ma_x$

$f_s - mg\sin\beta = 0$

$\mu_s mg\cos\beta - mg\sin\beta = 0$

$\tan\beta = \mu_s$

$\mu_s = 0.60$ gives that $\beta = 31°$

$\beta = 27°$ to tip; $\beta = 31°$ to slip, so tips first

(b) The magnitude of the friction force didn't enter into the calculation of the tipping angle; still tips at $\beta = 27°$. For $\mu_s = 0.40$ slips at $\beta = \arctan(0.40) = 22°$.

Now the bale will start to slide down the incline before it tips.

EVALUATE: With a smaller μ_s the slope angle β where the bale slips is smaller.

11.80. **IDENTIFY:** Apply $\sum \tau_z = 0$ to the slab.

SET UP: The free-body diagram is given in Figure 11.80a. $\tan\beta = \dfrac{3.75 \text{ m}}{1.75 \text{ m}}$ so $\beta = 65.0°$.

$20.0° + \beta + \alpha = 90°$ so $\alpha = 5.0°$. The distance from the axis to the center of the block is

$$\sqrt{\left(\frac{3.75 \text{ m}}{2}\right)^2 + \left(\frac{1.75 \text{ m}}{2}\right)^2} = 2.07 \text{ m}.$$

EXECUTE: **(a)** $w(2.07 \text{ m})\sin 5.0° - T(3.75 \text{ m})\sin 52.0° = 0$. $T = 0.061w$. Each worker must exert a force of $0.012w$, where w is the weight of the slab.

(b) As θ increases, the moment arm for w decreases and the moment arm for T increases, so the worker needs to exert less force.

(c) $T \to 0$ when w passes through the support point. This situation is sketched in Figure 11.80b. $\tan\theta = \dfrac{(1.75 \text{ m})/2}{(3.75 \text{ m})/2}$ and $\theta = 25.0°$. If θ exceeds this value the gravity torque causes the slab to tip over.

EVALUATE: The moment arm for T is much greater than the moment arm for w, so the force the workers apply is much less than the weight of the slab.

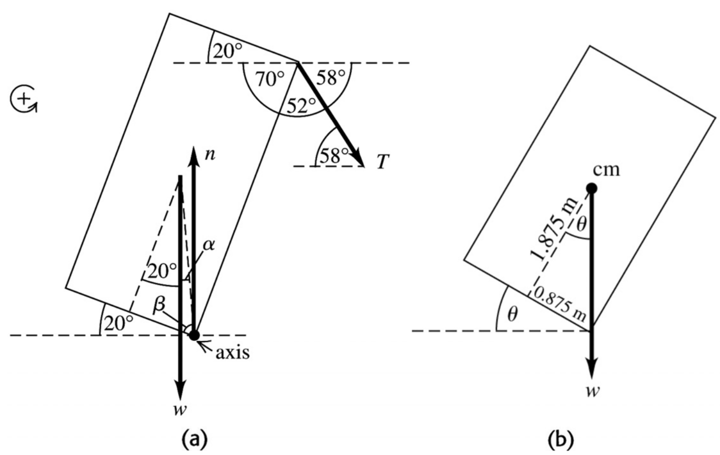

Figure 11.80

11.81. **IDENTIFY:** Apply the first and second conditions of equilibrium to the door.

(a) SET UP: The free-body diagram for the door is given in Figure 11.81.

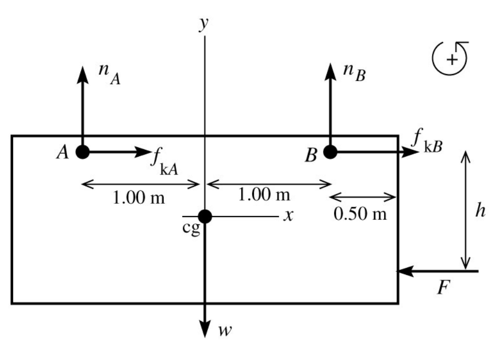

Figure 11.81

Take the origin of coordinates at the center of the door (at the cg). Let n_A, f_{kA}, n_B, and f_{kB} be the normal and friction forces exerted on the door at each wheel.

EXECUTE: $\sum F_y = ma_y$

$n_A + n_B - w = 0$

$n_A + n_B = w = 950\text{ N}$

$\sum F_x = ma_x$

$f_{kA} + f_{kB} - F = 0$

$F = f_{kA} + f_{kB}$

$f_{kA} = \mu_k n_A,\ \ f_{kB} = \mu_k n_B,$ so $F = \mu_k(n_A + n_B) = \mu_k w = (0.52)(950\text{ N}) = 494\text{ N}$

$\sum \tau_B = 0$

$n_B,\ f_{kA},$ and f_{kB} all have zero moment arms and hence zero torque about this point.

Thus $+w(1.00\text{ m}) - n_A(2.00\text{ m}) - F(h) = 0$

$$n_A = \frac{w(1.00\text{ m}) - F(h)}{2.00\text{ m}} = \frac{(950\text{ N})(1.00\text{ m}) - (494\text{ N})(1.60\text{ m})}{2.00\text{ m}} = 80\text{ N}$$

And then $n_B = 950\text{ N} - n_A = 950\text{ N} - 80\text{ N} = 870\text{ N}.$

(b) SET UP: If h is too large the torque of F will cause wheel A to leave the track. When wheel A just starts to lift off the track n_A and f_{kA} both go to zero.

EXECUTE: The equations in part (a) still apply.

$n_A + n_B - w = 0$ gives $n_B = w = 950\text{ N}$

Then $f_{kB} = \mu_k n_B = 0.52(950\text{ N}) = 494\text{ N}$

$F = f_{kA} + f_{kB} = 494\text{ N}$

$+w(1.00\text{ m}) - n_A(2.00\text{ m}) - F(h) = 0$

$$h = \frac{w(1.00\text{ m})}{F} = \frac{(950\text{ N})(1.00\text{ m})}{494\text{ N}} = 1.92\text{ m}$$

EVALUATE: The result in part (b) is larger than the value of h in part (a). Increasing h increases the clockwise torque about B due to F and therefore decreases the clockwise torque that n_A must apply.

11.82. IDENTIFY: Apply Newton's second law to the mass to find the tension in the wire. Then apply $Y = \dfrac{l_0 F_\perp}{A\Delta l}$ to the wire to find the elongation this tensile force produces.

(a) SET UP: Calculate the tension in the wire as the mass passes through the lowest point. The free-body diagram for the mass is given in Figure 11.82a.

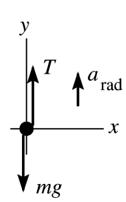

Figure 11.82a

The mass moves in an arc of a circle with radius $R = 0.70\text{ m}.$ It has acceleration $\vec{a}_{\text{rad}}$ directed in toward the center of the circle, so at this point $\vec{a}_{\text{rad}}$ is upward.

EXECUTE: $\sum F_y = ma_y$

$T - mg = mR\omega^2$ so that $T = m(g + R\omega^2).$

But ω must be in rad/s:

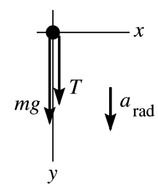
$\omega = (120\text{ rev/min})(2\pi\text{ rad/1 rev})(1\text{ min/60 s}) = 12.57\text{ rad/s}.$

Then $T = (12.0\text{ kg})\left[9.80\text{ m/s}^2 + (0.70\text{ m})(12.57\text{ rad/s})^2\right] = 1445\text{ N}.$

Now calculate the elongation Δl of the wire that this tensile force produces:

$Y = \dfrac{F_\perp l_0}{A\Delta l}$ so $\Delta l = \dfrac{F_\perp l_0}{YA} = \dfrac{(1445\text{ N})(0.70\text{ m})}{(7.0\times 10^{10}\text{ Pa})(0.014\times 10^{-4}\text{ m}^2)} = 0.0103\text{ m} = 1.0\text{ cm}.$

(b) SET UP: The acceleration $\vec{a}_{\text{rad}}$ is directed in toward the center of the circular path, and at this point in the motion this direction is downward. The free-body diagram is given in Figure 11.82b.



EXECUTE:

$\sum F_y = ma_y$

$mg + T = mR\omega^2$

$T = m(R\omega^2 - g)$

Figure 11.82b

$T = (12.0\text{ kg})\left[(0.70\text{ m})(12.57\text{ rad/s})^2 - 9.80\text{ m/s}^2\right] = 1210\text{ N}.$

$\Delta l = \dfrac{F_\perp l_0}{YA} = \dfrac{(1210\text{ N})(0.70\text{ m})}{(7.0\times 10^{10}\text{ Pa})(0.014\times 10^{-4}\text{ m}^2)} = 8.6\times 10^{-3}\text{ m} = 0.86\text{ cm}.$

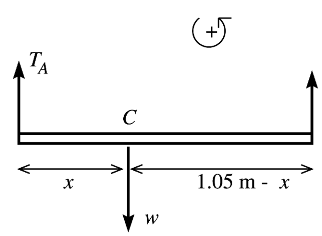
EVALUATE: At the lowest point T and w are in opposite directions and at the highest point they are in the same direction, so T is greater at the lowest point and the elongation is greatest there. The elongation is at most 1.4% of the length.

11.83. IDENTIFY: Use the second condition of equilibrium to relate the tension in the two wires to the distance w is from the left end. Use $\text{stress} = \dfrac{F_\perp}{A}$ and $Y = \dfrac{l_0 F_\perp}{A\Delta l}$ to relate the tension in each wire to its stress and strain.

(a) SET UP: $\text{stress} = F_\perp/A$, so equal stress implies T/A same for each wire.

$T_A/2.00\text{ mm}^2 = T_B/4.00\text{ mm}^2$ so $T_B = 2.00T_A$

The question is where along the rod to hang the weight in order to produce this relation between the tensions in the two wires. Let the weight be suspended at point C, a distance x to the right of wire A. The free-body diagram for the rod is given in Figure 11.83.



EXECUTE:

$\sum \tau_C = 0$

$+T_B(1.05\text{ m} - x) - T_A x = 0$

Figure 11.83

But $T_B = 2.00T_A$ so $2.00T_A(1.05\text{ m} - x) - T_A x = 0$

$2.10\text{ m} - 2.00x = x$ and $x = 2.10\text{ m}/3.00 = 0.70\text{ m}$ (measured from A).

(b) SET UP: $Y = \text{stress/strain}$ gives that $\text{strain} = \text{stress}/Y = F_\perp/AY$.

EXECUTE: Equal strain thus implies

$$\frac{T_A}{(2.00\text{ mm}^2)(1.80\times 10^{11}\text{ Pa})} = \frac{T_B}{(4.00\text{ mm}^2)(1.20\times 10^{11}\text{ Pa})}$$

$$T_B = \left(\frac{4.00}{2.00}\right)\left(\frac{1.20}{1.80}\right)T_A = 1.333T_A.$$

The $\sum \tau_C = 0$ equation still gives $T_B(1.05\text{ m} - x) - T_A x = 0.$

But now $T_B = 1.333T_A$ so $(1.333T_A)(1.05\text{ m} - x) - T_A x = 0.$

$1.40\text{ m} = 2.33x$ and $x = 1.40\text{ m}/2.33 = 0.60\text{ m}$ (measured from A).

EVALUATE: Wire B has twice the diameter so it takes twice the tension to produce the same stress. For equal stress the moment arm for T_B (0.35 m) is half that for T_A (0.70 m), since the torques must be equal. The smaller Y for B partially compensates for the larger area in determining the strain and for equal strain the moment arms are closer to being equal.

11.84. IDENTIFY: Apply $Y = \dfrac{l_0 F_\perp}{A\Delta l}$ and calculate Δl.

SET UP: When the ride is at rest the tension $F_\perp$ in the rod is the weight 1900 N of the car and occupants. When the ride is operating, the tension $F_\perp$ in the rod is obtained by applying $\sum \vec{F} = m\vec{a}$ to a car and its occupants. The free-body diagram is shown in Figure 11.84. The car travels in a circle of radius $r = l\sin\theta$, where l is the length of the rod and θ is the angle the rod makes with the vertical. For steel, $Y = 2.0\times10^{11}$ Pa. $\omega = 12.0\text{ rev/min} = 1.2566\text{ rad/s}$.

EXECUTE: (a) $\Delta l = \dfrac{l_0 F_\perp}{YA} = \dfrac{(15.0\text{ m})(1900\text{ N})}{(2.0\times10^{11}\text{ Pa})(8.00\times10^{-4}\text{ m}^2)} = 1.78\times10^{-4}\text{ m} = 0.18\text{ mm}$

(b) $\sum F_x = ma_x$ gives $F_\perp \sin\theta = mr\omega^2 = ml\sin\theta\omega^2$ and

$$F_\perp = ml\omega^2 = \left(\frac{1900\text{ N}}{9.80\text{ m/s}^2}\right)(15.0\text{ m})(1.2566\text{ rad/s})^2 = 4.592\times10^3\text{ N}.$$

$$\Delta l = \left(\frac{4.592\times10^3\text{ N}}{1900\text{ N}}\right)(0.18\text{ mm}) = 0.44\text{ mm}.$$

EVALUATE: $\sum F_y = ma_y$ gives $F_\perp\cos\theta = mg$ and $\cos\theta = mg/F_\perp$. As ω increases $F_\perp$ increases and $\cos\theta$ becomes small. Smaller $\cos\theta$ means θ increases, so the rods move toward the horizontal as ω increases.

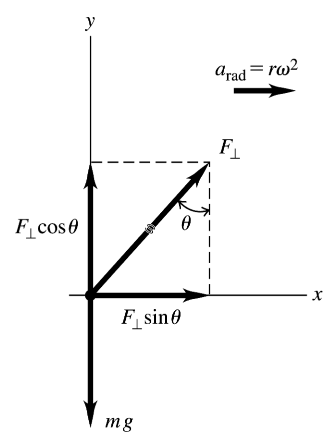


Figure 11.84

11.85. IDENTIFY: Apply $\dfrac{F_\perp}{A} = Y\left(\dfrac{\Delta l}{l_0}\right)$. The height from which he jumps determines his speed at the ground. The acceleration as he stops depends on the force exerted on his legs by the ground.

SET UP: In considering his motion take $+y$ downward. Assume constant acceleration as he is stopped by the floor.

EXECUTE: (a) $F_\perp = YA\left(\dfrac{\Delta l}{l_0}\right) = (3.0\times10^{-4}\text{ m}^2)(14\times10^9\text{ Pa})(0.010) = 4.2\times10^4\text{ N}$

(b) As he is stopped by the ground, the net force on him is $F_{net} = F_\perp - mg$, where $F_\perp$ is the force exerted on him by the ground. From part (a), $F_\perp = 2(4.2\times10^4\ \text{N}) = 8.4\times10^4\ \text{N}$ and $F = 8.4\times10^4\ \text{N} - (70\ \text{kg})(9.80\ \text{m/s}^2) = 8.33\times10^4\ \text{N}$. $F_{net} = ma$ gives $a = 1.19\times10^3\ \text{m/s}^2$. $a_y = -1.19\times10^3\ \text{m/s}^2$ since the acceleration is upward. $v_y = v_{0y} + a_y t$ gives $v_{0y} = -a_y t = (-1.19\times10^3\ \text{m/s}^2)(0.030\ \text{s}) = 35.7\ \text{m/s}$. His speed at the ground therefore is $v = 35.7\ \text{m/s}$. This speed is related to his initial height h above the floor by $\frac{1}{2}mv^2 = mgh$ and

$$h = \frac{v^2}{2g} = \frac{(35.7\ \text{m/s})^2}{2(9.80\ \text{m/s}^2)} = 65\ \text{m}.$$

EVALUATE: Our estimate is based solely on compressive stress; other injuries are likely at a much lower height.

11.86. **IDENTIFY:** The graph gives the change in length of the wire as a function of the weight hanging from it, which is equal to the tension in the wire. Young's modulus Y applies to the stretching of the wire. Energy conservation and Newton's second law apply to the swinging sphere.

SET UP: $Y = \dfrac{l_0 F_\perp}{A\Delta l}$, $K_1 + U_1 = K_2 + U_2$, $\Sigma\vec{F} = m\vec{a}$, $a_{rad} = v^2/R$.

EXECUTE: **(a)** Solve $Y = \dfrac{l_0 F_\perp}{A\Delta l}$ for Δl and realize that $F_\perp = mg$: $\Delta l = \dfrac{gl_0}{AY}m$. Therefore, in the graph of Δl versus m, the slope is equal to gl_0/AY. The equation of the graph is given in the problem as Δl = (0.422 mm/kg)m, so the slope is 0.422 mm/kg, so gl_0/AY = 0.422 mm/kg = 4.22 $\times 10^{-4}$ m/kg. Solving for Y gives $Y = \dfrac{gl_0}{A(4.22\times10^{-4}\ \text{m/kg})}$. Using $A = \pi r^2$ and putting in the given numbers gives

$$Y = \frac{(9.80\ \text{m/s})(22.0\ \text{m})}{\pi(4.30\times10^{-4}\ \text{m})^2(4.22\times10^{-4}\ \text{m/kg})} = 8.80\times10^{11}\ \text{Pa}.$$

(b) Use energy conservation to find the speed of the sphere. $K_1 + U_1 = K_2 + U_2$ gives $mgL(1-\cos\theta) = \dfrac{1}{2}mv^2$. Solving for v using θ = 36.0° and L = 22.0 m gives v = 9.075 m/s.

Now apply Newton's second law to the sphere at the bottom of the swing. $\Sigma\vec{F} = m\vec{a}$ and $a_{rad} = v^2/R$ give
$T - mg = mv^2/L$, so $T = mv^2/L + mg$ = (9.50 kg)(9.075 m/s)^2/(22.0 m) + (9.50 kg)(9.80 m/s^2) = 129 N.
Using the value of Y found in part (a), we have

$$\Delta l = \frac{F_\perp l_0}{AY} = (129\ \text{N})(22.0\ \text{m})/[\pi(4.30\times10^{-4}\ \text{m})^2(8.80\times10^{11}\ \text{Pa})] = 0.00554\ \text{m} = 5.54\ \text{mm}.$$

EVALUATE: For a wire 22 m long, 5.5 mm is a very small stretch, 0.0055/22 = 0.025%.

11.87. **IDENTIFY:** The bar is at rest, so the forces and torques on it must all balance.
SET UP: $\Sigma F_y = 0$, $\Sigma\tau_z = 0$.

EXECUTE: **(a)** The free-body diagram is shown in Figure 11.87a, where F_p is the force due to the knife-edge pivot.

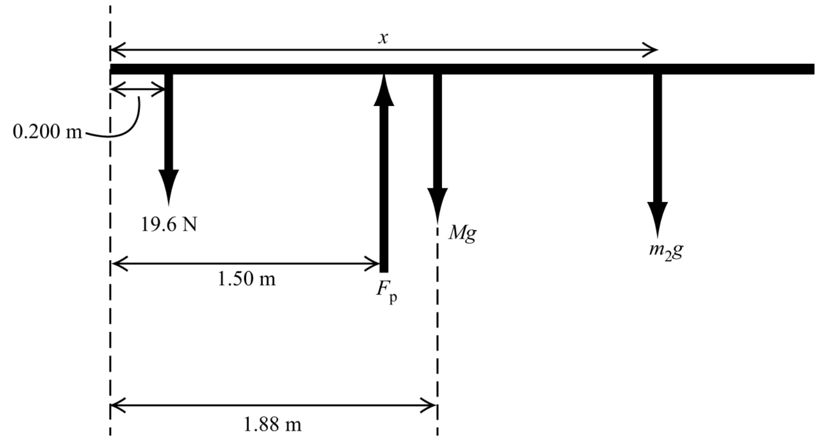

Figure 11.87a

(b) $\sum \tau_z = 0,$ with torques taken about the location of the knife-edge pivot, gives
(2.00 kg)g(1.30 m) – Mg(0.38 m) – $m_2g(x$ – 1.50 m) = 0
Solving for x gives
x = [(2.00 kg)(1.30 m) – M(0.38 m)](1/m_2) + 1.50 m
The graph of this equation (x versus 1/m_2) is a straight line of slope [(2.00 kg)(1.30 m) – M(0.38 m)].
(c) The plot of x versus 1/m_2 is shown in Figure 11.87b. The equation of the best-fit line is
x = (1.9955 $\text{m}\cdot\text{kg}$)/m_2 + 1.504 m. The slope of the best-fit line is 1.9955 $\text{m}\cdot\text{kg}$, so
[(2.00 kg)(1.30 m) – M(0.38 m)] = 1.9955 $\text{m}\cdot\text{kg}$, which gives M = 1.59 kg.

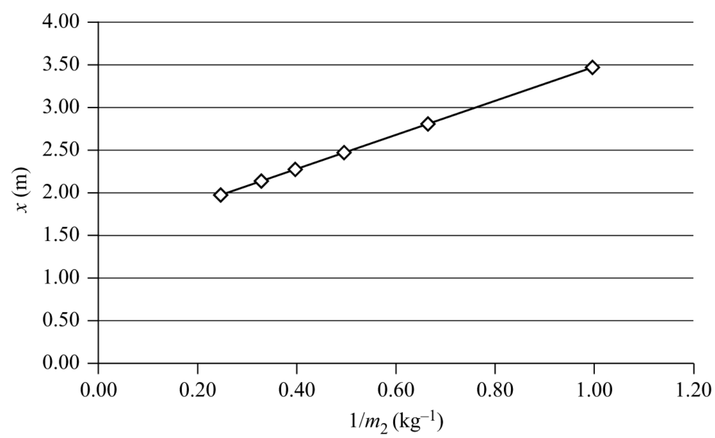

Figure 11.87b

(d) The y-intercept of the best-fit line is 1.50 m. This is plausible. As the graph approaches the y-axis, 1/m_2 approaches zero, which means that m_2 is getting extremely large. In that case, it would be much larger than any other masses involved, so to balance the system, m_2 would have to be at the knife-point pivot, which is at x = 1.50 m.
EVALUATE: The fact that the graph gave a physically plausible result in part (d) suggests that this graphical analysis is reasonable.

11.88. **IDENTIFY:** The bar is at rest, so the forces and torques on it must all balance.
SET UP: $\Sigma F_x = 0,\ \Sigma F_y = 0,\ \ \sum \tau_z = 0.$

EXECUTE: (a) Take torques about the hinge, calling m the mass of the bar and L its length. $\sum \tau_z = 0$ gives $xT\sin\theta = mg\frac{L}{2}$. Solving for T gives $T = \frac{mgL/2}{x\sin\theta}$. Therefore the alternative having the largest value of $x\sin\theta$ will have the smallest tension, and the one with the smallest value of $x\sin\theta$ will have the greatest tension. Calculating $x\sin\theta$ for each alternative gives the following values. A: 1.00 m, B: 1.30 m, C: 0.451 m, D: 0.483 m. Therefore alternative B gives the smallest tension and C produces the largest tension

(b) Calling H the magnitude of the hinge force, $\Sigma F_x = 0$ gives $H_x = T\cos\theta$. Using the value of T from part (a), we get $H_x = \frac{mg\,L/2}{x\sin\theta}.\cos\theta = \frac{mg\,L/2}{x\tan\theta}$. From this result, we can see that H_x is greatest when $x\tan\theta$ is the smallest, and H_x is least when $x\tan\theta$ is greatest. Calculating $x\tan\theta$ for each alternative gives A: 1.15 m, B: 2.60 m, C: 0.565 m, D: 1.87 m. Therefore alternative C gives the greatest H_x and B gives the smallest H_x.

(c) Taking torques about the point where the cable is connected to the bar, $\sum \tau_z = 0$ gives $H_y x = mg(x - L/2)$. Solving for H_y gives $H_y = mg(1 - L/2x)$. Since H_y could be positive or negative, we should calculate all four possibilities. For alternative A, we have $H_y = mg\left(1 - \frac{2.00\text{ m}}{4.00\text{ m}}\right) = 0.500mg$. For B we have $H_y = mg\left(1 - \frac{2.00\text{ m}}{3.00\text{ m}}\right) = 0.333mg$, and likewise we get $H_y = -0.333mg$ for C and $H_y = -1.00mg$ for D. Therefore alternative D gives the largest H_y and B and C both give the smallest value.

(d) Alternative B is clearly optimal because it results in the smallest values for T, H_x, and H_y. It might be a good idea to avoid alternative C because it has the greatest T and H_x.

EVALUATE: As a check, part (c) could be solved by using $\Sigma F_y = 0$.

11.89. IDENTIFY: Apply the equilibrium conditions to the ladder combination and also to each ladder.

SET UP: The geometry of the 3-4-5 right triangle simplifies some of the intermediate algebra. Denote the forces on the ends of the ladders by F_L and F_R (left and right). The contact forces at the ground will be vertical, since the floor is assumed to be frictionless.

EXECUTE: (a) Taking torques about the right end, $F_L(5.00\text{ m}) = (480\text{ N})(3.40\text{ m}) + (360\text{ N})(0.90\text{ m})$, so $F_L = 391\text{ N}$. F_R may be found in a similar manner, or from $F_R = 840\text{ N} - F_L = 449\text{ N}$.

(b) The tension in the rope may be found by finding the torque on each ladder, using the point A as the origin. The lever arm of the rope is 1.50 m. For the left ladder, $T(1.50\text{ m}) = F_L(3.20\text{ m}) - (480\text{ N})(1.60\text{ m})$, so $T = 322.1\text{ N}$ (322 N to three figures). As a check, using the torques on the right ladder, $T(1.50\text{ m}) = F_R(1.80\text{ m}) - (360\text{ N})(0.90\text{ m})$ gives the same result.

(c) The horizontal component of the force at A must be equal to the tension found in part (b). The vertical force must be equal in magnitude to the difference between the weight of each ladder and the force on the bottom of each ladder, $480\text{ N} - 391\text{ N} = 449\text{ N} - 360\text{ N} = 89\text{ N}$. The magnitude of the force at A is then $\sqrt{(322.1\text{ N})^2 + (89\text{ N})^2} = 334\text{ N}$.

(d) The easiest way to do this is to see that the added load will be distributed at the floor in such a way that $F_L' = F_L + (0.36)(800\text{ N}) = 679\text{ N}$, and $F_R' = F_R + (0.64)(800\text{ N}) = 961\text{ N}$. Using these forces in the form for the tension found in part (b) gives

$$T = \frac{F'_L(3.20\text{ m}) - (480\text{ N})(1.60\text{ m})}{(1.50\text{ m})} = \frac{F'_R(1.80\text{ m}) - (360\text{ N})(0.90\text{ m})}{(1.50\text{ m})} = 937\text{ N}.$$

EVALUATE: The presence of the painter increases the tension in the rope, even though his weight is vertical and the tension force is horizontal.

11.90. IDENTIFY: Apply $\sum \tau_z = 0$ to the post, for various choices of the location of the rotation axis.

SET UP: When the post is on the verge of slipping, f_s has its largest possible value, $f_s = \mu_s n.$

EXECUTE: (a) Taking torques about the point where the rope is fastened to the ground, the lever arm of the applied force is $h/2$ and the lever arm of both the weight and the normal force is $h\tan\theta,$ and so

$$F\frac{h}{2} = (n - w)h\tan\theta.$$

Taking torques about the upper point (where the rope is attached to the post), $fh = F\frac{h}{2}.$ Using $f \le \mu_s n$ and solving for F, $F \le 2w\left(\frac{1}{\mu_s} - \frac{1}{\tan\theta}\right)^{-1} = 2(400\text{ N})\left(\frac{1}{0.30} - \frac{1}{\tan 36.9°}\right)^{-1} = 400\text{ N}.$

(b) The above relations between F, n and f become $F\frac{3}{5}h = (n - w)h\tan\theta, f = \frac{2}{5}F,$ and eliminating f and n and solving for F gives $F \le w\left(\frac{2/5}{\mu_s} - \frac{3/5}{\tan\theta}\right)^{-1}$, and substitution of numerical values gives 750 N to two figures.

(c) If the force is applied a distance y above the ground, the above relations become $Fy = (n - w)h\tan\theta,\ F(h - y) = fh,$ which become, on eliminating n and f, $w \ge F\left[\frac{(1 - y/h)}{\mu_s} - \frac{(y/h)}{\tan\theta}\right].$

As the term in square brackets approaches zero, the necessary force becomes unboundedly large. The limiting value of y is found by setting the term in square brackets equal to zero. Solving for y gives

$$\frac{y}{h} = \frac{\tan\theta}{\mu_s + \tan\theta} = \frac{\tan 36.9°}{0.30 + \tan 36.9°} = 0.71.$$

EVALUATE: For the post to slip, for an axis at the top of the post the torque due to F must balance the torque due to the friction force. As the point of application of F approaches the top of the post, its moment arm for this axis approaches zero.

11.91. IDENTIFY: Apply $Y = \frac{l_0 F_\perp}{A\Delta l}$ to calculate $\Delta l.$

SET UP: For steel, $Y = 2.0\times10^{11}$ Pa.

EXECUTE: (a) From $Y = \frac{l_0 F_\perp}{A\Delta l}$, $\Delta l = \frac{(4.50\text{ kg})(9.80\text{ m/s}^2)(1.50\text{ m})}{(20\times10^{10}\text{ Pa})(5.00\times10^{-7}\text{ m}^2)} = 6.62\times10^{-4}$ m, or 0.66 mm to two figures.

(b) $(4.50\text{ kg})(9.80\text{ m/s}^2)(0.0500\times10^{-2}\text{ m}) = 0.022\text{ J}.$

(c) The magnitude F will vary with distance; the average force is $YA(0.0250\text{ cm}/l_0) = 16.7\text{ N},$ and so the work done by the applied force is $(16.7\text{ N})(0.0500\times10^{-2}\text{ m}) = 8.35\times10^{-3}\text{ J}.$

(d) The average force the wire exerts is $(4.50\text{ kg})g + 16.7\text{ N} = 60.8\text{ N}.$ The work done is negative, and equal to $-(60.8\text{ N})(0.0500\times10^{-2}\text{ m}) = -3.04\times10^{-2}\text{ J}.$

(e) The equation $Y = \frac{l_0 F_\perp}{A\Delta l}$ can be put into the form of Hooke's law, with $k = \frac{YA}{l_0}.$ $U_{el} = \frac{1}{2}kx^2,$ so $\Delta U_{el} = \frac{1}{2}k(x_2^2 - x_1^2).$ $x_1 = 6.62\times10^{-4}$ m and $x_2 = 0.500\times10^{-3}\text{ m} + x_1 = 11.62\times10^{-4}$ m. The change in elastic potential energy is

$$\frac{(20\times10^{10}\text{ Pa})(5.00\times10^{-7}\text{ m}^2)}{2(1.50\text{ m})}\left[(11.62\times10^{-4}\text{ m})^2 - (6.62\times10^{-4}\text{ m})^2\right] = 3.04\times10^{-2}\text{ J},$$ the negative of the result of part (d).

EVALUATE: The tensile force in the wire is conservative and obeys the relation $W = -\Delta U$.

11.92. **IDENTIFY** and **SET UP:** The forces and torques on the competitor must balance, so $\Sigma F_x = 0$, $\Sigma F_y = 0$, and $\sum \tau_z = 0$.

EXECUTE: Take torques about his feet, giving $(T_1 - T_2)(1.5\text{ m})(\cos 30°) = mg(1.0\text{ m})(\sin 30°)$. Solving for T_2 gives $T_2 = 1160\text{ N} - [(80.0\text{ kg})(9.80\text{ m/s}^2)/(1.5\text{ m})]\tan 30° = 858\text{ N} \approx 860\text{ N}$, which is choice (c).

EVALUATE: We find $T_2 < T_1$ as expected.

11.93. **IDENTIFY** and **SET UP:** The forces and torques on the competitor must balance, so $\Sigma F_x = 0$, $\Sigma F_y = 0$, and $\sum \tau_z = 0$.

EXECUTE: As in the previous problem, $T_1 - T_2$ is proportional to $\tan\theta$, so as θ increases, so does $\tan\theta$ and so does $T_1 - T_2$, which makes choice (a) correct.

EVALUATE: The result is physically reasonable. As he leans back, the ropes get lower, which reduces their moment arm, and his weight also gets lower, which increases its moment arm. Therefore to keep balance, the diffrerence in the tensions must be greater than before.

11.94. **IDENTIFY** and **SET UP:** Apply $\tau = Fl$.

EXECUTE: The moment arm for T_1 has increased, so T_1 can be smaller and still produce the same torque needed to balance the torque due to gravity, so choice (c) is correct.

EVALUATE: If the rope is held too high, it will be hard for the competitor to hold it, so there is a limit on how much the holding height can be effectively increased.

11.95. **IDENTIFY** and **SET UP:** The competitor will slip if the static friction force would need to be greater than its maximum possible value. $f_s^{\max} = \mu_s n$.

EXECUTE: From earlier work, we know that $T_1 - T_2 = 1160\text{ N} - 858\text{ N} = 302\text{ N}$. The maximum static friction force is $f_s^{\max} = \mu_s n = (0.50)(80.0\text{ kg})(9.80\text{ m/s}^2) = 392\text{ N}$. He needs only 302 N to balance the tension difference, yet the static friction force could be as great as 392 N, so he is not even ready to slip. Therefore he will not move, choice (d).

EVALUATE: The friction force is 302 N, not 392 N, because he is not just ready to slip.

12

FLUID MECHANICS

VP12.4.1. **IDENTIFY:** We want the pressure at a depth in a fluid.
SET UP: $p = p_0 + \rho gh$ gives the absolute pressure.

EXECUTE: $p = p_0 + \rho gh = 1.22\times 10^5$ Pa + (455 kg/m^3)(9.80 m/s^2)(2.00 m) = 1.31×10^5 Pa.

EVALUATE: This pressure is about 30% above atmospheric pressure.

VP12.4.2. **IDENTIFY:** We are dealing with the gauge pressure at a depth in a fluid.
SET UP: $p = \rho gh$ gives the gauge pressure which is the pressure above atmospheric pressure.

EXECUTE: **(a)** The gauge pressure is due only to the gasoline.
$p = \rho gh$ = (740 kg/m^3)(9.80 m/s^2)(0.150 m) = 1.09×10^3 Pa.

(b) The gauge pressure at the top of the water is 1.09×10^3 Pa, so the pressure at the bottom is
$p = p_0 + \rho gh = 1.09\times 10^3$ Pa + (1000 kg/m^3)(9.80 m/s^2)(0.150 m) = 2.56×10^3 Pa.

EVALUATE: To find the *absolute* pressure in each case we would have to add 1.01×10^5 Pa to our answers. A pressure gauge would read the gauge pressure.

VP12.4.3. **IDENTIFY:** We are dealing with the pressure at a depth in a fluid in a manometer.
SET UP: $p = p_0 + \rho gh$ gives the absolute pressure. Using Fig. 12.8a in the text, and looking at the right-hand column, the pressure in that column at a level y_1 is p. This is also the pressure due to the column from y_1 to the top which is a depth h in the right-hand column. Therefore the difference in heights h is $p - p_{\text{atm}} = \rho gh$.

EXECUTE: Solve for h: $h = \dfrac{p - p_{\text{atm}}}{\rho g} = \dfrac{2.1\times 10^5\ \text{Pa} - 1.01\times 10^5\ \text{Pa}}{(1.36\times 10^4\ \text{kg/m}^3)(9.80\ \text{m/s}^2)}$ = 0.818 m = 81.8 cm.

EVALUATE: According to our results, if the pressure p in the container were greater, h would be greater. If the density of the fluid in the manometer were less, h would also be greater. Both cases are physically reasonable, which suggests our solution is correct.

VP12.4.4. **IDENTIFY:** We are dealing with the pressure at a depth in a fluid in a manometer.
SET UP: $p = \rho gh$ gives the gauge pressure. The gauge pressure at the bottom of the oil is the same as the gauge pressure at the bottom of the water since both tubes are open to the air.
EXECUTE: **(a)** Equating the gauge pressures gives $\rho_{\text{oil}} g h_{\text{oil}} = \rho_{\text{water}} g h_{\text{water}}$.

$h_{\text{water}} = \dfrac{\rho_{\text{oil}}}{\rho_{\text{water}}} h_{\text{oil}} = \dfrac{916\ \text{kg/m}^3}{1000\ \text{kg/m}^3} \cdot 25.0\ \text{cm} = 22.9$ cm.

(b) $p_{\text{gauge}} = \rho gh$ = (1000 kg/m^3)(9.80 m/s^2)(0.150 m) = 1.47×10^3 Pa.

(c) Solve $p_{\text{gauge}} = \rho gh$ for h, giving

$h = p_{\text{gauge}}/\rho g = (1.47\times 10^3\ \text{Pa})/[(916\ \text{kg/m}^3)(9.80\ \text{m/s}^2)]$ = 0.164 m = 16.4 cm.

EVALUATE: From (b) and (c), we see that we would have to be 15.0 cm deep in water to have the same pressure as at 16.4 cm in oil. This is reasonable since the density of oil is less than that of water.

VP12.5.1. **IDENTIFY:** This problem involves, density, buoyancy, and Archimedes's principle.
SET UP: Density is $\rho = m/V$. Archimedes's principle says that the buoyant force B on an immersed object is equal to the weight of the fluid displaced.
EXECUTE: **(a)** $m = \rho V$, so $w = \rho Vg = (1150 \text{ kg/m}^3)(7.50\times10^{-4} \text{ m}^3)(9.80 \text{ m/s}^2) = 8.45$ N.
(b) B equals the weight of the displaced fluid or gas, so $B = \rho Vg$.
(i) $B_{\text{air}} = \rho_{\text{air}} Vg = (1.20 \text{ kg/m}^3)(7.50\times10^{-4} \text{ m}^3)(9.80 \text{ m/s}^2) = 8.82\times10^{-3}$ N. The object would sink since the buoyant force on it is less than its weight.
(ii) $B_{\text{water}} = \rho_{\text{water}} Vg = (1000 \text{ kg/m}^3)(7.50\times10^{-4} \text{ m}^3)(9.80 \text{ m/s}^2) = 7.35$ N. The object would sink since the buoyant force on it is less than its weight.
(iii) $B_{\text{glycerine}} = \rho_{\text{glycerine}} Vg = (1260 \text{ kg/m}^3)(7.50\times10^{-4} \text{ m}^3)(9.80 \text{ m/s}^2) = 9.26$ N. The object would rise since the buoyant force on it is greater than its weight.
EVALUATE: Notice that in each case in (b), the object sinks if its density is greater than the fluid and rises if its density is less than that of the fluid. This is a useful point to keep in mind.

VP12.5.2. **IDENTIFY:** This problem involves density, buoyancy, and Archimedes's principle.
SET UP: Density is $\rho = m/V$. Archimedes's principle says that the buoyant force B on an immersed object is equal to the weight of the fluid displaced. $\sum F_y = 0$ for the sphere.
EXECUTE: **(a)** $B = \rho Vg = (1000 \text{ kg/m}^3)(9.80 \text{ m/s}^2)(1.20\times10^{-3} \text{ m}^3) = 11.8$ N.
(b) $\sum F_y = 0$ gives $w = T + B = 29.4 \text{ N} + 11.8 \text{ N} = 41.2$ N.
(c) $\rho = m/V = (W/g)/V = (41.2 \text{ N})/[(9.80 \text{ m/s}^2)(1.20\times10^{-3} \text{ m}^3)] = 3.50\times10^3 \text{ kg/m}^3$.
EVALUATE: The sphere is denser than water, so the buoyant force is less than its weight, so there must be a tension in the cable. This agrees with our results.

VP12.5.3. **IDENTIFY:** This problem involves density, buoyancy, and Archimedes's principle.
SET UP: Density is $\rho = m/V$. Archimedes's principle says that the buoyant force B on an immersed object is equal to the weight of the fluid displaced. $\sum F_y = 0$ for the cube. Call V the volume of the cube and ρ_c its density. Let ρ be the density of the fluid.
EXECUTE: Archimedes's principle gives $B = \rho g(V/2)$. $\sum F_y = 0$ for the cube gives

$$T + B - w_{\text{cube}} = 0 \quad \rightarrow \quad T + \rho gV/2 - \rho_c gV = 0 \quad \rightarrow \quad \rho = \frac{2(\rho_c gV - T)}{gV}$$

$$\rho = \frac{2\left[(7.50\times10^3 \text{kg/m}^3)(9.80 \text{ m/s}^2)(5.50\times10^{-3}\text{m}^3) - 375 \text{ N}\right]}{(9.80 \text{ m/s}^2)(5.50\times10^{-3}\text{m}^3)} = 1.1\times10^3 \text{ kg/m}^3.$$

EVALUATE: The density of this fluid is slightly greater than that of water.

VP12.5.4. **IDENTIFY:** This problem involves density, buoyancy, and Archimedes's principle.
SET UP: Density is $\rho = m/V$. Archimedes's principle says that the buoyant force B on an immersed object is equal to the weight of the fluid displaced.
EXECUTE: **(a)** $B = \rho_L Vg$ and $V = Ad$, so $B = \rho_L Adg$.
(b) For floating $B = w_{\text{cyl}} \rightarrow \rho_L Vg = \rho_{\text{cyl}} ALg \rightarrow \rho_{\text{cyl}} = \dfrac{d}{L}\rho_L$.
EVALUATE: If $d = L$, our result gives $\rho_{\text{cyl}} = \rho_L$. In that case the cylinder would be fully submerged. Since the cylinder and liquid have the same densities, the volumes of the cylinder and the displaced liquid would have to be equal for the cylinder to float.

VP12.9.1. **IDENTIFY:** This is a problem in fluid flow involving Bernoulli's equation and the continuity equation.
SET UP: Bernoulli's equation is $p_1 + \rho gy_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho gy_2 + \frac{1}{2}\rho v_2^2$ and the continuity equation is $A_1v_1 = A_2v_2$.

EXECUTE: (a) Use $A_1v_1 = A_2v_2$ to find the speed of flow at ground level.

$A_1v_1 = A_2v_2 \quad \rightarrow \quad \pi r_1^2 v_1 = \pi r_2^2 v_2 \quad \rightarrow \quad v_2 = (r_1/r_2)^2 v_1$

$v_2 = [(1.0\text{ cm})/(0.50\text{ cm})]^2(1.6\text{ m/s}) = 6.4\text{ m/s}.$

(b) Use Bernoulli's equation with point 2 to be floor level. This makes $v_1 = 1.6$ m/s, $v_2 = 6.4$ m/s, $y_1 = 9.0$ m, $y_2 = 0$, $p_1 = 3.0\times 10^5$ Pa, and $\rho = 1000\text{ kg/m}^3$. We want p_2 at ground level. Solving Bernoulli's equation gives $p_2 = 3.7\times 10^5$ Pa.

EVALUATE: The pressure in the pipe is about 3.7 times atmospheric pressure. It would be even greater if the pipe were longer than 9.0 m.

VP12.9.2. IDENTIFY: This problem is about fluid flow. It involves Bernoulli's equation, volume flow rate, and the continuity equation.

SET UP: Bernoulli's equation is $p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$, the volume flow rate is $dV/dt = Av$, and the continuity equation is $A_1v_1 = A_2v_2$.

EXECUTE: (a) We know the volume flow rate, so use $dV/dt = Av$ to find v_2.

$$v = \frac{dV/dt}{A_2} = \frac{dV/dt}{\pi r_2^2} = \frac{4.4\times 10^{-3}\text{ m}^3/\text{s}}{\pi(0.010\text{ m})^2} = 14\text{ m/s}.$$

(b) Apply Bernoulli's equation. Call point 1 the top of the ethanol and point 2 the level of the out-coming ethanol at the bottom. We want $p_1 - p_{\text{atm}}$ (the *gauge* pressure) and we know that $p_2 = p_{\text{atm}}$, $y_1 = 3.2$ m, $y_2 = 0$, $\rho = 810\text{ kg/m}^3$, $v_2 = 14$ m/s, and $v_1 \approx 0$ (because $A_1 >> A_2$). Solve for $p_1 - p_{\text{atm}}$ gives $p_{\text{gauge}} = p_1 - p_{\text{atm}} = 5.4\times 10^4$ Pa.

EVALUATE: The tank is pressurized because $p_1 > p_{\text{atm}}$.

VP12.9.3. IDENTIFY: This problem deals with a Venturi meter.

SET UP: From Example 12.9, we have $p_1 - p_2 = \frac{1}{2}\rho v_1^2\left[\left(\frac{A_1}{A_2}\right)^2 - 1\right]$. We want the difference in height h of the liquid levels in the two tubes. We also know from Example 12.9 that $v = \sqrt{\frac{2gh}{(A_1/A_2)^2 - 1}}$. First solve for v_1 and then use that result to solve for h. The volume flow rate is $dV/dt = Av$.

EXECUTE: (a) First use $p_1 - p_2 = \frac{1}{2}\rho v_1^2\left[\left(\frac{A_1}{A_2}\right)^2 - 1\right]$ to find v_1.

$$810\text{ Pa} = \frac{1}{2}(1000\text{ kg/m}^3)v_1^2\left[\left(\frac{\pi(2.5\text{ cm})^2}{\pi(1.2\text{ cm})^2}\right)^2 - 1\right] \quad \rightarrow \quad v_1 = 0.3014\text{ m/s}.$$

Now use $v_1 = \sqrt{\frac{2gh}{(A_1/A_2)^2 - 1}}$ to solve for h. Use $v_1 = 0.3014$ m/s and the same areas as above. This gives $h = 5.9\times 10^{-4}\text{ m}^3/\text{s}$.

(b) $dV/dt = A_1v_1 = \pi r_1^2 v_1 = \pi(0.025\text{ m})^2(0.3014\text{ m/s}) = 5.9\times 10^{-4}\text{ m}^3/\text{s}.$

EVALUATE: The volume flow rate is the same throughout the pipe, so we calculated it at point 1. But it would also be true at point 2 or any other point in the pipe.

VP12.9.4. IDENTIFY: This problem is about fluid flow. It involves Bernoulli's equation, volume flow rate, and the continuity equation.

SET UP: Bernoulli's equation is $p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$, the volume flow rate is $dV/dt = Av$, and the continuity equation is $A_1 v_1 = A_2 v_2$. We follow exactly the same procedure as in problem VP12.9.2 *except* that v_1 cannot be neglected.

EXECUTE: The continuity equation gives v_1: $A_1 v_1 = A_2 v_2 \quad \rightarrow \quad v_1 = v_2(A_2/A_1)$. Now use Bernoulli's equation with $p_1 = p_0$, $p_2 = p_{atm}$, $y_1 = h$, $y_2 = 0$, $v_1 = v_2(A_2/A_1)$. This equation becomes $p_0 - p_{atm} + \rho g h = \frac{1}{2}\rho v_2^2 - \frac{1}{2}\rho v_2^2\left(\frac{A_2}{A_1}\right)^2$. Solving for v_2 gives $v_2 = \sqrt{\dfrac{2\left(\dfrac{p_0 - p_{atm}}{\rho}\right) + 2gh}{1 - (A_2/A_1)^2}}$.

EVALUATE: To check our result, consider the case of $A_1 >> A_2$. In that case the denominator approaches 1 and $v_2 \rightarrow \sqrt{2\left(\dfrac{p_0 - p_{atm}}{\rho}\right) + 2gh}$. This is the result obtained in Example 2.8 in the text, so our result looks reasonable. Also if $A_1 >> A_2$ and the tank is open at the top, $p_0 = p_{atm}$ and $v_2 \rightarrow \sqrt{2gh}$, which is the as for an object in freefall, as we would expect.

12.1. IDENTIFY: Use $\rho = m/V$ to calculate the mass and then use $w = mg$ to calculate the weight.

SET UP: $\rho = m/V$ so $m = \rho V$ From Table 12.1, $\rho = 7.8\times10^3\ \text{kg/m}^3$.

EXECUTE: For a cylinder of length L and radius R,

$V = (\pi R^2)L = \pi(0.01425\ \text{m})^2(0.858\ \text{m}) = 5.474\times10^{-4}\ \text{m}^3$.

Then $m = \rho V = (7.8\times10^3\ \text{kg/m}^3)(5.474\times10^{-4}\ \text{m}^3) = 4.27\ \text{kg}$, and

$w = mg = (4.27\ \text{kg})(9.80\ \text{m/s}^2) = 41.8\ \text{N}$ (about 9.4 lbs). A cart is not needed.

EVALUATE: The rod is less than 1m long and less than 3 cm in diameter, so a weight of around 10 lbs seems reasonable.

12.2. IDENTIFY: The volume of the remaining object is the volume of a cube minus the volume of a cylinder, and it is this object for which we know the mass. The target variables are the density of the metal of the cube and the original weight of the cube.

SET UP: The volume of a cube with side length L is L^3, the volume of a cylinder of radius r and length L is $\pi r^2 L$, and density is $\rho = m/V$.

EXECUTE: **(a)** The volume of the metal left after the hole is drilled is the volume of the solid cube minus the volume of the cylindrical hole:

$V = L^3 - \pi r^2 L = (5.0\ \text{cm})^3 - \pi(1.0\ \text{cm})^2(5.0\ \text{cm}) = 109\ \text{cm}^3 = 1.09\times10^{-4}\ \text{m}^3$. The cube with the hole has mass $m = \dfrac{w}{g} = \dfrac{6.30\ \text{N}}{9.80\ \text{m/s}^2} = 0.6429\ \text{kg}$ and density $\rho = \dfrac{m}{V} = \dfrac{0.6429\ \text{kg}}{1.09\times10^{-4}\ \text{m}^3} = 5.9\times10^3\ \text{kg/m}^3$.

(b) The solid cube has volume $V = L^3 = 125\ \text{cm}^3 = 1.25\times10^{-4}\ \text{m}^3$ and mass

$m = \rho V = (5.9\times10^3\ \text{kg/m}^3)(1.25\times10^{-4}\ \text{m}^3) = 0.7372\ \text{kg}$. The original weight of the cube was $w = mg = 7.2\ \text{N}$.

EVALUATE: As Table 12.1 shows, the density of this metal is about twice that of aluminum and half that of lead, so it is reasonable.

12.3. IDENTIFY: $\rho = m/V$

SET UP: The density of gold is $19.3\times10^3\ \text{kg/m}^3$.

EXECUTE: $V = (5.0\times10^{-3}\ \text{m})(15.0\times10^{-3}\ \text{m})(30.0\times10^{-3}\ \text{m}) = 2.25\times10^{-6}\ \text{m}^3$.

$\rho = \dfrac{m}{V} = \dfrac{0.0158\ \text{kg}}{2.25\times10^{-6}\ \text{m}^3} = 7.02\times10^3\ \text{kg/m}^3$. The metal is not pure gold.

EVALUATE: The average density is only 36% that of gold, so at most 36% of the mass is gold.

12.4. **IDENTIFY:** Average density is $\rho = m/V$.

SET UP: For a sphere, $V = \frac{4}{3}\pi R^3$. The sun has mass $M_{\text{sun}} = 1.99\times10^{30}\text{ kg}$ and radius $6.96\times10^{8}\text{ m}$.

EXECUTE: **(a)** $\rho = \dfrac{M_{\text{sun}}}{V_{\text{sun}}} = \dfrac{1.99\times10^{30}\text{ kg}}{\frac{4}{3}\pi(6.96\times10^{8}\text{ m})^3} = \dfrac{1.99\times10^{30}\text{ kg}}{1.412\times10^{27}\text{ m}^3} = 1.409\times10^{3}\text{ kg/m}^3$

(b) $\rho = \dfrac{1.99\times10^{30}\text{ kg}}{\frac{4}{3}\pi(2.00\times10^{4}\text{ m})^3} = \dfrac{1.99\times10^{30}\text{ kg}}{3.351\times10^{13}\text{ m}^3} = 5.94\times10^{16}\text{ kg/m}^3$

EVALUATE: For comparison, the average density of the earth is $5.5\times10^{3}\text{ kg/m}^3$. A neutron star is extremely dense.

12.5. **IDENTIFY:** Apply $\rho = m/V$ to relate the densities and volumes for the two spheres.

SET UP: For a sphere, $V = \frac{4}{3}\pi r^3$. For lead, $\rho_1 = 11.3\times10^{3}\text{ kg/m}^3$ and for aluminum, $\rho_{\text{a}} = 2.7\times10^{3}\text{ kg/m}^3$.

EXECUTE: $m = \rho V = \frac{4}{3}\pi r^3\rho$. Same mass means $r_{\text{a}}^3\rho_{\text{a}} = r_1^3\rho_1$. $\dfrac{r_{\text{a}}}{r_1} = \left(\dfrac{\rho_1}{\rho_{\text{a}}}\right)^{1/3} = \left(\dfrac{11.3\times10^{3}}{2.7\times10^{3}}\right)^{1/3} = 1.6.$

EVALUATE: The aluminum sphere is larger, since its density is less.

12.6. **IDENTIFY:** $w = mg$ and $m = \rho V$. Find the volume V of the pipe.

SET UP: For a hollow cylinder with inner radius R_1, outer radius R_2, and length L the volume is $V = \pi(R_2^2 - R_1^2)L$. $R_1 = 1.25\times10^{-2}\text{ m}$ and $R_2 = 1.75\times10^{-2}\text{ m}$.

EXECUTE: $V = \pi[(0.0175\text{ m})^2 - (0.0125\text{ m})^2](1.50\text{ m}) = 7.07\times10^{-4}\text{ m}^3$.

$m = \rho V = (8.9\times10^{3}\text{ kg/m}^3)(7.07\times10^{-4}\text{ m}^3) = 6.29\text{ kg}$. $w = mg = 61.6\text{ N}$.

EVALUATE: The pipe weighs about 14 pounds.

12.7. **IDENTIFY:** The gauge pressure $p - p_0$ at depth h is $p - p_0 = \rho g h$.

SET UP: Freshwater has density $1.00\times10^{3}\text{ kg/m}^3$ and seawater has density $1.03\times10^{3}\text{ kg/m}^3$.

EXECUTE: **(a)** $p - p_0 = (1.00\times10^{3}\text{ kg/m}^3)(3.71\text{ m/s}^2)(500\text{ m}) = 1.86\times10^{6}\text{ Pa}$.

(b) $h = \dfrac{p - p_0}{\rho g} = \dfrac{1.86\times10^{6}\text{ Pa}}{(1.03\times10^{3}\text{ kg/m}^3)(9.80\text{ m/s}^2)} = 184\text{ m}$

EVALUATE: The pressure at a given depth is greater on earth because a cylinder of water of that height weighs more on earth than on Mars.

12.8. **IDENTIFY:** The difference in pressure at points with heights y_1 and y_2 is $p - p_0 = \rho g(y_1 - y_2)$. The outward force $F_\perp$ is related to the surface area A by $F_\perp = pA$.

SET UP: For blood, $\rho = 1.06\times10^{3}\text{ kg/m}^3$. $y_1 - y_2 = 1.65\text{ m}$. The surface area of the segment is πDL, where $D = 1.50\times10^{-3}\text{ m}$ and $L = 2.00\times10^{-2}\text{ m}$.

EXECUTE: **(a)** $p_1 - p_2 = (1.06\times10^{3}\text{ kg/m}^3)(9.80\text{ m/s}^2)(1.65\text{ m}) = 1.71\times10^{4}\text{ Pa}$.

(b) The additional force due to this pressure difference is $\Delta F_\perp = (p_1 - p_2)A$.

$A = \pi DL = \pi(1.50\times10^{-3}\text{ m})(2.00\times10^{-2}\text{ m}) = 9.42\times10^{-5}\text{ m}^2$.

$\Delta F_\perp = (1.71\times10^{4}\text{ Pa})(9.42\times10^{-5}\text{ m}^2) = 1.61\text{ N}$.

EVALUATE: The pressure difference is about $\frac{1}{6}$ atm.

12.9. **IDENTIFY:** Apply $p = p_0 + \rho gh.$

SET UP: Gauge pressure is $p - p_{\text{air}}$.

EXECUTE: The pressure difference between the top and bottom of the tube must be at least 5980 Pa in order to force fluid into the vein: $\rho gh = 5980$ Pa and

$$h = \frac{5980\ \text{Pa}}{\rho g} = \frac{5980\ \text{N/m}^2}{(1050\ \text{kg/m}^3)(9.80\ \text{m/s}^2)} = 0.581\ \text{m}.$$

EVALUATE: The bag of fluid is typically hung from a vertical pole to achieve this height above the patient's arm.

12.10. **IDENTIFY:** $p_0 = p_{\text{surface}} + \rho gh$ where p_{surface} is the pressure at the surface of a liquid and p_0 is the pressure at a depth h below the surface.

SET UP: The density of water is $1.00\times10^3\ \text{kg/m}^3$.

EXECUTE: **(a)** For the oil layer, $p_{\text{surface}} = p_{\text{atm}}$ and p_0 is the pressure at the oil-water interface.

$p_0 - p_{\text{atm}} = p_{\text{gauge}} = \rho gh = (600\ \text{kg/m}^3)(9.80\ \text{m/s}^2)(0.120\ \text{m}) = 706\ \text{Pa}$

(b) For the water layer, $p_{\text{surface}} = 706\ \text{Pa} + p_{\text{atm}}$.

$p_0 - p_{\text{atm}} = p_{\text{gauge}} = 706\ \text{Pa} + \rho gh = 706\ \text{Pa} + (1.00\times10^3\ \text{kg/m}^3)(9.80\ \text{m/s}^2)(0.250\ \text{m}) = 3.16\times10^3\ \text{Pa}$

EVALUATE: The gauge pressure at the bottom of the barrel is due to the combined effects of the oil layer and water layer. The pressure at the bottom of the oil layer is the pressure at the top of the water layer.

12.11. **IDENTIFY:** The pressure due to the glycerin balances the pressure due to the unknown liquid, so we are dealing with the pressure at a depth in a liquid.

SET UP: Both sides of the U-shaped tube are open to the air, so it is the gauge pressures that balance. Therefore we use $p_g = \rho gh.$ At the level of the bottom of the column of the unknown, the pressure in the right side is equal to the pressure in the left side. (See Fig. 12.11.) On the right side, we have a 35.0-cm column of the unknown, and on the left side we have a column of glycerin whose top is 12.0 cm below that of the unknown, so its height is 35.0 cm – 12.0 cm = 23.0 cm above the bottom of the bottom of the column of the unknown liquid. The target variable is the density of the unknown liquid.

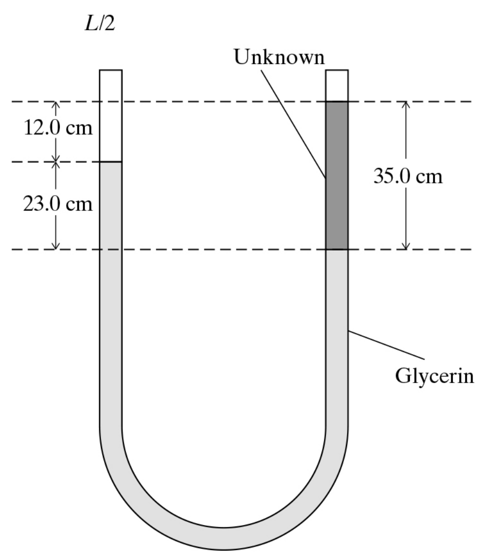

Figure 12.11

EXECUTE: We use $p_g = \rho gh$ to find the gauge pressure at the bottom of each column.

Right-hand column (the unknown): $p = \rho_x g(35.0\ \text{cm})$

Left-hand column (glycerin): $p = \rho_g g(35.0\ \text{cm} - 12.0\ \text{cm}) = \rho_g g(23.0\ \text{cm})$

Equating these pressures and solving for ρ_x gives $\rho_x = \dfrac{23\ \text{cm}}{35\ \text{cm}}\rho_g$. Using ρ_g = 1260 kg/m³ from Table 12.1, we have $\rho_x = \left(\dfrac{23\ \text{cm}}{35\ \text{cm}}\right)(1260\ \text{kg/m}^3) = 828\ \text{kg/m}^3$.

EVALUATE: Our result shows that the unknown is less dense than glycerin. This is reasonable because it takes only a 23-cm column of glycerin to balance a 35-cm column of the unknown.

12.12. **IDENTIFY** and **SET UP:** Use $p_g = \rho gh$ to calculate the gauge pressure at this depth. Use $F = pA$ to calculate the force the inside and outside pressures exert on the window, and combine the forces as vectors to find the net force.

EXECUTE: **(a)** gauge pressure $= p - p_0 = \rho gh$ From Table 12.1 the density of seawater is $1.03 \times 10^3\ \text{kg/m}^3$, so

$$p - p_0 = \rho gh = (1.03 \times 10^3\ \text{kg/m}^3)(9.80\ \text{m/s}^2)(250\ \text{m}) = 2.52 \times 10^6\ \text{Pa}.$$

(b) The force on each side of the window is $F = pA$. Inside the pressure is x p_0 and outside in the water the pressure is $p = p_0 + \rho gh$. The forces are shown in Figure 12.12.

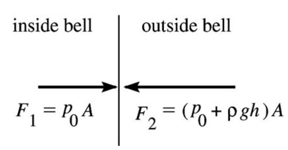

Figure 12.12

The net force is

$$F_2 - F_1 = (p_0 + \rho gh)A - p_0 A = (\rho gh)A$$
$$F_2 - F_1 = (2.52 \times 10^6\ \text{Pa})\pi(0.150\ \text{m})^2$$
$$F_2 - F_1 = 1.78 \times 10^5\ \text{N}$$

EVALUATE: The pressure at this depth is very large, over 20 times normal air pressure, and the net force on the window is huge. Diving bells used at such depths must be constructed to withstand these large forces.

12.13. **IDENTIFY:** The external pressure on the eardrum increases with depth in the ocean. This increased pressure could damage the eardrum.

SET UP: The density of seawater is $1.03 \times 10^3\ \text{kg/m}^3$. The area of the eardrum is $A = \pi r^2$, with $r = 4.1$ mm. The pressure increase with depth is $\Delta p = \rho gh$ and $F = pA$.

EXECUTE: $\Delta F = (\Delta p)A = \rho ghA$. Solving for h gives

$$h = \frac{\Delta F}{\rho gA} = \frac{1.5\ \text{N}}{(1.03 \times 10^3\ \text{kg/m}^3)(9.80\ \text{m/s}^2)\pi(4.1 \times 10^{-3}\ \text{m})^2} = 2.8\ \text{m}.$$

EVALUATE: 2.8 m is less than 10 ft, so it is probably a good idea to wear ear plugs if you scuba dive.

12.14. **IDENTIFY** and **SET UP:** Use $p = p_0 + \rho gh$ to calculate the pressure at the specified depths in the open tube. The pressure is the same at all points the same distance from the bottom of the tubes, so the pressure calculated in part (b) is the pressure in the tank. Gauge pressure is the difference between the absolute pressure and air pressure.

EXECUTE: $p_a = 980\ \text{millibar} = 9.80 \times 10^4\ \text{Pa}$

(a) Apply $p = p_0 + \rho gh$ to the right-hand tube. The top of this tube is open to the air so $p_0 = p_a$. The density of the liquid (mercury) is $13.6 \times 10^3\ \text{kg/m}^3$.

Thus $p = 9.80 \times 10^4\ \text{Pa} + (13.6 \times 10^3\ \text{kg/m}^3)(9.80\ \text{m/s}^2)(0.0700\ \text{m}) = 1.07 \times 10^5\ \text{Pa}$.

(b) a $p = p_0 + \rho gh = 9.80\times10^4\ \text{Pa} + (13.6\times10^3\ \text{kg/m}^3)(9.80\ \text{m/s}^2)(0.0400\ \text{m}) = 1.03\times10^5\ \text{Pa}.$

(c) Since $y_2 - y_1 = 4.00\ \text{cm}$ the pressure at the mercury surface in the left-hand end tube equals that calculated in part (b). Thus the absolute pressure of gas in the tank is $1.03\times10^5\ \text{Pa}.$

(d) $p - p_0 = \rho gh = (13.6\times10^3\ \text{kg/m}^3)(9.80\ \text{m/s}^2)(0.0400\ \text{m}) = 5.33\times10^3\ \text{Pa}.$

EVALUATE: If $p = p_0 + \rho gh$ is evaluated with the density of mercury and $p - p_a = 1\ \text{atm} = 1.01\times10^5\ \text{Pa},$ then $h = 76\ \text{cm}.$ The mercury columns here are much shorter than 76 cm, so the gauge pressures are much less than $1.0\times10^5\ \text{Pa}.$

12.15. **IDENTIFY:** Apply $p = p_0 + \rho gh.$

SET UP: For water, $\rho = 1.00\times10^3\ \text{kg/m}^3.$

EXECUTE: $p - p_{\text{air}} = \rho gh = (1.00\times10^3\ \text{kg/m}^3)(9.80\ \text{m/s}^2)(6.1\ \text{m}) = 6.0\times10^4\ \text{Pa}.$

EVALUATE: The pressure difference increases linearly with depth.

12.16. **IDENTIFY:** The gauge pressure of the person must be equal to the pressure due to the column of water in the straw.

SET UP: Apply $p = p_0 + \rho gh.$

EXECUTE: **(a)** The gauge pressure is $p_g = \rho gh = -(1000\ \text{kg/m}^3)(9.80\ \text{m/s}^2)(1.1\ \text{m}) = -1.1\times10^4\ \text{Pa}.$

(b) In order for water to go up the straw, the pressure at the top of the straw must be lower than atmospheric pressure. Therefore the gauge pressure, $p - p_{\text{atm}}$, must be negative.

EVALUATE: The actual pressure is not negative, just the difference between the pressure at the top of the straw and atmospheric pressure.

12.17. **IDENTIFY:** $p = p_0 + \rho gh.$ $F = pA.$

SET UP: For seawater, $\rho = 1.03\times10^3\ \text{kg/m}^3.$

EXECUTE: The force F that must be applied is the difference between the upward force of the water and the downward forces of the air and the weight of the hatch. The difference between the pressure inside and out is the gauge pressure, so

$$F = (\rho gh)A - w = (1.03\times10^3\ \text{kg/m}^3)(9.80\ \text{m/s}^2)(30\ \text{m})(0.75\ \text{m}^2) - 300\ \text{N} = 2.27\times10^5\ \text{N}.$$

EVALUATE: The force due to the gauge pressure of the water is much larger than the weight of the hatch and would be impossible for the crew to apply it just by pushing.

12.18. **IDENTIFY** and **SET UP:** Apply $p = p_0 + \rho gh$ to the water and mercury columns. The pressure at the bottom of the water column is the pressure at the top of the mercury column.

EXECUTE: With just the mercury, the gauge pressure at the bottom of the cylinder is $p - p_0 = \rho_m g h_m.$ With the water to a depth h_w, the gauge pressure at the bottom of the cylinder is $p - p_0 = \rho_m g h_m + \rho_w g h_w.$ If this is to be double the first value, then $\rho_w g h_w = \rho_m g h_m.$

$$h_w = h_m(\rho_m/\rho_w) = (0.0800\ \text{m})(13.6\times10^3/1.00\times10^3) = 1.088\ \text{m}$$

The volume of water is $V = hA = (1.088\ \text{m})(12.0\times10^{-4}\ \text{m}^2) = 1.306\times10^{-3}\ \text{m}^3 = 1310\ \text{cm}^3 = 1.31\ \text{L}.$

EVALUATE: The density of mercury is 13.6 times the density of water and $(13.6)(8\ \text{cm}) = 109\ \text{cm},$ so the pressure increase from the top to the bottom of a 109-cm tall column of water is the same as the pressure increase from top to bottom for an 8-cm tall column of mercury.

12.19. **IDENTIFY:** The gauge pressure at the top of the oil column must produce a force on the disk that is equal to its weight.

SET UP: The area of the bottom of the disk is $A = \pi r^2 = \pi(0.150\ \text{m})^2 = 0.0707\ \text{m}^2.$

EXECUTE: **(a)** $p - p_0 = \dfrac{w}{A} = \dfrac{45.0\text{ N}}{0.0707\text{ m}^2} = 636\text{ Pa}.$

(b) The increase in pressure produces a force on the disk equal to the increase in weight. By Pascal's law the increase in pressure is transmitted to all points in the oil.

(i) $\Delta p = \dfrac{83.0\text{ N}}{0.0707\text{ m}^2} = 1170\text{ Pa}.$ (ii) 1170 Pa

EVALUATE: The absolute pressure at the top of the oil produces an upward force on the disk but this force is partially balanced by the force due to the air pressure at the top of the disk.

12.20. **IDENTIFY:** This problem deals with the absolute pressure at a depth in a fluid.

SET UP: The absolute (or total) pressure is $p = p_0 + \rho g h$. The target variable is the depth at which the absolute pressure is twice and four times the surface pressure. The density of seawater is 1030 kg/m³.

EXECUTE: **(a)** Using $p = p_0 + \rho g h$ gives $2p_0 = p_0 + \rho g h$, so $h = \dfrac{p_0}{\rho g}$, which gives

$$h = \frac{1.0\times10^5\text{ Pa}}{(1030\text{ kg/m}^3)(9.80\text{ m/s}^2)} = 10.2\text{ m}.$$

(b) Follow the same procedure as in part (a), giving $4p_0 = p_0 + \rho g h$, so $h = \dfrac{3p_0}{\rho g}$, which gives

$$h = \frac{3p_0}{\rho g} = \frac{3(1.03\times10^5\text{ Pa})}{(1030\text{ kg/m}^3)(9.80\text{ m/s}^2)} = 30.6\text{ m}.$$

EVALUATE: Notice that by tripling the depth we do not triple the absolute pressure. But we would triple the gauge pressure.

12.21. **IDENTIFY:** $F_2 = \dfrac{A_2}{A_1}F_1.$ F_2 must equal the weight $w = mg$ of the car.

SET UP: $A = \pi D^2/4.$ D_1 is the diameter of the vessel at the piston where F_1 is applied and D_2 is the diameter at the car.

EXECUTE: $mg = \dfrac{\pi D_2^2/4}{\pi D_1^2/4}F_1.$ $\dfrac{D_2}{D_1} = \sqrt{\dfrac{mg}{F_1}} = \sqrt{\dfrac{(1520\text{ kg})(9.80\text{ m/s}^2)}{125\text{ N}}} = 10.9$

EVALUATE: The diameter is smaller where the force is smaller, so the pressure will be the same at both pistons.

12.22. **IDENTIFY:** Apply $\Sigma F_y = ma_y$ to the piston, with $+y$ upward. $F = pA.$

SET UP: $1\text{ atm} = 1.013\times10^5\text{ Pa}.$ The force diagram for the piston is given in Figure 12.22. p is the absolute pressure of the hydraulic fluid.

EXECUTE: $pA - w - p_{\text{atm}}A = 0$ and

$$p - p_{\text{atm}} = p_{\text{gauge}} = \frac{w}{A} = \frac{mg}{\pi r^2} = \frac{(1200\text{ kg})(9.80\text{ m/s}^2)}{\pi(0.15\text{ m})^2} = 1.7\times10^5\text{ Pa} = 1.7\text{ atm}$$

EVALUATE: The larger the diameter of the piston, the smaller the gauge pressure required to lift the car.

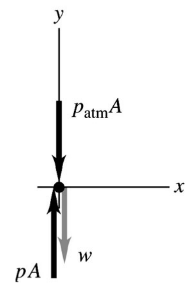

Figure 12.22

12.23. **IDENTIFY:** We are dealing with the pressure at a depth in a fluid.

SET UP: The pressure with the wine is the same as the pressure with mercury, except that the heights of the fluids are different because they have different densities. $p = p_0 + \rho gh$ gives the pressure in each case, with p_0 the same for both cases. The target variable is the height of the wine column.

EXECUTE: $p_0 + \rho_w gh_w = p_0 + \rho_m gh_m$, so $h_w = h_m \dfrac{\rho_m}{\rho_w} = (0.750\ \text{m})\dfrac{13.6\times10^3\ \text{kg/m}^3}{990\ \text{kg/m}^3} = 10.3\ \text{m}.$

EVALUATE: A wine barometer over 10 m high is highly unwieldy compared to one around 1 m high for mercury. Besides, there are better uses for wine!

12.24. **IDENTIFY:** This problem deals with buoyant force on your floating body. Archimedes's principle applies.

SET UP: Estimate: About 5% of the body is above water. Weight is 165 lb ≈ 734 N. The buoyant force B is equal to your weight and is equal to the weight of the seawater displaced by your body. The volume of seawater is 95% of your volume. The weight of a volume of material is $w = \rho gV$ and average density is $\rho_{\text{av}} = m/V$. The target variables are the volume of your body and its average density.

EXECUTE: **(a)** Let subscripts w refer to water and quantities without susbscripts refer to you. When floating, $B = w_{\text{w}} = \rho_{\text{w}} gV_{\text{w}}$ and $V_{\text{w}} = 0.95V$. Using $B = w$ gives $\rho_w g(0.95V) = w$. Solving for V gives

$$V = \frac{w}{0.95\rho_{\text{w}} g} = \frac{734\ \text{N}}{(0.95)(1030\ \text{kg/m}^3)(9.80\ \text{m/s}^2)} = 7.7\times10^{-2}\ \text{m}^3.$$

(b) $\rho_{\text{av}} = \dfrac{m}{V} = \dfrac{W/g}{V} = \dfrac{(734\ \text{N})/(9.80\ \text{m/s}^2)}{7.7\times10^{-2}\ \text{m}^3} = 970\ \text{kg/m}^3 \approx 95\%\ \rho_{\text{seawater}}$.

EVALUATE: To see if your volume is reasonable, assume you are all pure water and calculate your weight. $w_{\text{w}} = \rho_{\text{w}} gV_{\text{w}} = (1000\ \text{kg/m}^3)(9.80\ \text{m/s}^2)(0.077\ \text{m}^3) = 755$ N, which is very close to your weight. So the volume is reasonable.

12.25. **IDENTIFY:** A buoyant force acts on the athlete, so Archimedes's principle applies. He doesn't sink, so the forces on him must balance.

SET UP: Apply $\sum F_y = 0$ to the athlete. The volume of water he displaces is equal to his volume since he is totally submerged, so $V_{\text{w}} = V_{\text{ath}}$. The buoyant force it exerts is equal to the weight of that volume of water. We want to find the volume and average density of the athlete. $\rho_{\text{av}} = m/V$.

EXECUTE: Using $\sum F_y = 0$ gives $B + 20\ \text{N} - 900\ \text{N} = 0$, so $B = 880$ N. The buoyant force is equal to the weight of the water he displaces, and $V_{\text{w}} = V_{\text{ath}}$, so $B = \rho_{\text{w}} gV_{\text{w}} = \rho_{\text{w}} gV_{\text{ath}}$. Solving for his volume gives $V_{\text{ath}} = \dfrac{B}{\rho_{\text{w}} g} = \dfrac{880\ \text{N}}{(1000\ \text{kg/m}^3)(9.80\ \text{m/s}^2)} = 8.98\times10^{-2}\ \text{m}^3$. His average density is $\rho_{\text{av}} = \dfrac{m}{V} = \dfrac{W/g}{V} = \dfrac{(900\ \text{N})/(9.80\ \text{m/s}^2)}{8.98\times10^{-2}\ \text{m}^3} = 1020\ \text{kg/m}^3$.

EVALUATE: The athlete is slightly denser than pure water. This is reasonable because he probably has little fat, which is less dense than muscle.

12.26. **IDENTIFY:** The buoyant force B acts upward on the rock, opposing gravity. Archimedes's principle applies, and the forces must balance.

SET UP: $\rho = m/V$.

EXECUTE: With the rock of mass m in the water: $T + B = mg$. where T is the tension in the string. Call V the volume of the rock and ρ_w the density of water. By Archimedes's principle, $m = \rho_w V$, so we get $T + \rho_w Vg = mg$. Solving for V gives $V = (mg - T)/\rho_w g$. Now look at the rock in the liquid, where ρ is the density of the liquid. For the smallest density liquid, the rock is totally submerged, so the volume of liquid displaced is V. For floating we have $B = mg$, which gives $\rho gV = mg$. Solving for ρ and using the equation for V that we just found, we get

$$\rho = \frac{m}{\frac{mg - T}{\rho_w g}} = \frac{\rho_w mg}{mg - T} = \frac{(1000\ \text{kg/m}^3)(1.80\ \text{kg})(9.80\ \text{m/s}^2)}{(1.80\ \text{kg})(9.80\ \text{m/s}^2) - 12.8\ \text{N}} = 3640\ \text{kg/m}^3.$$

EVALUATE: In the water, the buoyant force was not enough to balance the weight of the rock, so there was a tension of 12.8 N in the string. In the new liquid, the buoyant force is equal to the weight. Therefore the liquid must be denser than water, which in fact it is.

12.27. **IDENTIFY:** By Archimedes's principle, the additional buoyant force will be equal to the additional weight (the man).

SET UP: $V = \dfrac{m}{\rho}$ where $dA = V$ and d is the additional distance the buoy will sink.

EXECUTE: With man on buoy must displace additional 80.0 kg of water.

$$V = \frac{m}{\rho} = \frac{80.0\ \text{kg}}{1030\ \text{kg/m}^3} = 0.07767\ \text{m}^3.\quad dA = V \text{ so } d = \frac{V}{A} = \frac{0.07767\ \text{m}^3}{\pi(0.450\ \text{m})^2} = 0.122\ \text{m}.$$

EVALUATE: We do not need to use the mass of the buoy because it is already floating and hence in balance.

12.28. **IDENTIFY:** Apply Newton's second law to the woman plus slab. The buoyancy force exerted by the water is upward and given by $B = \rho_{\text{water}} V_{\text{displ}} g$, where V_{displ} is the volume of water displaced.

SET UP: The floating object is the slab of ice plus the woman; the buoyant force must support both. The volume of water displaced equals the volume V_{ice} of the ice. The free-body diagram is given in Figure 12.28.

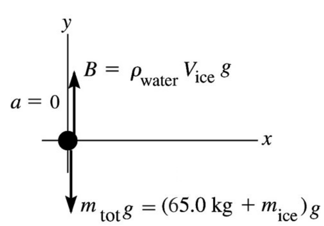

Figure 12.28

EXECUTE: $\Sigma F_y = ma_y$

$B - m_{\text{tot}} g = 0$

$\rho_{\text{water}} V_{\text{ice}} g = (65.0\ \text{kg} + m_{\text{ice}})g$

But $\rho = m/V$ so $m_{\text{ice}} = \rho_{\text{ice}} V_{\text{ice}}$

$$V_{\text{ice}} = \frac{65.0\ \text{kg}}{\rho_{\text{water}} - \rho_{\text{ice}}} = \frac{65.0\ \text{kg}}{1000\ \text{kg/m}^3 - 920\ \text{kg/m}^3} = 0.81\ \text{m}^3.$$

EVALUATE: The mass of ice is $m_{\text{ice}} = \rho_{\text{ice}} V_{\text{ice}} = 750\ \text{kg}$.

12.29. **IDENTIFY:** Apply $\Sigma F_y = ma_y$ to the sample, with $+y$ upward. $B = \rho_{\text{water}} V_{\text{obj}} g$.

SET UP: $w = mg = 17.50\ \text{N}$ and $m = 1.79\ \text{kg}$.

EXECUTE: $T + B - mg = 0$. $a_x = 0$

$$V_{\text{obj}} = \frac{B}{\rho_{\text{water}} g} = \frac{6.30\ \text{N}}{(1.00\times10^3\ \text{kg/m}^3)(9.80\ \text{m/s}^2)} = 6.43\times10^{-4}\ \text{m}^3.$$

$$\rho = \frac{m}{V} = \frac{1.79\ \text{kg}}{6.43\times10^{-4}\ \text{m}^3} = 2.78\times10^3\ \text{kg/m}^3.$$

EVALUATE: The density of the sample is greater than that of water and it doesn't float.

12.30. IDENTIFY: The upward buoyant force B exerted by the liquid equals the weight of the fluid displaced by the object. Since the object floats the buoyant force equals its weight.

SET UP: Glycerin has density $\rho_{\text{gly}} = 1.26\times10^3\ \text{kg/m}^3$ and seawater has density $\rho_{\text{sw}} = 1.03\times10^3\ \text{kg/m}^3$. Let V_{obj} be the volume of the apparatus. $g_{\text{E}} = 9.80\ \text{m/s}^2$; $g_{\text{C}} = 5.40\ \text{m/s}^2$. Let V_{sub} be the volume submerged on Caasi.

EXECUTE: On earth $B = \rho_{\text{sw}}(0.250V_{\text{obj}})g_{\text{E}} = mg_{\text{E}}$. $m = (0.250)\rho_{\text{sw}}V_{\text{obj}}$. On Caasi, $B = \rho_{\text{gly}}V_{\text{sub}}g_{\text{C}} = mg_{\text{C}}$. $m = \rho_{\text{gyl}}V_{\text{sub}}$. The two expressions for m must be equal, so

$$(0.250)V_{\text{obj}}\rho_{\text{sw}} = \rho_{\text{gly}}V_{\text{sub}} \text{ and } V_{\text{sub}} = \left(\frac{0.250\rho_{\text{sw}}}{\rho_{\text{gly}}}\right)V_{\text{obj}} = \left(\frac{[0.250][1.03\times10^3\ \text{kg/m}^3]}{1.26\times10^3\ \text{kg/m}^3}\right)V_{\text{obj}} = 0.204V_{\text{obj}}.$$

20.4% of the volume will be submerged on Caasi.

EVALUATE: Less volume is submerged in glycerin since the density of glycerin is greater than the density of seawater. The value of g on each planet cancels out and has no effect on the answer. The value of g changes the weight of the apparatus and the buoyant force by the same factor.

12.31. IDENTIFY: In air and in the liquid, the forces on the rock must balance. Archimedes's principle applies in the liquid.

SET UP: $B = \rho V g$, $\rho = m/V$, call m the mass of the rock, V its volume, and ρ its density; T is the tension in the string and ρ_{L} is the density of the liquid.

EXECUTE: In air: $T = mg = \rho V g$. $V = T/\rho g = (28.0\ \text{N})/[(1200\ \text{kg/m}^3)(9.80\ \text{m/s}^2)] = 0.00238\ \text{m}^3$.

In the liquid: $T + B = mg$, so

$T = mg - B = \rho V g - \rho_{\text{L}} V g = gV(\rho - \rho_{\text{L}}) = (9.80\ \text{m/s}^2)(0.00238\ \text{m}^3)(1200\ \text{kg/m}^3 - 750\ \text{kg/m}^3) = 10.5$ N.

EVALUATE: When the rock is in the liquid, the tension in the string is less than the tension when the rock is in air since the buoyant force helps balance some of the weight of the rock.

12.32. IDENTIFY: $B = \rho_{\text{water}}V_{\text{obj}}g$. The net force on the sphere is zero.

SET UP: The density of water is $1.00\times10^3\ \text{kg/m}^3$.

EXECUTE: **(a)** $B = (1000\ \text{kg/m}^3)(0.650\ \text{m}^3)(9.80\ \text{m/s}^2) = 6.37\times10^3\ \text{N}$

(b) $B = T + mg$ and $m = \dfrac{B - T}{g} = \dfrac{6.37\times10^3\ \text{N} - 1120\ \text{N}}{9.80\ \text{m/s}^2} = 536\ \text{kg}.$

(c) Now $B = \rho_{\text{water}}V_{\text{sub}}g$, where V_{sub} is the volume of the sphere that is submerged. $B = mg$.

$$\rho_{\text{water}}V_{\text{sub}}g = mg \text{ and } V_{\text{sub}} = \frac{m}{\rho_{\text{water}}} = \frac{536\ \text{kg}}{1000\ \text{kg/m}^3} = 0.536\ \text{m}^3. \quad \frac{V_{\text{sub}}}{V_{\text{obj}}} = \frac{0.536\ \text{m}^3}{0.650\ \text{m}^3} = 0.824 = 82.4\%.$$

EVALUATE: The average density of the sphere is $\rho_{\text{sph}} = \dfrac{m}{V} = \dfrac{536\ \text{kg}}{0.650\ \text{m}^3} = 825\ \text{kg/m}^3$. $\rho_{\text{sph}} < \rho_{\text{water}}$, and that is why it floats with 82.4% of its volume submerged.

12.33. IDENTIFY and SET UP: Use $p = p_0 + \rho g h$ to calculate the gauge pressure at the two depths.

(a) The distances are shown in Figure 12.33a.

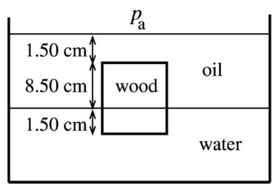

Figure 12.33a

EXECUTE: $p - p_0 = \rho g h$

The upper face is 1.50 cm below the top of the oil, so

$$p - p_0 = (790\ \text{kg/m}^3)(9.80\ \text{m/s}^2)(0.0150$$

$$p - p_0 = 116\ \text{Pa}$$

(b) The pressure at the interface is $p_{\text{interface}} = p_a + \rho_{\text{oil}} g(0.100\ \text{m})$. The lower face of the block is 1.50 cm below the interface, so the pressure there is $p = p_{\text{interface}} + \rho_{\text{water}} g(0.0150\ \text{m})$. Combining these two equations gives

$$p - p_a = \rho_{\text{oil}} g(0.100\ \text{m}) + \rho_{\text{water}} g(0.0150\ \text{m})$$

$$p - p_a = [(790\ \text{kg/m}^3)(0.100\ \text{m}) + (1000\ \text{kg/m}^3)(0.0150\ \text{m})](9.80\ \text{m/s}^2)$$

$$p - p_a = 921\ \text{Pa}$$

(c) IDENTIFY and **SET UP:** Consider the forces on the block. The area of each face of the block is $A = (0.100\ \text{m})^2 = 0.0100\ \text{m}^2$. Let the absolute pressure at the top face be p_t and the pressure at the bottom face be p_b. In $p = \dfrac{F_\perp}{A}$, use these pressures to calculate the force exerted by the fluids at the top and bottom of the block. The free-body diagram for the block is given in Figure 12.33b.

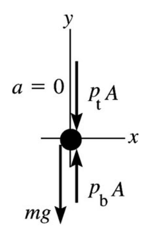

Figure 12.33b

EXECUTE: $\Sigma F_y = m a_y$

$$p_b A - p_t A - mg = 0$$

$$(p_b - p_t)A = mg$$

Note that $(p_b - p_t) = (p_b - p_a) - (p_t - p_a) = 921\ \text{Pa} - 116\ \text{Pa} = 805\ \text{Pa}$; the difference in absolute pressures equals the difference in gauge pressures.

$$m = \frac{(p_b - p_t)A}{g} = \frac{(805\ \text{Pa})(0.0100\ \text{m}^2)}{9.80\ \text{m/s}^2} = 0.821\ \text{kg}.$$

And then $\rho = m/V = 0.821\ \text{kg}/(0.100\ \text{m})^3 = 821\ \text{kg/m}^3$.

EVALUATE: We can calculate the buoyant force as $B = (\rho_{\text{oil}} V_{\text{oil}} + \rho_{\text{water}} V_{\text{water}})g$ where $V_{\text{oil}} = (0.0100\ \text{m}^2)(0.0850\ \text{m}) = 8.50 \times 10^{-4}\ \text{m}^3$ is the volume of oil displaced by the block and $V_{\text{water}} = (0.0100\ \text{m}^2)(0.0150\ \text{m}) = 1.50 \times 10^{-4}\ \text{m}^3$ is the volume of water displaced by the block. This gives $B = (0.821\ \text{kg})g$. The mass of water displaced equals the mass of the block.

12.34. IDENTIFY: The sum of the vertical forces on the ingot is zero. $\rho = m/V$. The buoyant force is $B = \rho_{\text{water}} V_{\text{obj}} g$.

SET UP: The density of aluminum is $2.7 \times 10^3\ \text{kg/m}^3$. The density of water is $1.00 \times 10^3\ \text{kg/m}^3$.

EXECUTE: **(a)** $T = mg = 89\ \text{N}$ so $m = 9.08\ \text{kg}$. $V = \dfrac{m}{\rho} = \dfrac{9.08\ \text{kg}}{2.7 \times 10^3\ \text{kg/m}^3} = 3.36 \times 10^{-3}\ \text{m}^3 = 3.4\ \text{L}$.

(b) When the ingot is totally immersed in the water while suspended, $T + B - mg = 0$.

$B = \rho_{\text{water}} V_{\text{obj}} g = (1.00\times10^3\ \text{kg/m}^3)(3.36\times10^{-3}\ \text{m}^3)(9.80\ \text{m/s}^2) = 32.9\ \text{N}$.

$T = mg - B = 89\ \text{N} - 32.9\ \text{N} = 56\ \text{N}$.

EVALUATE: The buoyant force is equal to the difference between the apparent weight when the object is submerged in the fluid and the actual gravity force on the object.

12.35. **IDENTIFY:** The vertical forces on the rock sum to zero. The buoyant force equals the weight of liquid displaced by the rock. $V = \frac{4}{3}\pi R^3$.

SET UP: The density of water is $1.00\times10^3\ \text{kg/m}^3$.

EXECUTE: The rock displaces a volume of water whose weight is $39.2\ \text{N} - 28.4\ \text{N} = 10.8\ \text{N}$. The mass of this much water is thus $10.8\ \text{N}/(9.80\ \text{m/s}^2) = 1.102\ \text{kg}$ and its volume, equal to the rock's volume, is $\dfrac{1.102\ \text{kg}}{1.00\times10^3\ \text{kg/m}^3} = 1.102\times10^{-3}\ \text{m}^3$. The weight of unknown liquid displaced is $39.2\ \text{N} - 21.5\ \text{N} = 17.7\ \text{N}$, and its mass is $(17.7\ \text{N})/(9.80\ \text{m/s}^2) = 1.806\ \text{kg}$. The liquid's density is thus $(1.806\ \text{kg})/(1.102\times10^{-3}\ \text{m}^3) = 1.64\times10^3\ \text{kg/m}^3$.

EVALUATE: The density of the unknown liquid is a little more than 1.5 times the density of water.

12.36. **IDENTIFY:** The block floats in water and then in a second liquid, so we apply Archimedes's principle.

SET UP: In both cases, the buoyant force is equal to the weight of the block and is also equal to the weight of the liquid displaced by the block. Call V the volume of the block and use $w = \rho g V$. The target variable is the density of the second liquid.

EXECUTE: In water: $B = \rho_{\text{w}} g V_{\text{W}} = \rho_{\text{w}} g(0.700V)$

In the second liquid: $B = \rho_{\text{L}} g V_{\text{L}} = \rho_{\text{L}} g(0.800V)$

Equate the buoyant forces and solve for ρ_{L}: $\rho_{\text{L}} = \dfrac{0.700}{0.800}\rho_{\text{w}} = 875\ \text{kg/m}^3$.

EVALUATE: In the second liquid the block has more of its volume submerged than in the water, so the second liquid must be less dense than water. This agrees with our result.

12.37. **IDENTIFY:** The cylinder is partially submerged in water, so we apply Archimedes's principle. The vertical forces on it must balance.

SET UP: The density of this cylinder is 370/1000 = 37% that of water, so it would float with 37% of its volume under the water and 63% above water. But it is partially submerged with 70.0% under water. Therefore the buoyant force B on it must be greater than its weight, and this would force the cylinder upward. The tension in the cable prevents this from happening. The target variable is the tension T in the cable. We apply $\Sigma F_y = 0$ and $w = \rho g V$.

EXECUTE: Start with $\Sigma F_y = 0$: $B - T - w_{\text{c}} = 0$. We see that we first need to find B. Call V the volume of the cylinder and ρ_{c} its density. Therefore $w_{\text{c}} = \rho_{\text{c}} gV$. By Archimedes's principle, the buoyant force B is equal to the weight of the water displaced by the cylinder, and we know that the cylinder has 70% of its volume below the water, which is $0.700V$. Therefore $B = \rho_{\text{w}} g(0.700V)$. Dividing B by w_{c} gives

$\dfrac{B}{w_{\text{c}}} = \dfrac{\rho_{\text{w}} g(0.700V)}{\rho_{\text{c}} gV} = \dfrac{\rho_{\text{w}}}{\rho_{\text{c}}} = \dfrac{1000\ \text{kg/m}^3}{370\ \text{kg/m}^3} = 2.7027$, so $B = 2.7027w_{\text{c}}$. Putting this result into $\Sigma F_y = 0$ gives

$2.7027w_{\text{c}} - T - w_{\text{c}} = 0$. Solving for T gives

$T = 1.7027w_{\text{c}} = (1.7027)(30.0\ \text{kg})(9.80\ \text{m/s}^2) = 501\ \text{N}$.

EVALUATE: If the cable were to break, the net upward force at that instant on the cylinder would be $B - w_{\text{c}} = 2.7027w_{\text{c}} - w_{\text{c}} = 1.70w_{\text{c}}$, so the cylinder would accelerate upward and eventually float with 63% of its volume above water.

12.38. **IDENTIFY:** The volume flow rate is Av.

SET UP: $Av = 0.750\ \text{m}^3/\text{s}$. $A = \pi D^2/4$.

EXECUTE: **(a)** $v\pi D^2/4 = 0.750\ \text{m}^3/\text{s}$. $v = \dfrac{4(0.750\ \text{m}^3/\text{s})}{\pi(4.50\times10^{-2}\ \text{m})^2} = 472\ \text{m/s}$.

(b) vD^2 must be constant, so $v_1D_1^2 = v_2D_2^2$. $v_2 = v_1\left(\dfrac{D_1}{D_2}\right)^2 = (472\ \text{m/s})\left(\dfrac{D_1}{3D_1}\right)^2 = 52.4\ \text{m/s}$.

EVALUATE: The larger the hole, the smaller the speed of the fluid as it exits.

12.39. **IDENTIFY:** Apply the equation of continuity.

SET UP: $A = \pi r^2$, $v_1A_1 = v_2A_2$.

EXECUTE: $v_2 = v_1(A_1/A_2)$.

$A_1 = \pi(0.80\ \text{cm})^2$, $A_2 = 20\pi(0.10\ \text{cm})^2$. $v_2 = (3.0\ \text{m/s})\dfrac{\pi(0.80)^2}{20\pi(0.10)^2} = 9.6\ \text{m/s}$.

EVALUATE: The total area of the shower head openings is less than the cross-sectional area of the pipe, and the speed of the water in the shower head opening is greater than its speed in the pipe.

12.40. **IDENTIFY:** Apply the equation of continuity. The volume flow rate is vA.

SET UP: $1.00\ \text{h} = 3600\ \text{s}$. $v_1A_1 = v_2A_2$.

EXECUTE: **(a)** $v_2 = v_1\left(\dfrac{A_1}{A_2}\right) = (3.50\ \text{m/s})\left(\dfrac{0.070\ \text{m}^2}{0.105\ \text{m}^2}\right) = 2.3\ \text{m/s}$

(b) $v_2 = v_1\left(\dfrac{A_1}{A_2}\right) = (3.50\ \text{m/s})\left(\dfrac{0.070\ \text{m}^2}{0.047\ \text{m}^2}\right) = 5.2\ \text{m/s}$

(c) $V = v_1A_1t = (3.50\ \text{m/s})(0.070\ \text{m}^2)(3600\ \text{s}) = 880\ \text{m}^3$.

EVALUATE: The equation of continuity says the volume flow rate is the same at all points in the pipe.

12.41. **IDENTIFY** and **SET UP:** Apply the continuity equation, $v_1A_1 = v_2A_2$. In part (a) the target variable is V. In part (b) solve for A and then from that get the radius of the pipe.

EXECUTE: **(a)** $vA = 1.20\ \text{m}^3/\text{s}$

$$v = \frac{1.20\ \text{m}^3/\text{s}}{A} = \frac{1.20\ \text{m}^3/\text{s}}{\pi r^2} = \frac{1.20\ \text{m}^3/\text{s}}{\pi(0.150\ \text{m})^2} = 17.0\ \text{m/s}$$

(b) $vA = 1.20\ \text{m}^3/\text{s}$

$v\pi r^2 = 1.20\ \text{m}^3/\text{s}$

$$r = \sqrt{\frac{1.20\ \text{m}^3/\text{s}}{v\pi}} = \sqrt{\frac{1.20\ \text{m}^3/\text{s}}{(3.80\ \text{m/s})\pi}} = 0.317\ \text{m}$$

EVALUATE: The speed is greater where the area and radius are smaller.

12.42. **IDENTIFY:** This problem is about fluid flow, so we use Bernoulli's equation and the volume flow rate.

SET UP: Apply $p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$ and $dv/dt = Av$. Choose $y = 0$ at the base of the tank, so $y_2 = 0$ and $y_1 = h$. Since the tank is large, assume that $v_2 >> v_1$, so we use $v_1 = 0$. The top of the tank and the end of the pipe are open to the atmosphere, so $p_1 = p_2$. We need to find a relationship between the volume flow rate dV/dt and h in order to interpret the graph. The target variable is g on this planet.

EXECUTE: Bernoulli's equation reduces to $\rho g h = \frac{1}{2}\rho v_2^2$, which gives $v_2 = \sqrt{2gh}$. The continuity equation gives $dV/dt = Av_2$. Using our result for v_2 gives $dV/dt = Av_2 = A\sqrt{2gh}$. Squaring gives $(dV/dt)^2 = 2A^2gh$.

From this result we see that a graph of $(dV/dt)^2$ versus h should be a straight line with slope $2A^2g$. This gives $g = \frac{\text{slope}}{2A^2} = g = \frac{1.94\times10^{-5}\ \text{m}^5/\text{s}^2}{2(9.0\times10^{-4}\ \text{m}^2)} = 9.0\ \text{m/s}^2$.

EVALUATE: This is a reasonable value for g on a solid planet.

12.43. **IDENTIFY:** Water is flowing out of the tank and collecting in a bucket, so we use Bernoulli's equation and the volume flow rate.

SET UP: $p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$, $dV/dt = Av$. Choose $y = 0$ at the base of the tank, so $y_2 = 0$ and $y_1 = h$. The top of the tank and the end of the pipe are open to the atmosphere, so $p_1 = p_2$. The target variable is the time it takes to collect a gallon of water. Call R the radius of the tank and r the radius of the small hole at the bottom.

EXECUTE: **(a)** As 1 gal flows out of the tank the change in volume in the tank is 1 gal = $3.788\times10^{-3}\ \text{m}^3$. The change in volume ΔV of water in the tank due to a height change Δh is $\Delta V = \pi R^2 \Delta h$, so Δh = $\Delta V/(\pi R^2)$ = ($3.788\times10^{-3}\ \text{m}^3$)/[$\pi$(1.50 m)^2] = 5.36×10^{-4} m = 0.536 mm.

(b) Now use $p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$. Based upon the result in part (a), we can treat the height of water in the tank as constant while a gallon flows out and treat the speed v_1 of the water at the top of the tank as being essentially zero. The top of the tank and the end of the pipe are open to the atmosphere, so $p_1 = p_2$. Take $y = 0$ at the bottom of the tank. We need to find the speed v_2 of the water as it comes out of the small hole at the bottom of the tank. Bernoulli's equation becomes $\rho g h = \frac{1}{2}\rho v_2^2$, which gives $v_2 = \sqrt{2gh}$. Now use the volume flow rate at the bottom. $dV/dt = Av_2 = \pi r^2 \sqrt{2gh}$. This gives $\Delta V = \pi r^2 \sqrt{2gh}\,\Delta t$, so $\Delta t = \frac{\Delta V}{\pi r^2 \sqrt{2gh}}$. Using ΔV = $3.788\times10^{-3}\ \text{m}^3$, r = 0.250 cm = 0.0025 m, and h = 2.00 m gives Δt = 30.8 s.

EVALUATE: It is reasonable to neglect the change in depth of the water in the tank as one gallon flows out because $\Delta h \ll h$: 0.536 mm << 2.00 m.

12.44. **IDENTIFY:** $\rho = m/V$. Apply the equation of continuity and Bernoulli's equation to points 1 and 2.

SET UP: The density of water is 1 kg/L.

EXECUTE: **(a)** $\frac{(220)(0.355\ \text{kg})}{60.0\ \text{s}} = 1.30\ \text{kg/s}$.

(b) The density of the liquid is $\frac{0.355\ \text{kg}}{0.355\times10^{-3}\ \text{m}^3} = 1000\ \text{kg/m}^3$, and so the volume flow rate is $\frac{1.30\ \text{kg/s}}{1000\ \text{kg/m}^3} = 1.30\times10^{-3}\ \text{m}^3/\text{s} = 1.30\ \text{L/s}$. This result may also be obtained from $\frac{(220)(0.355\ \text{L})}{60.0\ \text{s}} = 1.30\ \text{L/s}$.

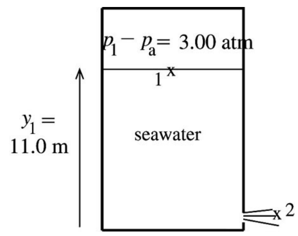
(c) $v_1 = \frac{1.30\times10^{-3}\ \text{m}^3/\text{s}}{2.00\times10^{-4}\ \text{m}^2} = 6.50\ \text{m/s}$. $v_2 = v_1/4 = 1.63\ \text{m/s}$.

(d) $p_1 = p_2 + \frac{1}{2}\rho(v_2^2 - v_1^2) + \rho g(y_2 - y_1)$.

$p_1 = 152\ \text{kPa} + (1000\ \text{kg/m}^3)\left(\tfrac{1}{2}\left[(1.63\ \text{m/s})^2 - (6.50\ \text{m/s})^2\right] + (9.80\ \text{m/s}^2)(-1.35\ \text{m})\right)$. $p_1 = 119\ \text{kPa}$.

EVALUATE: The increase in height and the increase in fluid speed at point 1 both cause the pressure at point 1 to be less than the pressure at point 2.

12.45. **IDENTIFY** and **SET UP:**



Apply Bernoulli's equation with points 1 and 2 chosen as shown in Figure 12.45. Let $y = 0$ at the bottom of the tank so $y_1 = 11.0$ m and $y_2 = 0$. The target variable is v_2.

Figure 12.45

$p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$

$A_1 v_1 = A_2 v_2$, so $v_1 = (A_2/A_1)v_2$. But the cross-sectional area of the tank (A_1) is much larger than the cross-sectional area of the hole (A_2), so $v_1 << v_2$ and the $\frac{1}{2}\rho v_1^2$ term can be neglected.

EXECUTE: This gives $\frac{1}{2}\rho v_2^2 = (p_1 - p_2) + \rho g y_1$.

Use $p_2 = p_a$ and solve for v_2:

$$v_2 = \sqrt{2(p_1 - p_a)/\rho + 2gy_1} = \sqrt{\frac{2(3.039\times 10^5\ \text{Pa})}{1030\ \text{kg/m}^3} + 2(9.80\ \text{m/s}^2)(11.0\ \text{m})}$$

$v_2 = 28.4$ m/s

EVALUATE: If the pressure at the top surface of the water were air pressure, then Toricelli's theorem (Example: 12.8) gives $v_2 = \sqrt{2g(y_1 - y_2)} = 14.7$ m/s. The actual afflux speed is much larger than this due to the excess pressure at the top of the tank.

12.46. **IDENTIFY:** A change in the speed of the blood indicates that there is a difference in the cross-sectional area of the artery. Bernoulli's equation applies to the fluid.

SET UP: Bernoulli's equation is $p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$. The two points are close together so we can neglect $\rho g(y_1 - y_2)$. $\rho = 1.06\times 10^3$ kg/m^3. The continuity equation is $A_1 v_1 = A_2 v_2$.

EXECUTE: Solve $p_1 - p_2 + \frac{1}{2}\rho v_1^2 = \frac{1}{2}\rho v_2^2$ for v_2:

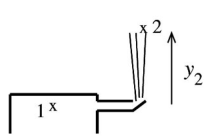
$$v_2 = \sqrt{\frac{2(p_1 - p_2)}{\rho} + v_1^2} = \sqrt{\frac{2(1.20\times 10^4\ \text{Pa} - 1.15\times 10^4\ \text{Pa})}{1.06\times 10^3\ \text{kg/m}^3} + (0.300\ \text{m/s})^2} = 1.0\ \text{m/s} = 100\ \text{cm/s}.$$

$v_2 = 1.0$ m/s $= 100$ cm/s.

The continuity equation gives $\frac{A_2}{A_1} = \frac{v_1}{v_2} = \frac{30\ \text{cm/s}}{100\ \text{cm/s}} = 0.30$. $A_2 = 0.30 A_1$, so 70% of the artery is blocked.

EVALUATE: A 70% blockage reduces the blood speed from 100 cm/s to 30 cm/s, which should easily be detectable.

12.47. **IDENTIFY** and **SET UP:**



Apply Bernoulli's equation to points 1 and 2 as shown in Figure 12.47. Point 1 is in the mains and point 2 is at the maximum height reached by the stream, so $v_2 = 0$.

Figure 12.47

Solve for p_1 and then convert this absolute pressure to gauge pressure.

EXECUTE: $p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$

Let $y_1 = 0$, $y_2 = 15.0$ m. The mains have large diameter, so $v_1 \approx 0$.

Thus $p_1 = p_2 + \rho g y_2$.

But $p_2 = p_a$, so $p_1 - p_a = \rho g y_2 = (1000\ \text{kg/m}^3)(9.80\ \text{m/s}^2)(15.0\ \text{m}) = 1.47\times10^5$ Pa.

EVALUATE: This is the gauge pressure at the bottom of a column of water 15.0 m high.

12.48. **IDENTIFY:** Toricelli's theorem says the speed of efflux is $v = \sqrt{2gh}$, where h is the distance of the small hole below the surface of the water in the tank. The volume flow rate is vA.

SET UP: $A = \pi D^2/4$, with $D = 6.00\times10^{-3}$ m.

EXECUTE: **(a)** $v = \sqrt{2(9.80\ \text{m/s}^2)(14.0\ \text{m})} = 16.6$ m/s

(b) $vA = (16.6\ \text{m/s})\pi(6.00\times10^{-3}\ \text{m})^2/4 = 4.69\times10^{-4}\ \text{m}^3/\text{s}$. A volume of $4.69\times10^{-4}\ \text{m}^3 = 0.469$ L is discharged each second.

EVALUATE: We have assumed that the diameter of the hole is much less than the diameter of the tank.

12.49. **IDENTIFY:** Apply Bernoulli's equation to the two points.

SET UP: $y_1 = y_2$. $v_1A_1 = v_2A_2$. $A_2 = 2A_1$.

EXECUTE: $p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$. $v_2 = v_1\left(\dfrac{A_1}{A_2}\right) = (2.50\ \text{m/s})\left(\dfrac{A_1}{2A_1}\right) = 1.25$ m/s.

$$p_2 = p_1 + \tfrac{1}{2}\rho(v_1^2 - v_2^2) = 1.80\times10^4\ \text{Pa} + \tfrac{1}{2}(1000\ \text{kg/m}^3)[(2.50\ \text{m/s})^2 - (1.25\ \text{m/s})^2] = 2.03\times10^4\ \text{Pa}.$$

EVALUATE: The gauge pressure is higher at the second point because the water speed is less there.

12.50. **IDENTIFY:** Apply Bernoulli's equation to the two points.

SET UP: The continuity equation says $v_1A_1 = v_2A_2$. In Bernoulli's equation, either absolute or gauge pressures can be used at both points. $p_1 + \frac{1}{2}\rho v_1^2 + \rho g y_1 = p_2 + \frac{1}{2}\rho v_2^2 + \rho g y_2$.

EXECUTE: Using $v_2 = \frac{1}{4}v_1$,

$$p_2 = p_1 + \frac{1}{2}\rho(v_1^2 - v_2^2) + \rho g(y_1 - y_2) = p_1 + \rho\left[\left(\frac{15}{32}\right)v_1^2 + g(y_1 - y_2)\right]$$

$$p_2 = 5.00\times10^4\ \text{Pa} + (1.00\times10^3\ \text{kg/m}^3)\left(\frac{15}{32}(3.00\ \text{m/s})^2 + (9.80\ \text{m/s}^2)(11.0\ \text{m})\right) = 1.62\times10^5\ \text{Pa}.$$

EVALUATE: The decrease in speed and the decrease in height at point 2 both cause the pressure at point 2 to be greater than the pressure at point 1.

12.51. **IDENTIFY** and **SET UP:** Let point 1 be where $r_1 = 4.00$ cm and point 2 be where $r_2 = 2.00$ cm. The volume flow rate vA has the value $7200\ \text{cm}^3/\text{s}$ at all points in the pipe. Apply $v_1A_1 = v_2A_2$ to find the fluid speed at points 1 and 2 and then use Bernoulli's equation for these two points to find p_2.

EXECUTE: $v_1A_1 = v_1\pi r_1^2 = 7200\ \text{cm}^3$, so $v_1 = 1.43$ m/s

$v_2A_2 = v_2\pi r_2^2 = 7200\ \text{cm}^3/\text{s}$, so $v_2 = 5.73$ m/s

$p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$

$y_1 = y_2$ and $p_1 = 2.40\times10^5$ Pa, so $p_2 = p_1 + \frac{1}{2}\rho(v_1^2 - v_2^2) = 2.25\times10^5$ Pa.

EVALUATE: Where the area decreases the speed increases and the pressure decreases.

12.52. IDENTIFY: Since a pressure difference is needed to keep the fluid flowing, there must be viscosity in the fluid.

SET UP: From Section 12.6, the pressure difference Δp over a length L of cylindrical pipe of radius R is proportional to L/R^4. In this problem, the length L is the same in both cases, so $R^4\,\Delta p$ must be constant. The target variable is the pressure difference.

EXECUTE: Since $R^4\,\Delta p$ is constant, we have $\Delta p_1 R_1^4 = \Delta p_2 R_2^4$.

$$\Delta p_2 = \Delta p_1\left(\frac{R_1}{R_2}\right)^4 = (6.00\times10^4\ \text{Pa})\left(\frac{0.21\ \text{m}}{0.0700\ \text{m}}\right)^4 = 4.86\times10^6\ \text{Pa}.$$

EVALUATE: The pipe is narrower, so the pressure difference must be greater.

12.53. IDENTIFY: Increasing the cross-sectional area of the artery will increase the amount of blood that flows through it per second.

SET UP: The flow rate, $\dfrac{\Delta V}{\Delta t}$, is related to the radius R or diameter D of the artery by Poiseuille's law: $\dfrac{\Delta V}{\Delta t} = \dfrac{\pi R^4}{8\eta}\left(\dfrac{p_1-p_2}{L}\right) = \dfrac{\pi D^4}{128\eta}\left(\dfrac{p_1-p_2}{L}\right)$. Assume the pressure gradient $(p_1-p_2)/L$ in the artery remains the same.

EXECUTE: $(\Delta V/\Delta t)/D^4 = \dfrac{\pi}{128\eta}\left(\dfrac{p_1-p_2}{L}\right) = \text{constant}$, so $(\Delta V/\Delta t)_{\text{old}}/D_{\text{old}}{}^4 = (\Delta V/\Delta t)_{\text{new}}/D_{\text{new}}{}^4$.

$(\Delta V/\Delta t)_{\text{new}} = 2(\Delta V/\Delta t)_{\text{old}}$ and $D_{\text{old}} = D$. This gives $D_{\text{new}} = D_{\text{old}}\left[\dfrac{(\Delta V/\Delta t)_{\text{new}}}{(\Delta V/\Delta t)_{\text{old}}}\right]^{1/4} = 2^{1/4}D = 1.19D.$

EVALUATE: Since the flow rate is proportional to D^4, a 19% increase in D doubles the flow rate.

12.54. IDENTIFY: Apply $p = p_0 + \rho g h$ and $\Delta V = -\dfrac{(\Delta p)V_0}{B}$, where B is the bulk modulus.

SET UP: Seawater has density $\rho = 1.03\times10^3\ \text{kg/m}^3$. The bulk modulus of water is $B = 2.2\times10^9$ Pa. $p_{\text{air}} = 1.01\times10^5$ Pa.

EXECUTE: (a)

$$p_0 = p_{\text{air}} + \rho g h = 1.01\times10^5\ \text{Pa} + (1.03\times10^3\ \text{kg/m}^3)(9.80\ \text{m/s}^2)(10.92\times10^3\ \text{m}) = 1.10\times10^8\ \text{Pa}$$

(b) At the surface $1.00\ \text{m}^3$ of seawater has mass 1.03×10^3 kg. At a depth of 10.92 km the change in volume is $\Delta V = -\dfrac{(\Delta p)V_0}{B} - \dfrac{(1.10\times10^8\ \text{Pa})(1.00\ \text{m}^3)}{2.2\times10^9\ \text{Pa}} = -0.050\ \text{m}^3$. The volume of this mass of water at this depth therefore is $V = V_0 + \Delta V = 0.950\ \text{m}^3$. $\rho = \dfrac{m}{V} = \dfrac{1.03\times10^3\ \text{kg}}{0.950\ \text{m}^3} = 1.08\times10^3\ \text{kg/m}^3$. The density is 5% larger than at the surface.

EVALUATE: For water B is small and a very large increase in pressure corresponds to a small fractional change in volume.

12.55. IDENTIFY: In part (a), the force is the weight of the water. In part (b), the pressure due to the water at a depth h is $\rho g h$. $F = pA$ and $m = \rho V$.

SET UP: The density of water is $1.00\times10^3\ \text{kg/m}^3$.

EXECUTE: (a) The weight of the water is

$$\rho g V = (1.00\times10^3\ \text{kg/m}^3)(9.80\ \text{m/s}^2)((5.00\ \text{m})(4.0\ \text{m})(3.0\ \text{m})) = 5.9\times10^5\ \text{N}.$$

(b) Integration gives the expected result that the force is what it would be if the pressure were uniform and equal to the pressure at the midpoint. If d is the depth of the pool and A is the area of one end of the pool, then $F = \rho g A \dfrac{d}{2} = (1.00\times10^3 \text{ kg/m}^3)(9.80 \text{ m/s}^2)((4.0 \text{ m})(3.0 \text{ m}))(1.50 \text{ m}) = 1.76\times10^5$ N.

EVALUATE: The answer to part (a) can be obtained as $F = pA$, where $p = \rho g d$ is the gauge pressure at the bottom of the pool and $A = (5.0 \text{ m})(4.0 \text{ m})$ is the area of the bottom of the pool.

12.56. **IDENTIFY:** A buoyant force acts on the rock when it is suspended in the liquids, so we apply Archimedes's principle. The vertical forces on the rock must balance.

SET UP: Apply $\sum F_y = 0$ and $w = \rho g V$. The target variable is the weight of the rock. In both cases, the rock is totally immersed, so the volume of fluid displaced is equal to the volume V of the rock. We know the densities of the fluids from Table 12.1.

EXECUTE: Call T the tension in the string. $\sum F_y = 0$ gives $T + B = w$, where $B = \rho g V$.

In water: $T_w + \rho_w g V = w$ (Eq. 1)

In ethanol: $T_e + \rho_e g V = w$ (Eq. 2)

Combine Eq. (1) and Eq. (2): $\dfrac{\rho_w g V}{\rho_e g V} = \dfrac{w - T_w}{w - T_e}$. Solving for w gives $w = \dfrac{(\rho_w/\rho_e)T_e - T_w}{(\rho_w/\rho_e) - 1}$. Using ρ_w = 1000 kg/m^3, ρ_e = 810 kg/m^3, T_w = 1.20 N, and T_e = 1.60 N, we get w = 3.3 N.

EVALUATE: The tension in ethanol is greater than the tension in water because ethanol is less than water and therefore produces a smaller buoyant force.

12.57. **IDENTIFY:** Use $p = p_0 + \rho g h$ to find the gauge pressure versus depth, use $p = \dfrac{F_\perp}{A}$ to relate the pressure to the force on a strip of the gate, calculate the torque as force times moment arm, and follow the procedure outlined in the hint to calculate the total torque.

SET UP: The gate is sketched in Figure 12.57a.

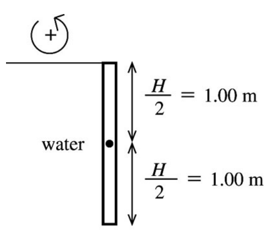


Figure 12.57a

Let τ_u be the torque due to the net force of the water on the upper half of the gate, and τ_l be the torque due to the force on the lower half.

With the indicated sign convention, τ_l is positive and τ_u is negative, so the net torque about the hinge is $\tau = \tau_l - \tau_u$. Let H be the height of the gate.

Upper half of gate:

Calculate the torque due to the force on a narrow strip of height dy located a distance y below the top of the gate, as shown in Figure 12.57b. Then integrate to get the total torque.

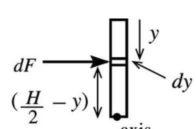

Figure 12.57b

The net force on the strip is $dF = p(y)\,dA$, where $p(y) = \rho g y$ is the pressure at this depth and $dA = W\,dy$ with $W = 4.00$ m.

$dF = \rho g y W\,dy$

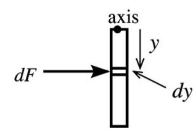
The moment arm is $(H/2-y)$, so $d\tau = \rho gW(H/2-y)y\,dy$.

$\tau_\text{u} = \int_0^{H/2} d\tau = \rho gW \int_0^{H/2}(H/2-y)y\,dy = \rho gW((H/4)y^2 - y^3/3)\Big|_0^{H/2}$

$\tau_\text{u} = \rho gW(H^3/16 - H^3/24) = \rho gW(H^3/48)$

$\tau_\text{u} = (1000\text{ kg/m}^3)(9.80\text{ m/s}^2)(4.00\text{ m})(2.00\text{ m})^3/48 = 6.533\times10^3\text{ N}\cdot\text{m}$

<u>Lower half of gate</u>:



Consider the narrow strip shown in Figure 12.57c. The depth of the strip is $(H/2+y)$ so the force dF is $dF = p(y)\,dA = \rho g(H/2+y)W\,dy$.

Figure 12.57c

The moment arm is y, so $d\tau = \rho gW(H/2+y)y\,dy$.

$\tau_1 = \int_0^{H/2} d\tau = \rho gW \int_0^{H/2}(H/2+y)y\,dy = \rho gW((H/4)y^2 + y^3/3)\Big|_0^{H/2}$

$\tau_1 = \rho gW(H^3/16 + H^3/24) = \rho gW(5H^3/48)$

$\tau_1 = (1000\text{ kg/m}^3)(9.80\text{ m/s}^2)(4.00\text{ m})5(2.00\text{ m})^3/48 = 3.267\times10^4\text{ N}\cdot\text{m}$

Then $\tau = \tau_1 - \tau_\text{u} = 3.267\times10^4\text{ N}\cdot\text{m} - 6.533\times10^3\text{ N}\cdot\text{m} = 2.61\times10^4\text{ N}\cdot\text{m}$.

EVALUATE: The forces and torques on the upper and lower halves of the gate are in opposite directions so find the net value by subtracting the magnitudes. The torque on the lower half is larger than the torque on the upper half since pressure increases with depth.

12.58. **IDENTIFY:** A dense cube floats in a tank containing water and glycerin, so Archimedes's principle applies and the vertical forces on it must balance.

SET UP: The buoyant force B is equal to the weight of the fluid displaced, and $w = \rho gV$. We want to find out what fraction of the cube's volume is below the surface of the glycerin. The water layer is on top of the glycerin layer, so we should first find out if *any* of the cube gets into the glycerin. Calling m the mass of the cube and V its volume, its density is $\rho_c = m/V = \dfrac{9.20\times10^{-3}\text{ kg}}{(0.0200\text{ m})^3} = 1150\text{ kg/m}^3$. This is greater than the density of water (1000 kg/m^3) but less than the density of glycerin (1260 kg/m^3). Therefore water alone cannot support the cube, so some of it must be in the glycerin. The cube is floating, so $\sum F_y = 0$.

EXECUTE: With V the total volume of the cube and x the volume that is in the glycerin, $V-x$ is the volume in water. By Archimedes's principle, there are *two* buoyant forces on it: one due to the displaced water and the other due to the displaced glycerin. Therefore $\sum F_y = 0$ tells us that $B_w + B_g = mg$. Using $w = \rho gV$, this gives $\rho_w gV_w + \rho_g gV_g = mg$, so $\rho_w g(V-x) + \rho_g gx = mg$. Rearranging gives $x(\rho_g - \rho_w) = m - \rho_w V$. We want the fraction of the cube's volume that is in glycerin, so we want x/V. Solving for this gives $\dfrac{x}{V} = \dfrac{m/V - \rho_w}{\rho_g - \rho_w} = \dfrac{\rho_c - \rho_w}{\rho_g - \rho_w}$. Using the given numbers gives $\dfrac{x}{V} = \dfrac{(1150-1000)\text{ kg/m}^3}{(1260-1000)\text{ kg/m}^3} = 0.577$, so 57.7% of its volume is in glycerin.

EVALUATE: It might seem strange that the water can exert any buoyant force on the cube since the only horizontal surface of the cube that is exposed the water is the *top*, and the force there is *downward*. However, let us look at the buoyant force in terms of the pressure in the fluids. This pressure is

$p = p_0 + \rho gh$. Fig. 12.58 shows the pressure on the upper and lower surfaces of the cube, with p_0 the atmospheric pressure.

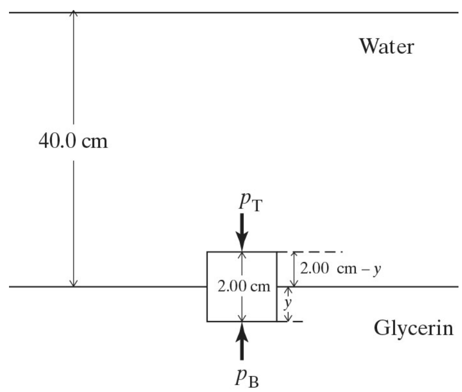


Figure 12.58

The upper surface of the cube is a distance 40 cm – (2 cm – y) = 38 cm + y below the top of the water. The pressure at that depth is the pressure at the top of the cube $p_T = p_0 + \rho_w g(38 \text{ cm} + y)$. The bottom of the cube is a distance y below the surface of the glycerin. The pressure at the surface of the glycerin layer is due to atmospheric pressure and the pressure from 40 cm of water, which is $p_0 + p_w =$ $p_0 + \rho_w g(40 \text{ cm})$. The pressure at a depth y in the glycerin is the pressure at the bottom face of the cube and is $p_B = p_0 + \rho_w g(40 \text{ cm}) + \rho_w gy.$ The force on an area A is pA, so the buoyant force on the cube is $B = p_B A - p_T A = (p_B - p_T)A.$ Using the expressions we just found for p_B and p_T gives $B = \{p_0 + \rho_w g(40 \text{ cm}) + \rho_w gy - [p_0 + \rho_w g(38 \text{ cm} + y)]\}A$. Simplifying gives $B = [\rho_w(2 \text{ cm} - y) + \rho_g y]Ag$. The buoyant force supports the cube, so $B = \rho_c g V_c$, which gives $\rho_c g V_c = [\rho_w(2 \text{ cm} - y) + \rho_g y]Ag.$ In terms of the surface area, $V_c = A(2 \text{ cm})$. Using this we get $\rho_c(2\text{cm}) = \rho_w(2\text{cm} - y) + \rho_g y$. Solving for y gives $y = \dfrac{(\rho_c - \rho_w)(2\text{cm})}{\rho_g - \rho_w}$. The fraction of the volume in the glycerin is $\dfrac{y}{2\text{cm}}$, so we get $\dfrac{y}{2\text{cm}} = \dfrac{\rho_c - \rho_w}{\rho_g - \rho_w}$, which is the same result we got above, so our result checks.

12.59. IDENTIFY: This problem deals with the pressure at a depth in a fluid and requires graphical interpretation.

SET UP: The gauge pressure on the bottom of the block supports the weight of the block and the coins. The graph is a plot of the depth h of the bottom of the block versus the mass m of the coins, so we need to look for a relationship between these quantities. The target variable is the mass M of the block. The gauge pressure is $p = \rho gh$ and the force on an area is $F = pA$.

EXECUTE: The net force on the block is $p_g A$, and that force must be equal to the weight of the box plus the coins. This gives $p_g A = mg + Mg.$ Using $p_g = \rho gh$, this becomes $\rho ghA = mg + Mg$ so $h = \dfrac{1}{\rho A}m + \dfrac{M}{\rho A}$. Therefore a graph of h versus m should have a slope of $\dfrac{1}{\rho A}$ and a y-intercept of $\dfrac{M}{\rho A}$. From the slope we get $A = \dfrac{1}{\rho(\text{slope})}$. The y-intercept gives $y\text{-int} = \dfrac{M}{\rho A}$, so $M = (y\text{-int})\rho A$. Putting the result for A into the equation for M gives $M = (y\text{-int})\rho A = (y\text{-int})\rho\left(\dfrac{1}{\rho(\text{slope})}\right) = \dfrac{y\text{-int}}{\text{slope}} =$

$\dfrac{0.0312\text{ m}}{0.0390\text{ m/kg}} = 0.800\text{ kg}.$

EVALUATE: Careful graphing is important because the answer depends on *both* the slope and y-intercept of the graph.

12.60. **IDENTIFY:** The buoyant force B equals the weight of the air displaced by the balloon.

SET UP: $B = \rho_{\text{air}}Vg$. Let g_{M} be the value of g for Mars. For a sphere $V = \frac{4}{3}\pi R^3$. The surface area of a sphere is given by $A = 4\pi R^2$. The mass of the balloon is $(5.00\times10^{-3}\text{ kg/m}^2)(4\pi R^2)$.

EXECUTE: **(a)** $B = mg_{\text{M}}$. $\rho_{\text{air}}Vg_{\text{M}} = mg_{\text{M}}$. $\rho_{\text{air}}\frac{4}{3}\pi R^3 = (5.00\times10^{-3}\text{ kg/m}^2)(4\pi R^2)$.

$R = \dfrac{3(5.00\times10^{-3}\text{ kg/m}^2)}{\rho_{\text{air}}} = 0.974\text{ m}.$ $m = (5.00\times10^{-3}\text{ kg/m}^2)(4\pi R^2) = 0.0596\text{ kg}.$

(b) $F_{\text{net}} = B - mg = ma$. $B = \rho_{\text{air}}Vg = \rho_{\text{air}}\frac{4}{3}\pi R^3 g = (1.20\text{ kg/m}^3)\left(\dfrac{4\pi}{3}\right)(0.974\text{ m})^3(9.80\text{ m/s}^2) = 45.5\text{ N}.$

$a = \dfrac{B - mg}{m} = \dfrac{45.5\text{ N} - (0.0596\text{ kg})(9.80\text{ m/s}^2)}{0.0596\text{ m}} = 754\text{ m/s}^2,$ upward.

(c) $B = m_{\text{tot}}g$. $\rho_{\text{air}}Vg = (m_{\text{balloon}} + m_{\text{load}})g$. $m_{\text{load}} = \rho_{\text{air}}\frac{4}{3}\pi R^3 - (5.00\times10^{-3}\text{ kg/m}^2)4\pi R^2$.

$m_{\text{load}} = (0.0154\text{ kg/m}^3)\left(\dfrac{4\pi}{3}\right)(5[0.974\text{ m}])^3 - (5.00\times10^{-3}\text{ kg/m}^2)(4\pi)(5[0.974\text{ m}])^2$

$m_{\text{load}} = 7.45\text{ kg} - 1.49\text{ kg} = 5.96\text{ kg}$

EVALUATE: The buoyant force is proportional to R^3 and the mass of the balloon is proportional to R^2, so the load that can be carried increases when the radius of the balloon increases. We calculated the mass of the load. To find the weight of the load we would need to know the value of g for Mars.

12.61. **IDENTIFY:** The buoyant force on an object in a liquid is equal to the weight of the liquid it displaces.

SET UP: $V = \dfrac{m}{\rho}$.

EXECUTE: When it is floating, the ice displaces an amount of glycerin equal to its weight. From Table 12.1, the density of glycerin is 1260 kg/m^3. The volume of this amount of glycerin is $V = \dfrac{m}{\rho} = \dfrac{0.180\text{ kg}}{1260\text{ kg/m}^3} = 1.429\times10^{-4}\text{ m}^3$. The ice cube produces 0.180 kg of water. The volume of this mass of water is $V = \dfrac{m}{\rho} = \dfrac{0.180\text{ kg}}{1000\text{ kg/m}^3} = 1.80\times10^{-4}\text{ m}^3$. The volume of water from the melted ice is greater than the volume of glycerin displaced by the floating cube and the level of liquid in the cylinder rises. The distance the level rises is $\dfrac{1.80\times10^{-4}\text{ m}^3 - 1.429\times10^{-4}\text{ m}^3}{\pi(0.0350\text{ m})^2} = 9.64\times10^{-3}\text{ m} = 0.964\text{ cm}.$

EVALUATE: The melted ice has the same mass as the solid ice, but a different density.

12.62. **IDENTIFY:** The pressure must be the same at the bottom of the tube. Therefore since the liquids have different densities, they must have difference heights.

SET UP: After the barrier is removed the top of the water moves downward a distance x and the top of the oil moves up a distance x, as shown in Figure 12.62. After the heights have changed, the gauge pressure at the bottom of each of the tubes is the same. The gauge pressure p at a depth h is $p - p_{\text{atm}} = \rho gh$.

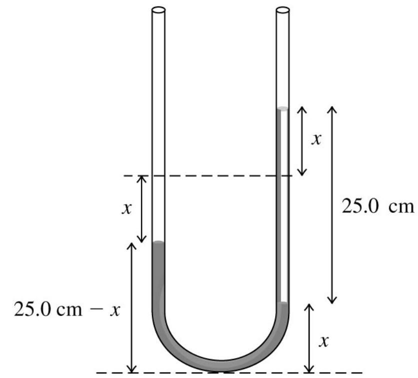

Figure 12.62

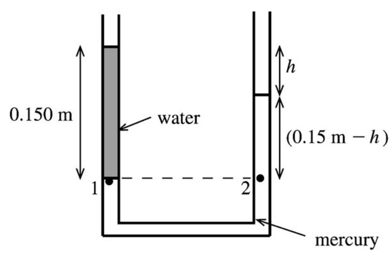
EXECUTE: The gauge pressure at the bottom of arm *A* of the tube is $p - p_{atm} = \rho_w g(25.0\text{ cm} - x)$. The gauge pressure at the bottom of arm *B* of the tube is $p - p_{atm} = \rho_{oil} g(25.0\text{ cm}) + \rho_w gx$. The gauge pressures must be equal, so $\rho_w g(25.0\text{ cm} - x) = \rho_{oil} g(25.0\text{ cm}) + \rho_w gx$. Dividing out *g* and using $\rho_{oil} = 0.80\rho_w$, we have $\rho_w(25.0\text{ cm} - x) = 0.80\rho_w(25.0\text{ cm}) + \rho_w x$. ρ_w divides out and leaves $25.0\text{ cm} - x = 20.0\text{ cm} + x$, so $x = 2.5\text{ cm}$. The height of fluid in arm *A* is $25.0\text{ cm} - x = 22.5\text{ cm}$ and the height in arm *B* is $25.0\text{ cm} + x = 27.5\text{ cm}$.

(b) (i) If the densities were the same there would be no reason for a difference in height and the height would be 25.0 cm on each side. (ii) The pressure exerted by the column of oil would be very small and the water would divide equally on both sides. The height in arm *A* would be 12.5 cm and the height in arm *B* would be $25.0\text{ cm} + 12.5\text{ cm} = 37.5\text{ cm}$.

EVALUATE: The less dense fluid rises to a higher height, which is physically reasonable.

12.63. (a) IDENTIFY and SET UP:



Apply $p = p_0 + \rho gh$ to the water in the left-hand arm of the tube. See Figure 12.63.

Figure 12.63

EXECUTE: $p_0 = p_a$, so the gauge pressure at the interface (point 1) is

$p - p_a = \rho gh = (1000\text{ kg/m}^3)(9.80\text{ m/s}^2)(0.150\text{ m}) = 1470\text{ Pa}$.

(b) IDENTIFY and SET UP: The pressure at point 1 equals the pressure at point 2. Apply $p = p_0 + \rho gh$ to the right-hand arm of the tube and solve for *h*.

EXECUTE: $p_1 = p_a + \rho_w g(0.150\text{ m})$ and $p_2 = p_a + \rho_{Hg} g(0.150\text{ m} - h)$

$p_1 = p_2$ implies $\rho_w g(0.150\text{ m}) = \rho_{Hg} g(0.150\text{ m} - h)$

$$0.150\text{ m} - h = \frac{\rho_w(0.150\text{ m})}{\rho_{Hg}} = \frac{(1000\text{ kg/m}^3)(0.150\text{ m})}{13.6\times10^3\text{ kg/m}^3} = 0.011\text{ m}$$

$h = 0.150\text{ m} - 0.011\text{ m} = 0.139\text{ m} = 13.9\text{ cm}$

EVALUATE: The height of mercury above the bottom level of the water is 1.1 cm. This height of mercury produces the same gauge pressure as a height of 15.0 cm of water.

12.64. IDENTIFY: Follow the procedure outlined in the hint. $F = pA$.

SET UP: The circular ring has area $dA = (2\pi R)dy$. The pressure due to the molasses at depth y is ρgy.

EXECUTE: $F = \int_0^h (\rho gy)(2\pi R)dy = \rho g\pi Rh^2$ where R and h are the radius and height of the tank.

Using the given numerical values gives $F = 2.11\times10^8$ N.

EVALUATE: The net outward force is the area of the wall of the tank, $A = 2\pi Rh$, times the average pressure, the pressure $\rho gh/2$ at depth $h/2$.

12.65. IDENTIFY: Archimedes's principle applies.

SET UP: $\rho = m/V$, the buoyant force B is equal to the weight of the liquid displaced. Call m the mass of the block.

EXECUTE: **(a)** The volume of water displaced by the block is 80.0% of the volume of the block. Using $B = mg$: $\rho_w V_w g = mg$ gives $\rho_w (0.800 V_{block}) = m$. Therefore $V_{block} = m/(0.800\,\rho_w)$, so

$V_{block} = (40.0\text{ kg})/[(0.800)(1000\text{ kg/m}^3)] = 0.0500\text{ m}^3$.

(b) With the maximum amount of bricks added on, the block is completely submerged but the bricks are not under water. Therefore $m_{bricks}g + mg = \rho_w V_{block}g$. Solving for m_{bricks} and putting in the numbers gives

$m_{bricks} = \rho_w V_{block} - m = (1000\text{ kg/m}^3)(0.0500\text{ m}^3) - 40.0\text{ kg} = 10.0\text{ kg}$.

EVALUATE: If the bricks were to go under water, the buoyant force would increase because a greater volume of water would be displaced.

12.66. IDENTIFY: The buoyant force on the balloon must equal the total weight of the balloon fabric, the basket and its contents and the gas inside the balloon. $m_{gas} = \rho_{gas}V$. $B = \rho_{air}Vg$.

SET UP: The total weight, exclusive of the gas inside the balloon, is $900\text{ N} + 1700\text{ N} + 3200\text{ N} = 5800\text{ N}$.

EXECUTE: $5800\text{ N} + \rho_{gas}Vg = \rho_{air}Vg$ and $\rho_{gas} = 1.23\text{ kg/m}^3 - \dfrac{(5800\text{ N})}{(9.80\text{ m/s}^2)(2200\text{ m}^3)} = 0.96\text{ kg/m}^3$.

EVALUATE: The volume of a given mass of gas increases when the gas is heated, and the density of the gas therefore decreases.

12.67. IDENTIFY: Apply Newton's second law to the barge plus its contents. Apply Archimedes's principle to express the buoyancy force B in terms of the volume of the barge.

SET UP: The free-body diagram for the barge plus coal is given in Figure 12.67.

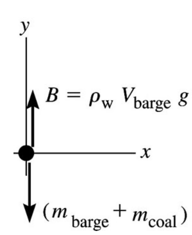


Figure 12.67

EXECUTE: $\sum F_y = ma_y$

$B - (m_{barge} + m_{coal})g = 0$

$\rho_w V_{barge} g = (m_{barge} + m_{coal})g$

$m_{coal} = \rho_w V_{barge} - m_{barge}$

$V_{barge} = (22\text{ m})(12\text{ m})(40\text{ m}) = 1.056\times10^4\text{ m}^3$

The mass of the barge is $m_{barge} = \rho_s V_s$, where s refers to steel.

From Table 12.1, $\rho_s = 7800\ \text{kg/m}^3$. The volume V_s is 0.040 m times the total area of the five pieces of steel that make up the barge

$$V_s = (0.040\ \text{m})[2(22\ \text{m})(12\ \text{m}) + 2(40\ \text{m})(12\ \text{m}) + (22\ \text{m})(40\ \text{m})] = 94.7\ \text{m}^3.$$

Therefore, $m_{\text{barge}} = \rho_s V_s = (7800\ \text{kg/m}^3)(94.7\ \text{m}^3) = 7.39\times10^5\ \text{kg}$.

Then $m_{\text{coal}} = \rho_w V_{\text{barge}} - m_{\text{barge}} = (1000\ \text{kg/m}^3)(1.056\times10^4\ \text{m}^3) - 7.39\times10^5\ \text{kg} = 9.8\times10^6\ \text{kg}$.

The volume of this mass of coal is $V_{\text{coal}} = m_{\text{coal}}/\rho_{\text{coal}} = 9.8\times10^6\ \text{kg}/1500\ \text{kg/m}^3 = 6500\ \text{m}^3$; this is less than V_{barge} so it will fit into the barge.

EVALUATE: The buoyancy force B must support both the weight of the coal and also the weight of the barge. The weight of the coal is about 13 times the weight of the barge. The buoyancy force increases when more of the barge is submerged, so when it holds the maximum mass of coal the barge is fully submerged.

12.68. **IDENTIFY:** For a floating object the buoyant force equals the weight of the object. The buoyant force when the wood sinks is $B = \rho_{\text{water}} V_{\text{tot}} g$, where V_{tot} is the volume of the wood plus the volume of the lead. $\rho = m/V$.

SET UP: The density of lead is $11.3\times10^3\ \text{kg/m}^3$.

EXECUTE: $V_{\text{wood}} = (0.600\ \text{m})(0.250\ \text{m})(0.080\ \text{m}) = 0.0120\ \text{m}^3$.

$m_{\text{wood}} = \rho_{\text{wood}} V_{\text{wood}} = (700\ \text{kg/m}^3)(0.0120\ \text{m}^3) = 8.40\ \text{kg}$.

$B = (m_{\text{wood}} + m_{\text{lead}})g$. Using $B = \rho_{\text{water}} V_{\text{tot}} g$ and $V_{\text{tot}} = V_{\text{wood}} + V_{\text{lead}}$ gives

$\rho_{\text{water}}(V_{\text{wood}} + V_{\text{lead}})g = (m_{\text{wood}} + m_{\text{lead}})g$. $m_{\text{lead}} = \rho_{\text{lead}} V_{\text{lead}}$ then gives

$\rho_{\text{water}} V_{\text{wood}} + \rho_{\text{water}} V_{\text{lead}} = m_{\text{wood}} + \rho_{\text{lead}} V_{\text{lead}}$.

$$V_{\text{lead}} = \frac{\rho_{\text{water}} V_{\text{wood}} - m_{\text{wood}}}{\rho_{\text{lead}} - \rho_{\text{water}}} = \frac{(1000\ \text{kg/m}^3)(0.0120\ \text{m}^3) - 8.40\ \text{kg}}{11.3\times10^3\ \text{kg/m}^3 - 1000\ \text{kg/m}^3} = 3.50\times10^{-4}\ \text{m}^3.$$

$m_{\text{lead}} = \rho_{\text{lead}} V_{\text{lead}} = 3.95\ \text{kg}$.

EVALUATE: The volume of the lead is only 2.9% of the volume of the wood. If the contribution of the volume of the lead to F_B is neglected, the calculation is simplified: $\rho_{\text{water}} V_{\text{wood}} g = (m_{\text{wood}} + m_{\text{lead}})g$ and $m_{\text{lead}} = 3.6\ \text{kg}$. The result of this calculation is in error by about 9%.

12.69. **IDENTIFY:** The water shoots out of the hole at the bottom of the jug and is then in free-fall downward to the floor. We will need to use Bernoulli's equation as well as projectile motion after the milk leaves the jug.

SET UP: Estimates: The milk is 10 in. (25.4 cm = 0.254 m) high in the jug and the table height is 30 in. (0.762 m). We use $p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$, $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$, and $x = x_0 + v_{0x}t + \frac{1}{2}a_x t^2$. The target variable is the horizontal distance the milk travels before hitting the floor. Call h the height of the milk in the jug and H the height of the table.

EXECUTE: Using $p_1 = p_2 = p_{\text{atm}}$, $v_1 = 0$ ($A_{-1} >> A_2$), $y_1 = h$ = 10 in. = 0.54 m, $y_2 = 0$, we get $\rho g h = \frac{1}{2}\rho v_2^2$, which gives $v_2 = \sqrt{2gh}$. Now use projectile motion. Find the time to fall a distance H from rest vertically. $y = y_0 + v_{0y}t + \frac{1}{2}a_y t^2$ gives $t = \sqrt{\frac{2H}{g}}$. The horizontal distance traveled in this time is

$$x = v_2 t = \sqrt{2gh}\sqrt{\frac{2H}{g}} = 2\sqrt{hH} = 2\sqrt{(0.254\ \text{m})(0.762\ \text{m})} = 0.88\ \text{m} = 88\ \text{cm} = 35\ \text{in.}$$

EVALUATE: As the jug drains, h will decrease so the distance x will also decrease.

12.70. **IDENTIFY:** The ethanol is flowing through a pipe, so we need to use Bernoulli's equation, the continuity equation, and volume flow rate.

SET UP: Use $p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$, $A_1 v_1 = A_2 v_2$ (continuity equation) and $dV/dt = Av$. We want to find the pressure at A so that the volume flow rate at B is $0.0800\ \text{m}^3/\text{s}$.

EXECUTE: $p_1 = p$ (unknown), $y_1 = 0$, $y_2 = 3.00$ m, $p_2 = p_{\text{atm}}$, v_1 and v_2 are unknown. Use the volume flow rate to find v_2. Using $dV/dt = A_B v_2$ gives $v_2 = \frac{dV/dt}{A_B} = \frac{0.0800\ \text{m}^3/\text{s}}{0.0200\ \text{m}^2} = 4.00\ \text{m/s}$. Now use the continuity equation to find v_1. Solving $A_1 v_1 = A_2 v_2$ for v_1 gives $v_1 = \frac{A_B}{A_A} v_2$. For the numbers here we have $v_1 = \frac{0.0200\ \text{m}^2}{0.0500\ \text{m}^2}(4.00\ \text{m/s}) = 1.60\ \text{m/s}$. Now return to Bernoulli's equation. We want the gauge pressure at A so we want $p = p_2 - p_{\text{atm}}$. The Bernoulli equation now becomes $p + \frac{1}{2}\rho v_1^2 = \rho g y_2 + \frac{1}{2}\rho v_2^2$. Solving for p gives $p = \rho\left[g y_2 + \frac{1}{2}\left(v_2^2 - v_1^2\right)\right]$. Using (from Table 12.1) $\rho = 810\ \text{kg/m}^3$ for ethanol, $v_1 = 1.60$ m/s, $v_2 = 4.00$ m/s, and $y_2 = 3.00$ m, we get $p = 2.9 \times 10^4$ Pa.

EVALUATE: This is about 30% of atmospheric pressure. The absolute pressure would be about 1.3 atm.

12.71. **IDENTIFY:** After the water leaves the hose the only force on it is gravity. Use conservation of energy to relate the initial speed to the height the water reaches. The volume flow rate is Av.

SET UP: $A = \pi D^2/4$

EXECUTE: **(a)** $\frac{1}{2}mv^2 = mgh$ gives $v = \sqrt{2gh} = \sqrt{2(9.80\ \text{m/s}^2)(28.0\ \text{m})} = 23.4\ \text{m/s}$.

$(\pi D^2/4)v = 0.500\ \text{m/s}^3$. $D = \sqrt{\frac{4(0.500\ \text{m/s}^3)}{\pi v}} = \sqrt{\frac{4(0.500\ \text{m/s}^3)}{\pi(23.4\ \text{m/s})}} = 0.165\ \text{m} = 16.5\ \text{cm}$.

(b) $D^2 v$ is constant so if D is twice as great, then v is decreased by a factor of 4. h is proportional to v^2, so h is decreased by a factor of 16. $h = \frac{28.0\ \text{m}}{16} = 1.75\ \text{m}$.

EVALUATE: The larger the diameter of the nozzle the smaller the speed with which the water leaves the hose and the smaller the maximum height.

12.72. **IDENTIFY:** $B = \rho V_A g$. Apply Newton's second law to the beaker, liquid and block as a combined object and also to the block as a single object.

SET UP: Take $+y$ upward. Let F_D and F_E be the forces corresponding to the scale reading.

EXECUTE: Forces on the combined object: $F_D + F_E - (w_A + w_B + w_C) = 0$. $w_A = F_D + F_E - w_B - w_C$. D and E read mass rather than weight, so write the equation as $m_A = m_D + m_E - m_B - m_C$. $m_D = F_D/g$ is the reading in kg of scale D; a similar statement applies to m_E.

$m_A = 3.50\ \text{kg} + 7.50\ \text{kg} - 1.00\ \text{kg} - 1.80\ \text{kg} = 8.20\ \text{kg}$.

Forces on A: $B + F_D - w_A = 0$. $\rho V_A g + F_D - m_A g = 0$. $\rho V_A + m_D = m_A$.

$$\rho = \frac{m_A - m_D}{V_A} = \frac{8.20\ \text{kg} - 3.50\ \text{kg}}{3.80 \times 10^{-3}\ \text{m}^3} = 1.24 \times 10^3\ \text{kg/m}^3$$

(b) D reads the mass of A: 8.20 kg. E reads the total mass of B and C: 2.80 kg.

EVALUATE: The sum of the readings of the two scales remains the same.

12.73. **IDENTIFY:** As water flows from the tank, the water level changes. This affects the speed with which the water flows out of the tank and the pressure at the bottom of the tank.

SET UP: Bernoulli's equation, $p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$, and the continuity equation, $A_1 v_1 = A_2 v_2$, both apply.

EXECUTE: **(a)** Let point 1 be at the surface of the water in the tank and let point 2 be in the stream of water that is emerging from the tank. $p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$. $v_1 = \dfrac{\pi d_2^2}{\pi d_1^2} v_2$, with $d_2 = 0.0200\text{ m}$ and $d_1 = 2.00\text{ m}$. $v_1 << v_2$ so the $\frac{1}{2}\rho v_1^2$ term can be neglected. $v_2 = \sqrt{\dfrac{2p_0}{\rho} + 2gh}$, where $h = y_1 - y_2$ and $p_0 = p_1 - p_2 = 5.00\times10^3\text{ Pa}$. Initially $h = h_0 = 0.800\text{ m}$ and when the tank has drained $h = 0$. At $t = 0$, $v_2 = \sqrt{\dfrac{2(5.00\times10^3\text{ Pa})}{1000\text{ kg/m}^3} + 2(9.8\text{ m/s}^2)(0.800\text{ m})} = \sqrt{10 + 15.68}\text{ m/s} = 5.07\text{ m/s}$.

If the tank is open to the air, $p_0 = 0$ and $v_2 = 3.96\text{ m/s}$. The ratio is 1.28.

(b) $v_1 = -\dfrac{dh}{dt} = \dfrac{A_2}{A_1} v_2 = \left(\dfrac{d_2}{d_1}\right)^2 \sqrt{\dfrac{2p_0}{\rho} + 2gh} = \left(\dfrac{d_2}{d_1}\right)^2 \sqrt{2g}\sqrt{\dfrac{p_0}{g\rho} + h}$. Separating variables gives $\dfrac{dh}{\sqrt{\dfrac{p_0}{g\rho} + h}} = -\left(\dfrac{d_2}{d_1}\right)^2 \sqrt{2g}\, dt$. We now must integrate $\displaystyle\int_{h_0}^{0} \dfrac{dh'}{\sqrt{\dfrac{p_0}{g\rho} + h'}} = -\left(\dfrac{d_2}{d_1}\right)^2 \sqrt{2g} \int_0^t dt'$. To do the left-hand side integral, make the substitution $u = \dfrac{p_0}{g\rho} + h'$, which makes $du = dh'$. The integral is then of the form $\displaystyle\int \dfrac{du}{u^{1/2}}$, which can be readily integrated using $\displaystyle\int u^n\, du = \dfrac{u^{n+1}}{n+1}$. The result is

$2\left(\sqrt{\dfrac{p_0}{g\rho}} - \sqrt{\dfrac{p_0}{g\rho} + h_0}\right) = -\left(\dfrac{d_2}{d_1}\right)^2 \sqrt{2g}\, t$. Solving for t gives $t = \left(\dfrac{d_1}{d_2}\right)^2 \sqrt{\dfrac{2}{g}}\left(\sqrt{\dfrac{p_0}{g\rho} + h_0} - \sqrt{\dfrac{p_0}{g\rho}}\right)$. Since

$\dfrac{p_0}{g\rho} = \dfrac{5.00\times10^3\text{ Pa}}{(9.8\text{ m/s}^2)(1000\text{ kg/m}^3)} = 0.5102\text{ m}$, we get

$t = \left(\dfrac{2.00}{0.0200}\right)^2 \sqrt{\dfrac{2}{9.8\text{ m/s}^2}}\left(\sqrt{0.5102\text{ m} + 0.800\text{ m}} - \sqrt{0.5102}\text{ m}\right) = 1.944\times10^3\text{ s} = 32.4\text{ min}$. When $p_0 = 0$,

$t = \left(\dfrac{2.00}{0.0200}\right)^2 \sqrt{\dfrac{2}{9.8\text{ m/s}^2}}\left(\sqrt{0.800\text{ m}}\right) = 4.04\times10^3\text{ s} = 67.3\text{ min}$. The ratio is 2.08.

EVALUATE: Both ratios are greater than one because a surface pressure greater than atmospheric pressure causes the water to drain with a greater speed and in a shorter time than if the surface were open to the atmosphere with a pressure of one atmosphere.

12.74. **IDENTIFY:** Apply $\sum F_y = ma_y$ to the ball, with $+y$ upward. The buoyant force is given by Archimedes's principle.

SET UP: The ball's volume is $V = \frac{4}{3}\pi r^3 = \frac{4}{3}\pi(12.0\text{ cm})^3 = 7238\text{ cm}^3$. As it floats, it displaces a weight of water equal to its weight.

EXECUTE: **(a)** By pushing the ball under water, you displace an additional amount of water equal to 76.0% of the ball's volume or $(0.760)(7238\text{ cm}^3) = 5501\text{ cm}^3$. This much water has a mass of

$5501\ g = 5.501\ \text{kg}$ and weighs $(5.501\ \text{kg})(9.80\ \text{m/s}^2) = 53.9\ \text{N}$, which is how hard you'll have to push to submerge the ball.

(b) The upward force on the ball in excess of its own weight was found in part (a): 53.9 N. The ball's mass is equal to the mass of water displaced when the ball is floating:

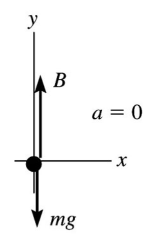
$$(0.240)(7238\ \text{cm}^3)(1.00\ \text{g/cm}^3) = 1737\ \text{g} = 1.737\ \text{kg},$$

and its acceleration upon release is thus $a = \dfrac{F_{\text{net}}}{m} = \dfrac{53.9\ \text{N}}{1.737\ \text{kg}} = 31.0\ \text{m/s}^2$.

EVALUATE: When the ball is totally immersed the upward buoyant force on it is much larger than its weight.

12.75. IDENTIFY: Apply Newton's second law to the block. In part (a), use Archimedes's principle for the buoyancy force. In part (b), use $p = p_0 + \rho g h$ to find the pressure at the lower face of the block and then use $p = \dfrac{F_\perp}{A}$ to calculate the force the fluid exerts.

(a) SET UP: The free-body diagram for the block is given in Figure 12.75a.



EXECUTE: $\sum F_y = ma_y$

$B - mg = 0$

$\rho_{\text{L}} V_{\text{sub}} g = \rho_{\text{B}} V_{\text{obj}} g$

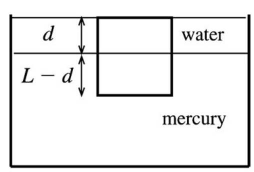
Figure 12.75a

The fraction of the volume that is submerged is $V_{\text{sub}}/V_{\text{obj}} = \rho_{\text{B}}/\rho_{\text{L}}$.

Thus the fraction that is *above* the surface is $V_{\text{above}}/V_{\text{obj}} = 1 - \rho_{\text{B}}/\rho_{\text{L}}$.

EVALUATE: If $\rho_{\text{B}} = \rho_{\text{L}}$ the block is totally submerged as it floats.

(b) SET UP: Let the water layer have depth *d*, as shown in Figure 12.75b.



EXECUTE: $p = p_0 + \rho_{\text{w}} g d + \rho_{\text{L}} g (L - d)$

Applying $\sum F_y = ma_y$ to the block gives

$$(p - p_0)A - mg = 0.$$

Figure 12.75b

$[\rho_{\text{w}} g d + \rho_{\text{L}} g (L - d)]A = \rho_{\text{B}} L A g$

A and *g* divide out and $\rho_{\text{w}} d + \rho_{\text{L}}(L - d) = \rho_{\text{B}} L$

$d(\rho_{\text{w}} - \rho_{\text{L}}) = (\rho_{\text{B}} - \rho_{\text{L}})L$

$$d = \left(\frac{\rho_{\text{L}} - \rho_{\text{B}}}{\rho_{\text{L}} - \rho_{\text{w}}}\right)L$$

(c) $d = \left(\dfrac{13.6\times10^3\ \text{kg/m}^3 - 7.8\times10^3\ \text{kg/m}^3}{13.6\times10^3\ \text{kg/m}^3 - 1000\ \text{kg/m}^3}\right)(0.100\ \text{m}) = 0.0460\ \text{m} = 4.60\ \text{cm}$

EVALUATE: In the expression derived in part (b), if $\rho_B = \rho_L$ the block floats in the liquid totally submerged and no water needs to be added. If $\rho_L \to \rho_w$ the block continues to float with a fraction $1 - \rho_B/\rho_w$ above the water as water is added, and the water never reaches the top of the block $(d \to \infty)$.

12.76. IDENTIFY: For the floating tanker, the buoyant force equals its total weight. The buoyant force is given by Archimedes's principle.

SET UP: When the metal is in the tanker, it displaces its weight of water and after it has been pushed overboard it displaces its volume of water.

EXECUTE: **(a)** The change in height Δy is related to the displaced volume ΔV by $\Delta y = \dfrac{\Delta V}{A}$, where A is the surface area of the water in the lock. ΔV is the volume of water that has the same weight as the metal, so

$$\Delta y = \frac{\Delta V}{A} = \frac{w/(\rho_{\text{water}} g)}{A} = \frac{w}{\rho_{\text{water}} g A} = \frac{(2.50\times10^6 \text{ N})}{(1.00\times10^3 \text{ kg/m}^3)(9.80 \text{ m/s}^2)[(60.0 \text{ m})(20.0 \text{ m})]} = 0.213 \text{ m}.$$

(b) In this case, ΔV is the volume of the metal; in the above expression, ρ_{water} is replaced by $\rho_{\text{metal}} = 7.20\rho_{\text{water}}$, which gives , $\Delta y' = \dfrac{\Delta y}{7.2}$, so

$$\Delta y - \Delta y' = \Delta y - \frac{\Delta y}{7.20} = \Delta y\left(1 - \frac{1}{7.20}\right) = (0.213 \text{ m})\left(1 - \frac{1}{7.20}\right) = 0.183 \text{ m};$$ the water level falls this amount.

EVALUATE: The density of the metal is greater than the density of water, so the volume of water that has the same weight as the steel is greater than the volume of water that has the same volume as the steel.

12.77. IDENTIFY: After leaving the tank, the water is in free fall, with $a_x = 0$ and $a_y = +g$.

SET UP: The speed of efflux is $\sqrt{2gh}$.

EXECUTE: **(a)** The time it takes any portion of the water to reach the ground is $t = \sqrt{\dfrac{2(H-h)}{g}}$, in which time the water travels a horizontal distance $R = vt = 2\sqrt{h(H-h)}$.

(b) Note that if $h' = H - h$, $h'(H - h') = (H - h)h$, and so $h' = H - h$ gives the same range. A hole $H - h$ below the water surface is a distance h above the bottom of the tank.

EVALUATE: For the special case of $h = H/2$, $h = h'$ and the two points coincide. For the upper hole the speed of efflux is less but the time in the air during the free fall is greater.

12.78. IDENTIFY: Bernoulli's equation applies to the water.

SET UP: First use Bernoulli's equation, $p_1 + \frac{1}{2}\rho v_1^2 + \rho g y_1 = p_2 + \frac{1}{2}\rho v_2^2 + \rho g y_2$, to find the speed of the water as it enters the hold. Then use $dV/dt = Av$ to find the rate at which water flows into the hole, and then solve for the time for 10.0 L to flow in. The pressure at the top of the water is the same as the pressure of the cabin into which the water flows (atmospheric pressure), and the speed of the water at the surface is zero. 1 m^3 = 1000 L.

EXECUTE: **(a)** Using the above conditions, Bernoulli's equation gives

$$p_1 + \tfrac{1}{2}\rho v_1^2 + \rho g y_1 = p_2 + \tfrac{1}{2}\rho v_2^2 + \rho g y_2$$

$$p_0 + 0 + 0 = p_0 + \tfrac{1}{2}\rho v^2 + \rho g y$$

Solving for v gives $v = \sqrt{-2gy}$. The rate at which water enters ship is $V/t = Av = A\sqrt{-2gy}$. Thus

$$t = V/Av = \frac{V}{A\sqrt{-2gy}} = \frac{10\times10^{-3} \text{ m}^3}{(1.20\times10^{-4} \text{ m}^2)\sqrt{-2(9.80 \text{ m/s}^2)(-0.900 \text{ m})}} = 19.8 \text{ s}.$$

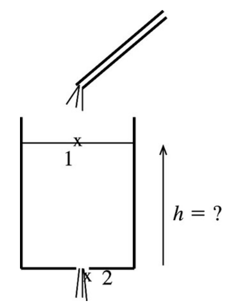
(b) The mass of 10.0 L of water is 10 kg, which will have no appreciable effect on the weight of a ship.
EVALUATE: The speed at which the water enters the hole is the same as if it had just fallen a distance of 0.900 m.

12.79. **IDENTIFY:** As you constrict the hose, you decrease its area, but the equation of continuity applies to the water.
SET UP: $A_1 v_1 = A_2 v_2$. The distance traveled by a projectile that is fired from a height h with an initial horizontal velocity v is $x = vt$ where $t = \sqrt{\dfrac{2h}{g}}$.
EXECUTE: Since h is fixed, t does not change as we constrict the nozzle. Looking at the ratio of distances we obtain $\dfrac{x_1}{x_2} = \dfrac{v_1 t}{v_2 t} = \dfrac{A_2}{A_1} = \dfrac{\pi r_2^2}{\pi r_1^2}$, which gives

$$x_1 = x_2\left(\frac{r_2}{r_1}\right)^2 = (0.950\text{ m})\left(\frac{1.80\text{ cm}}{0.750\text{ cm}}\right)^2 = 5.47\text{ m}.$$

EVALUATE: A smaller constriction results in a higher exit velocity, which results in a greater range, so our result is plausible.

12.80. **IDENTIFY:** Use Bernoulli's equation to find the velocity with which the water flows out the hole.
SET UP: The water level in the vessel will rise until the volume flow rate into the vessel, $2.40\times10^{-4}\text{ m}^3/\text{s}$, equals the volume flow rate out the hole in the bottom.



Let points 1 and 2 be chosen as in Figure 12.80.

Figure 12.80

EXECUTE: Bernoulli's equation: $p_1 + \rho g y_1 + \frac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \frac{1}{2}\rho v_2^2$

Volume flow rate out of hole equals volume flow rate from tube gives that $v_2 A_2 = 2.40\times10^{-4}\text{ m}^3/\text{s}$ and

$$v_2 = \frac{2.40\times10^{-4}\text{ m}^3/\text{s}}{1.50\times10^{-4}\text{ m}^2} = 1.60\text{ m/s}$$

$A_1 \gg A_2$ and $v_1 A_1 = v_2 A_2$ says that $\frac{1}{2}\rho v_1^2 \ll \frac{1}{2}\rho v_2^2$; neglect the $\frac{1}{2}\rho v_1^2$ term.

Measure y from the bottom of the bucket, so $y_2 = 0$ and $y_1 = h$.

$p_1 = p_2 = p_a$ (air pressure)

Then $p_a + \rho g h = p_a + \frac{1}{2}\rho v_2^2$ and $h = v_2^2/2g = (1.60\text{ m/s})^2/2(9.80\text{ m/s}^2) = 0.131\text{ m} = 13.1\text{ cm}$

EVALUATE: The greater the flow rate into the bucket, the larger v_2 will be at equilibrium and the higher the water will rise in the bucket.

12.81. **IDENTIFY:** Apply Bernoulli's equation and the equation of continuity.
SET UP: The speed of efflux is $\sqrt{2gh}$, where h is the distance of the hole below the surface of the fluid.

EXECUTE: **(a)** $v_3 A_3 = \sqrt{2g(y_1 - y_3)}A_3 = \sqrt{2(9.80\text{ m/s}^2)(8.00\text{ m})}(0.0160\text{ m}^2) = 0.200\text{ m}^3/\text{s}.$

(b) Since p_3 is atmospheric pressure, the gauge pressure at point 2 is

$$p_2 = \frac{1}{2}\rho(v_3^2 - v_2^2) = \frac{1}{2}\rho v_3^2\left(1 - \left(\frac{A_3}{A_2}\right)^2\right) = \frac{8}{9}\rho g(y_1 - y_3),$$ using the expression for v_3 found above.

Substitution of numerical values gives $p_2 = 6.97\times10^4$ Pa.

EVALUATE: We could also calculate p_2 by applying Bernoulli's equation to points 1 and 2.

12.82 **IDENTIFY:** Apply Bernoulli's equation to the air in the hurricane.
SET UP: For a particle a distance r from the axis, the angular momentum is $L = mvr$.
EXECUTE: **(a)** Using the constancy of angular momentum, the product of the radius and speed is constant, so the speed at the rim is about $(200\text{ km/h})\left(\frac{30}{350}\right) = 17\text{ km/h}$.

(b) The pressure is lower at the eye, by an amount

$$\Delta p = \frac{1}{2}(1.2\text{ kg/m}^3)((200\text{ km/h})^2 - (17\text{ km/h})^2)\left(\frac{1\text{ m/s}}{3.6\text{ km/h}}\right)^2 = 1.8\times10^3\text{ Pa}.$$

(c) $\frac{v^2}{2g} = 160$ m.

(d) The pressure difference at higher altitudes is even greater.
EVALUATE: According to Bernoulli's equation, the pressure decreases when the fluid velocity increases.

12.83. **IDENTIFY:** Apply Bernoulli's equation and the equation of continuity.
SET UP: The speed of efflux at point D is $\sqrt{2gh_1}$.

EXECUTE: Applying the equation of continuity to points at C and D gives that the fluid speed is $\sqrt{8gh_1}$ at C. Applying Bernoulli's equation to points A and C gives that the gauge pressure at C is $\rho gh_1 - 4\rho gh_1 = -3\rho gh_1$, and this is the gauge pressure at the surface of the fluid at E. The height of the fluid in the column is $h_2 = 3h_1$.

EVALUATE: The gauge pressure at C is less than the gauge pressure ρgh_1 at the bottom of tank A because of the speed of the fluid at C.

12.84. **(a) IDENTIFY:** Apply constant acceleration equations to the falling liquid to find its speed as a function of the distance below the outlet. Then apply $v_1 A_1 = v_2 A_2$ to relate the speed to the radius of the stream.
SET UP:

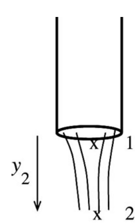


Figure 12.84

Let point 1 be at the end of the pipe and let point 2 be in the stream of liquid at a distance y_2 below the end of the tube, as shown in Figure 12.84.

Consider the free fall of the liquid. Take $+y$ to be downward.

Free fall implies $a_y = g$. v_y is positive, so replace it by the speed v.

EXECUTE: $v_2^2 = v_1^2 + 2a(y - y_0)$ gives $v_2^2 = v_1^2 + 2gy_2$ and $v_2 = \sqrt{v_1^2 + 2gy_2}$.

Equation of continuity says $v_1 A_1 = v_2 A_2$

And since $A = \pi r^2$ this becomes $v_1 \pi r_1^2 = v_2 \pi r_2^2$ and $v_2 = v_1 (r_1/r_2)^2$.

Use this in the above to eliminate v_2: $v_1 (r_1^2/r_2^2) = \sqrt{v_1^2 + 2gy_2}$

$r_2 = r_1 \sqrt{v_1}/(v_1^2 + 2gy_2)^{1/4}$

To correspond to the notation in the problem, let $v_1 = v_0$ and $r_1 = r_0$, since point 1 is where the liquid first leaves the pipe, and let r_2 be r and y_2 be y. The equation we have derived then becomes

$r = r_0 \sqrt{v_0}/(v_0^2 + 2gy)^{1/4}$.

(b) $v_0 = 1.20$ m/s

We want the value of y that gives $r = \frac{1}{2} r_0$, or $r_0 = 2r$.

The result obtained in part (a) says $r^4 (v_0^2 + 2gy) = r_0^4 v_0^2$.

Solving for y gives $y = \dfrac{[(r_0/r)^4 - 1]v_0^2}{2g} = \dfrac{(16-1)(1.20\ \text{m/s})^2}{2(9.80\ \text{m/s}^2)} = 1.10$ m.

EVALUATE: The equation derived in part (a) says that r decreases with distance below the end of the pipe.

12.85. **IDENTIFY** and **SET UP:** We are given the densities of elements in the table and look up their atomic masses in Appendix D.

EXECUTE: For example, for aluminum, the density is 2.7 g/cm^3 and the atomic mass is 26.98 g/mol.

(a) Figure 12.85 shows the graph of density versus atomic mass.

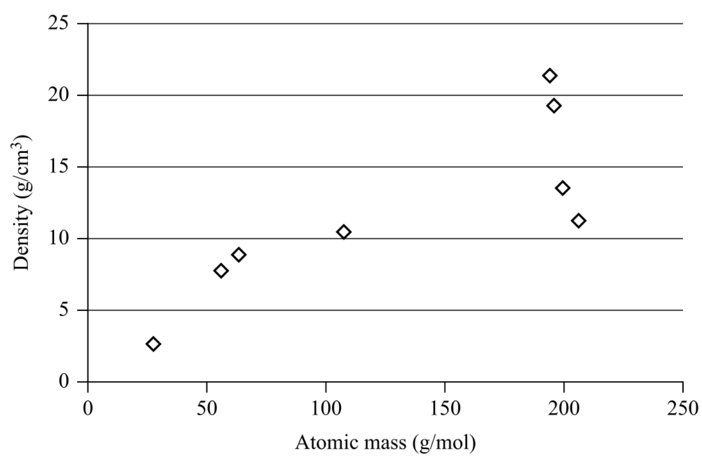

Figure 12.85

(b) From the graph, we see that there is no obvious mathematical relation between the two variables. No straight line or simple curve can be fitted to the data points.

(c) Density depends not only on atomic mass, but also on how tightly atoms are packed together. This packing is determined by the electrical interactions between atoms.

EVALUATE: Not all data can be reduced to straight-line graphs!

12.86. **IDENTIFY:** Archimedes's principle applies. For a floating object, the buoyant force balances the weight.

SET UP: Call m_b the mass of the block and m_n the mass of n quarters, so $m_n = nM$, where $M = 5.670$ g is the mass of a single quarter. $m_b + m_n$. The submerged volume is $(L - h)L^2$, where $L = 8.0$ cm.

EXECUTE: The forces balance, so $(m_b + m_n)g = \rho_{\text{liq}} L^2 (L - h)g$. Solving for h gives

$h = \dfrac{\rho_{\text{liq}}L^3 - m_b}{\rho_{\text{liq}}L^2} - \left(\dfrac{M}{\rho_{\text{liq}}L^2}\right)n$. If we plot h versus n, the slope is $-\dfrac{M}{\rho_{\text{liq}}L^2}$ and the y-intercept is $\dfrac{\rho_{\text{liq}}L^3 - m_b}{\rho_{\text{liq}}L^2}$. For the graph in the problem, we can calculate the slope by reading points from the graph. The top and bottom points seem easiest to read, so they give a slope of (1.2 cm – 3.0 cm)/25 = 0.072 cm. (Due to uncertainties in reading the graph, your answers may differ slightly from the ones here.) Using this slope, we get ρ_{liq} = –(5.670 g)/[(–0.072 cm)(8.0 cm)^2] = 1.24 g/cm^3 , which rounds to 1.2 g/cm^3 = 1200 kg/m^3.

(b) Simplifying the y-intercept gives y-intercept = $L - m_b/[(\rho_{\text{liq}})(L^2)]$. From the graph, the y-intercept is 3.0 cm, so we have 3.0 cm = 8.0 cm – m_b/[(1.24 g/cm^3)(8.0 cm)^2] , which gives m_b = 400 g = 0.40 kg.

EVALUATE: The unknown liquid is 20% denser than water.

12.87. IDENTIFY: Bernoulli's equation applies. We have free-fall projectile motion after the liquid leaves the tank. The pressure at the hole where the liquid exits is atmospheric pressure p_0. The absolute pressure at the top of the liquid is $p_g + p_0$.

SET UP: $p_1 + \frac{1}{2}\rho v_1^2 + \rho g y_1 = p_2 + \frac{1}{2}\rho v_2^2 + \rho g y_2$.

EXECUTE: **(a)** The graph of R^2 versus p_g is shown in Figure 12.87.

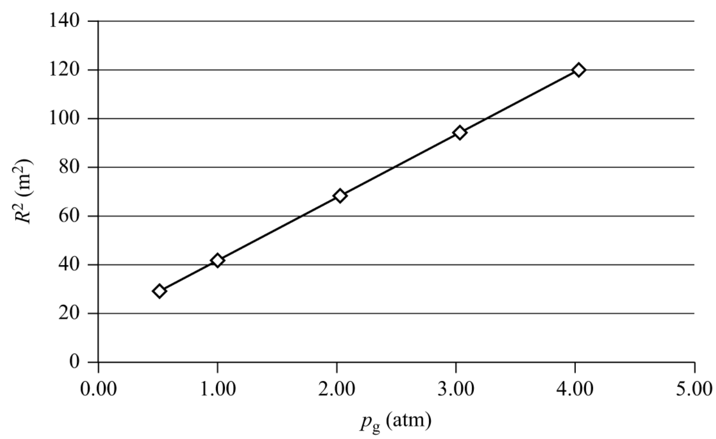

Figure 12.87

Applying Bernoulli's equation between the top and bottom of the liquid in the tank gives $p_0 + p_g + \rho g h = \frac{1}{2}\rho v^2 + p_0$, which simplifies to $p_g + \rho g h = \frac{1}{2}\rho v^2$.

The free-fall motion after leaving the tank gives $vt = R$ and $y = \frac{1}{2}gt^2$, where y = 50.0 cm. Eliminating t between these two equations gives $v^2 = (\rho g/4y)R^2$. Putting this into the result from Bernoulli's equation gives $p_g + \rho g h = (\rho g/4y)R^2$. Solving for R^2 in terms of h gives $R^2 = (4y/\rho g)\ p_g + 4yh$. This is the equation of a straight line of slope $4y/\rho g$, which gives $\rho = 4y/[g(\text{slope})]$ and y-intercept $4yh$. The best-fit equation is R^2 = (25.679 m^2/atm) p_g + 16.385 m^2. The y-intercept gives us h: $4yh$ = y-intercept, so h = (y-intercept)/(4y) = (16.385 m^2)/[4(0.500 m)] = 8.2 m. And the density is ρ = 4y/[g(slope)] = 4(0.500 m)/[(9.80 m/s^2)(25.679 m^2/atm)(1 atm/1.01 × 10^5 Pa)] = 803 kg/m^3.

EVALUATE: The liquid is about 80% as dense as water, and h = 8.2 m which is about 25 ft, so this is a rather large tank.

12.88. IDENTIFY: Apply Bernoulli's equation to the fluid in the siphon.
SET UP: The efflux speed from a small hole a distance h below the surface of fluid in a large open tank is $\sqrt{2gh}$.
EXECUTE: **(a)** The fact that the water first moves upward before leaving the siphon does not change the efflux speed, $\sqrt{2gh}$.
(b) Water will not flow if the absolute (not gauge) pressure would be negative. The hose is open to the atmosphere at the bottom, so the pressure at the top of the siphon is $p_a - \rho g(H+h)$, where the assumption that the cross-sectional area is constant has been used to equate the speed of the liquid at the top and bottom. Setting $p = 0$ and solving for H gives $H = (p_a/\rho g) - h$.
EVALUATE: The analysis shows that $H + h < \dfrac{p_a}{\rho g}$, so there is also a limitation on $H + h$. For water and normal atmospheric pressure, $\dfrac{p_a}{\rho g} = 10.3$ m.

12.89. IDENTIFY and **SET UP:** One atmosphere of pressure is 760 mm Hg. The gauge pressure is $p_g = \rho gh$.
EXECUTE: Since 1 atm is 760 mm Hg, the pressure is (150 mm/750 mm)P_{atm}. Solving for the depth h gives $h = \dfrac{P}{\rho g} = \dfrac{\left(\dfrac{150\text{ mm}}{760\text{ mm}}\right)(1.01\times 10^5\text{ Pa})}{(1000\text{ kg/m}^3)(9.80\text{ m/s}^2)} = 2.0$ m, which is choice (b).
EVALUATE: This result is reasonable since an elephant can have its chest several meters under water.

12.90. IDENTIFY and **SET UP:** Use the definition of pressure. $\Delta p = F/A$.
EXECUTE: $\Delta p = F/A$ = (24,000 N)/[π(0.60 m)^2] = 21,200 Pa. Converting to mm Hg gives 21,200 Pa [(760 mm Hg)/(1.01×10^5 Pa)] = 160 mm Hg, which is choice (a).
EVALUATE: The force (24,000 N) is large, but the pressure cannot be too large since the area of the diaphragm is quite large.

12.91. IDENTIFY and **SET UP:** The gauge pressure increases with depth, and since the force is proportional to the pressure, so does the force. $p_g = \rho gh$ and $p = F/A$.
EXECUTE: The force is $F = pA = (\rho gh)A$, which tells us that the force increases linearly with distance, as in choice (a).
EVALUATE: The diaphragm experiences greater force as the elephant goes into deeper water.

12.92. IDENTIFY and **SET UP:** The gauge pressure depends on the density of the liquid, $p_g = \rho gh$.
EXECUTE: Since $p_g = \rho gh$, a denser liquid will exert a greater pressure. Since salt water is denser than fresh water, the gauge pressure at a given depth will be greater in salt water than in freshwater. Therefore the maximum depth in salt water would be less than in freshwater, which is choice (b).
EVALUATE: Although the pressure in salt water would be greater than in freshwater, it would not be much greater since the density of seawater (1030 kg/m^3) is only slightly greater than that of freshwater (1000 kg/m^3).

13

GRAVITATION

VP13.5.1. **IDENTIFY:** This problem involves gravitational potential energy.

SET UP: The minimum amount of work is just the magnitude of the spacecraft's initial potential energy at the earth's surface. $U_{grav} = -Gm_1m_2/r$.

EXECUTE: $U_{grav} = -Gm_1m_2/r = -Gm_sm_E/R_E$. The magnitude of this energy is equal to the work, so

$$W = \frac{\left(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)(478\ \text{kg})\left(5.97\times10^{24}\ \text{kg}\right)}{6.37\times10^6\ \text{m}} = 2.99\times10^{10}\ \text{J}.$$

EVALUATE: Technically this is the energy given to the earth-satellite system, but it essentially all goes to the satellite because the earth is so massive that it does not change its kinetic energy.

VP13.5.2. **IDENTIFY:** This problem involves gravitational potential energy. Energy conservation applies.

SET UP: No air resistance, so $K_1 + U_1 = K_2 + U_2$, $U_{grav} = -Gm_1m_2/r$, $K = \frac{1}{2}mv^2$. Let m be the mass of the debris, R the radius of the earth, and m_E its mass. Call point 1 the original location of the debris and point 2 the surface of the earth.

EXECUTE: $K_1 = 0$, so $-Gmm_E/(3R/2) = -Gmm_E/R + \frac{1}{2}mv^2$, which gives $v = \sqrt{\frac{2Gm_E}{3R}}$. Using $R = 6.37\times10^6$ m and $m_E = 5.97\times10^{24}$ kg gives $v = 6.46\times10^3$ m/s.

EVALUATE: The equation $\sqrt{\frac{2Gm_E}{3R}}$ does not contain the mass of the satellite, so *any* object dropped from the same height would reach the earth's surface with the same speed.

VP13.5.3. **IDENTIFY:** This problem involves gravitational potential energy. Energy conservation applies.

SET UP: No air resistance, so $K_1 + U_1 = K_2 + U_2$, $U_{grav} = -Gm_1m_2/r$, $K = \frac{1}{2}mv^2$. Let m be the mass of the probe, R the radius of Mars, and M its mass. Call point 1 at the surface of Mars and point 2 at the maximum height of the probe. At that point, the probe's distance from the center of Mars is h and its speed is zero. Call v the speed at the surface.

EXECUTE: $K_1 + U_1 = K_2 + U_2$ gives $\frac{1}{2}mv^2 - \frac{GmM}{R} = -\frac{GmM}{h}$. Using $M = 6.42\times10^{23}$ kg, $R = 3.39\times10^6$ m, and $v = 3.00\times10^3$ m/s, we find $h = 5.27\times10^6$ m from the center of Mars. The height H above the surface is $H = h - R = 5.27\times10^6\ \text{m} - 3.39\times10^6\ \text{m} = 1.88\times10^6$ m.

EVALUATE: The answer is independent of the mass of the probe since m cancels from the equations, so *any* probe would reach that height if it started at 3000 m/s.

VP13.5.4. **IDENTIFY:** This problem involves gravitational potential energy. Energy conservation applies.

SET UP: No air resistance, so $K_1 + U_1 = K_2 + U_2$, $U_{grav} = -Gm_1m_2/r$, $K = \frac{1}{2}mv^2$. Let m be the mass of the spacecraft, R the radius of the earth and M its mass. Call point 1 at the surface of the earth and point 2 at the height of the spacecraft when it has reached the desired speed. Call v_1 its initial speed at the surface and v_2 the desired speed when it has reached the desired height r from the earth's center. We want to find v_1.

EXECUTE: Energy conservation gives $\frac{1}{2}mv_1^2 - \frac{GmM}{R} = \frac{1}{2}mv_2^2 - \frac{GmM}{r}$. Using $v_2 = 8.50\times10^3$ m/s, $r = 2.50\times10^8$ m, $M = 5.97\times10^{24}$ kg, and $R = 6.37\times10^6$ m, we get $v_1 = 1.39\times10^4$ m/s = 13.9 km/s.

EVALUATE: Any spacecraft, regardless of mass, would need the same launch speed since the mass m cancels from the equations.

VP13.6.1. **IDENTIFY:** This problem deals with satellite orbits. The force of gravity applies, as well as Newton's second law for circular motion.

SET UP: $F = Gm_1m_2/r^2$. $\sum F = m\frac{v^2}{r}$ for circular motion. Let m be the satellite mass, v its speed, and M the earth's mass. $M = 5.97\times10^{24}$ kg and $v = 4.00\times10^3$ m/s.

EXECUTE: **(a)** $\sum F = m\frac{v^2}{r}$ gives $\frac{GmM}{r^2} = \frac{mv^2}{r} \rightarrow r = \frac{GM}{v^2} = 2.49\times10^7$ m.

(b) The height H above the surface is $H = r - R = 2.49\times10^7\text{ m} - 6.37\times10^6\text{ m} = 1.85\times10^7$ m.

(c) $v = 2\pi r/T$, so $T = 2\pi r/v = 2\pi(2.49\times10^7\text{ m})/(4.00\times10^3\text{ m/s}) = 3.91\times10^4\text{ s} = 10.9$ h.

EVALUATE: The results are independent of the mass of the satellite.

VP13.6.2. **IDENTIFY:** This problem deals with satellite orbits. The force of gravity applies, as well as Newton's second law for circular motion.

SET UP: $F = Gm_1m_2/r^2$. $\sum F = m\frac{v^2}{r}$ for circular motion. Let m be the satellite mass, v its speed, T its orbital period, and M the mass of Mars.

EXECUTE: **(a)** We want the radius r of the orbit. $\sum F = m\frac{v^2}{r}$ gives $\frac{GmM}{r^2} = \frac{m\left(\frac{2\pi r}{T}\right)}{r}$. Solving for r gives $r = \left(\frac{GMT^2}{4\pi^2}\right)^{1/3}$. Using $M = 6.42\times10^{23}$ kg and $T = 24.66\text{ h} = 8.8776\times10^4$ s gives $r = 2.04\times10^7$ m.

(b) Using the $r = 2.04\times10^7$ m and $R = 3.39\times10^6$ m gives $v = 2\pi r/T = 1.45\times10^3$ m/s.

EVALUATE: The orbital radius does not depend on the mass of the satellite, but it *does* depend on the mass of the planet. On the earth the radius would be larger since $r \propto M^{1/3}$.

VP13.6.3. **IDENTIFY:** This problem deals with orbits around the sun and involves gravitational potential energy and kinetic energy. Newton's second law also applies.

SET UP: $U_{grav} = -Gm_1m_2/r$, $K = \frac{1}{2}mv^2$. Let m be the mass of the spacecraft, M the mass of the sun, r_1 the radius of the outer orbit and r_2 that of the inner orbit. Apply $\sum F = m\frac{v^2}{r}$ to the spacecraft.

EXECUTE: **(a)** First find the kinetic energy in both orbits. $\sum F = m\frac{v^2}{r}$ to the spacecraft gives

$\dfrac{GmM}{r^2} = \dfrac{mv^2}{r} = \dfrac{2}{r}\left(\dfrac{1}{2}mv^2\right) = \dfrac{2K}{r}$, so $K = \dfrac{GmM}{2r}$. Therefore change in kinetic energy is

$\Delta K = K_2 - K_1 = \dfrac{GmM}{2}\left(\dfrac{1}{r_2} - \dfrac{1}{r_1}\right)$. Using m = 1000 kg, $M = 1.99\times10^{30}$ kg, $r_1 = 1.50\times10^{11}$ m, and $r_2 = 1.08\times10^{11}$ m, we get $\Delta K = 1.72\times10^{11}$ J.

(b) $U_2 - U_1 = -\dfrac{GmM}{r_2} - \left(-\dfrac{GmM}{r_1}\right) = GmM\left(\dfrac{1}{r_1} - \dfrac{1}{r_2}\right) = -3.44\times10^{11}$ J.

(c) $E = K + U$, so $\Delta E = \Delta K + \Delta U = 1.72\times10^{11}\ \text{J} + (-3.44\times10^{11}\ \text{J}) = -1.72\times10^{11}$ J.

EVALUATE: The spacecraft lost twice as much potential energy as it gained in kinetic energy, so it had a net loss equal to the kinetic energy gain.

VP13.6.4 **IDENTIFY:** This problem deals with orbits around the sun and involves gravitational potential energy and kinetic energy. Newton's second law also applies.

SET UP: $U_{\text{grav}} = -Gm_1m_2/r$, $K = \dfrac{1}{2}mv^2$. Let m be the mass of the spacecraft and M the mass of the earth. Apply $\sum F = m\dfrac{v^2}{r}$ to the spacecraft.

EXECUTE: **(a)** The work you would need to do is equal to the change in energy of the satellite. The potential energy does not change because r is the same, so the change in energy is the change in the kinetic energy of the satellite. Apply $\sum F = m\dfrac{v^2}{r}$ for a circular orbit.

$6.37\times10^6\ \text{m} = \dfrac{2}{r}\left(\dfrac{1}{2}mv^2\right) = \dfrac{2K}{r}$, which gives $K = \dfrac{GmM}{2r}$.

$\Delta K = K_2 - K_1 = \dfrac{GmM}{2r} - \dfrac{1}{2}mv_1^2$, where v_1 is the initial speed. Using m = 1500 kg, $M = 5.97\times10^{24}$ kg, v_1 = 7500 m/s, and $r = 3.50\times10^6\ \text{m} + 6.37\times10^6\ \text{m} = 9.87\times10^6$ m, we find that $\Delta E = \Delta K = -1.19\times10^{10}$ J.

(b) The minimum energy you would have to give the satellite for it to escape earth would be its total energy, which is $E_1 = K_1 + U_1 = \dfrac{1}{2}mv_1^2 - \dfrac{GmM}{r}$. Using the numbers from part (a), this energy is $E_1 = -1.83\times10^{10}$ J. The work you would have to would be $+1.83\times10^{10}$ J.

EVALUATE: Orbital parameters such as period, speed, and radius do not depend on the mass of the satellite, but energies do depend on that mass.

VP13.9.1. **IDENTIFY:** We are dealing with a comet in noncircular orbit.

SET UP: The semi-major axis a is $2a = r_p + r_a$, where r_p is the perihelion distance and r_a is the aphelion distance. $T = \dfrac{2\pi a^{3/2}}{\sqrt{Gm_S}}$, where m_S is the mass of the sun (or central star for another solar system). $a = ea + r_p$, where e is the eccentricity of the orbit. Refer to Fig. 13.18 in the textbook.

EXECUTE: **(a)** We want a, so we use $2a = = r_p + r_a = 6.00\times10^9\ \text{m} + 3.00\times10^{12}$ m, so $a = 1.50\times10^{12}$ m.

(b) $a = ea + r_p$, so $e = (a - r_{-p})/a = 1 - r_p/a = 1 - (6.00\times10^9\ \text{m})/(1.50\times10^{12}\ \text{m}) = 0.996$.

(c) Use $T = \dfrac{2\pi a^{3/2}}{\sqrt{Gm_S}}$ with a from (a) and $m_S = 1.99\times10^{30}$ kg gives $T = 1.00\times10^9$ s = 31.8 y.

EVALUATE: This orbital period is roughly the same as that of Saturn.

VP13.9.2. **IDENTIFY:** We are dealing with an asteroid in a noncircular orbit.

SET UP: The semi-major axis a is $2a = r_p + r_a$, where r_p is the perihelion distance and r_a is the aphelion distance. $T = \dfrac{2\pi a^{3/2}}{\sqrt{Gm_S}}$, where m_S is the mass of the sun (or central star for another solar system). $a = ea + r_p$, where e is the eccentricity of the orbit. Refer to Fig. 13.18 in the textbook. $T = 7.85$ y $= 2.4775\times10^8$ s, and $e = 0.250$.

EXECUTE: **(a)** Use $T = \dfrac{2\pi a^{3/2}}{\sqrt{Gm_S}}$ to find a. Solve for a: $a = \left[\dfrac{T^2 Gm_S}{4\pi^2}\right]^{1/3}$. Using T from above and $m_S = 1.99\times10^{30}$ kg gives $a = 5.91\times10^{11}$ m.

(b) $a = ea + r_p \rightarrow r_p = a(1-e) = (5.91\times10^{11}\text{ m})(1-0.250) = 4.43\times10^{11}$ m.

(c) $r_a = 2a - r_p = 2(5.91\times10^{11}\text{ m}) - 4.43\times10^{11}\text{ m} = 7.39\times10^{11}$ m.

EVALUATE: This orbit is considerably more eccentric than those of the major planets. Its aphelion distance is about 1.7 times greater than its perihelion distance.

VP13.9.3. **IDENTIFY:** We are dealing with a satellite in a noncircular orbit.

SET UP: The semi-major axis a is $2a = r_p + r_a$, where r_p is the perihelion distance and r_a is the aphelion distance. $T = \dfrac{2\pi a^{3/2}}{\sqrt{Gm_S}}$, where m_S is the mass of the sun (or central star for another solar system). $a = ea + r_p$, where e is the eccentricity of the orbit. Refer to Fig. 13.18 in the textbook. The minor planet makes 2 orbits in the time it takes Neptune to make 3 orbits, so the minor planet must have a longer period than Neptune: $T_{mp} = 3/2\, T_N$, and its eccentricity is $e = 0.330$.

EXECUTE: **(a)** We want to find the semi-major axis a. If we take the ratio of the period of Neptune and minor planet, the factors in common will cancel.

$$\frac{T_{mp}}{T_N} = \frac{\dfrac{2\pi a^{3/2}}{\sqrt{Gm_S}}}{\dfrac{2\pi r_N^{3/2}}{\sqrt{Gm_S}}} = \left(\frac{a}{r_N}\right)^{3/2} = \frac{3}{2} \quad \rightarrow \quad (a/r_N)^{3/2} = 3/2 \quad \rightarrow \quad a = r_N(3/2)^{2/3}$$

$a = (4.50\times10^{12}\text{ m})(3/2)^{2/3} = 5.90\times10^{12}$ m.

(b) $a = ea + r_p \rightarrow r_p = a(1-e) = (5.90\times10^{12}\text{ m})(1-0.330) = 3.95\times10^{12}$ m.

EVALUATE: At perihelion, this comet is *inside* Neptune's orbit. The eccentricity of its orbit is much greater than that of Neptune's orbit.

VP13.9.4. **IDENTIFY:** We are dealing with a planet in a noncircular orbit around another star.

SET UP: The semi-major axis a is $2a = r_p + r_a$, where r_p is the perihelion distance and r_a is the aphelion distance. $T = \dfrac{2\pi a^{3/2}}{\sqrt{Gm_S}}$, where m_S is the mass of the central star. $a = ea + r_p$, where e is the eccentricity of the orbit. In this case, $T = 4.39$ d $= 3.7930\times10^5$ s. Refer to Fig. 13.18 in the textbook.

EXECUTE: **(a)** We want the distance of the planet from its star at perigee (point of closest approach). $a = ea + r_p \rightarrow r_p = a(1-e) = (7.41\times10^9\text{ m})(1-0.173) = 6.13\times10^9$ m.

(b) We want the mass of HATS-43, so we use $T = \dfrac{2\pi a^{3/2}}{\sqrt{Gm_S}}$. Solving for m_S gives $m_S = \dfrac{4\pi^2 a^3}{GT^2}$. Using $a = 7.41\times10^9$ m and $T = 3.793\times10^5$ s, we get $m_S = 1.67\times10^{30}$ kg.

EVALUATE: This planet is considerably closer to its star than Mercury is to our sun. Comparing the mass of this star to that of our sun gives $m_{HATS}/m_{sun} = 1.67/1.99 = 0.839$, so the mass of this star is about 84% the mass of our sun.

13.1. **IDENTIFY** and **SET UP:** Use the law of gravitation, $F_g = \dfrac{Gm_1m_2}{r^2}$, to determine F_g.

EXECUTE: $F_{\text{S on M}} = G\dfrac{m_\text{S} m_\text{M}}{r_\text{SM}^2}$ (S = sun, M = moon); $F_{\text{E on M}} = G\dfrac{m_\text{E} m_\text{M}}{r_\text{EM}^2}$ (E = earth)

$$\frac{F_{\text{S on M}}}{F_{\text{E on M}}} = \left(G\frac{m_\text{S} m_\text{M}}{r_\text{SM}^2}\right)\left(\frac{r_\text{EM}^2}{G m_\text{E} m_\text{M}}\right) = \frac{m_\text{S}}{m_\text{E}}\left(\frac{r_\text{EM}}{r_\text{SM}}\right)^2$$

r_EM, the radius of the moon's orbit around the earth is given in Appendix F as 3.84×10^8 m. The moon is much closer to the earth than it is to the sun, so take the distance r_SM of the moon from the sun to be r_SE, the radius of the earth's orbit around the sun.

$$\frac{F_{\text{S on M}}}{F_{\text{E on M}}} = \left(\frac{1.99\times10^{30}\text{ kg}}{5.98\times10^{24}\text{ kg}}\right)\left(\frac{3.84\times10^8\text{ m}}{1.50\times10^{11}\text{ m}}\right)^2 = 2.18.$$

EVALUATE: The force exerted by the sun is larger than the force exerted by the earth. The moon's motion is a combination of orbiting the sun and orbiting the earth.

13.2. **IDENTIFY:** We want to calculate the gravitational force between two persons.

SET UP: Estimates: Mass of instructor is 75 kg, your mass is 70 kg, distance between the two of you is 3.0 m. Approximation: Treat both of you as point-masses. Use $F_\text{g} = \dfrac{Gm_1m_2}{r^2}$. We want to approximate the gravitational force that your physics instructor exerts on you.

EXECUTE: $F_\text{instr} = Gm_1m_2/r^2 = (6.67\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(75\text{ kg})(70\text{ kg})/(3.0\text{ m})^2 = 3.9\times10^{-8}$ N.

$F_\text{earth} = mg = (70\text{ kg})(9.80\text{ m/s}^2) = 690$ N.

EVALUATE: $F_\text{instr}/F_\text{earth} = (3.9\times10^{-8}\text{ N})/(690\text{ N}) = 5.7\times10^{-11}$ so F_instr is insignificant compared to the force the earth exerts on you.

13.3. **IDENTIFY:** The gravitational attraction of the astronauts on each other causes them to accelerate toward each other, so Newton's second law of motion applies to their motion.

SET UP: The net force on each astronaut is the gravity force exerted by the other astronaut. Call the astronauts *A* and *B*, where $m_A = 65$ kg and $m_B = 72$ kg. $F_\text{g} = Gm_1m_2/r^2$ and $\Sigma F = ma$.

EXECUTE: **(a)** The free-body diagram for astronaut *A* is given in Figure 13.3(a) and for astronaut *B* in Figure 13.3(b) (next page).

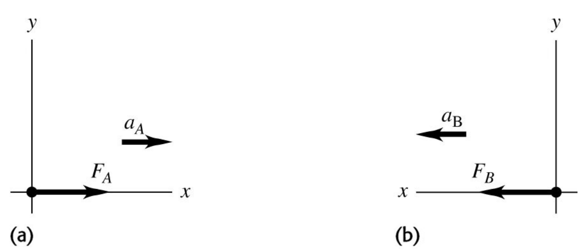

Figure 13.3

$\Sigma F_x = ma_x$ for *A* gives $F_A = m_A a_A$ and $a_A = \dfrac{F_A}{m_A}$. And for *B*, $a_B = \dfrac{F_B}{m_B}$.

$$F_A = F_B = G\frac{m_A m_B}{r^2} = (6.673\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)\frac{(65\text{ kg})(72\text{ kg})}{(20.0\text{ m})^2} = 7.807\times10^{-10}\text{ N so}$$

$$a_A = \frac{7.807\times10^{-10}\text{ N}}{65\text{ kg}} = 1.2\times10^{-11}\text{ m/s}^2 \text{ and } a_B = \frac{7.807\times10^{-10}\text{ N}}{72\text{ kg}} = 1.1\times10^{-11}\text{ m/s}^2.$$

(b) Using constant-acceleration kinematics, we have $x = x_0 + v_{0x}t + \frac{1}{2}a_x t^2$, which gives $x_A = \frac{1}{2}a_A t^2$ and $x_B = \frac{1}{2}a_B t^2$. $x_A + x_B = 20.0\text{ m}$, so $20.0\text{ m} = \frac{1}{2}(a_A + a_B)t^2$ and

$$t = \sqrt{\frac{2(20.0\text{ m})}{1.2\times10^{-11}\text{ m/s}^2 + 1.1\times10^{-11}\text{ m/s}^2}} = 1.32\times10^6\text{ s} = 15\text{ days.}$$

(c) Their accelerations would increase as they moved closer and the gravitational attraction between them increased.

EVALUATE: Even though the gravitational attraction of the astronauts is much weaker than ordinary forces on earth, if it were the only force acting on the astronauts, it would produce noticeable effects.

13.4. IDENTIFY: Apply $F_g = \dfrac{Gm_1m_2}{r^2}$, generalized to any pair of spherically symmetric objects.

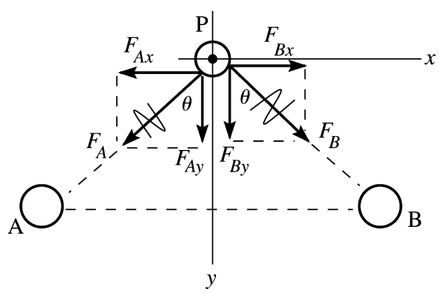
SET UP: The separation of the centers of the spheres is $2R$.

EXECUTE: The magnitude of the gravitational attraction is $GM^2/(2R)^2 = GM^2/4R^2$.

EVALUATE: The formula $F_g = \dfrac{Gm_1m_2}{r^2}$ applies to any pair of spherically symmetric objects; one of the objects doesn't have to be the earth.

13.5. IDENTIFY: Use $F_g = \dfrac{Gm_1m_2}{r^2}$ to find the force exerted by each large sphere. Add these forces as vectors to get the net force and then use Newton's second law to calculate the acceleration.

SET UP: The forces are shown in Figure 13.5.



$\sin\theta = 0.80$
$\cos\theta = 0.60$
Take the origin of coordinate at point P.

Figure 13.5

EXECUTE: $F_A = G\dfrac{m_Am}{r^2} = G\dfrac{(0.26\text{ kg})(0.010\text{ kg})}{(0.100\text{ m})^2} = 1.735\times10^{-11}\text{ N}$

$F_B = G\dfrac{m_Bm}{r^2} = 1.735\times10^{-11}\text{ N}$

$F_{Ax} = -F_A\sin\theta = -(1.735\times10^{-11}\text{ N})(0.80) = -1.39\times10^{-11}\text{ N}$

$F_{Ay} = +F_A\cos\theta = +(1.735\times10^{-11}\text{ N})(0.60) = +1.04\times10^{-11}\text{ N}$

$F_{Bx} = +F_B\sin\theta = +1.39\times10^{-11}\text{ N}$

$F_{By} = +F_B\cos\theta = +1.04\times10^{-11}\text{ N}$

$\Sigma F_x = ma_x$ gives $F_{Ax} + F_{Bx} = ma_x$

$0 = ma_x$ so $a_x = 0$

$\Sigma F_y = ma_y$ gives $F_{Ay} + F_{By} = ma_y$

$2(1.04\times10^{-11}\text{ N}) = (0.010\text{ kg})a_y$

$a_y = 2.1\times10^{-9}\text{ m/s}^2$, directed downward midway between A and B

EVALUATE: For ordinary size objects the gravitational force is very small, so the initial acceleration is very small. By symmetry there is no x-component of net force and the y-component is in the direction of the two large spheres, since they attract the small sphere.

13.6. **IDENTIFY:** The net force on A is the vector sum of the force due to B and the force due to C. In part (a), the two forces are in the same direction, but in (b) they are in opposite directions.
SET UP: Use coordinates where $+x$ is to the right. Each gravitational force is attractive, so is toward the mass exerting it. Treat the masses as uniform spheres, so the gravitational force is the same as for point masses with the same center-to-center distances. The free-body diagrams for (a) and (b) are given in Figures 13.6a and 13.6b. The gravitational force is $F_g = Gm_1m_2/r^2$.

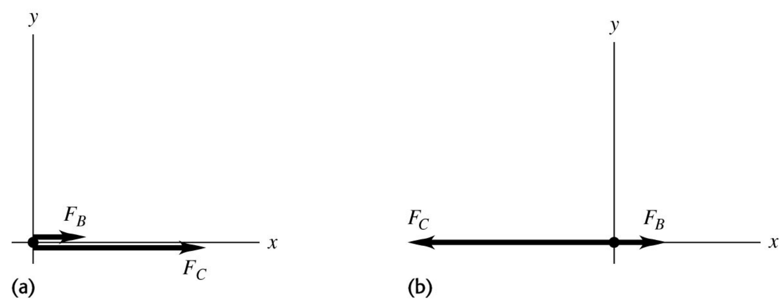


Figure 13.6

EXECUTE: **(a)** Calling F_B the force due to mass B and likewise for C, we have

$$F_B = G\frac{m_A m_B}{r_{AB}^2} = (6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\frac{(2.00\ \text{kg})^2}{(0.50\ \text{m})^2} = 1.069\times10^{-9}\ \text{N} \text{ and}$$

$$F_C = G\frac{m_A m_C}{r_{AC}^2} = (6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\frac{(2.00\ \text{kg})^2}{(0.10\ \text{m})^2} = 2.669\times10^{-8}\ \text{N}.$$ The net force is

$$F_{\text{net},x} = F_{Bx} + F_{Cx} = 1.069\times10^{-9}\ \text{N} + 2.669\times10^{-8}\ \text{N} = 2.8\times10^{-8}\ \text{N} \text{ to the right.}$$

(b) Following the same procedure as in (a), we have

$$F_B = G\frac{m_A m_B}{r_{AB}^2} = (6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\frac{(2.00\ \text{kg})^2}{(0.40\ \text{m})^2} = 1.668\times10^{-9}\ \text{N}$$

$$F_C = G\frac{m_A m_C}{r_{AC}^2} = (6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\frac{(2.00\ \text{kg})^2}{(0.10\ \text{m})^2} = 2.669\times10^{-8}\ \text{N}$$

$$F_{\text{net},x} = F_{Bx} + F_{Cx} = 1.668\times10^{-9}\ \text{N} - 2.669\times10^{-8}\ \text{N} = -2.5\times10^{-8}\ \text{N}$$

The net force on A is 2.5×10^{-8} N, to the left.

EVALUATE: As with any force, the gravitational force is a vector and must be treated like all other vectors. The formula $F_g = Gm_1m_2/r^2$ only gives the magnitude of this force.

13.7. **IDENTIFY:** The force exerted by the moon is the gravitational force, $F_g = \dfrac{Gm_M m}{r^2}$. The force exerted on the person by the earth is $w = mg$.

SET UP: The mass of the moon is $m_M = 7.35\times10^{22}$ kg. $G = 6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2$.

EXECUTE: **(a)** $F_{\text{moon}} = F_g = (6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\dfrac{(7.35\times10^{22}\ \text{kg})(70\ \text{kg})}{(3.78\times10^8\ \text{m})^2} = 2.4\times10^{-3}\ \text{N}.$

(b) $F_{\text{earth}} = w = (70\ \text{kg})(9.80\ \text{m/s}^2) = 690\ \text{N}.$ $F_{\text{moon}}/F_{\text{earth}} = 3.5\times10^{-6}.$

EVALUATE: The force exerted by the earth is much greater than the force exerted by the moon. The mass of the moon is less than the mass of the earth and the center of the earth is much closer to the person than is the center of the moon.

13.8. IDENTIFY: Use $F_g = Gm_1m_2/r^2$ to find the force each point mass exerts on the particle, find the net force, and use Newton's second law to calculate the acceleration.

SET UP: Each force is attractive. The particle (mass m) is a distance $r_1 = 0.200$ m from $m_1 = 8.00$ kg and therefore a distance $r_2 = 0.300$ m from $m_2 = 12.0$ kg. Let $+x$ be toward the 12.0-kg mass.

EXECUTE: $F_1 = \dfrac{Gm_1m}{r_1^2} = (6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\dfrac{(8.00\ \text{kg})m}{(0.200\ \text{m})^2} = (1.334\times10^{-8}\ \text{N/kg})m,$ in the $-x$-direction. $F_2 = \dfrac{Gm_2m}{r_2^2} = (6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\dfrac{(12.0\ \text{kg})m}{(0.300\ \text{m})^2} = (8.893\times10^{-9}\ \text{N/kg})m,$ in the $+x$-direction. The net force is

$F_x = F_{1x} + F_{2x} = (-1.334\times10^{-8}\ \text{N/kg} + 8.893\times10^{-9}\ \text{N/kg})m = (-4.447\times10^{-9}\ \text{N/kg})m.$

$a_x = \dfrac{F_x}{m} = -4.45\times10^{-9}\ \text{m/s}^2$. The acceleration is $4.45\times10^{-9}\ \text{m/s}^2$, toward the 8.00 kg mass.

EVALUATE: The smaller mass exerts the greater force, because the particle is closer to the smaller mass.

13.9. IDENTIFY: Use $F_g = Gm_1m_2/r^2$ to calculate the gravitational force each particle exerts on the third mass. The equilibrium is stable when for a displacement from equilibrium the net force is directed toward the equilibrium position and it is unstable when the net force is directed away from the equilibrium position.

SET UP: For the net force to be zero, the two forces on M must be in opposite directions. This is the case only when M is on the line connecting the two particles and between them. The free-body diagram for M is given in Figure 13.9. $m_1 = 3m$ and $m_2 = m$. If M is a distance x from m_1, it is a distance $1.00\ \text{m} - x$ from m_2.

EXECUTE: **(a)** $F_x = F_{1x} + F_{2x} = -G\dfrac{3mM}{x^2} + G\dfrac{mM}{(1.00\ \text{m} - x)^2} = 0$. Cancelling and simplifying gives $3(1.00\ \text{m} - x)^2 = x^2$. Taking square roots gives $1.00\ \text{m} - x = \pm x/\sqrt{3}$. Since M is between the two particles, x must be less than 1.00 m and $x = \dfrac{1.00\ \text{m}}{1+1/\sqrt{3}} = 0.634$ m. M must be placed at a point that is 0.634 m from the particle of mass $3m$ and 0.366 m from the particle of mass m.

(b) (i) If M is displaced slightly to the right in Figure 13.9, the attractive force from m is larger than the force from $3m$ and the net force is to the right. If M is displaced slightly to the left in Figure 13.9, the attractive force from $3m$ is larger than the force from m and the net force is to the left. In each case the net force is away from equilibrium and the equilibrium is unstable.

(ii) If M is displaced a very small distance along the y-axis in Figure 13.9, the net force is directed opposite to the direction of the displacement and therefore the equilibrium is stable.

EVALUATE: The point where the net force on M is zero is closer to the smaller mass.

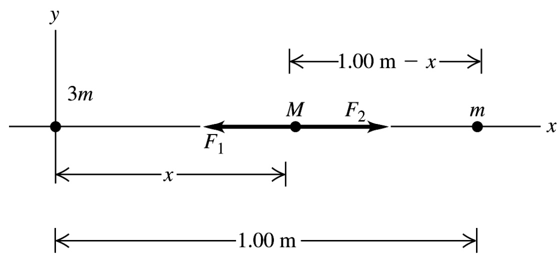

Figure 13.9

13.10. **IDENTIFY:** The force $\vec{F}_1$ exerted by m on M and the force $\vec{F}_2$ exerted by $2m$ on M are each given by $F_g = Gm_1m_2/r^2$ and the net force is the vector sum of these two forces.

SET UP: Each force is attractive. The forces on M in each region are sketched in Figure 13.10a. Let M be at coordinate x on the x-axis.

EXECUTE: **(a)** For the net force to be zero, $\vec{F}_1$ and $\vec{F}_2$ must be in opposite directions and this is the case only for $0 < x < L$. $\vec{F}_1 + \vec{F}_2 = 0$ then requires $F_1 = F_2$. $\dfrac{GmM}{x^2} = \dfrac{G(2m)M}{(L-x)^2}$. $2x^2 = (L-x)^2$ and $L - x = \pm\sqrt{2}x$. x must be less than L, so $x = \dfrac{L}{1+\sqrt{2}} = 0.414L$.

(b) For $x < 0$, $F_x > 0$. $F_x \to 0$ as $x \to -\infty$ and $F_x \to +\infty$ as $x \to 0$. For $x > L$, $F_x < 0$. as $x \to \infty$ and $F_x \to -\infty$ as $x \to L$. For $0 < x < 0.414L$, $F_x < 0$ and F_x increases from $-\infty$ to 0 as x goes from 0 to $0.414L$. For $0.414L < x < L$, $F_x > 0$ and F_x increases from 0 to $+\infty$ as x goes from $0.414L$ to L. The graph of F_x versus x is sketched in Figure 13.10b (next page).

EVALUATE: Any real object is not exactly a point so it is not possible to have both m and M exactly at $x = 0$ or $2m$ and M both exactly at $x = L$. But the magnitude of the gravitational force between two objects approaches infinity as the objects get very close together.

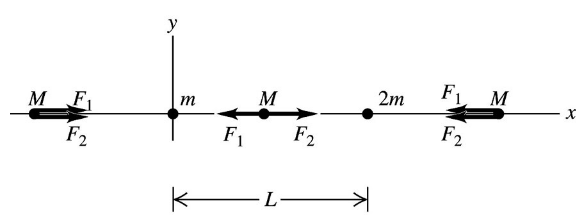

Figure 13.10a

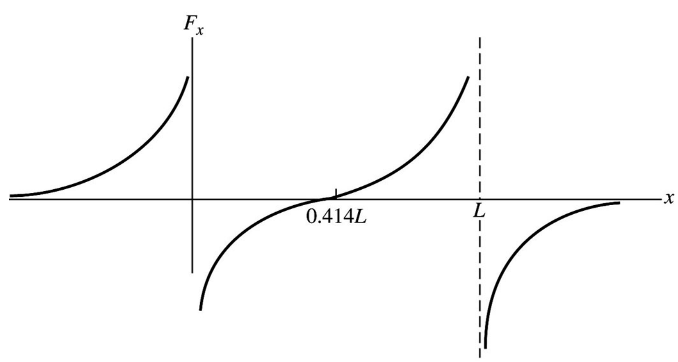

Figure 13.10b

13.11. IDENTIFY: $F_g = G\dfrac{mm_E}{r^2} = mg$, so ssc where r is the distance of the object from the center of the earth.

SET UP: $r = h + R_E$, where h is the distance of the object above the surface of the earth and $R_E = 6.37\times10^6$ m is the radius of the earth.

EXECUTE: To decrease the acceleration due to gravity by one-tenth, the distance from the center of the earth must be increased by a factor of $\sqrt{10}$, and so the distance above the surface of the earth is $(\sqrt{10}-1)R_E = 1.38\times10^7$ m.

EVALUATE: This height is about twice the radius of the earth.

13.12. IDENTIFY: Apply $g = G\dfrac{m_E}{r^2}$ to the earth and to Venus. $w = mg$.

SET UP: $g = \dfrac{Gm_E}{R_E^2} = 9.80\text{ m/s}^2$. $m_V = 0.815m_E$ and $R_V = 0.949R_E$. $w_E = mg_E = 75.0$ N.

EXECUTE: **(a)** $g_V = \dfrac{Gm_V}{R_V^2} = \dfrac{G(0.815m_E)}{(0.949R_E)^2} = 0.905\dfrac{Gm_E}{R_E^2} = 0.905g_E$.

(b) $w_V = mg_V = 0.905mg_E = (0.905)(75.0\text{ N}) = 67.9$ N.

EVALUATE: The mass of the rock is independent of its location but its weight equals the gravitational force on it and that depends on its location.

13.13. (a) IDENTIFY and **SET UP:** Apply $g = G\dfrac{m_E}{r^2}$ to the earth and to Titania. The acceleration due to gravity at the surface of Titania is given by $g_T = Gm_T/R_T^2$, where m_T is its mass and R_T is its radius. For the earth, $g_E = Gm_E/R_E^2$.

EXECUTE: For Titania, $m_T = m_E/1700$ and $R_T = R_E/8$, so

$$g_T = \frac{Gm_T}{R_T^2} = \frac{G(m_E/1700)}{(R_E/8)^2} = \left(\frac{64}{1700}\right)\frac{Gm_E}{R_E^2} = 0.0377g_E.$$

Since $g_E = 9.80\text{ m/s}^2$, $g_T = (0.0377)(9.80\text{ m/s}^2) = 0.37\text{ m/s}^2$.

EVALUATE: g on Titania is much smaller than on earth. The smaller mass reduces g and is a greater effect than the smaller radius, which increases g.

(b) IDENTIFY and **SET UP:** Use density = mass/volume. Assume Titania is a sphere.

EXECUTE: From Section 13.2 we know that the average density of the earth is 5500 kg/m³. For Titania

$$\rho_T = \frac{m_T}{\frac{4}{3}\pi R_T^3} = \frac{m_E/1700}{\frac{4}{3}\pi(R_E/8)^3} = \frac{512}{1700}\rho_E = \frac{512}{1700}(5500\text{ kg/m}^3) = 1700\text{ kg/m}^3.$$

EVALUATE: The average density of Titania is about a factor of 3 smaller than for earth. We can write $a_g = G\dfrac{m_E}{r^2}$ for Titania as $g_T = \frac{4}{3}\pi GR_T\rho_T$. $g_T < g_E$ both because $\rho_T < \rho_E$ and $R_T < R_E$.

13.14. IDENTIFY: Apply $g = G\dfrac{m_E}{r^2}$ to Rhea.

SET UP: $\rho = m/V$. The volume of a sphere is $V = \frac{4}{3}\pi R^3$.

EXECUTE: $M = \dfrac{gR^2}{G} = 2.32\times10^{21}$ kg and $\rho = \dfrac{M}{(4\pi/3)R^3} = 1.24\times10^3\text{ kg/m}^3$.

EVALUATE: The average density of Rhea is a bit less than one-fourth that of the earth.

13.15. IDENTIFY: We are dealing with the acceleration due to gravity on another planet.

SET UP: We want to find g at the surface of a planet. At the surface, $g = GM/R^2$. Since we know the density ρ of the planet, we should put g in terms of ρ using $\rho = m/V$.

EXECUTE: (a) We want g at the surface of this planet. Using $m = \rho V = \rho(4/3\ \pi R^3)$, we have

$g = \dfrac{Gm}{R^2} = \dfrac{G\rho\left(\frac{4}{3}\pi R^3\right)}{R^2} = \dfrac{4}{3}\pi G\rho R.$ Now take the ratio of $g_{\text{planet}}/g_{\text{earth}}$ using the same density for both planets but $R = 1.25R_{\text{earth}}$. We get $\dfrac{g_{\text{p}}}{g_{\text{e}}} = \dfrac{\frac{4}{3}\pi G\rho R_{\text{p}}}{\frac{4}{3}\pi G\rho R_{\text{e}}} = \dfrac{R_{\text{p}}}{R_{\text{e}}} = \dfrac{1.25R_{\text{e}}}{R_{\text{e}}} = 1.25$, from which we get $g_{\text{p}} = 1.25$ $g_{\text{e}} = (1.25)(9.80\ \text{m/s}^2) = 12.3\ \text{m/s}^2$.

(b) We now want to change the density of this planet (a neat trick if you can do it!) so that g at its surface is the same as on earth. Use the result we found in part (a) for g: $g = \frac{4}{3}\pi G\rho R.$ Since $g_{\text{p}} = g_{\text{e}}$, we equate the two expressions for g, giving $\frac{4}{3}\pi G\rho_{\text{p}}R_{\text{p}} = \frac{4}{3}\pi G\rho_{\text{e}}R_{\text{e}}$. Solving for ρ_{p} gives

$\rho_{\text{p}} = \dfrac{R_{\text{e}}}{R_{\text{p}}}\rho_{\text{e}} = \dfrac{R_{\text{e}}}{1.25R_{\text{e}}}\rho_{\text{e}} = 0.800\rho_{\text{e}}.$ The planet should have 80.0% the density of earth.

EVALUATE: The planet is less dense than earth but it has more mass since it is larger, so g at its surface is the same as it is on earth.

13.16. IDENTIFY: The gravity of Io limits the height to which volcanic material will rise. The acceleration due to gravity at the surface of Io depends on its mass and radius.

SET UP: The radius of Io is $R = 1.821\times10^6$ m. Use coordinates where $+y$ is upward. At the maximum height, $v_{0y} = 0$, $a_y = -g_{\text{Io}}$, which is assumed to be constant. Therefore the constant-acceleration kinematics formulas apply. The acceleration due to gravity at Io's surface is given by $g_{\text{Io}} = Gm/R^2$.

EXECUTE: At the surface of Io, $g_{\text{Io}} = \dfrac{Gm}{R^2} = \dfrac{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(8.93\times10^{22}\ \text{kg})}{(1.821\times10^6\ \text{m})^2} = 1.797\ \text{m/s}^2.$

For constant acceleration (assumed), the equation $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ applies, so

$v_{0y} = \sqrt{-2a_y(y - y_0)} = \sqrt{-2(-1.797\ \text{m/s}^2)(5.00\times10^5\ \text{m})} = 1.3405\times10^3\ \text{m/s}.$ Now solve for $y - y_0$ when $v_{0y} = 1.3405\times10^3$ m/s and $a_y = -9.80\ \text{m/s}^2$. The equation $v_y^2 = v_{0y}^2 + 2a_y(y - y_0)$ gives

$y - y_0 = \dfrac{v_y^2 - v_{0y}^2}{2a_y} = \dfrac{-(1.3405\times10^3\ \text{m/s})^2}{2(-9.80\ \text{m/s}^2)} = 9.17\times10^4\ \text{m} = 91.7\ \text{km}.$

EVALUATE: Even though the mass of Io is around 100 times smaller than that of the earth, the acceleration due to gravity at its surface is only about 1/6 of that of the earth because Io's radius is much smaller than earth's radius.

13.17. IDENTIFY: The escape speed, as shown in Example 13.5, is $\sqrt{2GM/R}$.

SET UP: For Mars, $M = 6.42\times10^{23}$ kg and $R = 3.39\times10^6$ m. For Jupiter, $M = 1.90\times10^{27}$ kg and $R = 6.99\times10^7$ m.

EXECUTE: (a) $v = \sqrt{2(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(6.42\times10^{23}\ \text{kg})/(3.39\times10^6\ \text{m})} = 5.03\times10^3$ m/s.

(b) $v = \sqrt{2(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2(1.90\times10^{27}\ \text{kg})/(6.99\times10^7\ \text{m})} = 6.02\times10^4$ m/s.

(c) Both the kinetic energy and the gravitational potential energy are proportional to the mass of the spacecraft.

EVALUATE: Example 13.5 calculates the escape speed for earth to be 1.12×10^4 m/s. This is larger than our result for Mars and less than our result for Jupiter.

13.18. IDENTIFY: The kinetic energy is $K=\frac{1}{2}mv^2$ and the potential energy is $U=-\dfrac{GMm}{r}$.

SET UP: The mass of the earth is $M_E = 5.97\times10^{24}$ kg.

EXECUTE: **(a)** $K=\frac{1}{2}(629\text{ kg})(3.33\times10^3\text{ m/s})^2 = 3.49\times10^9$ J

(b) $U=-\dfrac{GM_E m}{r} = -\dfrac{(6.673\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(5.97\times10^{24}\text{ kg})(629\text{ kg})}{2.87\times10^9\text{ m}} = -8.73\times10^7$ J.

EVALUATE: The total energy $K+U$ is positive.

13.19. IDENTIFY: Mechanical energy is conserved. At the escape speed, the object has no kinetic energy when it is very far away from the planet.

SET UP: Call m the mass of the object, M the mass of the planet, and r its radius. $K_1 + U_1 = K_2 + U_2$, $K = \frac{1}{2}mv^2$, $U = -GmM/r$, $g = GM/r^2$.

EXECUTE: Energy conservation gives $\frac{1}{2}mv^2 - GmM/r = 0 + 0$. $M = rv^2/2G$. Putting this into $g =$ GM/r^2 gives $g = \dfrac{G\left(\dfrac{rv^2}{2G}\right)}{r^2} = \dfrac{v^2}{2r}$. Putting in the numbers gives

$g = (7.65\times10^3\text{ m/s})^2/[2(3.24\times10^6\text{ m})] = 9.03\text{ m/s}^2$.

EVALUATE: This result is not very different from g on earth, so it is physically reasonable for a planet.

13.20. IDENTIFY: This problem involves gravitational potential energy.

SET UP: Estimate: Altitude is h = 30,000 ft (≈10,000 m) above the earth's surface. We want to find the percent change in the gravitational potential energy of the system (you and the earth) when you are at this altitude compared to when you are at the surface. Use $U=-\dfrac{Gm_E m}{r}$, where m is your mass.

EXECUTE: At the surface: $U_s = -\dfrac{Gm_E m}{R}$, and at altitude h: $U_h = -\dfrac{Gm_E m}{R_E+h}$. The fractional change in potential energy is $\dfrac{\Delta U}{U_s} = \dfrac{U_h-U_s}{U_s} = \dfrac{U_h}{U_s}-1$. Using the expressions for U_h and U_s gives

$$\frac{\Delta U}{U_s} = \frac{-\dfrac{Gm_E m}{R_E+h}}{-\dfrac{Gm_E m}{R_E}} - 1 = \frac{R_E}{R_E+h} - 1 = \frac{1}{1+h/R_E} - 1 = \left(1+h/R_E\right)^{-1} - 1.$$ From Appendix B, we have

$(1+x)^n = 1^n + n1^{n-1}x + \dfrac{n(n-1)1^{n-2}}{2!}x^2 + \cdots$. If $x \ll 1$, we can neglect all the x^2 and higher terms, so for $n = -1$, we have $(1+x)^{-1} \approx 1 - x$. In our case, $x = h/R_E \ll 1$, so $\dfrac{1}{1+h/R_E} \approx 1 - \dfrac{h}{R_E}$, which yields

$\dfrac{\Delta U}{U_s} \approx \left(1-\dfrac{h}{R_E}\right) - 1 \approx -\dfrac{h}{R_E}$. This gives $\dfrac{\Delta U}{U_s} \approx -\dfrac{10{,}000\text{ m}}{6.37\times10^6\text{ m}} \approx -1.6\times10^{-3}$. This result gives us only the *magnitude* of the change. Since U is negative, its magnitude decreases with altitude, but it is becoming *less negative*, so it is actually increasing. So the gravitational potential energy is 0.16% greater when you are in the plane.

EVALUATE: Fractional changes in gravitational potential energy only become apparent when $\Delta r/r$ is fairly large.

13.21. IDENTIFY: This problem involves the gravitational force and gravitational potential energy.

SET UP: $F_g = \dfrac{Gm_1m_2}{r^2}$ and $U_g = -\dfrac{Gm_p m}{r}$. We know U_g and want to find the force F_g on you at the surface of the planet when $r = R$.

EXECUTE: Relate F_g and U_g: $F_g = \dfrac{Gmm_p}{R^2} = \left(\dfrac{Gmm_p}{R}\right)\dfrac{1}{R} = -\dfrac{U_g}{R} = -\dfrac{-1.20\times10^9\text{ J}}{5.00\times10^6\text{ m}} = 240\text{ N}.$

EVALUATE: Knowing your mass, we could find g at the surface.

13.22. **IDENTIFY:** The satellite is in orbit, so we need to use Newton's second law, the gravitational force, and gravitational potential energy.

SET UP: Use $\sum F = m\dfrac{v^2}{R}$, $F_g = \dfrac{Gm_1m_2}{r^2}$, and $U_g = -\dfrac{Gm_pm}{r}$. We want to find r_B so that $K_B = 2K_A$.

EXECUTE: $\sum F = m\dfrac{v^2}{R}$ gives $\dfrac{Gmm_p}{r^2} = \dfrac{mv^2}{r} = \dfrac{2}{r}\left(\dfrac{1}{2}mv^2\right) = \dfrac{2K}{r}$, so $K = \dfrac{Gmm_p}{2r}$.

At A: $K_A = \dfrac{Gmm_p}{2r_A}$

At B: $K_B = \dfrac{Gmm_p}{2r_B} = 2K_A = \dfrac{2Gmm_p}{2r_A}$.

Solving the last equation for r_B gives $r_B = r_A/2$.

EVALUATE: It is reasonable that $r_B < r_A$ since when it is closer to the planet, the satellite must move faster to remain in orbit.

13.23. **IDENTIFY:** This problem involves the total energy of the earth-satellite system.

SET UP: Eq. 13.13: $E = -\dfrac{Gm_Em}{2r}$, where E is the total energy of the system. Also use $\sum F = m\dfrac{v^2}{R}$, $F_g = \dfrac{Gm_1m_2}{r^2}$, and $U_g = -\dfrac{Gm_pm}{r}$.

EXECUTE: $\sum F = m\dfrac{v^2}{R} = \dfrac{Gmm_E}{r^2}$ gives $v^2 = \dfrac{Gm_E}{r}$, so $K = \dfrac{1}{2}mv^2 = \dfrac{1}{2}m\left(\dfrac{Gm_E}{r}\right) = \dfrac{Gmm_E}{2r} =$

2.00×10^6 J. Using Eq. 13.13 gives $E = -\dfrac{Gm_Em}{2r} = -K = -2.00\times10^6$ J. The total energy is $E = K + U$, so $U = E - K = -2.00\times10^6\text{ J} - 2.00\times10^6\text{ J} = -4.00\times10^6$ J.

EVALUATE: Note that $K = -\dfrac{1}{2}U$, which is a general result for orbits.

13.24. **IDENTIFY:** Newton's second law and his law of gravitation both apply to the satellite.

SET UP: $T = \dfrac{2\pi r}{v}$. r and v are also related by applying $\sum\vec{F} = m\vec{a}$ to the motion of the satellite. The satellite has $a_{rad} = v^2/R$, and the only force on the satellite is the gravitational force, $F_g = G\dfrac{m_Em}{r^2}$.

$m_E = 5.97\times10^{24}$ kg.

EXECUTE: **(a)** The free-body diagram of the satellite is shown in Figure 13.24. $F_g = ma_{rad}$ gives $G\dfrac{m_Em}{r^2} = m\dfrac{v^2}{r}$, which simplifies to $G\dfrac{m_E}{r} = v^2$. Solving for r gives

$$r = \frac{Gm_E}{v^2} = \frac{(6.673\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(5.97\times10^{24}\text{ kg})}{(6200\text{ m/s})^2} = 1.04\times10^7\text{ m}.$$

$$T = \frac{2\pi r}{v} = \frac{2\pi(1.04\times10^7\text{ m})}{6200\text{ m/s}} = 1.05\times10^4\text{ s} = 176\text{ min} = 2.93\text{ h}.$$

(b) $a_{rad} = \dfrac{v^2}{r} = \dfrac{(6200\text{ m/s})^2}{1.04\times10^7\text{ m}} = 3.70\text{ m/s}^2.$

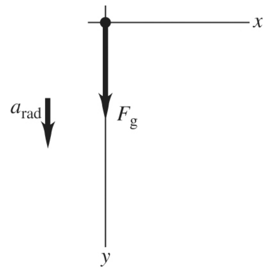

Figure 13.24

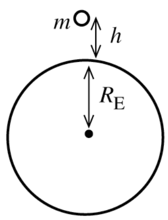
EVALUATE: The acceleration of the satellite is 38% of the acceleration due to gravity at the earth's surface.

13.25. **IDENTIFY:** Apply Newton's second law to the motion of the satellite and obtain an equation that relates the orbital speed v to the orbital radius r.

SET UP: The distances are shown in Figure 13.25a.

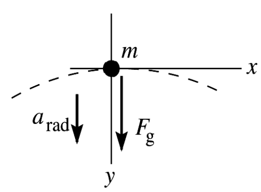


The radius of the orbit is $r = h + R_E$.

$r = 8.90\times10^5 \text{ m} + 6.37\times10^6 \text{ m} = 7.26\times10^6 \text{ m}.$

Figure 13.25a

The free-body diagram for the satellite is given in Figure 13.25b.



(a) EXECUTE: $\Sigma F_y = ma_y$

$F_g = ma_{rad}$

$$G\frac{mm_E}{r^2} = m\frac{v^2}{r}$$

Figure 13.25b

$$v = \sqrt{\frac{Gm_E}{r}} = \sqrt{\frac{(6.673\times10^{-11} \text{ N}\cdot\text{m}^2/\text{kg}^2)(5.97\times10^{24} \text{ kg})}{7.26\times10^6 \text{ m}}} = 7.408\times10^3 \text{ m/s which rounds to 7410 m/s.}$$

(b) $T = \dfrac{2\pi r}{v} = \dfrac{2\pi(7.26\times10^6 \text{ m})}{7.408\times10^3 \text{ m/s}} = 6158 \text{ s} = 1.71 \text{ h}.$

EVALUATE: Note that $r = h + R_E$ is the radius of the orbit, measured from the center of the earth. For this satellite r is greater than for the satellite in Example 13.6, so its orbital speed is less.

13.26. **IDENTIFY:** The time to complete one orbit is the period T, given by $T = \dfrac{2\pi r^{3/2}}{\sqrt{Gm_E}}$. The speed v of the satellite is given by $v = \dfrac{2\pi r}{T}$.

SET UP: If h is the height of the orbit above the earth's surface, the radius of the orbit is $r = h + R_E$. $R_E = 6.37\times10^6$ m and $m_E = 5.97\times10^{24}$ kg.

Execute: **(a)** $T = \dfrac{2\pi r^{3/2}}{\sqrt{Gm_E}} = \dfrac{2\pi(7.05\times10^5\ \text{m} + 6.37\times10^6\ \text{m})^{3/2}}{\sqrt{(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(5.97\times10^{24}\ \text{kg})}} = 5.93\times10^3\ \text{s} = 98.8\ \text{min}$

(b) $v = \dfrac{2\pi(7.05\times10^5\ \text{m} + 6.37\times10^6\ \text{m})}{5.93\times10^3\ \text{s}} = 7.50\times10^3\ \text{m/s} = 7.50\ \text{km/s}.$

Evaluate: The satellite in Example 13.6 is at a lower altitude and therefore has a smaller orbit radius than the satellite in this problem. Therefore, the satellite in this problem has a larger period and a smaller orbital speed. But a large percentage change in h corresponds to a small percentage change in r and the values of T and v for the two satellites do not differ very much.

13.27. **Identify:** We know orbital data (speed and orbital radius) for one satellite and want to use it to find the orbital speed of another satellite having a known orbital radius. Newton's second law and the law of universal gravitation apply to both satellites.

Set Up: For circular motion, $F_{\text{net}} = ma = mv^2/r$, which in this case is $G\dfrac{mm_p}{r^2} = m\dfrac{v^2}{r}$.

Execute: Using $G\dfrac{mm_p}{r^2} = m\dfrac{v^2}{r}$, we get $Gm_p = rv^2 = \text{constant}$. $r_1v_1^2 = r_2v_2^2$.

$v_2 = v_1\sqrt{\dfrac{r_1}{r_2}} = (4800\ \text{m/s})\sqrt{\dfrac{7.00\times10^7\ \text{m}}{3.00\times10^7\ \text{m}}} = 7330\ \text{m/s}.$

Evaluate: The more distant satellite moves slower than the closer satellite, which is reasonable since the planet's gravity decreases with distance. The masses of the satellites do not affect their orbits.

13.28. **Identify:** We can calculate the orbital period T from the number of revolutions per day. Then the period and the orbit radius are related by $T = \dfrac{2\pi r^{3/2}}{\sqrt{Gm_E}}$.

Set Up: $m_E = 5.97\times10^{24}$ kg and $R_E = 6.37\times10^6$ m. The height h of the orbit above the surface of the earth is related to the orbit radius r by $r = h + R_E$. $1\ \text{day} = 8.64\times10^4$ s.

Execute: The satellite moves 15.65 revolutions in 8.64×10^4 s, so the time for 1.00 revolution is

$T = \dfrac{8.64\times10^4\ \text{s}}{15.65} = 5.52\times10^3\ \text{s}$. $T = \dfrac{2\pi r^{3/2}}{\sqrt{Gm_E}}$ gives

$r = \left(\dfrac{Gm_ET^2}{4\pi^2}\right)^{1/3} = \left(\dfrac{[6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2][5.97\times10^{24}\ \text{kg}][5.52\times10^3\ \text{s}]^2}{4\pi^2}\right)^{1/3}$. $r = 6.75\times10^6$ m and

$h = r - R_E = 3.8\times10^5\ \text{m} = 380\ \text{km}.$

Evaluate: The period of this satellite is slightly larger than the period for the satellite in Example 13.6 and the altitude of this satellite is therefore somewhat greater.

13.29. **Identify:** Apply $\Sigma\vec{F} = m\vec{a}$ to the motion of the baseball. $v = \dfrac{2\pi r}{T}$.

Set Up: $r_D = 6\times10^3$ m.

Execute: **(a)** $F_g = ma_{\text{rad}}$ gives $G\dfrac{m_Dm}{r_D^2} = m\dfrac{v^2}{r_D}$.

$v = \sqrt{\dfrac{Gm_D}{r_D}} = \sqrt{\dfrac{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(1.5\times10^{15}\ \text{kg})}{6\times10^3\ \text{m}}} = 4.07\ \text{m/s}$ which rounds to 4.1 m/s.

$4.1\ \text{m/s} = 9.1\ \text{mph}$, which is easy to achieve.

(b) $T = \dfrac{2\pi r}{v} = \dfrac{2\pi(6\times10^3\ \text{m})}{4.07\ \text{m/s}} = 9263\ \text{s} = 154.4\ \text{min} = 2.6\ \text{h}.$ The game would last a very long time indeed!

EVALUATE: The speed v is relative to the center of Deimos. The baseball would already have some speed before we throw it because of the rotational motion of Deimos.

13.30. IDENTIFY: $T = \dfrac{2\pi r^{3/2}}{\sqrt{Gm_{\text{star}}}}$, where m_{star} is the mass of the star. $v = \dfrac{2\pi r}{T}.$

SET UP: $3.09\ \text{days} = 2.67\times10^5\ \text{s}.$ The orbit radius of Mercury is $5.79\times10^{10}\ \text{m}.$ The mass of our sun is $1.99\times10^{30}\ \text{kg}.$

EXECUTE: **(a)** $T = 2.67\times10^5\ \text{s}.$ $r = (5.79\times10^{10}\ \text{m})/9 = 6.43\times10^9\ \text{m}.$ $T = \dfrac{2\pi r^{3/2}}{\sqrt{Gm_{\text{star}}}}$ gives

$m_{\text{star}} = \dfrac{4\pi^2 r^3}{T^2 G} = \dfrac{4\pi^2(6.43\times10^9\ \text{m})^3}{(2.67\times10^5\ \text{s})^2(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)} = 2.21\times10^{30}\ \text{kg}.$ $\dfrac{m_{\text{star}}}{m_{\text{sun}}} = 1.11,$ so $m_{\text{star}} = 1.11 m_{\text{sun}}.$

(b) $v = \dfrac{2\pi r}{T} = \dfrac{2\pi(6.43\times10^9\ \text{m})}{2.67\times10^5\ \text{s}} = 1.51\times10^5\ \text{m/s} = 151\ \text{km/s}$

EVALUATE: The orbital period of Mercury is 88.0 d. The period for this planet is much less primarily because the orbit radius is much less and also because the mass of the star is greater than the mass of our sun.

13.31. IDENTIFY: The orbital speed is given by $v = \sqrt{Gm/r}$, where m is the mass of the star. The orbital period is given by $T = \dfrac{2\pi r}{v}.$

SET UP: The sun has mass $m_S = 1.99\times10^{30}\ \text{kg}.$ The orbit radius of the earth is $1.50\times10^{11}\ \text{m}.$

EXECUTE: **(a)** $v = \sqrt{Gm/r}.$

$v = \sqrt{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(0.85\times1.99\times10^{30}\ \text{kg})/((1.50\times10^{11}\ \text{m})(0.11))} = 8.27\times10^4\ \text{m/s}.$

(b) $2\pi r/v = 1.25\times10^6\ \text{s} = 14.5\ \text{days}$ (about two weeks).

EVALUATE: The orbital period is less than the 88-day orbital period of Mercury; this planet is orbiting very close to its star, compared to the orbital radius of Mercury.

13.32. IDENTIFY: The period of each satellite is given by $T = \dfrac{2\pi r^{3/2}}{\sqrt{Gm_p}}.$ Set up a ratio involving T and r.

SET UP: $T = \dfrac{2\pi r^{3/2}}{\sqrt{Gm_p}}$ gives $\dfrac{T}{r^{3/2}} = \dfrac{2\pi}{\sqrt{Gm_p}} = \text{constant},$ so $\dfrac{T_1}{r_1^{3/2}} = \dfrac{T_2}{r_2^{3/2}}.$

EXECUTE: $T_2 = T_1\left(\dfrac{r_2}{r_1}\right)^{3/2} = (6.39\ \text{days})\left(\dfrac{48{,}000\ \text{km}}{19{,}600\ \text{km}}\right)^{3/2} = 24.5\ \text{days}.$ For the other satellite,

$T_2 = (6.39\ \text{days})\left(\dfrac{64{,}000\ \text{km}}{19{,}600\ \text{km}}\right)^{3/2} = 37.7\ \text{days}.$

EVALUATE: T increases when r increases.

13.33. IDENTIFY: Kepler's third law applies.

SET UP: $T = \dfrac{2\pi a^{3/2}}{\sqrt{Gm_S}}$, $d_{\min} = a(1 - e)$, $d_{\max} = a(1 + e)$.

EXECUTE: **(a)** Kepler's third law gives

$$T = \frac{2\pi a^{3/2}}{\sqrt{Gm_S}} = \frac{2\pi(5.91\times10^{12}\ \text{m})^{3/2}}{\sqrt{(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(1.99\times10^{30}\ \text{kg})}} = 7.84\times10^9\ \text{s}\ [(1\ \text{y})/(3.156\times10^7\ \text{s})] = 248\ \text{y}.$$

(b) $d_{min} = a(1 - e) = (5.91\times10^{12}\ \text{m})(1 - 0.249) = 4.44\times10^{12}\ \text{m}$; $d_{max} = a(1 + e) = 7.38\times10^{12}\ \text{m}$.

EVALUATE: $d_{max} = 1.66 d_{min}$, which is *much* greater than for the earth's orbit since the earth moves in a much more circular orbit than Pluto.

13.34. **IDENTIFY:** Knowing the orbital radius and orbital period of a satellite, we can calculate the mass of the object about which it is revolving.

SET UP: The radius of the orbit is $r = 10.5\times10^9$ m and its period is $T = 6.3\ \text{days} = 5.443\times10^5$ s. The mass of the sun is $m_S = 1.99\times10^{30}$ kg. The orbital period is given by $T = \dfrac{2\pi r^{3/2}}{\sqrt{Gm_{HD}}}$.

EXECUTE: Solving $T = \dfrac{2\pi r^{3/2}}{\sqrt{Gm_{HD}}}$ for the mass of the star gives

$$m_{HD} = \frac{4\pi^2 r^3}{T^2 G} = \frac{4\pi^2(10.5\times10^9\ \text{m})^3}{(5.443\times10^5\ \text{s})^2(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)} = 2.3\times10^{30}\ \text{kg},$$ which is $m_{HD} = 1.2 m_S$.

EVALUATE: The mass of the star is only 20% greater than that of our sun, yet the orbital period of the planet is much shorter than that of the earth, so the planet must be much closer to the star than the earth is.

13.35. **IDENTIFY:** We are dealing with the gravitational force due to spherical shells.

SET UP: Outside a uniform spherical shell, $F_g = \dfrac{Gm_1m_2}{r^2}$, and inside of it $F_g = 0$. Our target variable is the net force F at various distances from the center, where $F = F_A + F_B$.

EXECUTE: **(a)** At $r = 2.00$ m, the point mass is inside both shells, so $F = 0$.

(b) At $r = 5.00$ m, the mass is between the shells, so $F_B = 0$, so $F = F_A$. This gives

$$F = F_A = \frac{Gmm_A}{r^2} = \frac{G(0.0200\ \text{kg})(20.0\ \text{kg})}{(5.00\ \text{m})^2} = 1.07\times10^{-12}\ \text{N}.$$

(c) At $r = 8.00$ m, the mass is outside of both shells. We treat each one as a point mass at its center.

$$F = \frac{G(m_A + m_B)}{r^2} = \frac{G(0.0200\ \text{kg})(60.0\ \text{kg})}{(8.00\ \text{m})^2} = 1.25\times10^{-12}\ \text{N}.$$

EVALUATE: If a shell is not uniform, we cannot treat it as a point mass at its center. And the force on a mass inside of it is not necessarily zero.

13.36. **IDENTIFY:** Section 13.6 states that for a point mass outside a spherical shell the gravitational force is the same as if all the mass of the shell were concentrated at its center. It also states that for a point inside a spherical shell the force is zero.

SET UP: For $r = 5.01$ m the point mass is outside the shell and for $r = 4.99$ m and $r = 2.72$ m the point mass is inside the shell.

EXECUTE: **(a)** (i) $F_g = \dfrac{Gm_1m_2}{r^2} = (6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\dfrac{(1000.0\ \text{kg})(2.00\ \text{kg})}{(5.01\ \text{m})^2} = 5.31\times10^{-9}$ N. (ii) $F_g = 0$. (iii) $F_g = 0$.

(b) For $r < 5.00$ m the force is zero and for $r > 5.00$ m the force is proportional to $1/r^2$. The graph of F_g versus r is sketched in Figure 13.36.

EVALUATE: Inside the shell the gravitational potential energy is constant and the force on a point mass inside the shell is zero.

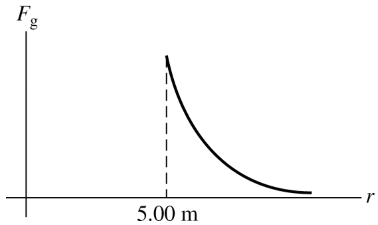


Figure 13.36

13.37. **IDENTIFY:** Section 13.6 states that for a point mass outside a uniform sphere the gravitational force is the same as if all the mass of the sphere were concentrated at its center. It also states that for a point mass a distance r from the center of a uniform sphere, where r is less than the radius of the sphere, the gravitational force on the point mass is the same as though we removed all the mass at points farther than r from the center and concentrated all the remaining mass at the center.

SET UP: The density of the sphere is $\rho = \dfrac{M}{\frac{4}{3}\pi R^3}$, where M is the mass of the sphere and R is its radius.

The mass inside a volume of radius $r < R$ is $M_r = \rho V_r = \left(\dfrac{M}{\frac{4}{3}\pi R^3}\right)\left(\frac{4}{3}\pi r^3\right) = M\left(\dfrac{r}{R}\right)^3$. $r = 5.01\text{ m}$ is outside the sphere and $r = 2.50\text{ m}$ is inside the sphere. $F_g = \dfrac{Gm_1m_2}{r^2}$.

EXECUTE: **(a)** (i) $F_g = \dfrac{GMm}{r^2} = (6.67\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)\dfrac{(1000.0\text{ kg})(2.00\text{ kg})}{(5.01\text{ m})^2} = 5.31\times10^{-9}\text{ N}.$

(ii) $F_g = \dfrac{GM'm}{r^2}$. $M' = M\left(\dfrac{r}{R}\right)^3 = (1000.0\text{ kg})\left(\dfrac{2.50\text{ m}}{5.00\text{ m}}\right)^3 = 125\text{ kg}.$

$F_g = (6.67\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)\dfrac{(125\text{ kg})(2.00\text{ kg})}{(2.50\text{ m})^2} = 2.67\times10^{-9}\text{ N}.$

(b) $F_g = \dfrac{GM(r/R)^3 m}{r^2} = \left(\dfrac{GMm}{R^3}\right)r$ for $r < R$ and $F_g = \dfrac{GMm}{r^2}$ for $r > R$. The graph of F_g versus r is sketched in Figure 13.37.

EVALUATE: At points outside the sphere the force on a point mass is the same as for a shell of the same mass and radius. For $r < R$ the force is different in the two cases of uniform sphere versus hollow shell.

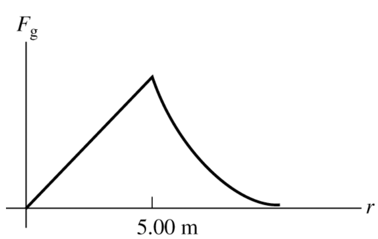

Figure 13.37

13.38. **IDENTIFY:** The gravitational potential energy of a pair of point masses is $U = -G\dfrac{m_1m_2}{r}$. Divide the rod into infinitesimal pieces and integrate to find U.

SET UP: Divide the rod into differential masses dm at position l, measured from the right end of the rod. $dm = dl(M/L)$.

EXECUTE: **(a)** $U = -\dfrac{Gm\,dm}{l+x} = -\dfrac{GmM}{L}\dfrac{dl}{l+x}.$

Integrating, $U = -\dfrac{GmM}{L}\displaystyle\int_0^L \frac{dl}{l+x} = -\frac{GmM}{L}\ln\left(1+\frac{L}{x}\right)$. For $x \gg L$, the natural logarithm is ~(L/x), and $U \to -GmM/x$.

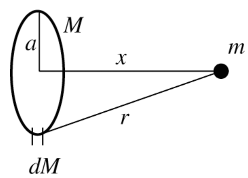
(b) The x-component of the gravitational force on the sphere is

$F_x = -\dfrac{\partial U}{\partial x} = \dfrac{GmM}{L}\dfrac{(-L/x^2)}{1+(L/x)} = -\dfrac{GmM}{x^2+Lx}$, with the minus sign indicating an attractive force. As $x \gg L$, the denominator in the above expression approaches x^2, and $F_x \to -GmM/x^2$, as expected.

EVALUATE: When x is much larger than L the rod can be treated as a point mass, and our results for U and F_x do reduce to the correct expression when $x \gg L$.

13.39. **IDENTIFY:** Find the potential due to a small segment of the ring and integrate over the entire ring to find the total U.

(a) SET UP:



Divide the ring up into small segments dM, as indicated in Figure 13.39.

Figure 13.39

EXECUTE: The gravitational potential energy of dM and m is $dU = -GmdM/r$.

The total gravitational potential energy of the ring and particle is $U = \int dU = -Gm\int dM/r$.

But $r = \sqrt{x^2+a^2}$ is the same for all segments of the ring, so

$U = -\dfrac{Gm}{r}\displaystyle\int dM = -\frac{GmM}{r} = -\frac{GmM}{\sqrt{x^2+a^2}}.$

(b) EVALUATE: When $x \gg a$, $\sqrt{x^2+a^2} \to \sqrt{x^2} = x$ and $U = -GmM/x$. This is the gravitational potential energy of two point masses separated by a distance x. This is the expected result.

(c) IDENTIFY and **SET UP:** Use $F_x = -dU/dx$ with $U(x)$ from part (a) to calculate F_x.

EXECUTE: $F_x = -\dfrac{dU}{dx} = -\dfrac{d}{dx}\left(-\dfrac{GmM}{\sqrt{x^2+a^2}}\right)$

$F_x = +GmM\dfrac{d}{dx}(x^2+a^2)^{-1/2} = GmM\left(-\dfrac{1}{2}(2x)(x^2+a^2)^{-3/2}\right)$

$F_x = -GmMx/(x^2+a^2)^{3/2}$; the minus sign means the force is attractive.

EVALUATE: **(d)** For $x \gg a$, $(x^2+a^2)^{3/2} \to (x^2)^{3/2} = x^3$

Then $F_x = -GmMx/x^3 = -GmM/x^2$. This is the force between two point masses separated by a distance x and is the expected result.

(e) For $x = 0$, $U = -GMm/a$. Each small segment of the ring is the same distance from the center and the potential is the same as that due to a point charge of mass M located at a distance a.

For $x = 0$, $F_x = 0$. When the particle is at the center of the ring, symmetrically placed segments of the ring exert equal and opposite forces and the total force exerted by the ring is zero.

13.40. **IDENTIFY:** We are investigating the gravitational field $\vec{g}$ for a spherical shell.

SET UP: The field is defined as $\vec{g} = \dfrac{\vec{F}_g}{m}$. We want to find $\vec{g}$ inside and outside a spherical shell.

EXECUTE: **(a)** Inside ($r < R$) the shell $\vec{F}_g = 0$, so $\vec{g} = 0$.

(b) Outside ($r > R$) the shell behaves like a point mass at its center, so $g = \dfrac{GmM / r^2}{m} = \dfrac{GM}{r^2}$.

EVALUATE: The gravitational field obeys an inverse-square law.

13.41. **IDENTIFY** and **SET UP:** At the north pole, $F_g = w_0 = mg_0$, where g_0 is given by $g = G\dfrac{m_E}{r^2}$ applied to Neptune. At the equator, the apparent weight is given by $w = w_0 - mv^2/R$. The orbital speed v is obtained from the rotational period using $v = 2\pi R/T$.

EXECUTE: **(a)** $g_0 = Gm/R^2 = (6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(1.02\times10^{26}\ \text{kg})/(2.46\times10^7\ \text{m})^2 = 11.25\ \text{m/s}^2$. This agrees with the value of g given in the problem.

$F = w_0 = mg_0 = (3.00\ \text{kg})(11.25\ \text{m/s}^2) = 33.74\ \text{N}$, which rounds to 33.7 N. This is the true weight of the object.

(b) We have $w = w_0 - mv^2/R$

$T = \dfrac{2\pi r}{v}$ gives $v = \dfrac{2\pi r}{T} = \dfrac{2\pi(2.46\times10^7\ \text{m})}{(16\ \text{h})(3600\ \text{s}/1\ \text{h})} = 2.683\times10^3\ \text{m/s}$

$v^2/R = (2.683\times10^3\ \text{m/s})^2/(2.46\times10^7\ \text{m}) = 0.2927\ \text{m/s}^2$

Then $w = 33.74\ \text{N} - (3.00\ \text{kg})(0.2927\ \text{m/s}^2) = 32.9\ \text{N}$.

EVALUATE: The apparent weight is less than the true weight. This effect is larger on Neptune than on earth.

13.42. **IDENTIFY:** At the North Pole, Sneezy has no circular motion and therefore no acceleration. But at the equator he has acceleration toward the center of the earth due to the earth's rotation.

SET UP: The earth has mass $m_E = 5.97\times10^{24}\ \text{kg}$, radius $R_E = 6.37\times10^6\ \text{m}$ and rotational period $T = 24\ \text{hr} = 8.64\times10^4\ \text{s}$. Use coordinates for which the $+y$ direction is toward the center of the earth. The free-body diagram for Sneezy at the equator is given in Figure 13.42. The radial acceleration due to Sneezy's circular motion at the equator is $a_{rad} = \dfrac{4\pi^2 R}{T^2}$, and Newton's second law applies to Sneezy.

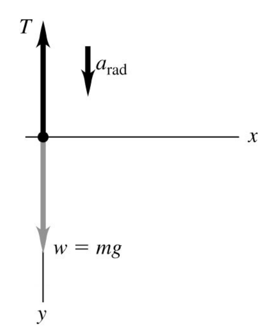


Figure 13.42

EXECUTE: At the north pole Sneezy has $a = 0$ and $T = w = 395.0\ \text{N}$ (the gravitational force exerted by the earth). Sneezy has mass $m = w/g = 40.31\ \text{kg}$. At the equator Sneezy is traveling in a circular path and has radial acceleration $a_{\text{rad}} = \dfrac{4\pi^2 R}{T^2} = \dfrac{4\pi^2(6.37\times10^6\ \text{m})}{(8.64\times10^4\ \text{s})^2} = 0.03369\ \text{m/s}^2$. Newton's second law $\Sigma F_y = ma_y$ gives $w - T = ma_{\text{rad}}$. Solving for T gives

$T = w - ma_{\text{rad}} = m(g - a_{\text{rad}}) = (40.31\ \text{kg})(9.80\ \text{m/s}^2 - 0.03369\ \text{m/s}^2) = 394\ \text{N}$.

EVALUATE: At the equator Sneezy has an inward acceleration and the outward tension is less than the true weight, since there is a net inward force.

13.43. **IDENTIFY:** The orbital speed for an object a distance r from an object of mass M is $v = \sqrt{\dfrac{GM}{r}}$. The mass M of a black hole and its Schwarzschild radius R_S are related by $R_S = \dfrac{2GM}{c^2}$.

SET UP: $c = 3.00\times10^8$ m/s. 1 ly $= 9.461\times10^{15}$ m.

EXECUTE:

(a) $M = \dfrac{rv^2}{G} = \dfrac{(7.5\ \text{ly})(9.461\times10^{15}\ \text{m/ly})(200\times10^3\ \text{m/s})^2}{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)} = 4.3\times10^{37}\ \text{kg} = 2.1\times10^7\ \text{M}_\text{S}$.

(b) No, the object has a mass very much greater than 50 solar masses.

(c) $R_S = \dfrac{2GM}{c^2} = \dfrac{2v^2 r}{c^2} = 6.32\times10^{10}$ m, which does fit.

EVALUATE: The Schwarzschild radius of a black hole is approximately the same as the radius of Mercury's orbit around the sun.

13.44. **IDENTIFY:** The clumps orbit the black hole. Their speed, orbit radius and orbital period are related by $v = \dfrac{2\pi r}{T}$. Their orbit radius and period are related to the mass M of the black hole by $T = \dfrac{2\pi r^{3/2}}{\sqrt{GM}}$. The radius of the black hole's event horizon is related to the mass of the black hole by $R_S = \dfrac{2GM}{c^2}$.

SET UP: $v = 3.00\times10^7$ m/s. $T = 27\ \text{h} = 9.72\times10^4$ s. $c = 3.00\times10^8$ m/s.

EXECUTE: **(a)** $r = \dfrac{vT}{2\pi} = \dfrac{(3.00\times10^7\ \text{m/s})(9.72\times10^4\ \text{s})}{2\pi} = 4.64\times10^{11}$ m.

(b) $T = \dfrac{2\pi r^{3/2}}{\sqrt{GM}}$ gives $M = \dfrac{4\pi^2 r^3}{GT^2} = \dfrac{4\pi^2(4.64\times10^{11}\ \text{m})^3}{(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(9.72\times10^4\ \text{s})^2} = 6.26\times10^{36}$ kg.

$= 3.15\times10^6 M_S$, where M_S is the mass of our sun

(c) $R_S = \dfrac{2GM}{c^2} = \dfrac{2(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(6.26\times10^{36}\ \text{kg})}{(3.00\times10^8\ \text{m/s})^2} = 9.28\times10^9$ m

EVALUATE: The black hole has a mass that is about 3×10^6 solar masses.

13.45. **IDENTIFY:** Use $F_g = Gm_1m_2/r^2$ to find each gravitational force. Each force is attractive. In part (b) apply conservation of energy.

SET UP: For a pair of masses m_1 and m_2 with separation r, $U = -G\dfrac{m_1m_2}{r}$.

EXECUTE: **(a)** From symmetry, the net gravitational force will be in the direction 45° from the x-axis (bisecting the x- and y-axes), with magnitude

$$F = (6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(0.0150\ \text{kg})\left[\frac{(2.0\ \text{kg})}{(2(0.50\ \text{m})^2)} + 2\frac{(1.0\ \text{kg})}{(0.50\ \text{m})^2}\sin 45^\circ\right] = 9.67\times10^{-12}\ \text{N}$$

(b) The initial displacement is so large that the initial potential energy may be taken to be zero. From the work-energy theorem, $\frac{1}{2}mv^2 = Gm\left[\frac{(2.0\text{ kg})}{\sqrt{2}\,(0.50\text{ m})} + 2\frac{(1.0\text{ kg})}{(0.50\text{ m})}\right]$. Cancelling the factor of m, solving for v, and using the numerical values gives $v = 3.02\times10^{-5}$ m/s.

EVALUATE: The result in part (b) is independent of the mass of the particle. It would take the particle a long time to reach point P.

13.46. **IDENTIFY:** Use $g = G\frac{m_E}{r^2}$ to calculate g for Europa. The acceleration of a particle moving in a circular path is $a_{rad} = r\omega^2$.

SET UP: In $a_{rad} = r\omega^2$, ω must be in rad/s. For Europa, $R = 1.560\times10^6$ m.

EXECUTE: $g = \frac{Gm}{R^2} = \frac{(6.67\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(4.80\times10^{22}\text{ kg})}{(1.560\times10^6\text{ m})^2} = 1.316\text{ m/s}^2$. $g = a_{rad}$ gives

$$\omega = \sqrt{\frac{g}{r}} = \sqrt{\frac{1.316\text{ m/s}^2}{4.25\text{ m}}} = (0.5565\text{ rad/s})\left(\frac{60\text{ s}}{1\text{ min}}\right)\left(\frac{1\text{ rev}}{2\pi\text{ rad}}\right) = 5.31\text{ rpm}.$$

EVALUATE: The radius of Europa is about one-fourth that of the earth and its mass is about one-hundredth that of earth, so g on Europa is much less than g on earth. The lander would have some spatial extent so different points on it would be different distances from the rotation axis and a_{rad} would have different values. For the ω we calculated, $a_{rad} = g$ at a point that is precisely 4.25 m from the rotation axis.

13.47. **IDENTIFY:** Apply conservation of energy and conservation of linear momentum to the motion of the two spheres.

SET UP: Denote the 50.0-kg sphere by a subscript 1 and the 100-kg sphere by a subscript 2.

EXECUTE: **(a)** Linear momentum is conserved because we are ignoring all other forces, that is, the net external force on the system is zero. Hence, $m_1v_1 = m_2v_2$.

(b) (i) From the work-energy theorem in the form $K_i + U_i = K_f + U_f$, with the initial kinetic energy $K_i = 0$ and $U = -G\frac{m_1m_2}{r}$, $Gm_1m_2\left[\frac{1}{r_f} - \frac{1}{r_i}\right] = \frac{1}{2}(m_1v_1^2 + m_2v_2^2)$. Using the conservation of momentum relation $m_1v_1 = m_2v_2$ to eliminate v_2 in favor of v_1 and simplifying yields $v_1^2 = \frac{2Gm_2^2}{m_1 + m_2}\left[\frac{1}{r_f} - \frac{1}{r_i}\right]$, with a similar expression for v_2. Substitution of numerical values gives $v_1 = 1.49\times10^{-5}$ m/s, $v_2 = 7.46\times10^{-6}$ m/s. (ii) The magnitude of the relative velocity is the sum of the speeds, 2.24×10^{-5} m/s.

(c) The distance the centers of the spheres travel $(x_1$ and $x_2)$ is proportional to their acceleration, and $\frac{x_1}{x_2} = \frac{a_1}{a_2} = \frac{m_2}{m_1}$, or $x_1 = 2x_2$. When the spheres finally make contact, their centers will be a distance of $2r$ apart, or $x_1 + x_2 + 2r = 40$ m, or $2x_2 + x_2 + 2r = 40$ m. Thus, $x_2 = 40/3\text{ m} - 2r/3$, and $x_1 = 80/3\text{ m} - 4r/3$. The point of contact of the surfaces is $80/3\text{ m} - r/3 = 26.6$ m from the initial position of the center of the 50.0-kg sphere.

EVALUATE: The result $x_1/x_2 = 2$ can also be obtained from the conservation of momentum result that $\frac{v_1}{v_2} = \frac{m_2}{m_1}$, at every point in the motion.

EVALUATE: The work done by the attractive gravity forces is negative. The work you do is positive.

13.48. IDENTIFY: The gravitational pulls of Titan and Saturn on the *Huygens* probe should be in opposite directions and of equal magnitudes to cancel.

SET UP: The mass of Saturn is $m_S = 5.68\times10^{26}$ kg. When the probe is a distance d from the center of Titan it is a distance $1.22\times10^9\ \text{m} - d$ from the center of Saturn. The magnitude of the gravitational force is given by $F_{grav} = GmM/r^2$.

EXECUTE: Equal gravity forces means the two gravitational pulls on the probe must balance, so $G\dfrac{mm_T}{d^2} = G\dfrac{mm_S}{(1.22\times10^9\ \text{m} - d)^2}$. Simplifying, this becomes $d = \sqrt{\dfrac{m_T}{m_S}}(1.22\times10^9\ \text{m} - d)$. Using the masses from the text and solving for d we get

$$d = \sqrt{\frac{1.35\times10^{23}\ \text{kg}}{5.68\times10^{26}\ \text{kg}}}(1.22\times10^9\ \text{m} - d) = (0.0154)(1.22\times10^9\ \text{m} - d),\ \text{so}\ d = 1.85\times10^7\ \text{m} = 1.85\times10^4\ \text{km}.$$

EVALUATE: For the forces to balance, the probe must be much closer to Titan than to Saturn since Titan's mass is much smaller than that of Saturn.

13.49. IDENTIFY and **SET UP:** **(a)** To stay above the same point on the surface of the earth the orbital period of the satellite must equal the orbital period of the earth:

$T = 1\ \text{d}(24\ \text{h/1 d})(3600\ \text{s/1 h}) = 8.64\times10^4$ s. The equation $T = \dfrac{2\pi r^{3/2}}{\sqrt{Gm_E}}$ gives the relation between the orbit radius and the period.

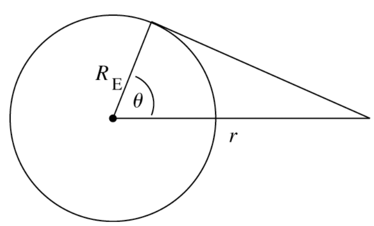
EXECUTE: $T = \dfrac{2\pi r^{3/2}}{\sqrt{Gm_E}}$ gives $T^2 = \dfrac{4\pi^2 r^3}{Gm_E}$. Solving for r gives

$$r = \left(\frac{T^2 Gm_E}{4\pi^2}\right)^{1/3} = \left(\frac{(8.64\times10^4\ \text{s})^2(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(5.97\times10^{24}\ \text{kg})}{4\pi^2}\right)^{1/3} = 4.23\times10^7\ \text{m}.$$

This is the radius of the orbit; it is related to the height h above the earth's surface and the radius R_E of the earth by $r = h + R_E$. Thus $h = r - R_E = 4.23\times10^7\ \text{m} - 6.37\times10^6\ \text{m} = 3.59\times10^7$ m.

EVALUATE: The orbital speed of the geosynchronous satellite is $2\pi r/T = 3080$ m/s. The altitude is much larger and the speed is much less than for the satellite in Example 13.6.

(b) Consider Figure 13.49.



$$\cos\theta = \frac{R_E}{r} = \frac{6.37\times10^6\ \text{m}}{4.23\times10^7\ \text{m}}$$

$$\theta = 81.3°$$

Figure 13.49

A line from the satellite is tangent to a point on the earth that is at an angle of $81.3°$ above the equator. The sketch shows that points at higher latitudes are blocked by the earth from viewing the satellite.

13.50. IDENTIFY: We are dealing with satellites orbiting two different planets.

SET UP: The period is $T = \dfrac{2\pi r^{3/2}}{\sqrt{Gm_p}}$. We want to compare the period around two different planets. The planets have the same average density ρ, so first express T in terms of ρ.

EXECUTE: $m = \rho V = \rho\left(\frac{4}{3}\pi R^3\right) = \frac{4}{3}\pi\rho R^3$. Now find T. The satellites are just above the surface, so $r = R$. In this case $T = \frac{2\pi R^{3/2}}{\sqrt{Gm_p}} = \frac{2\pi R^{3/2}}{\sqrt{G\left(\frac{4}{3}\pi\rho R^3\right)}} = \frac{2\pi}{\sqrt{4G\pi\rho/3}}$. This result depends only on ρ, which is the same for both planets. Therefore T is the same in both cases, so $T_A = T_B$.

EVALUATE: The planets have the same density, but not the same mass. The smaller planet has less mass than the larger planet, but since it is smaller the satellite orbits closer to it so both satellites have the same period.

13.51. IDENTIFY: From Example 13.5, the escape speed is $v = \sqrt{\frac{2GM}{R}}$. Use $\rho = M/V$ to write this expression in terms of ρ.

SET UP: For a sphere $V = \frac{4}{3}\pi R^3$.

EXECUTE: In terms of the density ρ, the ratio M/R is $(4\pi/3)\rho R^2$, and so the escape speed is

$v = \sqrt{(8\pi/3)(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(2500\ \text{kg/m}^3)(150\times10^3\ \text{m})^2} = 177\ \text{m/s}.$

EVALUATE: This is much less than the escape speed for the earth, 11,200 m/s.

13.52. IDENTIFY: Apply $T = \frac{2\pi r^{3/2}}{\sqrt{Gm_E}}$ to relate the orbital period T and M_P, the planet's mass, and then use $w = \frac{Gm_E m}{r^2}$ applied to the planet to calculate the astronaut's weight.

SET UP: The radius of the orbit of the lander is $5.75\times10^5\ \text{m} + 4.80\times10^6\ \text{m}$.

EXECUTE: From $T = \frac{2\pi r^{3/2}}{\sqrt{Gm_E}}$, we get $T^2 = \frac{4\pi^2 r^3}{GM_P}$ and

$$M_P = \frac{4\pi^2 r^3}{GT^2} = \frac{4\pi^2(5.75\times10^5\ \text{m} + 4.80\times10^6\ \text{m})^3}{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(5.8\times10^3\ \text{s})^2} = 2.731\times10^{24}\ \text{kg},$$

or about half the earth's mass. Now we can find the astronaut's weight on the surface from $w = \frac{Gm_E m}{r^2}$. (The landing on the north pole removes any need to account for centripetal acceleration.)

$$w = \frac{GM_P m_a}{r_P^2} = \frac{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(2.731\times10^{24}\ \text{kg})(85.6\ \text{kg})}{(4.80\times10^6\ \text{m})^2} = 677\ \text{N}.$$

EVALUATE: At the surface of the earth the weight of the astronaut would be 839 N.

13.53. IDENTIFY: Apply the law of gravitation to the astronaut at the north pole to calculate the mass of the planet. Then apply $\Sigma\vec{F} = m\vec{a}$ to the astronaut, with $a_{rad} = \frac{4\pi^2 R}{T^2}$, toward the center of the planet, to calculate the period T. Apply $T = \frac{2\pi r^{3/2}}{\sqrt{Gm_E}}$ to the satellite in order to calculate its orbital period.

SET UP: Get radius of X: $\frac{1}{4}(2\pi R) = 18{,}850\ \text{km}$ and $R = 1.20\times10^7\ \text{m}$. Astronaut mass:

$m = \frac{w}{g} = \frac{943\ \text{N}}{9.80\ \text{m/s}^2} = 96.2\ \text{kg}.$

EXECUTE: $\dfrac{GmM_X}{R^2} = w$, where $w = 915.0$ N.

$M_X = \dfrac{mg_x R^2}{Gm} = \dfrac{(915\text{ N})(1.20\times 10^7\text{ m})^2}{(6.67\times 10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(96.2\text{ kg})} = 2.05\times 10^{25}\text{ kg}$

Apply Newton's second law to the astronaut on a scale at the equator of X. $F_{\text{grav}} - F_{\text{scale}} = ma_{\text{rad}}$, so

$F_{\text{grav}} - F_{\text{scale}} = \dfrac{4\pi^2 mR}{T^2}$. $915.0\text{ N} - 850.0\text{ N} = \dfrac{4\pi^2(96.2\text{ kg})(1.20\times 10^7\text{ m})}{T^2}$ and

$T = 2.65\times 10^4\text{ s}\left(\dfrac{1\text{ h}}{3600\text{ s}}\right) = 7.36\text{ h}.$

(b) For the satellite,

$T = \sqrt{\dfrac{4\pi^2 r^3}{Gm_X}} = \sqrt{\dfrac{4\pi^2(1.20\times 10^7\text{ m} + 2.0\times 10^6\text{ m})^3}{(6.67\times 10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(2.05\times 10^{25}\text{ kg})}} = 8.90\times 10^3\text{ s} = 2.47\text{ hours}.$

EVALUATE: The acceleration of gravity at the surface of the planet is $g_X = \dfrac{915.0\text{ N}}{96.2\text{ kg}} = 9.51\text{ m/s}^2$, similar to the value on earth. The radius of the planet is about twice that of earth. The planet rotates more rapidly than earth and the length of a day is about one-third what it is on earth.

13.54. **IDENTIFY:** We are dealing with a planet that is spherically symmetric but not radially uniform. We will need to integrate to find the mass as a function of distance r from the center. To determine the equation for the density we use the slope-intercept form of the equation of a straight line, which is $y = mx + b$.

SET UP: The graph in Fig. 13.9 slopes downward. Its slope is $m = -\dfrac{(13{,}000 - 3000)\text{ kg/m}^3}{R_E} = -\dfrac{10{,}000\text{ kg/m}^3}{R_E}$ and its y-intercept is $b = 13{,}000$ kg/m^3. Using the slope-intercept form of a straight-line equation ($y = mx + b$), the density is $\rho(r) = -\dfrac{10{,}000\text{ kg/m}^3}{R_E}r + 13{,}000\text{ kg/m}^3$, which we simplify as $\rho(r) = mr + b$ for convenience while integrating.

EXECUTE: **(a)** $M(r) = \int \rho(r')dV = \int \rho(r')4\pi r'^2 dr' = \int_0^r (mr' + b)4\pi r'^2 dr' = \pi m r^4 + \dfrac{4\pi b r^3}{3}$. Substitute for m, b and R_E. $M(r) = -(4.932\times 10^{-3}\text{ kg/m}^4)r^4 + (5.4454\times 10^4\text{ kg/m}^3)r^3$ for $r \le R_E$.

(b) For $r \le R_E$ we use the result from (a) for the mass enclosed within a sphere of radius r. To find the force the mass in this shell exerts on a mass m a distance r from the center, we use $F_g = \dfrac{GmM(r)}{r^2} = \dfrac{Gm\left[-(4.932\times 10^{-3}\text{ kg/m}^4)r^4 + (5.4454\times 10^4\text{ kg/m}^3)r^3\right]}{r^2}$, which gives

$F_g = Gm\left[-(4.932\times 10^{-3}\text{ kg/m}^4)r^2 + (5.4454\times 10^4\text{ kg/m}^3)r\right]$. Putting in for G gives

$F_g = m\left[-(3.29\times 10^{-13}\text{ N/kg}\cdot\text{m}^2)r^2 + (3.63\times 10^{-6}\text{ N/kg}\cdot\text{m})r\right]$

For $r \ge R_E$, evaluate the final equation in part (a) for $M(r)$ when $r = R_E = 6.37\times 10^6$ m. This gives 5.95×10^{24} kg. Outside the earth, we can treat it as a point mass at its center, so we use $F_g = \dfrac{GmM}{r^2} = \dfrac{Gm(5.95\times 10^{24}\text{ kg})}{r^2} = \dfrac{m(3.79\times 10^{14}\text{ N}\cdot\text{m}^2/\text{kg})}{r^2}$.

EVALUATE: The mass we calculated in part (a) for the earth (5.95×10^{24} kg) is extremely close to the actual value of 5.97×10^{24} kg , so our model is very good. In addition, in the equation for F_g from part (b), $F_g = m\left[-(3.29\times10^{-13}\ \text{N/kg}\cdot\text{m}^2)r^2+(3.63\times10^{-6}\ \text{N/kg}\cdot\text{m})r\right]$, the quantity in square brackets should give the acceleration due to gravity at the surface of the earth if we use $r = 6.37\times10^6$ m . Doing so gives a value of 9.79 m/s^2, which is extremely close to 9.80 m/s^2.

13.55. IDENTIFY: The free-fall time of the rock will give us the acceleration due to gravity at the surface of the planet. Applying Newton's second law and the law of universal gravitation will give us the mass of the planet since we know its radius.

SET UP: For constant acceleration, $y-y_0=v_{0y}t+\frac{1}{2}a_yt^2$. At the surface of the planet, Newton's second law gives $m_{\text{rock}}g=\dfrac{Gm_{\text{rock}}m_{\text{p}}}{R_{\text{p}}^2}$.

EXECUTE: First find $a_y=g$. $y-y_0=v_{0y}t+\frac{1}{2}a_yt^2$. $a_y=\dfrac{2(y-y_0)}{t^2}=\dfrac{2(1.90\ \text{m})}{(0.480\ \text{s})^2}=16.49\ \text{m/s}^2=g$.

$g=16.49\ \text{m/s}^2$. $m_{\text{p}}=\dfrac{gR_{\text{p}}^2}{G}=\dfrac{(16.49\ \text{m/s})(8.60\times10^7\ \text{m})^2}{6.674\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2}=1.83\times10^{27}\ \text{kg}.$

EVALUATE: The planet's mass is over 100 times that of the earth, which is reasonable since it is larger (in size) than the earth yet has a greater acceleration due to gravity at its surface.

13.56. IDENTIFY: Use the measurements of the motion of the rock to calculate g_{M}, the value of g on Mongo. Then use this to calculate the mass of Mongo. For the ship, $F_g=ma_{\text{rad}}$ and $T=\dfrac{2\pi r}{v}$.

SET UP: Take $+y$ upward. When the stone returns to the ground its velocity is 12.0 m/s, downward. $g_{\text{M}}=G\dfrac{m_{\text{M}}}{R_{\text{M}}^2}$. The radius of Mongo is $R_{\text{M}}=\dfrac{c}{2\pi}=\dfrac{2.00\times10^8\ \text{m}}{2\pi}=3.18\times10^7\ \text{m}$. The ship moves in an orbit of radius $r=3.18\times10^7\ \text{m}+3.00\times10^7\ \text{m}=6.18\times10^7\ \text{m}$.

EXECUTE: **(a)** $v_{0y}=+12.0$ m/s, $v_y=-12.0$ m/s, $a_y=-g_{\text{M}}$ and $t=4.80$ s. $v_y=v_{0y}+a_yt$ gives

$-g_{\text{M}}=\dfrac{v_y-v_{0y}}{t}=\dfrac{-12.0\ \text{m/s}-12.0\ \text{m/s}}{4.80\ \text{s}}$ and $g_{\text{M}}=5.00\ \text{m/s}^2$.

$m_{\text{M}}=\dfrac{g_{\text{M}}R_{\text{M}}^2}{G}=\dfrac{(5.00\ \text{m/s}^2)(3.18\times10^7\ \text{m})^2}{6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2}=7.577\times10^{25}\ \text{kg}$ which rounds to 7.58×10^{25} kg.

(b) $F_g=ma_{\text{rad}}$ gives $G\dfrac{m_{\text{M}}m}{r^2}=m\dfrac{v^2}{r}$ and $v^2=\dfrac{Gm_{\text{M}}}{r}$.

$$T=\frac{2\pi r}{v}=2\pi r\sqrt{\frac{r}{Gm_{\text{M}}}}=\frac{2\pi r^{3/2}}{\sqrt{Gm_{\text{M}}}}=\frac{2\pi(6.18\times10^7\ \text{m})^{3/2}}{\sqrt{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(7.577\times10^{25}\ \text{kg})}}$$

$T=4.293\times10^4\ \text{s}=11.9\ \text{h}.$

EVALUATE: $R_{\text{M}}=5.0R_{\text{E}}$ and $m_{\text{M}}=12.7m_{\text{E}}$, so $g_{\text{M}}=\dfrac{12.7}{(5.0)^2}g_{\text{E}}=0.508g_{\text{E}}$, which agrees with the value calculated in part (a).

13.57. IDENTIFY: Use the orbital speed and altitude to find the mass of the planet. Use this mass and the planet's radius to find g at the surface. Use projectile motion to find the horizontal range x, where $x=\dfrac{v_0^2\sin(2\alpha)}{g}$.

SET UP: For an object in a circular orbit, $v = \sqrt{GM/r}$. $g = GM/r^2$. Call r the orbital radius and R the radius of the planet.

EXECUTE: $v = \sqrt{GM/r}$ gives $M = rv^2/G$. Using this to find g gives
$g = GM/R^2 = G(rv^2/G)/R^2 = v^2r/R^2 = (4900 \text{ m/s})^2(4.48\times10^6 \text{ m} + 6.30\times10^5 \text{ m})/(4.48\times10^6 \text{ m})^2 = 6.113$ m/s^2. Now use this acceleration to find the horizontal range.

$x = \dfrac{v_0^2\sin(2\alpha)}{g}$ = (12.6 m/s)^2 sin[2(30.8°)]/(6.113 m/s^2) = 22.8 m.

EVALUATE: On this planet, $g = 0.624g_E$, so the range is about 1.6 times what it would be on earth.

13.58. **IDENTIFY:** The 0.100 kg sphere has gravitational potential energy due to the other two spheres. Its mechanical energy is conserved.

SET UP: From energy conservation, $K_1 + U_1 = K_2 + U_2$, where $K = \frac{1}{2}mv^2$, and $U = -GmM/r$.

EXECUTE: Using $K_1 + U_1 = K_2 + U_2$, we have $K_1 = 0$, $m_A = 5.00$ kg, $m_B = 10.0$ kg and $m = 0.100$ kg.

$$U_1 = -\frac{Gmm_A}{r_{A1}} - \frac{Gmm_B}{r_{B1}} = -(6.674\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(0.100\ \text{kg})\left(\frac{5.00\ \text{kg}}{0.400\ \text{m}} + \frac{10.0\ \text{kg}}{0.600\ \text{m}}\right)$$

$U_1 = -1.9466\times10^{-10}$ J.

$$U_2 = -\frac{Gmm_A}{r_{A2}} - \frac{Gmm_B}{r_{B2}} = -(6.674\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(0.100\ \text{kg})\left(\frac{5.00\ \text{kg}}{0.800\ \text{m}} + \frac{10.0\ \text{kg}}{0.200\ \text{m}}\right)$$

$U_2 = -3.7541\times10^{-10}$ J. $K_2 = U_1 - U_2 = -1.9466\times10^{-10}\ \text{J} - (-3.7541\times10^{-10}\ \text{J}) = 1.8075\times10^{-10}$ J.

$$\frac{1}{2}mv^2 = K_2 \text{ and } v = \sqrt{\frac{2K_2}{m}} = \sqrt{\frac{2(1.8075\times10^{-10}\ \text{J})}{0.100\ \text{kg}}} = 6.01\times10^{-5}\ \text{m/s}.$$

EVALUATE: The kinetic energy gained by the sphere is equal to the loss in its potential energy.

13.59. **IDENTIFY:** This problem involves the gravitational flux, as defined in Ex. 13.40.

SET UP: From Ex. 13.40, the gravitational field is $g = GM/r^2$ outside of a spherically symmetric object of mass M. The flux is $\Phi_g = gA$. We want the flux through a spherical surface outside the object.

EXECUTE: $\Phi_g = gA = \left(\dfrac{GM}{r^2}\right)(4\pi r^2) = 4\pi GM$.

EVALUATE: The answer does *not* depend on the radius of the spherical surface since the r^2 factors cancel out.

13.60. **IDENTIFY:** In this problem we must calculate the gravitational force on a point mass M due to a uniform rod, so we need to use the gravitational force formula and integrate.

SET UP: Follow the hint in the problem. The magnitude of the force dF on M due to a tiny mass element dm is $dF_g = \dfrac{GMdm}{r^2}$. We integrate to find the total force. Fig. 13.60 shows the arrangement of masses and the force. Call the y-axis along the rod with the x-axis perpendicular to it at its midpoint. M is on the x-axis. We want to find the force on M.

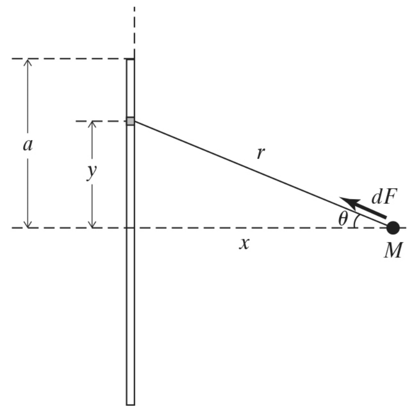


Figure 13.60

EXECUTE: **(a)** The rod is uniform. Therefore for every mass element dm above the x-axis, there is an equal element dm below the x-axis. The mass elements above the x-axis give M an upward pull and those below the x-axis give it a downward pull, and these pulls cancel. The mass elements also give a pull to the left (toward the rod), and these pulls add. Each of these pulls has an x-component $dF_x = dF\ \cos\theta$. Since the y-components cancel, the net force on M is due only to the x-components, so $F = \int dF_x$. We use $dF = \dfrac{GMdm}{r^2}$, where $\cos\theta = x/r$ and $r = \sqrt{x^2 + y^2}$. The mass element dm is the mass of a tiny segment of rod of length dy, so $dm = \rho dy$. Putting this information into the integral gives $F = \int_{-a}^{a} \dfrac{GM}{x^2 + y^2} \dfrac{x}{\sqrt{x^2 + y^2}} \rho dy = GM\rho x \int_{-a}^{a} \dfrac{dy}{\left(x^2 + y^2\right)^{3/2}}$. Using the integral tables in Appendix B gives

$F = GM\rho x \dfrac{1}{x^2} \dfrac{y}{\sqrt{x^2 + y^2}} \Bigg|_{-a}^{+a} = \dfrac{2GM\rho}{x} \dfrac{a}{\sqrt{x^2 + a^2}}$. In the problem statement we are given that r is the perpendicular distance from the center of the rod to M, which is x in our result. So rewriting in terms of r gives $F = \dfrac{2GM\rho a}{r\sqrt{r^2 + a^2}}$. The direction is toward the rod.

(b) If $a >> r$, the factor $\dfrac{a}{\sqrt{r^2 + a^2}} \to 1$, so $F \to \dfrac{2GM\rho}{r}$.

(c) For $a >> r$, we use the result in part (b), so the field is $g = \dfrac{F}{M} = \dfrac{\dfrac{2GM\rho}{r}}{M} = \dfrac{2G\rho}{r}$.

(d) For $a >> r$, we use the result in part (b), so the field is $g = \dfrac{2G\rho}{r}$ and the flux is

$\Phi_g = gA = \left(\dfrac{2G\rho}{r}\right)(2\pi rL) = 4\pi G\rho L$. The mass inside the cylinder is $m_{\text{inside}} = \rho L$, so the flux is

$\Phi_g = 4\pi Gm_{\text{inside}}$.

EVALUATE: In part (b) we see that the force obeys an inverse r law instead of an inverse square law.

13.61. **IDENTIFY** and **SET UP:** Apply conservation of energy. We must use $U = -\dfrac{GMm}{r}$ for the gravitational potential energy since h is not small compared to R_E.

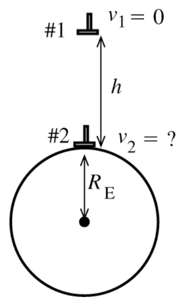

Figure 13.61

As indicated in Figure 13.61, take point 1 to be where the hammer is released and point 2 to be just above the surface of the earth, so $r_1 = R_E + h$ and $r_2 = R_E$.

EXECUTE: $K_1 + U_1 + W_{other} = K_2 + U_2$

Only gravity does work, so $W_{other} = 0$.

$K_1 = 0, \quad K_2 = \frac{1}{2}mv_2^2$

$$U_1 = -G\frac{mm_E}{r_1} = -\frac{Gmm_E}{h + R_E}, \quad U_2 = -G\frac{mm_E}{r_2} = -\frac{Gmm_E}{R_E}$$

Thus, $-G\dfrac{mm_E}{h + R_E} = \dfrac{1}{2}mv_2^2 - G\dfrac{mm_E}{R_E}$

$$v_2^2 = 2Gm_E\left(\frac{1}{R_E} - \frac{1}{R_E + h}\right) = \frac{2Gm_E}{R_E(R_E + h)}(R_E + h - R_E) = \frac{2Gm_E h}{R_E(R_E + h)}$$

$$v_2 = \sqrt{\frac{2Gm_E h}{R_E(R_E + h)}}$$

EVALUATE: If $h \to \infty$, $v_2 \to \sqrt{2Gm_E/R_E}$, which equals the escape speed. In this limit this event is the reverse of an object being projected upward from the surface with the escape speed. If $h \ll R_E$, then $v_2 = \sqrt{2Gm_E h/R_E^2} = \sqrt{2gh}$, the same result if mgh is used for U.

13.62. IDENTIFY: In orbit the total mechanical energy of the satellite is $E = -\dfrac{Gm_E m}{2R_E}$. $U = -G\dfrac{m_E m}{r}$.

$W = E_2 - E_1$.

SET UP: $U \to 0$ as $r \to \infty$.

EXECUTE: **(a)** The energy the satellite has as it sits on the surface of the Earth is $E_1 = \dfrac{-GmM_E}{R_E}$. The energy it has when it is in orbit at a radius $R \approx R_E$ is $E_2 = \dfrac{-GmM_E}{2R_E}$. The work needed to put it in orbit is the difference between these: $W = E_2 - E_1 = \dfrac{GmM_E}{2R_E}$.

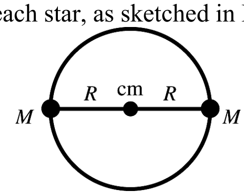
(b) The total energy of the satellite far away from the earth is zero, so the additional work needed is

$$0 - \left(\frac{-GmM_E}{2R_E}\right) = \frac{GmM_E}{2R_E}.$$

EVALUATE: **(c)** The work needed to put the satellite into orbit was the same as the work needed to put the satellite from orbit to the edge of the universe.

13.63. IDENTIFY: Use $F_g = Gm_1m_2/r^2$ to calculate F_g. Apply Newton's second law to circular motion of each star to find the orbital speed and period. Apply the conservation of energy to calculate the energy input (work) required to separate the two stars to infinity.

(a) SET UP: The cm is midway between the two stars since they have equal masses. Let R be the orbit radius for each star, as sketched in Figure 13.63.



The two stars are separated by a distance $2R$, so

$$F_g = GM^2/(2R)^2 = GM^2/4R^2$$

Figure 13.63

(b) EXECUTE: $F_g = ma_{rad}$

$GM^2/4R^2 = M(v^2/R)$ so $v = \sqrt{GM/4R}$

And $T = 2\pi R/v = 2\pi R\sqrt{4R/GM} = 4\pi\sqrt{R^3/GM}$

(c) SET UP: Apply $K_1 + U_1 + W_{other} = K_2 + U_2$ to the system of the two stars. Separate to infinity implies $K_2 = 0$ and $U_2 = 0$.

EXECUTE: $K_1 = \frac{1}{2}Mv^2 + \frac{1}{2}Mv^2 = 2\left(\frac{1}{2}M\right)(GM/4R) = GM^2/4R$

$U_1 = -GM^2/2R$

Thus the energy required is $W_{other} = -(K_1 + U_1) = -(GM^2/4R - GM^2/2R) = GM^2/4R$.

EVALUATE: The closer the stars are and the greater their mass, the larger their orbital speed, the shorter their orbital period and the greater the energy required to separate them.

13.64. IDENTIFY: In the center of mass coordinate system, $r_{cm} = 0$. Apply $\vec{F} = m\vec{a}$ to each star, where F is the gravitational force of one star on the other and $a = a_{rad} = \dfrac{4\pi^2 R}{T^2}$.

SET UP: $v = \dfrac{2\pi R}{T}$ allows R to be calculated from v and T.

EXECUTE: **(a)** The radii R_1 and R_2 are measured with respect to the center of mass, and so $M_1R_1 = M_2R_2$, and $R_1/R_2 = M_2/M_1$.

(b) The forces on each star are equal in magnitude, so the product of the mass and the radial accelerations are equal: $\dfrac{4\pi^2 M_1 R_1}{T_1^2} = \dfrac{4\pi^2 M_2 R_2}{T_2^2}$. From the result of part (a), the numerators of these expressions are equal, and so the denominators are equal, and the periods are the same. To find the period in the symmetric form desired, there are many possible routes. An elegant method, using a bit of hindsight, is to use the above expressions to relate the periods to the force $F_g = \dfrac{GM_1M_2}{(R_1+R_2)^2}$, so that equivalent expressions for the period are $M_2T^2 = \dfrac{4\pi^2 R_1(R_1+R_2)^2}{G}$ and $M_1T^2 = \dfrac{4\pi^2 R_2(R_1+R_2)^2}{G}$.

Adding the expressions gives $(M_1+M_2)T^2 = \dfrac{4\pi^2(R_1+R_2)^3}{G}$ or $T = \dfrac{2\pi(R_1+R_2)^{3/2}}{\sqrt{G(M_1+M_2)}}$.

(c) First we must find the radii of each orbit given the speed and period data. In a circular orbit,

$v = \dfrac{2\pi R}{T}$, or $R = \dfrac{vT}{2\pi}$. Thus $R_\alpha = \dfrac{(36\times10^3\ \text{m/s})(137\ \text{d})(86{,}400\ \text{s/d})}{2\pi} = 6.78\times10^{10}\ \text{m}$ and

$R_\beta = \dfrac{(12\times10^3\ \text{m/s})(137\ \text{d})(86{,}400\ \text{s/d})}{2\pi} = 2.26\times10^{10}\ \text{m}$. Now find the sum of the masses.

$(M_\alpha + M_\beta) = \dfrac{4\pi^2 (R_\alpha + R_\beta)^3}{T^2 G}$. Inserting the values of T and the radii gives

$(M_\alpha + M_\beta) = \dfrac{4\pi^2 (6.78\times10^{10}\ \text{m} + 2.26\times10^{10}\ \text{m})^3}{[(137\ \text{d})(86{,}400\ \text{s/d})]^2 (6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)} = 3.12\times10^{30}\ \text{kg}$. Since

$M_\beta = M_\alpha R_\alpha / R_\beta = 3M_\alpha$, $4M_\alpha = 3.12\times10^{30}$ kg, or $M_\alpha = 7.80\times10^{29}$ kg, and $M_\beta = 2.34\times10^{30}$ kg.

(d) Let α refer to the star and β refer to the black hole. Use the relationships derived in parts (a) and (b): $R_\beta = (M_\alpha / M_\beta) R_\alpha = (0.67/3.8) R_\alpha = (0.176) R_\alpha$, $R_\alpha + R_\beta = \sqrt[3]{\dfrac{(M_\alpha + M_\beta) T^2 G}{4\pi^2}}$. For Monocerotis, inserting the values for M and T gives $R_\alpha = 1.9\times10^9$ m, $v_\alpha = 4.4\times10^2$ km/s and for the black hole $R_\beta = 34\times10^8$ m, $v_\beta = 77$ km/s.

EVALUATE: Since T is the same, v is smaller when R is smaller.

13.65. **IDENTIFY** and **SET UP:** Use conservation of energy, $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$. The gravity force exerted by the sun is the only force that does work on the comet, so $W_{\text{other}} = 0$.

EXECUTE: $K_1 = \frac{1}{2} m v_1^2$, $v_1 = 2.0\times10^4$ m/s

$U_1 = -G m_S m / r_1$, where $r_1 = 2.5\times10^{11}$ m

$K_2 = \frac{1}{2} m v_2^2$

$U_2 = -G m_S m / r_2$, $r_2 = 5.0\times10^{10}$ m

$\frac{1}{2} m v_1^2 - G m_S m / r_1 = \frac{1}{2} m v_2^2 - G m_S m / r_2$

$$v_2^2 = v_1^2 + 2Gm_S\left(\frac{1}{r_2} - \frac{1}{r_1}\right) = v_1^2 + 2Gm_S\left(\frac{r_1 - r_2}{r_1 r_2}\right)$$

$v_2 = 6.8\times10^4$ m/s

EVALUATE: The comet has greater speed when it is closer to the sun.

13.66. **IDENTIFY:** $g = \dfrac{GM}{R^2}$, where M and R are the mass and radius of the planet.

SET UP: Let m_U and R_U be the mass and radius of Uranus and let g_U be the acceleration due to gravity at its poles. The orbit radius of Miranda is $r = h + R_U$, where $h = 1.04\times10^8$ m is the altitude of Miranda above the surface of Uranus.

EXECUTE: **(a)** From the value of g at the poles,

$$m_U = \frac{g_U R_U^2}{G} = \frac{(9.0\ \text{m/s}^2)(2.5360\times10^7\ \text{m})^2}{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)} = 8.674\times10^{25}\ \text{kg}$$ which rounds to 8.7×10^{25} kg.

(b) $G m_U / r^2 = g_U (R_U / r)^2 = 0.35\ \text{m/s}^2$.

(c) $G m_M / R_M^2 = 0.079\ \text{m/s}^2$.

EVALUATE: **(d)** No. Both the object and Miranda are in orbit together around Uranus, due to the gravitational force of Uranus. The object has additional force toward Miranda.

13.67. **(a) IDENTIFY** and **SET UP:** Use $T = \dfrac{2\pi a^{3/2}}{\sqrt{Gm_S}}$, applied to the satellites orbiting the earth rather than the sun.

EXECUTE: Find the value of a for the elliptical orbit:

$2a = r_a + r_p = R_E + h_a + R_E + h_p$, where h_a and h_p are the heights at apogee and perigee, respectively.

$a = R_E + (h_a + h_p)/2$

$a = 6.37\times10^6 \text{ m} + (400\times10^3 \text{ m} + 4000\times10^3 \text{ m})/2 = 8.57\times10^6 \text{ m}$

$$T = \frac{2\pi a^{3/2}}{\sqrt{GM_E}} = \frac{2\pi(8.57\times10^6 \text{ m})^{3/2}}{\sqrt{(6.67\times10^{-11} \text{ N}\cdot\text{m}^2/\text{kg}^2)(5.97\times10^{24} \text{ kg})}} = 7.90\times10^3 \text{ s}$$

(b) Conservation of angular momentum gives $r_a v_a = r_p v_p$

$$\frac{v_p}{v_a} = \frac{r_a}{r_p} = \frac{6.37\times10^6 \text{ m} + 4.00\times10^6 \text{ m}}{6.37\times10^6 \text{ m} + 4.00\times10^5 \text{ m}} = 1.53.$$

(c) Conservation of energy applied to apogee and perigee gives $K_a + U_a = K_p + U_p$

$\frac{1}{2}mv_a^2 - Gm_E m/r_a = \frac{1}{2}mv_p^2 - Gm_E m/r_p$

$v_p^2 - v_a^2 = 2Gm_E(1/r_p - 1/r_a) = 2Gm_E(r_a - r_p)/r_a r_p$

But $v_p = 1.532 v_a$, so $1.347 v_a^2 = 2Gm_E(r_a - r_p)/r_a r_p$

$v_a = 5.51\times10^3 \text{ m/s}$, $v_p = 8.43\times10^3 \text{ m/s}$

(d) Need v so that $E = 0$, where $E = K + U$.

at perigee: $\frac{1}{2}mv_p^2 - Gm_E m/r_p = 0$

$$v_p = \sqrt{2Gm_E/r_p} = \sqrt{2(6.67\times10^{-11} \text{ N}\cdot\text{m}^2/\text{kg}^2)(5.97\times10^{24} \text{ kg})/(6.77\times10^6 \text{ m})} = 1.085\times10^4 \text{ m/s}$$

This means an increase of $1.085\times10^4 \text{ m/s} - 8.43\times10^3 \text{ m/s} = 2.42\times10^3 \text{ m/s}$.

at apogee:

$$v_a = \sqrt{2Gm_E/r_a} = \sqrt{2(6.67\times10^{-11} \text{ N}\cdot\text{m}^2/\text{kg}^2)(5.97\times10^{24} \text{ kg})/(1.037\times10^7 \text{ m})} = 8.763\times10^3 \text{ m/s}$$

This means an increase of $8.763\times10^3 \text{ m/s} - 5.51\times10^3 \text{ m/s} = 3.25\times10^3 \text{ m/s}$.

EVALUATE: Perigee is more efficient. At this point r is smaller so v is larger and the satellite has more kinetic energy and more total energy.

13.68. **IDENTIFY:** The engines do work on the rocket and change its kinetic energy and gravitational potential energy.

SET UP: Call M the mass of the earth and m the mass of the rocket. $U_g = -GMm/r$, $K = \frac{1}{2}mMG/r$ for a circular orbit, $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$.

EXECUTE: **(a)** For a circular orbit, using $K = \frac{1}{2}mMG/r$ gives the difference in kinetic energy: $K_2 - K_1 = \frac{1}{2}mMG(1/r_2 - 1/r_1)$. Using the given numbers $m = 5000$ kg, $M = 5.97\times10^{24}$ kg, $r_2 = 8.80\times10^6$ m, and $r_1 = 7.20\times10^6$ m, we get $K_2 - K_1 = -2.52\times10^{10}$ J. The minus sign tells us that the kinetic energy decreases.

(b) $U_2 - U_1 = -GmM/r_2 - (-GmM/r_1) = GmM(1/r_1 - 1/r_2) = -2(K_2 - K_1) = +5.03\times10^{10}$ J. The plus sign means that the energy increases.

(c) $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ gives

$W_{\text{other}} = (K_2 - K_1) + (U_2 - U_1) = -2.51\times10^{10} \text{ J} + 5.03\times10^{10} \text{ J} = +2.51\times10^{10}$ J.

EVALUATE: In part (b), the potential energy increases because it becomes less negative. The work is positive because the total energy increases.

13.69. **IDENTIFY** and **SET UP:** Apply conservation of energy, $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$, and solve for W_{other}. Only $r = h + R_E$ is given, so use $v = \sqrt{GM/r}$ to relate r and v.

EXECUTE: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$

$U_1 = -Gm_M m/r_1$, where m_M is the mass of Mars and $r_1 = R_M + h$, where R_M is the radius of Mars and $h = 2000\times10^3$ m.

$$U_1 = -(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\frac{(6.42\times10^{23}\ \text{kg})(5000\ \text{kg})}{3.39\times10^6\ \text{m} + 2000\times10^3\ \text{m}} = -3.97230\times10^{10}\ \text{J}$$

$U_2 = -Gm_M m/r_2$, where r_2 is the new orbit radius.

$$U_2 = -(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\frac{(6.42\times10^{23}\ \text{kg})(5000\ \text{kg})}{3.39\times10^6\ \text{m} + 4000\times10^3\ \text{m}} = -2.89725\times10^{10}\ \text{J}$$

For a circular orbit $v = \sqrt{Gm_M/r}$, with the mass of Mars rather than the mass of the earth.

Using this gives $K = \frac{1}{2}mv^2 = \frac{1}{2}m(Gm_M/r) = \frac{1}{2}Gm_M m/r$, so $K = -\frac{1}{2}U$.

$K_1 = -\frac{1}{2}U_1 = +1.98615\times10^{10}$ J and $K_2 = -\frac{1}{2}U_2 = +1.44863\times10^{10}$ J

Then $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ gives

$W_{\text{other}} = (K_2 - K_1) + (U_2 - U)$

$W_{\text{other}} = (1.44863\times10^{10}\ \text{J} - 1.98615\times10^{10}\ \text{J}) + (+3.97230\times10^{10}\ \text{J} - 2.89725\times10^{10}\ \text{J})$

$W_{\text{other}} = 5.38\times10^9$ J.

EVALUATE: When the orbit radius increases the kinetic energy decreases and the gravitational potential energy increases. $K = -U/2$ so $E = K + U = -U/2$ and the total energy also increases (becomes less negative). Positive work must be done to increase the total energy of the satellite.

13.70. **IDENTIFY:** The engines do work on the rocket and change its kinetic energy and gravitational potential energy.

SET UP: $K = \frac{1}{2}mMG/r = -\frac{1}{2}U_g$ for a circular orbit; $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$.

EXECUTE: $K_1 + U_1 + W_{\text{other}} = K_2 + U_2$ and $U_g = -2K$. Combining these two equations gives $K_1 - 2K_1 + W_{\text{other}} = K_2 - 2K_2$, so $K_2 = K_1 - W_{\text{other}}$. This gives $\frac{1}{2}mv_2^2 = \frac{1}{2}mv_1^2 - W_{\text{other}}$. Solving for v_2 gives $v_2 = \sqrt{v_1^2 - \frac{2W_{\text{other}}}{m}} = \sqrt{(9640\ \text{m/s})^2 - \frac{2(-7.50\times10^9\ \text{J})}{848\ \text{kg}}} = 10{,}500$ m/s, which is greater than v_1, so the speed increases.

EVALUATE: The work is negative, yet the speed increases. The potential energy decreases (becomes more negative), so the total energy decreases. Due to the friction, the satellite will go to a lower orbit (closer to the earth), so it must have a greater speed to remain in orbit.

13.71. **IDENTIFY:** Integrate $dm = \rho dV$ to find the mass of the planet. Outside the planet, the planet behaves like a point mass, so at the surface $g = GM/R^2$.

SET UP: A thin spherical shell with thickness dr has volume $dV = 4\pi r^2 dr$. The earth has radius $R_E = 6.37\times10^6$ m.

EXECUTE: Get $M: M = \int dm = \int \rho dV = \int \rho 4\pi r^2 dr$. The density is $\rho = \rho_0 - br$, where $\rho_0 = 15.0\times10^3\ \text{kg/m}^3$ at the center and at the surface, $\rho_S = 2.0\times10^3\ \text{kg/m}^3$, so $b = \frac{\rho_0 - \rho_s}{R}$.

$$M = \int_0^R (\rho_0 - br)\,4\pi r^2 dr = \frac{4\pi}{3}\rho_0 R^3 - \pi b R^4 = \frac{4}{3}\pi R^3 \rho_0 - \pi R^4\left(\frac{\rho_0 - \rho_s}{R}\right) = \pi R^3\left(\frac{1}{3}\rho_0 + \rho_s\right)$$ and

$M = 5.71\times 10^{24}$ kg. Then $g = \dfrac{GM}{R^2} = \dfrac{G\pi R^3(\frac{1}{3}\rho_0 + \rho_s)}{R^2} = \pi R G\left(\dfrac{1}{3}\rho_0 + \rho_s\right)$.

$$g = \pi(6.37\times 10^6\,\text{m})(6.67\times 10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\left(\frac{15.0\times 10^3\ \text{kg/m}^3}{3} + 2.0\times 10^3\ \text{kg/m}^3\right).$$

$g = 9.34\ \text{m/s}^2$.

EVALUATE: The average density of the planet is

$\rho_{\text{av}} = \dfrac{M}{V} = \dfrac{M}{\frac{4}{3}\pi R^3} = \dfrac{3(5.71\times 10^{24}\ \text{kg})}{4\pi(6.37\times 10^6\ \text{m})^3} = 5.27\times 10^3\ \text{kg/m}^3$. Note that this is not $(\rho_0 + \rho_s)/2$.

13.72. IDENTIFY and **SET UP:** Use $T = \dfrac{2\pi a^{3/2}}{\sqrt{Gm_S}}$ to calculate a.

$T = 30{,}000\ \text{y}(3.156\times 10^7\ \text{s/1 y}) = 9.468\times 10^{11}$ s

EXECUTE: $T = \dfrac{2\pi a^{3/2}}{\sqrt{Gm_S}}$, which gives $T^2 = \dfrac{4\pi^2 a^3}{Gm_S}$, so $a = \left(\dfrac{Gm_S T^2}{4\pi^2}\right)^{1/3} = 1.4\times 10^{14}$ m.

EVALUATE: The average orbit radius of Pluto is 5.9×10^{12} m (Appendix F); the semi-major axis for this comet is larger by a factor of 24. Converting to meters gives 4.3 light years = $4.3(9.461\times 10^{15}\ \text{m})$ = 4.1×10^{16} m. The distance of Alpha Centauri is larger by a factor of 300. The orbit of the comet extends well past Pluto but is well within the distance to Alpha Centauri.

13.73. IDENTIFY: The direct calculation of the force that the sphere exerts on the ring is slightly more involved than the calculation of the force that the ring exerts on the sphere. These forces are equal in magnitude but opposite in direction, so it will suffice to do the latter calculation. By symmetry, the force on the sphere will be along the axis of the ring in Figure E13.35 in the textbook, toward the ring.

SET UP: Divide the ring into infinitesimal elements with mass dM.

EXECUTE: Each mass element dM of the ring exerts a force of magnitude $\dfrac{(Gm)dM}{a^2 + x^2}$ on the sphere,and the x-component of this force is $\dfrac{GmdM}{a^2 + x^2}\dfrac{x}{\sqrt{a^2 + x^2}} = \dfrac{GmdMx}{(a^2 + x^2)^{3/2}}$.

Therefore, the force on the sphere is $GmMx/(a^2 + x^2)^{3/2}$, in the $-x$-direction. The sphere attracts the ring with a force of the same magnitude.

EVALUATE: As $x \gg a$ the denominator approaches x^3 and $F \to \dfrac{GMm}{x^2}$, as expected.

13.74. IDENTIFY and **SET UP:** Use $F_g = Gm_1 m_2/r^2$ to calculate the force between the point mass and a small segment of the semicircle.

EXECUTE: The radius of the semicircle is $R = L/\pi$.

Divide the semicircle up into small segments of length $R\,d\theta$, as shown in Figure 13.74.

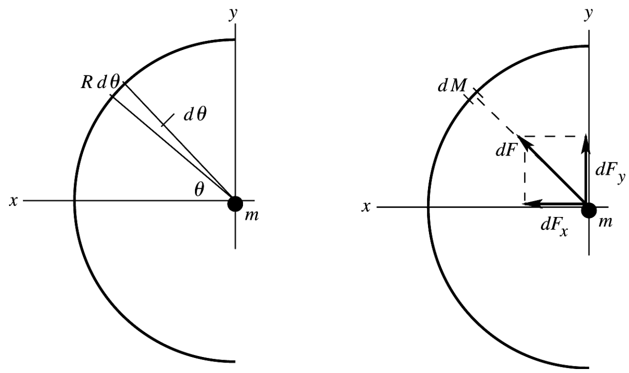


Figure 13.74

$dM = (M/L)R\,d\theta = (M/\pi)\,d\theta$

$d\vec{F}$ is the gravity force on m exerted by dM.

$\int dF_y = 0$; the y-components from the upper half of the semicircle cancel the y-components from the lower half.

The x-components are all in the $+x$-direction and all add.

$$dF = G\frac{mdM}{R^2}$$

$$dF_x = G\frac{mdM}{R^2}\cos\theta = \frac{Gm\pi M}{L^2}\cos\theta\,d\theta$$

$$F_x = \int_{-\pi/2}^{\pi/2} dF_x = \frac{Gm\pi M}{L^2}\int_{-\pi/2}^{\pi/2}\cos\theta\,d\theta = \frac{Gm\pi M}{L^2}(2)a$$

$$F = \frac{2\pi GmM}{L^2}$$

EVALUATE: If the semicircle were replaced by a point mass M at $x = R$, the gravity force would be $GmM/R^2 = \pi^2 GmM/L^2$. This is $\pi/2$ times larger than the force exerted by the semicirclar wire. For the semicircle it is the x-components that add, and the sum is less than if the force magnitudes were added.

13.75. **IDENTIFY:** Compare F_E to Hooke's law.

SET UP: The earth has mass $m_E = 5.97\times10^{24}$ kg and radius $R_E = 6.37\times10^6$ m.

EXECUTE: **(a)** For $F_x = -kx$, $U = \frac{1}{2}kx^2$. The force here is in the same form, so by analogy $U(r) = \frac{Gm_E m}{2R_E^3}r^2$. This is also given by the integral of F_g from 0 to r with respect to distance.

(b) From part (a), the initial gravitational potential energy is $\frac{Gm_E m}{2R_E}$. Equating initial potential energy and final kinetic energy (initial kinetic energy and final potential energy are both zero) gives $v^2 = \frac{Gm_E}{R_E}$, so $v = 7.91\times10^3$ m/s.

EVALUATE: When $r = 0$, $U(r) = 0$, as specified in the problem.

13.76. **IDENTIFY:** Kepler's third law applies to the planets.

SET UP: $T = \frac{2\pi a^{3/2}}{\sqrt{Gm_S}}$.

EXECUTE: Squaring $T = \dfrac{2\pi a^{3/2}}{\sqrt{Gm_S}}$ gives $T^2 = \left(\dfrac{4\pi^2}{Gm_S}\right)a^3$. If we graph T^2 versus a^3, the equation is of the slope-y-intercept form of a straight line, $y = mx + b$. In this case, the slope is $(4\pi^2/Gm_S)$, and the y-intercept is zero. Take logs of both sides of the equation in Kepler's third law, giving $\log T = \log\left[\left(\dfrac{2\pi}{\sqrt{Gm_S}}\right)a^{3/2}\right]$, which can be written as $\log T = \dfrac{3}{2}\log a + \log\left(\dfrac{2\pi}{\sqrt{Gm_s}}\right)$. Therefore graphing $\log T$ versus $\log a$ should yield a straight line. Figure 13.76 shows this graph.

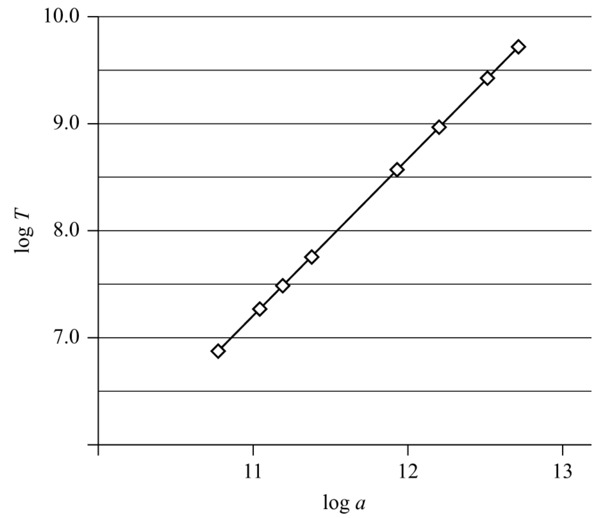

Figure 13.76

(b) In the slope-y-intercept form $y = mx + b$, the slope is 3/2. The best-fit equation of the graph in the figure is $y = 1.4986x - 9.2476$. Since 1.4986 rounds to 1.50, which is equal to 3/2, our graph has the expected slope.

(c) The y-intercept is $\log\left(\dfrac{2\pi}{\sqrt{Gm_S}}\right) = -9.2476$. Solving for m_S, we get $\dfrac{2\pi}{\sqrt{Gm_S}} = 10^{-9.2476}$. Squaring and solving for m_S gives $m_S = 4\pi^2[10^{2(9.2476)}]/G = 1.85\times10^{30}$ kg. From Appendix F, $m_S = 1.99\times10^{30}$ kg. Our result agrees to within about 7% with the value in Appendix F.

(d) Solving Kepler's third law for a gives $a = \left(\dfrac{T\sqrt{Gm_s}}{2\pi}\right)^{2/3}$. Expressing T in seconds, we get $T = 1325.4$ d (24 h/d)(3600 s/h) $= 1.145\times10^8$ s. Putting in $G = 6.674\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2$ and $m_S = 1.99\times10^{30}$ kg, we get $a = 3.53\times10^{11}$ m $= 353\times10^6$ km. From the table with the problem, we see that Vesta's orbit lies between that of Mars and Jupiter.

EVALUATE: The asteroid belt lies between Mars and Jupiter, which is why Vesta is usually considered an asteroid.

13.77. IDENTIFY and **SET UP:** At the surface of a planet, $g = \dfrac{GM}{R^2}$, and average density is $\rho = m/V$, where $V = 4/3\ \pi R^3$ for a sphere.

EXECUTE: We have expressions for g and M: $g = \dfrac{GM}{R^2}$ and $M = \rho V = \rho\left(\dfrac{4}{3}\pi R^3\right)$. Combining them

we get $g = \dfrac{G\rho\left(\dfrac{4}{3}\pi R^3\right)}{R^2} = \dfrac{4\pi G\rho R}{3}$. Using $R = D/2$ gives $g = \dfrac{2\pi G\rho D}{3}$.

(a) A graph of g versus D is shown in Figure 13.77. As this graph shows, the densities vary considerably and show no apparent pattern.

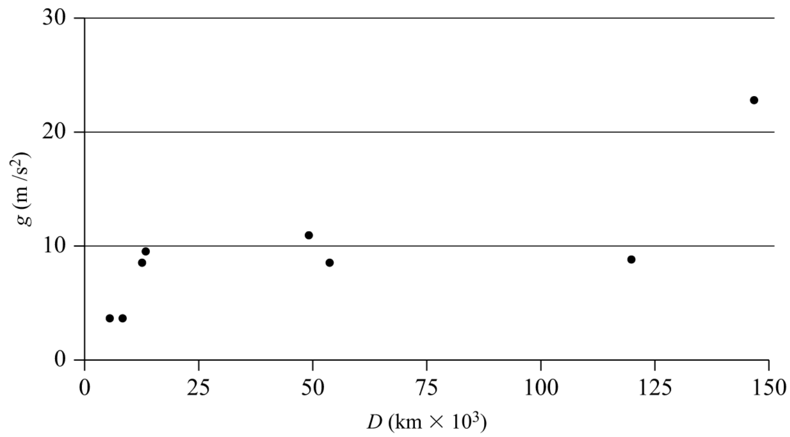

Figure 13.77

(b) Using the equation we just derived, $g = \dfrac{2\pi G\rho D}{3}$, we solve for ρ and use the values from the table given in the problem. For example, for Mercury we have

$\rho = \dfrac{3g}{2\pi DG} = \dfrac{3(3.7\ \text{m/s}^2)}{2\pi(4.879\times10^6\ \text{m})(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)} = 5400\ \text{kg/m}^3$. Continuing the calculations and putting the results in order of decreasing density, we get the following results.

Earth: 5500 kg/m^3
Mercury: 5400 kg/m^3
Venus: 5300 kg/m^3
Mars: 3900 kg/m^3
Neptune: 1600 kg/m^3
Uranus: 1200 kg/m^3
Jupiter: 1200 kg/m^3
Saturn: 534 kg/m^3

(c) For several reasons, it is reasonable that the other planets would be denser toward their centers. Gravity is stronger at close distances, so it would compress matter near the center. In addition, during the formation of planets, heavy elements would tend to sink toward the center and displace light elements, much as a rock sinks in water. This variation in density would have no effect on our analysis however, since the planets are still spherically symmetric.

(d) $g = \dfrac{2\pi G\rho D}{3} = \dfrac{2\pi(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(1.20536\times10^8\ \text{m})(5500\ \text{kg/m}^3)}{3} = 93\ \text{m/s}^2$.

EVALUATE: Saturn is less dense than water, so it would float if we could throw it into our ocean (which of course is impossible since it is much larger than the earth). This low density is the reason that g at its "surface" is less than g at the earth's surface, even though the mass of Saturn is much greater than that of the earth. Also note in our results in (b) that the inner four planets are much denser than the outer four (the gas giants), with the earth being the densest of all.

13.78. **IDENTIFY** and **SET UP:** $L = MvR$, $v = 2\pi R/T$.

EXECUTE: (a) Combining the two equations gives $L = mvR = m(2\pi R/T)R = 2\pi mR^2/T$.

(b) We use our formula with the quantities in Appendix F. For example, for Mercury we have $L = 2\pi(3.30\times10^{23}\text{ kg})(5.79\times10^{10}\text{ m})^2/[(88.0\text{ d})(24\text{ h/d})(3600\text{ s/h})] = 9.14\times10^{38}\text{ kg}\cdot\text{m}^2/\text{s}$. Similar calculations give the following results.

Mercury: 9.14×10^{38} kg · m^2/s
Venus: 1.84×10^{40} kg · m^2/s
Earth: 2.67×10^{40} kg · m^2/s
Mars: 3.53×10^{39} kg · m^2/s
Jupiter: 1.93×10^{43} kg · m^2/s
Saturn: 7.86×10^{42} kg · m^2/s
Uranus: 1.73×10^{42} kg · m^2/s
Neptune: 2.50×10^{42} kg · m^2/s

The total angular momentum is the sum of all of these since the planets all move in the same direction around the sun. $L_{\text{tot}} = 3.13\times10^{43}\text{ kg}\cdot\text{m}^2/\text{s}$.

(c) Treating the sun as a uniform solid sphere, we have

$$L = I\omega = \left(\frac{2}{5}MR^2\right)\left(\frac{2\pi}{T}\right) = \frac{4\pi MR^2}{5T} = \frac{4\pi(1.99\times10^{30}\text{ kg})(6.96\times10^8\text{ m})^2}{5(24.6\text{ d})(24\text{ h/d})(3600\text{ s/h})} = 1.14\times10^{42}\text{ kg}\cdot\text{m}^2/\text{s}.$$

(d) $L_S/L_P = (1.14\times10^{42}\text{ kg}\cdot\text{m}^2/\text{s})/(3.14\times10^{43}\text{ kg}\cdot\text{m}^2/\text{s}) = 0.0363$. The angular momentum of the sun is only 3.63% of the angular momentum of the planets. From Appendix F, the total mass of the planets is $m_P = 2.669\times10^{27}$ kg, so $m_S/m_P = (1.99\times10^{30}\text{ kg})/(2.669\times10^{27}\text{ kg}) = 746$, so the sun is 746 times as massive as the planets combined.

EVALUATE: The sun contains nearly all the mass in the solar system, yet it has only 3.6% of the angular momentum. There appears to be no progressive pattern in the angular momentum of the planets as we go from the inner plants to the outer ones.

13.79. **IDENTIFY:** Apply $T = \dfrac{2\pi a^{3/2}}{\sqrt{Gm_S}}$ to the transfer orbit.

SET UP: The orbit radius for earth is $r_E = 1.50\times10^{11}$ m and for Mars it is $r_M = 2.28\times10^{11}$ m. From Figure 13.18 in the textbook, $a = \frac{1}{2}(r_E + r_M)$.

EXECUTE: **(a)** To get from the circular orbit of the earth to the transfer orbit, the spacecraft's energy must increase, and the rockets are fired in the direction opposite that of the motion, that is, in the direction that increases the speed. Once at the orbit of Mars, the energy needs to be increased again, and so the rockets need to be fired in the direction opposite that of the motion. From Figure 13.18 in the textbook, the semimajor axis of the transfer orbit is the arithmetic average of the orbit radii of the earth and Mars, and so from $E = -Gm_Sm/2r$, the energy of the spacecraft while in the transfer orbit is intermediate between the energies of the circular orbits. Returning from Mars to the earth, the procedure is reversed, and the rockets are fired against the direction of motion.

(b) The time will be half the period as given in $T = \dfrac{2\pi a^{3/2}}{\sqrt{Gm_S}}$, with the semimajor axis equal to

$a = \frac{1}{2}(r_E + r_M) = 1.89\times10^{11}$ ma so

$$t = \frac{T}{2} = \frac{\pi\,(1.89\times10^{11}\text{ m})^{3/2}}{\sqrt{(6.673\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(1.99\times10^{30}\text{ kg})}} = 2.24\times10^7\text{ s} = 259\text{ days},$$ which is more than $8\frac{1}{2}$ months.

(c) During this time, Mars will pass through an angle of $(360°)\dfrac{(2.24\times10^{7}\text{ s})}{(687\text{ d})(86{,}400\text{ s/d})}=135.9°,$ and the spacecraft passes through an angle of $180°,$ so the angle between the earth-sun line and the Mars-sun line must be $44.1°.$

EVALUATE: The period T for the transfer orbit is 526 days, the average of the orbital periods for earth and Mars.

13.80. IDENTIFY: Apply $\Sigma\vec{F}=m\vec{a}$ to each ear.

SET UP: Denote the orbit radius as r and the distance from this radius to either ear as $\delta.$ Each ear, of mass $m,$ can be modeled as subject to two forces, the gravitational force from the black hole and the tension force (actually the force from the body tissues), denoted by $F.$

EXECUTE: The force equation for either ear is $\dfrac{GMm}{(r+\delta)^2}-F=m\omega^2(r+\delta),$ where δ can be of either sign. Replace the product $m\omega^2$ with the value for $\delta=0,$ $m\omega^2=GMm/r^3,$ and solve for F:

$$F=(GMm)\left[\frac{r+\delta}{r^3}-\frac{1}{(r+\delta)^2}\right]=\frac{GMm}{r^3}\left[r+\delta-r(1+(\delta/r)^{-2}\right].$$

Using the binomial theorem to expand the term in square brackets in powers of $\delta/r,$

$$F\approx\frac{GMm}{r^3}[r+\delta-r(1-2(\delta/r))]=\frac{GMm}{r^3}(3\delta)=2.1\text{ kN}.$$

This tension is much larger than that which could be sustained by human tissue, and the astronaut is in trouble.

(b) The center of gravity is not the center of mass. The gravity force on the two ears is not the same.

EVALUATE: The tension between her ears is proportional to their separation.

13.81. IDENTIFY: As suggested in the problem, divide the disk into rings of radius r and thickness dr.

SET UP: Each ring has an area $dA=2\pi r\,dr$ and mass $dM=\dfrac{M}{\pi a^2}dA=\dfrac{2M}{a^2}r\,dr.$

EXECUTE: The magnitude of the force that this small ring exerts on the mass m is then $(Gm\,dM)(x/(r^2+x^2)^{3/2}).$ The contribution dF to the force is $dF=\dfrac{2GMmx}{a^2}\dfrac{rdr}{(x^2+r^2)^{3/2}}.$

The total force F is then the integral over the range of r;

$$F=\int dF=\frac{2GMmx}{a^2}\int_0^a\frac{r}{(x^2+r^2)^{3/2}}dr.$$

The integral (either by looking in a table or making the substitution $u=r^2+a^2$) is

$$\int_0^a\frac{r}{(x^2+r^2)^{3/2}}dr=\left[\frac{1}{x}-\frac{1}{\sqrt{a^2+x^2}}\right]=\frac{1}{x}\left[1-\frac{x}{\sqrt{a^2+x^2}}\right].$$

Substitution yields the result $F=\dfrac{2GMm}{a^2}\left[1-\dfrac{x}{\sqrt{a^2+x^2}}\right].$ The force on m is directed toward the center of the ring. The second term in brackets can be written as

$$\frac{1}{\sqrt{1+(a/x)^2}}=(1+(a/x)^2)^{-1/2}\approx1-\frac{1}{2}\left(\frac{a}{x}\right)^2$$

if $x\gg a,$ where the binomial expansion has been used. Substitution of this into the above form gives $F\approx\dfrac{GMm}{x^2},$ as it should.

EVALUATE: As $x\to0,$ the force approaches a constant.

13.82. **IDENTIFY** and **SET UP:** Use $\rho = m/V$ to calculate the density of the planet and then use the table given in the problem to estimate its composition.
EXECUTE: Using $\rho = m/V$ gives

$$\rho = \frac{m}{V} = \frac{m}{\frac{4}{3}\pi R^3} = \frac{7.9m_{\mathrm{E}}}{\frac{4}{3}\pi(2.3R_{\mathrm{E}})^3} = \frac{7.9}{(2.3)^3}\frac{m_{\mathrm{E}}}{\frac{4}{3}\pi(R_{\mathrm{E}})^3} = 0.65\rho_{\mathrm{E}}.$$

From the table, this density is in the range 0.4–0.9 times the density of the earth, so the planet probably has an iron core with a rock mantle and some lighter elements, which is choice (c).
EVALUATE: A method such as this gives only an estimation of the composition of a planet.

13.83. **IDENTIFY** and **SET UP:** Use $g = GM/R^2$.
EXECUTE: $g = GM/R^2 = G(7.9m_{\mathrm{E}})/(2.3R_{\mathrm{E}})^2 = [(7.9)/(2.3)^2](Gm_{\mathrm{E}}/R_{\mathrm{E}}^2) = 1.5g_{\mathrm{E}}$, which is choice (c).
EVALUATE: Even though this planet has 7.9 times the mass of the earth, g at its surface is only $1.5g_{\mathrm{E}}$ because the planet is 2.3 times the radius of the earth, which makes the surface farther away from its center than is the case with the earth.

13.84. **IDENTIFY** and **SET UP:** Apply Newton's second law and the law of universal gravitation to the planet, calling m the mass of the planet, M the mass of the star, r the orbital radius, and T the time for one orbit. $\Sigma F = ma$, $F_{\mathrm{g}} = Gm_1m_2/r^2$, $a_{\mathrm{rad}} = mv^2/r$, $v = 2\pi r/T$.
EXECUTE: $\frac{GmM}{r^2} = \frac{mv^2}{r} = \frac{m(2\pi r/T)^2}{r} = \frac{4\pi^2 mr}{T^2}$. Now solve for r, which gives

$$r^3 = \frac{GMT^2}{4\pi^2} = \frac{G(0.70M_{\mathrm{sun}})\left(\frac{9.5}{365}T_{\mathrm{earth}}\right)^2}{4\pi^2} = (0.70)\left(\frac{9.5}{365}\right)^2\left(\frac{GM_{\mathrm{sun}}T_{\mathrm{earth}}^2}{4\pi^2}\right) = 0.000474r_{\mathrm{earth}}^3$$

$r = (0.000474)^{1/3}r_{\mathrm{earth}} = 0.078r_{\mathrm{earth}}$, which is choice (b).
EVALUATE: The planet takes only 9.5 days for one orbit, yet the star has 70% the mass of our sun, so the planet must be very close to the star compared to the earth. And this is, in fact, what we have found, since r for this planet iss 7.8% the distance of the earth from the sun.

14

PERIODIC MOTION

VP14.3.1. **IDENTIFY:** The glider undergoes SHM on the spring.

SET UP: For SHM, $T = 1/f$, $\omega = 2\pi f$, $f = \dfrac{1}{2\pi}\sqrt{k/m}$, and $F = kx$ for an ideal spring.

EXECUTE: **(a)** $\omega = 2\pi f = 2\pi(4.15\text{ Hz}) = 26.1\text{ rad/s}$. $T = 1/f = 1/(4.15\text{ Hz}) = 0.241\text{ s}$.

(b) Use $f = \dfrac{1}{2\pi}\sqrt{k/m}$ to solve for k: $k = 4\pi^2 f^2 m = 4\pi^2(4.15\text{ Hz})^2(0.400\text{ kg}) = 272\text{ N/m}$.

(c) $F = kx = (272\text{ N/m})(0.0200\text{ m}) = 5.44\text{ N}$.

EVALUATE: The force in part (c) is around a pound.

VP14.3.2. **IDENTIFY:** The puck is executing SHM on the spring.

SET UP: For SHM $T = 1/f$, $T = 2\pi\sqrt{m/k}$, and $a_{max} = A\omega^2$. Our target variables are the mass of the puck and the amplitude of the oscillations.

EXECUTE: **(a)** Solve $T = 2\pi\sqrt{m/k}$ for m: $m = \dfrac{T^2 k}{4\pi^2} = \dfrac{(1.20\text{ s})^2(4.50\text{ N/m})}{4\pi^2} = 0.164\text{ kg}$.

(b) Solve $a_{max} = A\omega^2$ for A: $A = \dfrac{a_{max}}{\omega^2} = \dfrac{a_{max}}{(2\pi/T)^2} = \dfrac{1.20\text{ m/s}^2}{[2\pi/(1.20\text{ s})]^2} = 0.0438\text{ m} = 4.38\text{ cm}$.

EVALUATE: The maximum acceleration occurs at the instants that the puck has stopped moving, which are at the extremes of its motion when $x = \pm A$.

VP14.3.3. **IDENTIFY:** The piston is moving in SHM.

SET UP: For SHM, $x(t) = A\cos(\omega t + \phi)$ and $v_{max} = A\omega$. We know that the frequency is 50.0 Hz and at a certain instant $x = 0.0300$ m and $v = 12.5$ m/s; but we don't know if either x or v are positive or negative. The target variables are the amplitude of the motion and the maximum speed of the piston.

EXECUTE: **(a)** With $x = A\cos(\omega t + \phi)$, we have $v = dx/dt = -A\omega\sin(\omega t + \phi)$. Since we don't know the sign of x or v at the instant in question, so we can neglect the minus sign for v. Taking the ration of v/x gives $\dfrac{v}{x} = \dfrac{A\omega\sin(\omega t + \phi)}{A\cos(\omega t + \phi)} = \omega\tan(\omega t + \phi)$. We know this ratio at the instant in question, so we can use this result to find $(\omega t + \phi)$. Knowing this, we can use the known value of x to find the amplitude A.

Using the known values, first find $(\omega t + \phi)$. Solving $\dfrac{v}{x} = \omega\tan(\omega t + \phi)$ for $(\omega t + \phi)$ gives

$(\omega t + \phi) = \arctan\left(\dfrac{v}{x\omega}\right) = \arctan\left(\dfrac{v}{2\pi f x}\right)$. Using the known values we have $(\omega t + \phi)$ =

$\arctan\left(\dfrac{12.5\text{ m/s}}{2\pi(50.0\text{ Hz})(0.0300\text{ m})}\right) = 52.984°$. Now use $x = A\cos(\omega t + \phi)$ to find A, giving 0.0300 m = A cos(52.984°), so $A = 0.0498$ m.

(b) $v_{max} = A\omega = 2\pi fA = 2\pi(50.0\text{ Hz})(0.0498\text{ m}) = 15.7\text{ m/s}$.

EVALUATE: From the information give, we don't know the exact position or velocity of the piston. It could be to the right or left of the origin moving either right or left. But none of this affects the amplitude or maximum speed.

VP14.3.4. IDENTIFY: The cat and platform oscillate together in SHM.

SET UP: We use $f = \frac{1}{2\pi}\sqrt{k/m}$ and $a_{max} = \omega^2 A$ with $\omega = 2\pi f$. The target variables are the frequency of vibration and the amplitude of the motion so that the acceleration that will not disturb the sleeping cat.

EXECUTE: **(a)** $f = \frac{1}{2\pi}\sqrt{k/m} = .\frac{1}{2\pi}\sqrt{\frac{185\text{ N/m}}{5.00\text{ kg}}} == 0.968\text{ Hz}.$.

(b) Use $a_{max} = \omega^2 A = (2\pi f)^2 A$ to solve for A: $A = \frac{a_{max}}{(2\pi f)^2} = \frac{1.52\text{ m/s}^2}{[2\pi(0.968\text{ Hz})]^2} = 0.0411\text{ m}$.

EVALUATE: This motion makes about one vibration per second with an amplitude of about 4 cm, so it is not particularly fast.

VP14.4.1. IDENTIFY: This problem deals with the energy of a glider attached to a spring and oscillating with SHM.

SET UP: We use $v_{max} = A\omega$, $\omega = \sqrt{k/m}$, $K = \frac{1}{2}mv^2$, and $U = \frac{1}{2}kx^2$. The target variables are the amplitude A of the motion, the total mechanical energy E of the system, and the potential energy and kinetic energy at a certain point.

EXECUTE: **(a)** Use $v_{max} = A\omega$ and $\omega = \sqrt{k/m}$ to solve for A. We get $A = \frac{v_{max}}{\omega}$, which gives

$$A = v_{max}\sqrt{\frac{m}{k}} = (0.350\text{ m/s})\sqrt{\frac{0.150\text{ kg}}{8.00\text{ N/m}}} = 0.0479\text{ m}.$$

(b) $E = K_{max} = \frac{1}{2}mv_{max}^2 = \frac{1}{2}(0.150\text{ kg})(0.350\text{ m/s})^2 = 9.19\times 10^{-3}\text{ J}$.

(c) $U = \frac{1}{2}kx^2 = \frac{1}{2}(8.00\text{ N/m})(0.0300\text{ m})^2 = 3.60\times 10^{-3}\text{ J}$.

$K = E - U = 9.19\times 10^{-3}\text{ J} - 3.60\times 10^{-3}\text{ J} = 5.59\times 10^{-3}\text{ J}$.

EVALUATE: Another way to find the amplitude is to realize that $K_{max} = U_{max}$. Therefore $\frac{1}{2}mv_{max}^2 = \frac{1}{2}kA^2$, which gives $A = \sqrt{\frac{mv_{max}^2}{k}} = \sqrt{\frac{(0.150\text{ kg})(0.350\text{ m/s})^2}{8.00\text{ N/m}}} = 0.479$ m, which agrees with your result.

VP14.4.2. IDENTIFY: The block oscillates in SHM on the spring.

SET UP: The total mechanical energy is $E = K + U$, where $K = \frac{1}{2}mv^2$. We also know that $\omega = \sqrt{k/m}$ and $v_{max} = A\omega$. Our target variables are the force constant of the spring and the speed of the block when the potential energy equals one-half the total mechanical energy.

EXECUTE: **(a)** When $x = 0$, $U = 0$ so $K = K_{max}$. Therefore $v = v_{max} = A\omega$. This tells us that $E = \frac{1}{2}mv_{max}^2 = \frac{1}{2}m(A\omega)^2$. Using $\omega = \sqrt{k/m}$, this becomes $E = \frac{1}{2}m\left(A\sqrt{\frac{k}{m}}\right)^2$, which gives

$$k = \frac{2E}{A^2} = \frac{2(6.00\times 10^{-2}\text{ J})}{(0.0440\text{ m})^2} = 62.0\text{ N/m}.$$

(b) If $U = E/2$, then K must also equal $E/2$, so $\frac{1}{2}mv^2 = \frac{1}{2}E$. This gives $v = \sqrt{\frac{E}{m}} = \sqrt{\frac{6.00\times10^{-2}\text{ J}}{0.300\text{ kg}}} =$ 0.447 m/s.

EVALUATE: Note that we *cannot* say that $v = v_{max}/2$ when $K = K_{max}/2$ because K depends on the *square* of v.

VP14.4.3. **IDENTIFY:** The glider oscillates in SHM on the spring.

SET UP: The total mechanical energy is $E = K + U$, where $K = \frac{1}{2}mv^2$ and $U = \frac{1}{2}kx^2$. We know the total mechanical energy E of the system, the amplitude of the oscillations, and the maximum speed of the glider. We also know that $a_{max} = \omega^2 A$ and $\omega = \sqrt{k/m}$, $x(t) = A\cos(\omega t + \phi)$, and $a(t) = -\omega^2 A\cos(\omega t + \phi)$. Our target variables are the force constant of the spring, the mass m of the glider, maximum acceleration of the glider, and its acceleration when the potential energy is 3.00×10^{-3} J.

EXECUTE: **(a)** When $x = 0$, $U = 0$ so $K = K_{max}$ and $E = K_{max}$. So $\frac{1}{2}mv_{max}^2 = E$, which gives

$$m = \frac{2E}{v_{max}^2} = \frac{2(4.00\times10^{-3}\text{ J})}{(0.125\text{ m/s})^2} = 0.512\text{ kg.}$$

When $x = A$, $K = 0$ so $U = U_{max}$, so $E = U_{max} = \frac{1}{2}kA^2$ which gives $k = \frac{2E}{A^2} = \frac{2(4.00\times10^{-3}\text{ J})}{(0.0300\text{ m})^2} = 8.89$ N/m.

(b) $a_{max} = \omega^2 A = \frac{k}{m}A = \left(\frac{8.89\text{ N/m}}{0.512\text{ kg}}\right)(0.0300\text{ m}) = 0.521\text{ m/s}^2$.

(c) We can use if we can find the value of $\cos(\omega t + \phi)$. We know that $U = 3.00\times10^{-3}\text{ J} = \frac{1}{2}kx^2$ and that $x(t) = A\cos(\omega t + \phi)$. Therefore $U = \frac{1}{2}kx^2 = \frac{1}{2}kA^2\cos^2(\omega t + \phi)$, which gives $\cos(\omega t + \phi) = \sqrt{\frac{2U}{kA^2}}$. Now find the acceleration for this value of $\cos(\omega t + \phi)$. We can drop the minus sign since we only want the magnitude of the acceleration. $a(t) = \omega^2 A\cos(\omega t + \phi) = \omega^2 A\sqrt{\frac{2U}{kA^2}} = \frac{k}{m}\sqrt{\frac{2U}{k}}$. Using $k = 8.89$ N/m, $m = 0.512$ kg, and $U = 3.00\times10^{-3}$ J, we have $a = 0.451\text{ m/s}^2$.

EVALUATE: In part (c) the acceleration is less than the maximum of 0.521 m/s^2 from part (b), so our result is reasonable.

VP14.4.4. **IDENTIFY:** An object is in SHM, and the energy of the system is conserved.

SET UP: The total energy is $E = K + U$ and is constant, where $U = \frac{1}{2}kx^2$. We want to know the values of x when the kinetic energy is equal to 1/3 of the total mechanical energy and to 1/5 of the total mechanical energy.

EXECUTE: **(a)** If $K = 1/3\ E$, then $U = 2/3\ E$, and $E = \frac{1}{2}kA^2$. This gives $\frac{1}{2}kx^2 = \frac{2}{3}\left(\frac{1}{2}kA^2\right)$, so

$$x = \pm A\sqrt{\frac{2}{3}}.$$

(b) Proceed as in part (a). If $K = 4/5\,E$, then $U = 1/5\,E$, which gives $\frac{1}{2}kx^2 = \frac{1}{5}\left(\frac{1}{2}kA^2\right)$, so $x = \pm\frac{A}{\sqrt{5}}$.

EVALUATE: We get square roots in our answers because U depends on the *square* of x and K depends on the *square* of v.

VP14.9.1. **IDENTIFY:** We are dealing with the small oscillations of a simple pendulum.

SET UP: $T = 1/f$ and $T = 2\pi\sqrt{L/g}$ for small oscillations. We want to find g on the alien planet, but first we need the period T.

EXECUTE: **(a)** $T = 1/f = 1/(0.609\text{ Hz}) = 1.64\text{ s}$.

(b) Solve $T = 2\pi\sqrt{L/g}$ for g, giving $g = \frac{4\pi^2 L}{T^2} = \frac{4\pi^2(0.500\text{ m})}{(1.64\text{ s})^2} = 7.32\text{ m/s}^2$.

EVALUATE: This would be a very simple way to determine g since measurements of L and T are quite easy to make.

VP14.9.2. **IDENTIFY:** We are comparing the oscillation frequencies of a simple pendulum and an object attached to a spring.

SET UP: For the glider $\omega = \sqrt{k/m}$, and for a simple pendulum $\omega = \sqrt{g/L}$. The target variable is the length L of the pendulum so that it oscillates with the same frequency as the object attached to the spring.

EXECUTE: If the oscillation frequencies are the same, the angular frequencies must also be the same. So $\sqrt{k/m} = \sqrt{g/L}$, which gives $L = \frac{mg}{k} = \frac{(0.350\text{ kg})(9.80\text{ m/s}^2)}{8.75\text{ N/m}} = 0.392\text{ m}$.

EVALUATE: Our result is only accurate if the pendulum makes small oscillations.

VP14.9.3. **IDENTIFY:** The bicycle tire oscillates, but it is a *physical* pendulum, not a simple pendulum.

SET UP: The angular frequency is $\omega = \sqrt{\frac{Mgd}{I}}$ and $\omega = 2\pi f$.

EXECUTE: Using the given moment of inertia, we have $2\pi f = \sqrt{\frac{Mgd}{I}} = \sqrt{\frac{MgR}{2MR^2}} = \sqrt{\frac{g}{2R}}$. The oscillation frequency is $f = \frac{1}{2\pi}\sqrt{\frac{g}{2R}}$.

EVALUATE: If R is large, f is small, meaning that the wheel oscillates with a long period. This is analogous to a long simple pendulum, which oscillates slowly. If g were large, the frequency would be large since gravity could pull it back quickly from its extremes. Both cases suggest that our result is physically plausible.

VP14.9.4. **IDENTIFY:** The rod swings back and forth, but it is not a *simple* pendulum because its mass is spread out. Instead it is a *physical* pendulum.

SET UP: The period of swing is $T = 2\pi\sqrt{\frac{I}{mgd}}$. We want to find the moment of inertia of the rod.

EXECUTE: Use $T = 2\pi\sqrt{\frac{I}{mgd}}$ and solve for I, giving $I = mgd\left(\frac{T}{2\pi}\right)^2$. Therefore we get

$$I = (0.600\text{ kg})(9.80\text{ m/s}^2)(0.500\text{ m})\left(\frac{1.59\text{ s}}{2\pi}\right)^2 = 0.188\text{ kg}\cdot\text{m}^2.$$

EVALUATE: If this rod were uniform, its moment of inertia about the pivot would be $I = \frac{1}{3}ML^2 = \frac{1}{3}(0.600\text{ kg})(0.900\text{ m})^2 = 0.162\text{ kg}\cdot\text{m}^2$, which is *less than* we found. This is reasonable because the center of mass of this pendulum is *below* the midpoint of the rod, so it will have a larger moment of inertia about the pivot point than if it were uniform.

14.1. **IDENTIFY:** We want to relate the characteristics of various waves, such as the period, frequency, and angular frequency.
SET UP: The frequency f in Hz is the number of cycles per second. The angular frequency ω is $\omega = 2\pi f$ and has units of radians per second. The period T is the time for one cycle of the wave and has units of seconds. The period and frequency are related by $T = \dfrac{1}{f}$.

EXECUTE: **(a)** $T = \dfrac{1}{f} = \dfrac{1}{466 \text{ Hz}} = 2.15\times10^{-3}$ s.

$\omega = 2\pi f = 2\pi(466 \text{ Hz}) = 2.93\times10^{3}$ rad/s.

(b) $f = \dfrac{1}{T} = \dfrac{1}{50.0\times10^{-6} \text{ s}} = 2.00\times10^{4}$ Hz. $\omega = 2\pi f = 1.26\times10^{5}$ rad/s.

(c) $f = \dfrac{\omega}{2\pi}$ so f ranges from $\dfrac{2.7\times10^{15} \text{ rad/s}}{2\pi \text{ rad}} = 4.3\times10^{14}$ Hz to $\dfrac{4.7\times10^{15} \text{ rad/s}}{2\pi \text{ rad}} = 7.5\times10^{14}$ Hz. $T = \dfrac{1}{f}$ so T ranges from $\dfrac{1}{7.5\times10^{14} \text{ Hz}} = 1.3\times10^{-15}$ s to $\dfrac{1}{4.3\times10^{14} \text{ Hz}} = 2.3\times10^{-15}$ s.

(d) $T = \dfrac{1}{f} = \dfrac{1}{5.0\times10^{6} \text{ Hz}} = 2.0\times10^{-7}$ s and $\omega = 2\pi f = 2\pi(5.0\times10^{6} \text{ Hz}) = 3.1\times10^{7}$ rad/s.

EVALUATE: Visible light has much higher frequency than either sounds we can hear or ultrasound. Ultrasound is sound with frequencies higher than what the ear can hear. Large f corresponds to small T.

14.2. **IDENTIFY** and **SET UP:** The amplitude is the maximum displacement from equilibrium. In one period the object goes from $x = +A$ to $x = -A$ and returns.
EXECUTE: **(a)** $A = 0.120$ m.
(b) $0.800 \text{ s} = T/2$ so the period is 1.60 s.
(c) $f = \dfrac{1}{T} = 0.625$ Hz.

EVALUATE: Whenever the object is released from rest, its initial displacement equals the amplitude of its SHM.

14.3. **IDENTIFY:** The period is the time for one vibration and $\omega = \dfrac{2\pi}{T}$.

SET UP: The units of angular frequency are rad/s.
EXECUTE: The period is $\dfrac{0.50 \text{ s}}{440} = 1.14\times10^{-3}$ s and the angular frequency is $\omega = \dfrac{2\pi}{T} = 5.53\times10^{3}$ rad/s.
EVALUATE: There are 880 vibrations in 1.0 s, so $f = 880$ Hz. This is equal to $1/T$.

14.4. **IDENTIFY:** The period is the time for one cycle and the amplitude is the maximum displacement from equilibrium. Both these values can be read from the graph.
SET UP: The maximum x is 10.0 cm. The time for one cycle is 16.0 s.

EXECUTE: **(a)** $T = 16.0$ s so $f = \dfrac{1}{T} = 0.0625$ Hz.

(b) $A = 10.0$ cm.
(c) $T = 16.0$ s

(d) $\omega = 2\pi f = 0.393$ rad/s

EVALUATE: After one cycle the motion repeats.

14.5. **IDENTIFY:** This displacement is $\frac{1}{4}$ of a period.

SET UP: $T = 1/f = 0.250$ s.

EXECUTE: $t = 0.0625$ s

EVALUATE: The time is the same for $x = A$ to $x = 0$, for $x = 0$ to $x = -A$, for $x = -A$ to $x = 0$ and for $x = 0$ to $x = A$.

14.6. **IDENTIFY:** The swing moves back and forth and can be approximated as a simple pendulum.

SET UP: Estimate: The length is about 6 ft ≈ 2.0 m. The time between pushes is the period T of swing, where $T = 2\pi\sqrt{L/g}$. We want to find the period.

EXECUTE: $T = 2\pi\sqrt{L/g} = 2\pi\sqrt{\dfrac{2.0\text{ m}}{9.80\text{ m/s}^2}} = 2.8$ s.

EVALUATE: A period of around 3 s seems reasonable for a small playground swing.

14.7. **IDENTIFY** and **SET UP:** The period is the time for one cycle. A is the maximum value of x.

EXECUTE: **(a)** From the figure with the problem, $T = 0.800$ s.

(b) $f = \dfrac{1}{T} = 1.25$ Hz.

(c) $\omega = 2\pi f = 7.85$ rad/s.

(d) From the figure with the problem, $A = 3.0$ cm.

(e) $T = 2\pi\sqrt{\dfrac{m}{k}}$, so $k = m\left(\dfrac{2\pi}{T}\right)^2 = (2.40\text{ kg})\left(\dfrac{2\pi}{0.800\text{ s}}\right)^2 = 148$ N/m.

EVALUATE: The amplitude shown on the graph does not change with time, so there must be little or no friction in this system.

14.8. **IDENTIFY:** Apply $T = \dfrac{1}{f} = \dfrac{2\pi}{\omega} = 2\pi\sqrt{\dfrac{m}{k}}$.

SET UP: The period will be twice the interval between the times at which the glider is at the equilibrium position.

EXECUTE: $k = \omega^2 m = \left(\dfrac{2\pi}{T}\right)^2 m = \left(\dfrac{2\pi}{2(2.60\text{ s})}\right)^2 (0.200\text{ kg}) = 0.292\text{ N/m}$.

EVALUATE: $1\text{ N} = 1\text{ kg}\cdot\text{m/s}^2$, so $1\text{ N/m} = 1\text{ kg/s}^2$.

14.9. **IDENTIFY** and **SET UP:** Use $T = 1/f$ to calculate T, $\omega = 2\pi f$ to calculate ω, and $\omega = \sqrt{k/m}$ for m.

EXECUTE: **(a)** $T = 1/f = 1/6.00\text{ Hz} = 0.167$ s.

(b) $\omega = 2\pi f = 2\pi(6.00\text{ Hz}) = 37.7$ rad/s.

(c) $\omega = \sqrt{k/m}$ implies $m = k/\omega^2 = (120\text{ N/m})/(37.7\text{ rad/s})^2 = 0.0844$ kg.

EVALUATE: We can verify that k/ω^2 has units of mass.

14.10. **IDENTIFY:** The mass and frequency are related by $f = \dfrac{1}{2\pi}\sqrt{\dfrac{k}{m}}$.

SET UP: $f\sqrt{m} = \dfrac{\sqrt{k}}{2\pi} =$ constant, so $f_1\sqrt{m_1} = f_2\sqrt{m_2}$.

EXECUTE: **(a)** $m_1 = 0.750\text{ kg}$, $f_1 = 1.75\text{ Hz}$ and $m_2 = 0.750\text{ kg} + 0.220\text{ kg} = 0.970\text{ kg}$.

$$f_2 = f_1\sqrt{\frac{m_1}{m_2}} = (1.75\text{ Hz})\sqrt{\frac{0.750\text{ kg}}{0.970\text{ kg}}} = 1.54\text{ Hz}.$$

(b) $m_2 = 0.750\text{ kg} - 0.220\text{ kg} = 0.530\text{ kg}$. $f_2 = (1.75\text{ Hz})\sqrt{\dfrac{0.750\text{ kg}}{0.530\text{ kg}}} = 2.08\text{ Hz}$.

EVALUATE: When the mass increases the frequency decreases, and when the mass decreases the frequency increases.

14.11. **IDENTIFY:** For SHM the motion is sinusoidal.
SET UP: $x(t) = A\cos(\omega t)$.

EXECUTE: $x(t) = A\cos(\omega t)$, where $A = 0.320\text{ m}$ and $\omega = \dfrac{2\pi}{T} = \dfrac{2\pi}{0.900\text{ s}} = 6.981\text{ rad/s}$.

(a) $x = 0.320\text{ m}$ at $t_1 = 0$. Let t_2 be the instant when $x = 0.160\text{ m}$. Then we have

$0.160\text{ m} = (0.320\text{ m})\cos(\omega t_2)$. $\cos(\omega t_2) = 0.500$. $\omega t_2 = 1.047\text{ rad}$. $t_2 = \dfrac{1.047\text{ rad}}{6.981\text{ rad/s}} = 0.150\text{ s}$. It takes

$t_2 - t_1 = 0.150\text{ s}$.

(b) Let t_3 be when $x = 0$. Then we have $\cos(\omega t_3) = 0$ and $\omega t_3 = 1.571\text{ rad}$. $t_3 = \dfrac{1.571\text{ rad}}{6.981\text{ rad/s}} = 0.225\text{ s}$.

It takes $t_3 - t_2 = 0.225\text{ s} - 0.150\text{ s} = 0.0750\text{ s}$.

EVALUATE: Note that it takes twice as long to go from $x = 0.320\text{ m}$ to $x = 0.160\text{ m}$ than to go from $x = 0.160\text{ m}$ to $x = 0$, even though the two distances are the same, because the speeds are different over the two distances.

14.12. **IDENTIFY:** For SHM the restoring force is directly proportional to the displacement and the system obeys Newton's second law.

SET UP: $F_x = ma_x$ and $f = \dfrac{1}{2\pi}\sqrt{\dfrac{k}{m}}$.

EXECUTE: $F_x = ma_x$ gives $a_x = -\dfrac{kx}{m}$, so $\dfrac{k}{m} = -\dfrac{a_x}{x} = -\dfrac{-5.30\text{ m/s}^2}{0.280\text{ m}} = 18.93\text{ s}^{-2}$.

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{m}} = \frac{1}{2\pi}\sqrt{18.93\text{ s}^{-2}} = 0.692\text{ Hz}$$

EVALUATE: The period is around 1.5 s, so this is a rather slow vibration.

14.13. **IDENTIFY:** Use $A = \sqrt{x_0^2 + \dfrac{v_{0x}^2}{\omega^2}}$ to calculate A. The initial position and velocity of the block determine ϕ. $x(t)$ is given by $x = A\cos(\omega t + \phi)$.

SET UP: $\cos\theta$ is zero when $\theta = \pm\pi/2$ and $\sin(\pi/2) = 1$.

EXECUTE: **(a)** From $A = \sqrt{x_0^2 + \dfrac{v_{0x}^2}{\omega^2}}$, $A = \left|\dfrac{v_0}{\omega}\right| = \left|\dfrac{v_0}{\sqrt{k/m}}\right| = 0.98\text{ m}$.

(b) Since $x(0) = 0$, $x = A\cos(\omega t + \phi)$ requires $\phi = \pm\frac{\pi}{2}$. Since the block is initially moving to the left, $v_{0x} < 0$ and $v_{0x} = -\omega A\sin\phi$ requires that $\sin\phi > 0$, so $\phi = +\frac{\pi}{2}$.

(c) $\cos(\omega t + \pi/2) = -\sin\omega t$, so $x = (-0.98\text{ m})\sin[(12.2\text{ rad/s})t]$.

EVALUATE: The $x(t)$ result in part (c) does give $x = 0$ at $t = 0$ and $x < 0$ for t slightly greater than zero.

14.14. **IDENTIFY** and **SET UP:** We are given k, m, x_0, and v_0. Use $A = \sqrt{x_0^2 + v_{0x}^2/\omega^2} = \sqrt{x_0^2 + mv_{0x}^2/k}$, $\phi = \arctan(-v_{0x}/\omega x_0)$, and $x = A\cos(\omega t + \phi)$.

EXECUTE: **(a)** $A = \sqrt{x_0^2 + v_{0x}^2/\omega^2} = \sqrt{x_0^2 + mv_{0x}^2/k}$:

$A = \sqrt{(0.200\text{ m})^2 + (2.00\text{ kg})(-4.00\text{ m/s})^2/(300\text{ N/m})} = 0.383\text{ m}$

(b) $\phi = \arctan(-v_{0x}/\omega x_0)$:

$\omega = \sqrt{k/m} = \sqrt{(300\text{ N/m})/2.00\text{ kg}} = 12.25\text{ rad/s}$

$$\phi = \arctan\left(-\frac{(-4.00\text{ m/s})}{(12.25\text{ rad/s})(0.200\text{ m})}\right) = \arctan(+1.633) = 58.5^\circ\text{ (or 1.02 rad)}$$

(c) $x = A\cos(\omega t + \phi)$ gives $x = (0.383\text{ m})\cos([12.2\text{rad/s}]t + 1.02\text{ rad})$

EVALUATE: At $t = 0$ the block is displaced 0.200 m from equilibrium but is moving, so $A > 0.200$ m. Since $v_x = -\omega A\cos(\omega t + \phi)$, a phase angle ϕ in the range $0 < \phi < 90^\circ$ gives $v_{0x} < 0$.

14.15. **IDENTIFY:** The block oscillates in SHM.

SET UP: For the given initial conditions $x(t) = A\cos\omega t$ where $\omega = \sqrt{k/m} = 2\pi/T$ and $T = 2\pi\sqrt{m/k}$.

EXECUTE: **(a)** We want to find the time when $x(t) = A/2$ for the first time.
$x(t) = A\cos\omega t = A/2$, so $\omega t = 60^\circ = \pi/3$ rad, which gives $t = \pi/3\omega$. Since $\omega = 2\pi/T$, we have

$$t = \frac{\pi}{3\left(\frac{2\pi}{T}\right)} = T/6.$$

(b) We want to find the time when the block first $v_{max}/2$. The velocity is $v = dx/dt$, which gives $\frac{d(A\cos\omega t)}{dt} = -A\omega\sin\omega t = -v_{max}\sin\omega t$. We can drop the minus sign because we are interested only in the speed. Therefore $v = \frac{1}{2}v_{max} = v_{max}\sin\omega t$, so $\sin\omega t = \frac{1}{2}$, which means that $\omega t = 30^\circ = \pi/6$. Using $\omega = 2\pi/T$, we get $t = \frac{\pi/6}{\omega} = \frac{\pi}{6\left(\frac{2\pi}{T}\right)} = T/12$.

(c) The answer is no, the block does not reach $v_{max}/2$ when $x = A/2$.

EVALUATE: We can check our result using energy conservation. The total mechanical energy E is $E = \frac{1}{2}mv^2 + \frac{1}{2}kx^2 = \frac{1}{2}mv_{max}^2 = \frac{1}{2}kA^2$. We know that $v_{max} = A\omega = A\sqrt{k/m}$. Use energy to find x when $v = v_{max}/2$, which gives $\frac{1}{2}m\left(\frac{v_{max}}{2}\right)^2 + \frac{1}{2}kx^2 = \frac{1}{2}kA^2$. Using $v_{max} = A\omega = A\sqrt{k/m}$, this becomes $\frac{1}{2}m\left(\frac{A\sqrt{k/m}}{2}\right)^2 + \frac{1}{2}kx^2 = \frac{1}{2}kA^2$. Squaring and solving for x gives $x = \frac{\sqrt{3}}{2}A$, which is *not* equal to $A/2$. This agrees with our result in part (c).

14.16. **IDENTIFY:** The motion is SHM, and in each case the motion described is one-half of a complete cycle.

SET UP: For SHM, $x = A\cos(\omega t)$ and $\omega = \frac{2\pi}{T}$.

EXECUTE: **(a)** The time is half a period. The period is independent of the amplitude, so it still takes 2.70 s.

(b) $x = 0.090$ m at time t_1. $T = 5.40$ s and $\omega = \dfrac{2\pi}{T} = 1.164$ rad/s. $x_1 = A\cos(\omega t_1)$. $\cos(\omega t_1) = 0.500$. $\omega t_1 = 1.047$ rad and $t_1 = 0.8997$ s. $x = -0.090$ m at time t_2. $\cos(\omega t_2) = -0.500$ m. $\omega t_2 = 2.094$ rad and $t_2 = 1.800$ s. The elapsed time is $t_2 - t_1 = 1.800\text{ s} - 0.8997\text{ s} = 0.900$ s.

EVALUATE: It takes less time to travel from ±0.090 m in (b) than it originally did because the block has larger speed at ± 0.090 m with the increased amplitude.

14.17. **IDENTIFY:** Apply $T = 2\pi\sqrt{\dfrac{m}{k}}$. Use the information about the empty chair to calculate k.

SET UP: When $m = 42.5$ kg, $T = 1.30$ s.

EXECUTE: Empty chair: $T = 2\pi\sqrt{\dfrac{m}{k}}$. gives $k = \dfrac{4\pi^2 m}{T^2} = \dfrac{4\pi^2(42.5\text{ kg})}{(1.30\text{ s})^2} = 993$ N/m.

With person in chair: $T = 2\pi\sqrt{\dfrac{m}{k}}$ gives $m = \dfrac{T^2 k}{4\pi^2} = \dfrac{(2.54\text{ s})^2(993\text{ N/m})}{4\pi^2} = 162$ kg and $m_{\text{person}} = 162\text{ kg} - 42.5\text{ kg} = 120$ kg.

EVALUATE: For the same spring, when the mass increases, the period increases.

14.18. **IDENTIFY** and **SET UP:** Use $T = 2\pi\sqrt{\dfrac{m}{k}}$ for T and $a_x = -\dfrac{k}{m}x$ to relate a_x and k.

EXECUTE: $T = 2\pi\sqrt{\dfrac{m}{k}}$, $m = 0.400$ kg

Use $a_x = -1.80\text{ m/s}^2$ to calculate k: $-kx = ma_x$ gives

$$k = -\frac{ma_x}{x} = -\frac{(0.400\text{ kg})(-1.80\text{ m/s}^2)}{0.300\text{ m}} = +2.40\text{ N/m, so } T = 2\pi\sqrt{\frac{m}{k}} = 2.57\text{ s.}$$

EVALUATE: a_x is negative when x is positive. ma_x/x has units of N/m and $\sqrt{m/k}$ has units of seconds.

14.19. **IDENTIFY:** $T = 2\pi\sqrt{\dfrac{m}{k}}$. $a_x = -\dfrac{k}{m}x$ so $a_{\max} = \dfrac{k}{m}A$. $F = -kx$.

SET UP: a_x is proportional to x so a_x goes through one cycle when the displacement goes through one cycle. From the graph, one cycle of a_x extends from $t = 0.10$ s to $t = 0.30$ s, so the period is $T = 0.20$ s. $k = 2.50\text{ N/cm} = 250$ N/m. From the graph the maximum acceleration is 12.0 m/s^2.

EXECUTE: **(a)** $T = 2\pi\sqrt{\dfrac{m}{k}}$ gives $m = k\left(\dfrac{T}{2\pi}\right)^2 = (250\text{ N/m})\left(\dfrac{0.20\text{ s}}{2\pi}\right)^2 = 0.253$ kg

(b) $A = \dfrac{ma_{\max}}{k} = \dfrac{(0.253\text{ kg})(12.0\text{ m/s}^2)}{250\text{ N/m}} = 0.0121\text{ m} = 1.21$ cm

(c) $F_{\max} = kA = (250\text{ N/m})(0.0121\text{ m}) = 3.03$ N.

EVALUATE: We can also calculate the maximum force from the maximum acceleration: $F_{\max} = ma_{\max} = (0.253\text{ kg})(12.0\text{ m/s}^2) = 3.04$ N, which agrees with our previous results.

14.20. **IDENTIFY:** The general expression for $v_x(t)$ is $v_x(t) = -\omega A\sin(\omega t + \phi)$. We can determine ω and A by comparing the equation in the problem to the general form.

SET UP: $\omega = 4.71$ rad/s. $\omega A = 3.60\text{ cm/s} = 0.0360$ m/s.

EXECUTE: **(a)** $T = \dfrac{2\pi}{\omega} = \dfrac{2\pi\text{ rad}}{4.71\text{ rad/s}} = 1.33$ s

(b) $A = \dfrac{0.0360\text{ m/s}}{\omega} = \dfrac{0.0360\text{ m/s}}{4.71\text{ rad/s}} = 7.64\times10^{-3}\text{ m} = 7.64\text{ mm}$

(c) $a_{\max} = \omega^2 A = (4.71\text{ rad/s})^2(7.64\times10^{-3}\text{ m}) = 0.169\text{ m/s}^2$

(d) $\omega = \sqrt{\dfrac{k}{m}}$ so $k = m\omega^2 = (0.500\text{ kg})(4.71\text{ rad/s})^2 = 11.1\text{ N/m}.$

EVALUATE: The overall negative sign in the expression for $v_x(t)$ and the factor of $-\pi/2$ both are related to the phase factor ϕ in the general expression.

14.21. **IDENTIFY:** Compare the specific $x(t)$ given in the problem to the general form $x = A\cos(\omega t + \phi)$.

SET UP: $A = 7.40\text{ cm}$, $\omega = 4.16\text{ rad/s}$, and $\phi = -2.42\text{ rad}$.

EXECUTE: **(a)** $T = \dfrac{2\pi}{\omega} = \dfrac{2\pi}{4.16\text{ rad/s}} = 1.51\text{ s}.$

(b) $\omega = \sqrt{\dfrac{k}{m}}$ so $k = m\omega^2 = (1.50\text{ kg})(4.16\text{ rad/s})^2 = 26.0\text{ N/m}$

(c) $v_{\max} = \omega A = (4.16\text{ rad/s})(7.40\text{ cm}) = 30.8\text{ cm/s}$

(d) $F_x = -kx$ so $F_{\max} = kA = (26.0\text{ N/m})(0.0740\text{ m}) = 1.92\text{ N}.$

(e) $x(t)$ evaluated at $t = 1.00\text{ s}$ gives $x = -0.0125\text{ m}$. $v_x = -\omega A\sin(\omega t + \phi) = 30.4\text{ cm/s}.$

$a_x = -kx/m = -\omega^2 x = +0.216\text{ m/s}^2.$

(f) $F_x = -kx = -(26.0\text{ N/m})(-0.0125\text{ m}) = +0.325\text{ N}$

EVALUATE: The maximum speed occurs when $x = 0$ and the maximum force is when $x = \pm A$.

14.22. **IDENTIFY:** The frequency of vibration of a spring depends on the mass attached to the spring. Differences in frequency are due to differences in mass, so by measuring the frequencies we can determine the mass of the virus, which is the target variable.

SET UP: The frequency of vibration is $f = \dfrac{1}{2\pi}\sqrt{\dfrac{k}{m}}.$

EXECUTE: **(a)** The frequency without the virus is $f_s = \dfrac{1}{2\pi}\sqrt{\dfrac{k}{m_s}}$, and the frequency with the virus is

$f_{s+v} = \dfrac{1}{2\pi}\sqrt{\dfrac{k}{m_s + m_v}}$. $\dfrac{f_{s+v}}{f_s} = \left(\dfrac{1}{2\pi}\sqrt{\dfrac{k}{m_s + m_v}}\right)\left(2\pi\sqrt{\dfrac{m_s}{k}}\right) = \sqrt{\dfrac{m_s}{m_s + m_v}} = \dfrac{1}{\sqrt{1 + m_v/m_s}}.$

(b) $\left(\dfrac{f_{s+v}}{f_s}\right)^2 = \dfrac{1}{1 + m_v/m_s}$. Solving for m_v gives

$m_v = m_s\left(\left[\dfrac{f_s}{f_{s+v}}\right]^2 - 1\right) = (2.10\times10^{-16}\text{ g})\left(\left[\dfrac{2.00\times10^{15}\text{ Hz}}{2.87\times10^{14}\text{ Hz}}\right]^2 - 1\right) = 9.99\times10^{-15}\text{ g}$, or

$m_v = 9.99$ femtograms.

EVALUATE: When the mass increases, the frequency of oscillation increases.

14.23. **IDENTIFY:** The *jerk* is defined as *da/dt*. We want to investigate the jerk for an object in SHM.

SET UP: $j_x = da_x/dt$, $v_x = -A\omega\sin\omega t$, and $a_x = dv_x/dt$.

EXECUTE: **(a)** First find a_x: $a_x = dv_x/dt = d(-A\omega\sin\omega t)/dt = -\omega^2 A\cos\omega t$. Now find j_x:

$j_x = da_x/dt = d(-\omega^2 A\cos\omega t)/dt = \omega^3 A\sin\omega t.$

(b) The jerk has its largest positive value when $\sin\omega t$ is 1, so $\omega t = \pi/2$. Since $v_x = -A\omega\sin\omega t$, integration tells us that $x(t) = A\cos\omega t$. So when j_x is a positive maximum, $x = A\cos(\pi/2) = 0$.

(c) The jerk is most negative when $\sin\omega t$ is -1, so $\omega t = 3\pi/2$. So when j_x is most negative, $x = A\cos(3\pi/2) = 0$.

(d) The jerk is zero when $\omega t = 0, \pi, 2\pi, \ldots$. At these values, $\cos\omega t$ is either +1 or –1, so $x = \pm A$.
(e) We know that $v_x = -Kj_x$ where $K = +0.040\ \text{s}^2$ and that $v_x = -A\omega\sin\omega t$. Using our result for j_x from part (a), we get $v_x = -K\omega^3 A\sin\omega t$. Equating these two expressions for v_x gives $K\omega^3 A = \omega A$, so $\omega = 1/\sqrt{K} = 1/\sqrt{0.040\ \text{s}^2} = 5.0$ rad/s. The period is $T = 2\pi/\omega,$ which gives $T = 2\pi/(5.0\ \text{rad/s}) = 1.3\ \text{s}.$

EVALUATE: The jerk also has simple harmonic behavior.

14.24. **IDENTIFY:** The mechanical energy of the system is conserved. The maximum acceleration occurs at the maximum displacement and the motion is SHM.

SET UP: Energy conservation gives $\frac{1}{2}mv_{\text{max}}^2 = \frac{1}{2}kA^2,\ T = 2\pi\sqrt{\frac{m}{k}},$ and $a_{\text{max}} = \frac{kA}{m}.$

EXECUTE: **(a)** From the graph, we read off $T = 16.0$ s and $A = 10.0$ cm = 0.100 m. $\frac{1}{2}mv_{\text{max}}^2 = \frac{1}{2}kA^2$ gives $v_{\text{max}} = A\sqrt{\frac{k}{m}}.$ $T = 2\pi\sqrt{\frac{m}{k}},$ so $\sqrt{\frac{k}{m}} = \frac{2\pi}{T}.$ Therefore

$$v_{\text{max}} = A\left(\frac{2\pi}{T}\right) = (0.100\ \text{m})\left(\frac{2\pi}{16.0\ \text{s}}\right) = 0.0393\ \text{m/s}.$$

(b) $a_{\text{max}} = \frac{kA}{m} = \left(\frac{2\pi}{T}\right)^2 A = \left(\frac{2\pi}{16.0\ \text{s}}\right)^2 (0.100\ \text{m}) = 0.0154\ \text{m/s}^2$

EVALUATE: The acceleration is much less than g.

14.25. **IDENTIFY:** The mechanical energy of the system is conserved. The maximum acceleration occurs at the maximum displacement and the motion is SHM.

SET UP: Energy conservation gives $\frac{1}{2}mv_{\text{max}}^2 = \frac{1}{2}kA^2$ and $a_{\text{max}} = \frac{kA}{m}.$

EXECUTE: $A = 0.165$ m. $\frac{1}{2}mv_{\text{max}}^2 = \frac{1}{2}kA^2$ gives $\frac{k}{m} = \left(\frac{v_{\text{max}}}{A}\right)^2 = \left(\frac{3.90\ \text{m/s}}{0.165\ \text{m}}\right)^2 = 558.7\ \text{s}^{-2}.$

$$a_{\text{max}} = \frac{kA}{m} = (558.7\ \text{s}^{-2})(0.165\ \text{m}) = 92.2\ \text{m/s}^2.$$

EVALUATE: The acceleration is much greater than g.

14.26. **IDENTIFY:** The mechanical energy of the system is conserved, Newton's second law applies and the motion is SHM.

SET UP: Energy conservation gives $\frac{1}{2}mv_x^2 + \frac{1}{2}kx^2 = \frac{1}{2}kA^2,\ F_x = ma_x,\ F_x = -kx,$ and the period is $T = 2\pi\sqrt{\frac{m}{k}}.$

EXECUTE: Solving $\frac{1}{2}mv_x^2 + \frac{1}{2}kx^2 = \frac{1}{2}kA^2$ for v_x gives $v_x = \pm\sqrt{\frac{k}{m}}\sqrt{A^2 - x^2}.$ $T = 2\pi\sqrt{\frac{m}{k}},$ so $\sqrt{\frac{k}{m}} = \frac{2\pi}{T} = \frac{2\pi}{3.20\ \text{s}} = 1.963\ \text{s}^{-1}.$ $v_x = \pm(1.963\ \text{s}^{-1})\sqrt{(0.250\ \text{m})^2 - (0.160\ \text{m})^2} = \pm 0.377\ \text{m/s}.$

$$a_x = -\frac{kx}{m} = -(1.963\ \text{s}^{-1})^2\ (0.160\ \text{m}) = -0.617\ \text{m/s}^2.$$

EVALUATE: The block is on the positive side of the equilibrium position $(x = 0)$. If $v_x = +0.377$ m/s, the block is moving in the positive direction and slowing down since the acceleration is in the negative direction. If $v_x = -0.377$ m/s, the block is moving in the negative direction and speeding up.

14.27. **IDENTIFY** and **SET UP:** Use $E=\frac{1}{2}mv^2+\frac{1}{2}kx^2=\frac{1}{2}kA^2$. $x=\pm A$ when $v_x=0$ and $v_x=\pm v_{\max}$ when $x=0$.

EXECUTE: **(a)** $E=\frac{1}{2}mv^2+\frac{1}{2}kx^2$

$E=\frac{1}{2}(0.150\text{ kg})(0.400\text{ m/s})^2+\frac{1}{2}(300\text{ N/m})(0.012\text{ m})^2=0.0336\text{ J}.$

(b) $E=\frac{1}{2}kA^2$ so $A=\sqrt{2E/k}=\sqrt{2(0.0336\text{ J})/(300\text{ N/m})}=0.0150\text{ m}$

(c) $E=\frac{1}{2}mv_{\max}^2$ so $v_{\max}=\sqrt{2E/m}=\sqrt{2(0.0336\text{ J})/(0.150\text{ kg})}=0.669\text{ m/s}.$

EVALUATE: The total energy E is constant but is transferred between kinetic and potential energy during the motion.

14.28. **IDENTIFY** and **SET UP:** Use $E=\frac{1}{2}mv^2+\frac{1}{2}kx^2=\frac{1}{2}kA^2$ to relate K and U. U depends on x and K depends on v_x.

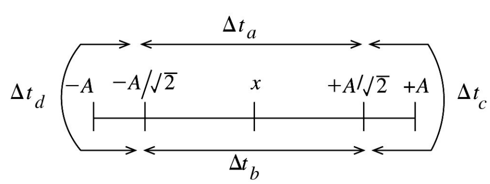
EXECUTE: **(a)** $U+K=E$, so $U=K$ says that $2U=E$

$2\left(\frac{1}{2}kx^2\right)=\frac{1}{2}kA^2$ and $x=\pm A/\sqrt{2}$; magnitude is $A/\sqrt{2}$

But $U=K$ also implies that $2K=E$

$2\left(\frac{1}{2}mv_x^2\right)=\frac{1}{2}kA^2$ and $v_x=\pm\sqrt{k/m}A/\sqrt{2}=\pm\omega A/\sqrt{2}$; magnitude is $\omega A/\sqrt{2}$.

(b) In one cycle x goes from A to 0 to $-A$ to 0 to $+A$. Thus $x=+A\sqrt{2}$ twice and $x=-A/\sqrt{2}$ twice in each cycle. Therefore, $U=K$ four times each cycle. The time between $U=K$ occurrences is the time Δt_a for $x_1=+A/\sqrt{2}$ to $x_2=-A\sqrt{2}$, time Δt_b for $x_1=-A/\sqrt{2}$ to $x_2=+A/\sqrt{2}$, time Δt_c for $x_1=+A/\sqrt{2}$ to $x_2=+A\sqrt{2}$, or the time Δt_d for $x_1=-A/\sqrt{2}$ to $x_2=-A/\sqrt{2}$, as shown in Figure 14.28.



$\Delta t_a=\Delta t_b$

$\Delta t_c=\Delta t_d$

Figure 14.28

Calculation of Δt_a:

Specify x in $x=A\cos\omega t$ (choose $\phi=0$ so $x=A$ at $t=0$) and solve for t.

$x_1=+A/\sqrt{2}$ implies $A/\sqrt{2}=A\cos(\omega t_1)$

$\cos\omega t_1=1/\sqrt{2}$ so $\omega t_1=\arccos(1/\sqrt{2})=\pi/4$ rad

$t_1=\pi/4\omega$

$x_2=-A/\sqrt{2}$ implies $-A/\sqrt{2}=A\cos(\omega t_2)$

$\cos\omega t_2=-1/\sqrt{2}$ so $\omega t_1=3\pi/4$ rad

$t_2=3\pi/4\omega$

$\Delta t_a=t_2-t_1=3\pi/4\omega-\pi/4\omega=\pi/2\omega$ (Note that this is $T/4$, one-fourth period.)

Calculation of Δt_d:

$x_1=-A/\sqrt{2}$ implies $t_1=3\pi/4\omega$

$x_2=-A/\sqrt{2}$, t_2 is the *next* time after t_1 that gives $\cos\omega t_2=-1/\sqrt{2}$

Thus $\omega t_2=\omega t_1+\pi/2=5\pi/4$ and $t_2=5\pi/4\omega$

$\Delta t_d = t_2 - t_1 = 5\pi/4\omega - 3\pi/4\omega = \pi/2\omega,$ so is the same as Δt_a.

Therfore the occurrences of $K = U$ are equally spaced in time, with a time interval between them of $\pi/2\omega$.

Evaluate: This is one-fourth *T*, as it must be if there are 4 equally spaced occurrences each period.

(c) Execute: $x = A/2$ and $U + K = E$

$$K = E - U = \tfrac{1}{2}kA^2 - \tfrac{1}{2}kx^2 = \tfrac{1}{2}kA^2 - \tfrac{1}{2}k(A/2)^2 = \tfrac{1}{2}kA^2 - \tfrac{1}{8}kA^2 = 3kA^2/8$$

Then $\dfrac{K}{E} = \dfrac{3kA^2/8}{\frac{1}{2}kA^2} = \dfrac{3}{4}$ and $\dfrac{U}{E} = \dfrac{\frac{1}{8}kA^2}{\frac{1}{2}kA^2} = \dfrac{1}{4}$

Evaluate: At $x = 0$ all the energy is kinetic and at $x = \pm A$ all the energy is potiential. But $K = U$ does not occur at $x = \pm A/2,$ since *U* is not linear in *x*.

14.29. **Identify:** Velocity and position are related by $E = \tfrac{1}{2}kA^2 = \tfrac{1}{2}mv_x^2 + \tfrac{1}{2}kx^2$. Acceleration and position are related by $-kx = ma_x$.

Set Up: The maximum speed is at $x = 0$ and the maximum magnitude of acceleration is at $x = \pm A$.

Execute: **(a)** For $x = 0,$ $\tfrac{1}{2}mv_{\text{max}}^2 = \tfrac{1}{2}kA^2$ and $v_{\text{max}} = A\sqrt{\dfrac{k}{m}} = (0.040\ \text{m})\sqrt{\dfrac{450\ \text{N/m}}{0.500\ \text{kg}}} = 1.20\ \text{m/s}$

(b) $v_x = \pm\sqrt{\dfrac{k}{m}}\sqrt{A^2 - x^2} = \pm\sqrt{\dfrac{450\ \text{N/m}}{0.500\ \text{kg}}}\sqrt{(0.040\ \text{m})^2 - (0.015\ \text{m})^2} = \pm 1.11\ \text{m/s}.$

The speed is $v = 1.11$ m/s.

(c) For $x = \pm A,$ $a_{\text{max}} = \dfrac{k}{m}A = \left(\dfrac{450\ \text{N/m}}{0.500\ \text{kg}}\right)(0.040\ \text{m}) = 36\ \text{m/s}^2$

(d) $a_x = -\dfrac{kx}{m} = -\dfrac{(450\ \text{N/m})(-0.015\ \text{m})}{0.500\ \text{kg}} = +13.5\ \text{m/s}^2$

(e) $E = \tfrac{1}{2}kA^2 = \tfrac{1}{2}(450\ \text{N/m})(0.040\ \text{m})^2 = 0.360\ \text{J}$

Evaluate: The speed and acceleration at $x = -0.015$ m are less than their maximum values.

14.30. **Identify:** The block moves in SHM attached to a spring.

Set Up: We are looking at the block's average speed and maximum speed. $v_{\text{av}} = d/t$, $v_{\text{max}} = A\omega$, $\omega = \sqrt{\dfrac{k}{m}}$ and $T = 2\pi\sqrt{\dfrac{m}{k}}$.

Execute: **(a)** During one cycle the block moves through a total distance of $d = 4A$ in time *T*, so

$$v_{\text{av}} = \frac{d}{t} = \frac{4A}{T} = \frac{4A}{2\pi\sqrt{\frac{m}{k}}} = \frac{2A}{\pi}\sqrt{\frac{k}{m}}.$$

(b) $v_{\text{max}} = A\omega = A\sqrt{\dfrac{k}{m}}$. Using this fact and our result from part (a), we have

$$v_{\text{av}} = \frac{2A}{\pi}\sqrt{\frac{k}{m}} = \left(A\sqrt{\frac{k}{m}}\right)\left(\frac{2}{\pi}\right) = \frac{2}{\pi}v_{\text{max}}.$$

(c) $\dfrac{v_{\text{av}}}{\frac{1}{2}v_{\text{max}}} = \dfrac{\frac{2}{\pi}v_{\text{max}}}{\frac{1}{2}v_{\text{max}}} = \dfrac{4}{\pi} > 1,$ so $v_{\text{av}} > \dfrac{v_{\text{max}}}{2}$. This suggests that the block spends more time traveling at speeds greater than $v_{\text{max}}/2$.

Evaluate: The answer in (c) is reasonable because $v_{\text{av}} = (2/\pi)v_{\text{max}} < v_{\text{max}}$.

14.31. **IDENTIFY:** A block moves in SHM on a spring.

SET UP: $x(t) = A\cos(\omega t + \phi)$, $v(t) = dx/dt$. We want to know how far the block is from the origin when its speed is one-half of its maximum speed.

EXECUTE: First find $v(t)$: $v(t) = dx/dt = \dfrac{d\left(A\cos(\omega t + \phi)\right)}{dt} = -A\omega\sin(\omega t + \phi)$. Now find the time when $v = v_{max}/2$. We can drop the minus sign since we are interested only in the speed, not its direction. We also realize that $A\omega = v_{max}$. This gives $\dfrac{v_{max}}{2} = v_{max}\sin(\omega t + \phi)$, so $\sin(\omega t + \phi) = \dfrac{1}{2}$, which gives $(\omega t + \phi) = 30° = \dfrac{\pi}{6}$. At this time $x = A\cos(\omega t + \phi) = A\cos\dfrac{\pi}{6} = A\dfrac{\sqrt{3}}{2} \approx 0.866A$. The distance is $x \approx 0.866A$, which is greater than $A/2$.

EVALUATE: The block changes its speed most rapidly when it is near $x = A$ because a_x is greatest then.

14.32. **IDENTIFY:** Newton's second law applies to the system, and mechanical energy is conserved.

SET UP: $\Sigma F_x = ma_x$, $K_1 + U_1 = K_2 + U_2$, $U = \frac{1}{2}kx^2$, $F_{spring} = -kx$.

EXECUTE: **(a)** $\Sigma F_x = ma_x$ gives $ma_x = -kx$, which gives

$(0.300 \text{ kg})(-12.0 \text{ m/s}^2) = -k(0.240 \text{ m})$.

Solving for k gives $k = 15.0$ N/m.

(b) Applying $K_1 + U_1 = K_2 + U_2$ gives $\frac{1}{2}mv^2 + \frac{1}{2}kx^2 = \frac{1}{2}kA^2$.

Putting in the numbers gives

$(0.300 \text{ kg})(4.00 \text{ m/s})^2 + (15.0 \text{ N/m})(0.240 \text{ m})^2 = (15.0 \text{ N/m})A^2$,

so $A = 0.61449$ m, which rounds to 0.614 m.

(c) The kinetic energy is maximum when the potential energy is zero, which is when $x = 0$. Therefore $\frac{1}{2}kA^2 = \frac{1}{2}mv^2$, which gives

$(15.0 \text{ N/m})(0.61449 \text{ m})^2 = (0.300 \text{ kg})v^2$

$v = 4.345$ m/s which rounds to 4.35 m/s.

(d) The maximum force occurs when $x = A$, so Newton's second law gives $F_{max} = ma_{max} = kA$.

$(15.0 \text{ N/m})(0.61449 \text{ m}) = (0.300 \text{ kg})a_{max}$, which gives $a_{max} = 30.7 \text{ m/s}^2$.

EVALUATE: It is frequently necessary to use a combination of energy conservation and Newton's laws.

14.33. **IDENTIFY:** Conservation of energy says $\frac{1}{2}mv^2 + \frac{1}{2}kx^2 = \frac{1}{2}kA^2$ and Newton's second law says $-kx = ma_x$.

SET UP: Let $+x$ be to the right. Let the mass of the object be m.

EXECUTE: $k = -\dfrac{ma_x}{x} = -m\left(\dfrac{-8.40 \text{ m/s}^2}{0.600 \text{ m}}\right) = (14.0 \text{ s}^{-2})m.$

$A = \sqrt{x^2 + (m/k)v^2} = \sqrt{(0.600 \text{ m})^2 + \left(\dfrac{m}{(14.0 \text{ s}^{-2})m}\right)(2.20 \text{ m/s})^2} = 0.840 \text{ m}$. The object will therefore travel $0.840 \text{ m} - 0.600 \text{ m} = 0.240 \text{ ma}$ to the right before stopping at its maximum amplitude.

EVALUATE: The acceleration is not constant and we cannot use the constant acceleration kinematic equations.

14.34. **IDENTIFY:** The mechanical energy (the sum of the kinetic energy and potential energy) is conserved.

SET UP: $K + U = E$, with $E = \frac{1}{2}kA^2$ and $U = \frac{1}{2}kx^2$

EXECUTE: $U = K$ says $2U = E$. This gives $2(\frac{1}{2}kx^2) = \frac{1}{2}kA^2$, so $x = A/\sqrt{2}$.

EVALUATE: When $x = A/2$ the kinetic energy is three times the elastic potential energy.

14.35. IDENTIFY and SET UP: Velocity, position, and total energy are related by $E = \frac{1}{2}kA^2 = \frac{1}{2}mv_x^2 + \frac{1}{2}kx^2$. Acceleration and position are related by $-kx = ma_x$. The maximum magnitude of acceleration is at $x = \pm A$.

EXECUTE: **(a)** $E = \frac{1}{2}mv_x^2 + \frac{1}{2}kx^2 = \frac{1}{2}(2.00 \text{ kg})(-4.00 \text{ m/s})^2 + \frac{1}{2}(315 \text{ N/m})(+0.200 \text{ m})^2$.

$E = 16.0 \text{ J} + 6.3 \text{ J} = 22.3 \text{ J}$. $E = \frac{1}{2}kA^2$ and

$$A = \sqrt{\frac{2E}{k}} = \sqrt{\frac{2(22.3 \text{ J})}{315 \text{ N/m}}} = 0.376 \text{ m}.$$

(b) $a_{\max} = \dfrac{k}{m}A = \left(\dfrac{315 \text{ N/m}}{2.00 \text{ kg}}\right)(0.376 \text{ m}) = 59.2 \text{ m/s}^2$

(c) $F_{\max} = ma_{\max} = (2.00 \text{ kg})(59.2 \text{ m/s}^2) = 118 \text{ N}$. Or, $F_x = -kx$ gives $F_{\max} = kA = (315 \text{ N/m})(0.376 \text{ m}) = 118 \text{ N}$, which checks.

EVALUATE: The maximum force and maximum acceleration occur when the displacement is maximum and the velocity is zero.

14.36. IDENTIFY: Use the amount the spring is stretched by the weight of the fish to calculate the force constant *k* of the spring. $T = 2\pi\sqrt{m/k}$. $v_{\max} = \omega A = 2\pi fA$.

SET UP: When the fish hangs at rest the upward spring force $|F_x| = kx$ equals the weight *mg* of the fish. $f = 1/T$. The amplitude of the SHM is 0.0500 m.

EXECUTE: **(a)** $mg = kx$ so $k = \dfrac{mg}{x} = \dfrac{(65.0 \text{ kg})(9.80 \text{ m/s}^2)}{0.180 \text{ m}} = 3.54 \times 10^3 \text{ N/m}$.

(b) $T = 2\pi\sqrt{\dfrac{m}{k}} = 2\pi\sqrt{\dfrac{65.0 \text{ kg}}{3.54 \times 10^3 \text{ N/m}}} = 0.8514 \text{ s}$ which rounds to 0.851 s.

(c) $v_{\max} = 2\pi fA = \dfrac{2\pi A}{T} = \dfrac{2\pi(0.0500 \text{ m})}{0.8514 \text{ s}} = 0.369 \text{ m/s}$.

EVALUATE: Note that *T* depends only on *m* and *k* and is independent of the distance the fish is pulled down. But $v_{\max}$ does depend on this distance.

14.37. IDENTIFY: Initially part of the energy is kinetic energy and part is potential energy in the stretched spring. When $x = \pm A$ all the energy is potential energy and when the glider has its maximum speed all the energy is kinetic energy. The total energy of the system remains constant during the motion.

SET UP: Initially $v_x = \pm 0.815 \text{ m/s}$ and $x = \pm 0.0300 \text{ m}$.

EXECUTE: **(a)** Initially the energy of the system is

$E = \frac{1}{2}mv^2 + \frac{1}{2}kx^2 = \frac{1}{2}(0.175 \text{ kg})(0.815 \text{ m/s})^2 + \frac{1}{2}(155 \text{ N/m})(0.0300 \text{ m})^2 = 0.128 \text{ J}$. $\frac{1}{2}kA^2 = E$ and

$A = \sqrt{\dfrac{2E}{k}} = \sqrt{\dfrac{2(0.128 \text{ J})}{155 \text{ N/m}}} = 0.0406 \text{ m} = 4.06 \text{ cm}$.

(b) $\frac{1}{2}mv_{\max}^2 = E$ and $v_{\max} = \sqrt{\dfrac{2E}{m}} = \sqrt{\dfrac{2(0.128 \text{ J})}{0.175 \text{ kg}}} = 1.21 \text{ m/s}$.

(c) $\omega = \sqrt{\dfrac{k}{m}} = \sqrt{\dfrac{155 \text{ N/m}}{0.175 \text{ kg}}} = 29.8 \text{ rad/s}$.

EVALUATE: The amplitude and the maximum speed depend on the total energy of the system but the angular frequency is independent of the amount of energy in the system and just depends on the force constant of the spring and the mass of the object.

14.38. **IDENTIFY:** The torsion constant κ is defined by $\tau_z = -\kappa\theta$. $f = \dfrac{1}{2\pi}\sqrt{\dfrac{\kappa}{I}}$ and $T = 1/f$.

$\theta(t) = \Theta\cos(\omega t + \phi)$.

SET UP: For the disk, $I = \frac{1}{2}MR^2$. $\tau_z = -FR$. At $t = 0$, $\theta = \Theta = 3.34° = 0.0583$ rad, so $\phi = 0$.

EXECUTE: **(a)** $\kappa = -\dfrac{\tau_z}{\theta} = -\dfrac{-FR}{0.0583\text{ rad}} = +\dfrac{(4.23\text{ N})(0.120\text{ m})}{0.0583\text{ rad}} = 8.71\text{ N}\cdot\text{m/rad}$

(b) $f = \dfrac{1}{2\pi}\sqrt{\dfrac{\kappa}{I}} = \dfrac{1}{2\pi}\sqrt{\dfrac{2\kappa}{MR^2}} = \dfrac{1}{2\pi}\sqrt{\dfrac{2(8.71\text{ N}\cdot\text{m/rad})}{(6.50\text{ kg})(0.120\text{ m})^2}} = 2.17\text{ Hz}$. $T = 1/f = 0.461$ s.

(c) $\omega = 2\pi f = 13.6$ rad/s. $\theta(t) = (3.34°)\cos([13.6\text{ rad/s}]t)$.

EVALUATE: The frequency and period are independent of the initial angular displacement, so long as this displacement is small.

14.39. **IDENTIFY:** $K = \frac{1}{2}mv^2$, $U_{\text{grav}} = mgy$ and $U_{\text{el}} = \frac{1}{2}kx^2$.

SET UP: At the lowest point of the motion, the spring is stretched an amount $2A$.

EXECUTE: **(a)** At the top of the motion, the spring is unstretched and so has no potential energy, the cat is not moving and so has no kinetic energy, and the gravitational potential energy relative to the bottom is $2mgA = 2(4.00\text{ kg})(9.80\text{ m/s}^2)(0.050\text{ m}) = 3.92$ J. This is the total energy, and is the same total for each part.

(b) $U_{\text{grav}} = 0, K = 0,$ so $U_{\text{spring}} = 3.92$ J.

(c) At equilibrium the spring is stretched half as much as it was for part (a), and so $U_{\text{spring}} = \frac{1}{4}(3.92\text{ J}) = 0.98$ J, $U_{\text{grav}} = \frac{1}{2}(3.92\text{ J}) = 1.96$ J, and so $K = 0.98$ J.

EVALUATE: During the motion, work done by the forces transfers energy among the forms kinetic energy, gravitational potential energy and elastic potential energy.

14.40. **IDENTIFY:** $f = \dfrac{1}{2\pi}\sqrt{\dfrac{\kappa}{I}}$ and $T = 1/f$ says $T = 2\pi\sqrt{\dfrac{I}{\kappa}}$.

SET UP: $I = \frac{1}{2}mR^2$.

EXECUTE: Solving $f = \dfrac{1}{2\pi}\sqrt{\dfrac{\kappa}{I}}$ for κ in terms of the period,

$$\kappa = \left(\frac{2\pi}{T}\right)^2 I = \left(\frac{2\pi}{1.00\text{ s}}\right)^2\left[\frac{1}{2}(2.00\times10^{-3}\text{ kg})(2.20\times10^{-2}\text{ m})^2\right] = 1.91\times10^{-5}\text{ N}\cdot\text{m/rad}.$$

EVALUATE: The longer the period, the smaller the torsion constant.

14.41. **IDENTIFY and SET UP:** The number of ticks per second tells us the period and therefore the frequency. We can use a formula from Table 9.2 to calculate *I*. Then $f = \dfrac{1}{2\pi}\sqrt{\dfrac{\kappa}{I}}$ allows us to calculate the torsion constant κ.

EXECUTE: Ticks four times each second implies 0.25 s per tick. Each tick is half a period, so $T = 0.50$ s and $f = 1/T = 1/0.50\text{ s} = 2.00$ Hz.

(a) Thin rim implies $I = MR^2$ (from Table 9.2).
$I = (0.900\times10^{-3}\text{ kg})(0.55\times10^{-2}\text{ m})^2 = 2.7\times10^{-8}\text{ kg}\cdot\text{m}^2$

(b) $T = 2\pi\sqrt{I/\kappa}$ so $\kappa = I(2\pi/T)^2 = (2.7\times10^{-8}\text{ kg}\cdot\text{m}^2)(2\pi/0.50\text{ s})^2 = 4.3\times10^{-6}\text{ N}\cdot\text{m/rad}$

EVALUATE: Both *I* and κ are small numbers.

14.42. **IDENTIFY:** $f = \dfrac{1}{2\pi}\sqrt{\dfrac{\kappa}{I}}$.

SET UP: $f = 165/(265\text{ s})$, the number of oscillations per second.

EXECUTE: $I = \dfrac{\kappa}{(2\pi f)^2} = \dfrac{0.450\text{ N}\cdot\text{m/rad}}{[2\pi(165)/(265\text{ s})]^2} = 0.0294\text{ kg}\cdot\text{m}^2.$

EVALUATE: For a larger I, f is smaller.

14.43. **IDENTIFY:** $T = 2\pi\sqrt{L/g}$ is the time for one complete swing.

SET UP: The motion from the maximum displacement on either side of the vertical to the vertical position is one-fourth of a complete swing.

EXECUTE: **(a)** To the given precision, the small-angle approximation is valid. The highest speed is at the bottom of the arc, which occurs after a quarter period, $\dfrac{T}{4} = \dfrac{\pi}{2}\sqrt{\dfrac{L}{g}} = 0.25\text{ s}.$

(b) The same as calculated in (a), 0.25 s. The period is independent of amplitude.

EVALUATE: For small amplitudes of swing, the period depends on L and g.

14.44. **IDENTIFY:** We are looking at a real pendulum for which the simplified formulas are not completely accurate.

SET UP: Equation (14.35), using only the first correction term, is $T = 2\pi\sqrt{\dfrac{L}{g}}\left(1 + \dfrac{1}{4}\sin^2\dfrac{\Theta}{2}\right)$. We want to find Θ so that the simplified formula $T = 2\pi\sqrt{\dfrac{L}{g}}$ is in error by 2.0%, which means that $\dfrac{\Delta T}{T} = 0.020$.

EXECUTE: $\dfrac{\Delta T}{T} = \dfrac{T_{\text{large }\Theta} - T_{\text{small }\Theta}}{T_{\text{large }\Theta}} = 1 - \dfrac{T_{\text{small }\Theta}}{T_{\text{large }\Theta}} = 1 - \dfrac{2\pi\sqrt{\dfrac{L}{g}}}{2\pi\sqrt{\dfrac{L}{g}}\left(1 + \dfrac{1}{4}\sin^2\dfrac{\Theta}{2}\right)}$, which simplifies to

$0.020 = \dfrac{\dfrac{1}{4}\sin^2\dfrac{\Theta}{2}}{1 + \dfrac{1}{4}\sin^2\dfrac{\Theta}{2}}$. Solving for $\sin^2\dfrac{\Theta}{2}$ gives $\sin^2\dfrac{\Theta}{2} = 8.163\times 10^{-2}$, so $\Theta = 33°$.

EVALUATE: For a 1% error, the maximum angle could be $\Theta = 23°$. These results show that it is adequate to use the simplified formula in a large number of cases.

14.45. **IDENTIFY:** Since the cord is much longer than the height of the object, the system can be modeled as a simple pendulum. We will assume the amplitude of swing is small, so that $T = 2\pi\sqrt{\dfrac{L}{g}}$.

SET UP: The number of swings per second is the frequency $f = \dfrac{1}{T} = \dfrac{1}{2\pi}\sqrt{\dfrac{g}{L}}$.

EXECUTE: $f = \dfrac{1}{2\pi}\sqrt{\dfrac{9.80\text{ m/s}^2}{1.50\text{ m}}} = 0.407$ swings per second.

EVALUATE: The period and frequency are both independent of the mass of the object.

14.46. **IDENTIFY:** Use $T = 2\pi\sqrt{L/g}$ to relate the period to g.

SET UP: Let the period on earth be $T_E = 2\pi\sqrt{L/g_E}$, where $g_E = 9.80\text{ m/s}^2$, the value on earth.

Let the period on Mars be $T_M = 2\pi\sqrt{L/g_M}$, where $g_M = 3.71\text{ m/s}^2$, the value on Mars.

We can eliminate L, which we don't know, by taking a ratio:

EXECUTE: $\dfrac{T_M}{T_E} = 2\pi\sqrt{\dfrac{L}{g_M}}\dfrac{1}{2\pi}\sqrt{\dfrac{g_E}{L}} = \sqrt{\dfrac{g_E}{g_M}}.$

$T_M = T_E\sqrt{\dfrac{g_E}{g_M}} = (1.60\text{ s})\sqrt{\dfrac{9.80\text{ m/s}^2}{3.71\text{ m/s}^2}} = 2.60\text{ s}.$

EVALUATE: Gravity is weaker on Mars so the period of the pendulum is longer there.

14.47. IDENTIFY: Apply $T = 2\pi\sqrt{L/g}$

SET UP: The period of the pendulum is $T = (136\text{ s})/100 = 1.36\text{ s}.$

EXECUTE: $g = \dfrac{4\pi^2 L}{T^2} = \dfrac{4\pi^2(0.500\text{ m})}{(1.36\text{ s})^2} = 10.7\text{ m/s}^2.$

EVALUATE: The same pendulum on earth, where g is smaller, would have a larger period.

14.48. IDENTIFY and SET UP: The period is for the time for one cycle. The angular amplitude is the maximum value of θ.

EXECUTE: **(a)** From the graph with the problem,

$T = 1.60\text{ s}.$ $f = \dfrac{1}{T} = 0.625\text{ Hz}.$ $\omega = 2\pi f = 3.93\text{ rad/s}.$ From the graph we also determine that the amplitude is 6 degrees.

(b) $T = 2\pi\sqrt{\dfrac{L}{g}}$ so $L = g\left(\dfrac{T}{2\pi}\right)^2 = (9.80\text{ m/s}^2)\left(\dfrac{1.60\text{ s}}{2\pi}\right)^2 = 0.635\text{ m}.$

(c) No. The graph is unchanged if the mass of the bob is changed while the length of the pendulum and amplitude of swing are kept constant. The period is independent of the mass of the bob.

EVALUATE: The amplitude of the graph in the problem does not decrease over the time shown, so there must be little or no friction in this pendulum.

14.49. IDENTIFY: $a_{tan} = L\alpha$, $a_{rad} = L\omega^2$ and $a = \sqrt{a_{tan}^2 + a_{rad}^2}$. Use energy conservation in parts (b) and (c).

SET UP: Just after the sphere is released, $\omega = 0$ and $a_{rad} = 0$. When the rod is vertical, $a_{tan} = 0$.

EXECUTE: **(a)** The forces and acceleration are shown in Figure 14.49(a). $a_{rad} = 0$ so $a = a_{tan} = g\sin\theta$.

(b) The forces and acceleration are shown in Figure 14.49(b). In this case, the sphere has radial and tangential acceleration, so we need to use $a = \sqrt{a_{tan}^2 + a_{rad}^2}$. Use energy conservation, calling point 1 the instant that the sphere is released from from rest at angle θ and point 2 the instant the rod makes an angle ϕ with the vertical. This gives $U_1 = U_2 + K_2$, so $mgL(1-\cos\theta) = mgL(1-\cos\phi) + \dfrac{1}{2}mv^2$. Solving for v^2 gives $v^2 = 2gL(\cos\phi - \cos\theta)$. Therefore $a_{rad} = \dfrac{v^2}{L} = 2g(\cos\phi - \cos\theta)$. To find a_{tan}, apply $\Sigma\vec{\tau} = I\alpha$: $mgL\sin\phi = mL^2\alpha = mL(L\alpha) = mL\tan\alpha$, which gives $a_{tan} = g\sin\phi$. The magnitude of the acceleration is $a = \sqrt{a_{tan}^2 + a_{rad}^2} = \sqrt{(g\sin\phi)^2 + [2g(\cos\phi - \cos\theta)]^2}$, which simplifies to $a = g\sqrt{\sin^2\phi + 4(\cos\phi - \cos\theta)^2}$. In this case $\phi = \theta/2$, so the acceleration is $a = g\sqrt{\sin^2(\theta/2) + 4[\cos(\theta/2) - \cos\theta]^2}$.

(c) The forces and acceleration are shown in Figure 14.49(c). Calling point 2 the lowest part of the swing, $U_1 = K_2$ gives $mgL(1-\cos\theta) = \frac{1}{2}mv^2$ and $v = \sqrt{2gL(1-\cos\theta)}$. Using the formula derived in part (b) with $\phi = 0°$, the acceleration is $a = g\sqrt{\sin^2 0° + 4(\cos 0° - \cos\theta)^2} = 2g(1-\cos\theta)$.

EVALUATE: As the rod moves toward the vertical, v increases, a_{rad} increases and a_{tan} decreases. The result in (c) agrees with the fact that $a_{\text{tan}} = 0$ when the rod is vertical because in that case $a = a_{\text{rad}} =$ $\dfrac{v^2}{L} = \dfrac{\left(\sqrt{2gL(1-\cos\theta)}\right)^2}{L} = 2g(1-\cos\theta),$ which is what we found in part (c).

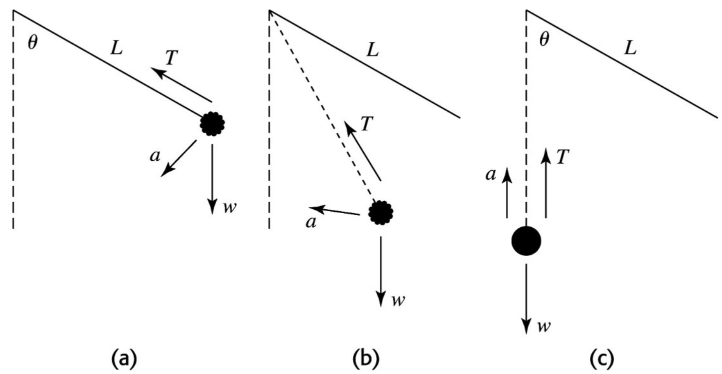


Figure 14.49

14.50. IDENTIFY: $T = 2\pi\sqrt{I/mgd}$

SET UP: From the parallel axis theorem, the moment of inertia of the hoop about the nail is $I = MR^2 + MR^2 = 2MR^2$. $d = R$.

EXECUTE: Solving for R, $R = gT^2/8\pi^2 = 0.496$ m.

EVALUATE: A simple pendulum of length $L = R$ has period $T = 2\pi\sqrt{R/g}$. The hoop has a period that is larger by a factor of $\sqrt{2}$.

14.51. IDENTIFY: Pendulum A can be treated as a simple pendulum. Pendulum B is a physical pendulum.

SET UP: For pendulum B the distance d from the axis to the center of gravity is $3L/4$. $I = \frac{1}{3}(m/2)L^2$ for a bar of mass $m/2$ and the axis at one end. For a small ball of mass $m/2$ at a distance L from the axis, $I_{\text{ball}} = (m/2)L^2$.

EXECUTE: Pendulum A: $T_A = 2\pi\sqrt{\dfrac{L}{g}}$.

Pendulum B: $I = I_{\text{bar}} + I_{\text{ball}} = \frac{1}{3}(m/2)L^2 + (m/2)L^2 = \frac{2}{3}mL^2$.

$T_B = 2\pi\sqrt{\dfrac{I}{mgd}} = 2\pi\sqrt{\dfrac{\frac{2}{3}mL^2}{mg(3L/4)}} = 2\pi\sqrt{\dfrac{L}{g}}\sqrt{\dfrac{2}{3}\cdot\dfrac{4}{3}} = \sqrt{\dfrac{8}{9}}\left(2\pi\sqrt{\dfrac{L}{g}}\right) = 0.943T_A$. The period is longer for pendulum A.

EVALUATE: Example 14.9 shows that for the bar alone, $T = \sqrt{\dfrac{2}{3}}T_A = 0.816T_A$. Adding the ball of equal mass to the end of the rod increases the period compared to that for the rod alone.

14.52. IDENTIFY: Apply $T = 2\pi\sqrt{\dfrac{I}{mgd}}$ to calculate I and conservation of energy to calculate the maximum angular speed, Ω_{max}.

SET UP: $d = 0.250$ m. In part (b), $y_{\text{i}} = d(1-\cos\Theta)$, with $\Theta = 0.400$ rad and $y_{\text{f}} = 0$.

EXECUTE: **(a)** Solving $T = 2\pi\sqrt{\dfrac{I}{mgd}}$ for *I*, we get

$$I = \left(\frac{T}{2\pi}\right)^2 mgd = \left(\frac{0.940\ \text{s}}{2\pi}\right)^2 (1.80\ \text{kg})(9.80\ \text{m/s}^2)(0.250\ \text{m}) = 0.0987\ \text{kg}\cdot\text{m}^2.$$

(b) The small-angle approximation will not give three-figure accuracy for $\Theta = 0.400$ rad. From energy considerations, $mgd(1-\cos\Theta) = \frac{1}{2}I\Omega_{\text{max}}^2$. Expressing Ω_{max} in terms of the period of small-angle oscillations, this becomes

$$\Omega_{\text{max}} = \sqrt{2\left(\frac{2\pi}{T}\right)^2(1-\cos\Theta)} = \sqrt{2\left(\frac{2\pi}{0.940\ \text{s}}\right)^2[1-\cos(0.400\ \text{rad})]} = 2.66\ \text{rad/s}.$$

EVALUATE: The time for the motion in part (b) is $t = T/4$, so $\Omega_{\text{av}} = \Delta\theta/\Delta t = (0.400\ \text{rad})/(0.235\ \text{s}) =$ 1.70 rad/s. Ω increases during the motion and the final Ω is larger than the average Ω.

14.53. **IDENTIFY:** Pendulum *A* can be treated as a simple pendulum. Pendulum *B* is a physical pendulum. Use the parallel-axis theorem to find the moment of inertia of the ball in *B* for an axis at the top of the string.
SET UP: For pendulum *B* the center of gravity is at the center of the ball, so $d = L$. For a solid sphere with an axis through its center, $I_{\text{cm}} = \frac{2}{5}MR^2$. $R = L/2$ and $I_{\text{cm}} = \frac{1}{10}ML^2$.

EXECUTE: Pendulum *A*: $T_A = 2\pi\sqrt{\dfrac{L}{g}}$.

Pendulum *B*: The parallel-axis theorem says $I = I_{\text{cm}} + ML^2 = \frac{11}{10}ML^2$.

$T = 2\pi\sqrt{\dfrac{I}{mgd}} = 2\pi\sqrt{\dfrac{11ML^2}{10MgL}} = \sqrt{\dfrac{11}{10}}\left(2\pi\sqrt{\dfrac{L}{g}}\right) = \sqrt{\dfrac{11}{10}}T_A = 1.05T_A$. It takes pendulum *B* longer to completea swing.

EVALUATE: The center of the ball is the same distance from the top of the string for both pendulums, but the mass is distributed differently and *I* is larger for pendulum *B*, even though the masses are the same.

14.54. **IDENTIFY:** The ornament is a physical pendulum, so $T = 2\pi\sqrt{I/mgd}$. *T* is the target variable.

SET UP: $I = 5MR^2/3$, the moment of inertia about an axis at the edge of the sphere. *d* is the distance from the axis to the center of gravity, which is at the center of the sphere, so $d = R$.

EXECUTE: $T = 2\pi\sqrt{5/3}\sqrt{R/g} = 2\pi\sqrt{5/3}\sqrt{0.050\ \text{m}/(9.80\ \text{m/s}^2)} = 0.58\ \text{s}.$

EVALUATE: A simple pendulum of length $R = 0.050$ m has period 0.45 s; the period of the physical pendulum is longer.

14.55. **IDENTIFY:** The object is moving with damped SHM.
SET UP: We want to know the angular frequency ω' if the damping constant is one-half the critical value. $\omega' = \sqrt{\dfrac{k}{m} - \dfrac{b^2}{4m^2}}$, where *b* is the damping constant and $b_{\text{crit}} = 2\sqrt{km}$. If there is no damping $(b = 0)$, then $\omega = \sqrt{k/m}$.

EXECUTE: If $b = \frac{1}{2}b_{\text{crit}} = \frac{1}{2}\left(2\sqrt{km}\right)$, the angular frequency becomes

$$\omega' = \sqrt{\frac{k}{m} - \frac{b^2}{4m^2}} = \sqrt{\frac{k}{m} - \frac{\left[\frac{1}{2}\left(2\sqrt{km}\right)\right]^2}{4m^2}} = \sqrt{\frac{k}{m} - \frac{k}{4m}} = \sqrt{\frac{3}{4}\frac{k}{m}} = \omega\frac{\sqrt{3}}{2}.$$

EVALUATE: Notice that if $b = \frac{1}{2}b_{\text{crit}}$, it does *not* follow that $\omega' = \frac{\omega}{2}$.

14.56. IDENTIFY: From a small damping force, $A_2 = A_1 e^{-(b/2m)t}$.

SET UP: $\ln(e^{-x}) = -x$

EXECUTE: $b = \frac{2m}{t}\ln\left(\frac{A_1}{A_2}\right) = \frac{2(0.050\text{ kg})}{(5.00\text{ s})}\ln\left(\frac{0.300\text{ m}}{0.100\text{ m}}\right) = 0.0220\text{ kg/s}.$

EVALUATE: As a check, note that the oscillation frequency is the same as the undamped frequency to $4.8\times10^{-3}\%$, so our assumption of a small damping force is valid.

14.57. IDENTIFY and SET UP: Use $\omega' = \sqrt{(k/m)-(b^2/4m^2)}$ to calculate ω', and then $f' = \omega'/2\pi$.

(a) EXECUTE: $\omega' = \sqrt{(k/m)-(b^2/4m^2)} = \sqrt{\frac{2.50\text{ N/m}}{0.300\text{ kg}} - \frac{(0.900\text{ kg/s})^2}{4(0.300\text{ kg})^2}} = 2.47\text{ rad/s}$

$f' = \omega'/2\pi = (2.47\text{ rad/s})/2\pi = 0.393\text{ Hz}$

(b) IDENTIFY and SET UP: The condition for critical damping is $b = 2\sqrt{km}$.

EXECUTE: $b = 2\sqrt{(2.50\text{ N/m})(0.300\text{ kg})} = 1.73\text{ kg/s}$

EVALUATE: The value of b in part (a) is less than the critical damping value found in part (b). With no damping, the frequency is $f = 0.459\text{ Hz}$; the damping reduces the oscillation frequency.

14.58. IDENTIFY: The graph with the problem shows that the amplitude of vibration is decreasing, so the system must be losing mechanical energy.

SET UP: The mechanical energy is $E = \frac{1}{2}mv_x^2 + \frac{1}{2}kx^2$.

EXECUTE: **(a)** When $|x|$ is a maximum and the tangent to the curve is horizontal the speed of the mass is zero. This occurs at $t = 0$, $t = 1.0\text{ s}$, $t = 2.0\text{ s}$, $t = 3.0\text{ s}$ and $t = 4.0\text{ s}$.

(b) At $t = 0$, $v_x = 0$ and $x = 7.0\text{ cm}$ so $E_0 = \frac{1}{2}kx^2 = \frac{1}{2}(225\text{ N/m})(0.070\text{ m})^2 = 0.55\text{ J}$.

(c) At $t = 1.0\text{ s}$, $v_x = 0$ and $x = -6.0\text{ cm}$ so $E_1 = \frac{1}{2}kx^2 = \frac{1}{2}(225\text{ N/m})(-0.060\text{ m})^2 = 0.405\text{ J}$. At $t = 4.0\text{ s}$, $v_x = 0$ and $x = 3.0\text{ cm}$ so $E_4 = \frac{1}{2}kx^2 = \frac{1}{2}(225\text{ N/m})(0.030\text{ m})^2 = 0.101\text{ J}$. The mechanical energy "lost" is $E_1 - E_4 = 0.30\text{ J}$. The mechanical energy lost was converted to other forms of energy by nonconservative forces, such as friction, air resistance, and other dissipative forces.

EVALUATE: After a while the mass will come to rest and then all its initial mechanical energy will have been "lost" because it will have been converted to other forms of energy by nonconservative forces.

14.59. IDENTIFY: Apply $A = \frac{F_{\text{max}}}{\sqrt{\left(k - m\omega_d^2\right)^2 + b^2\omega_d^2}}$.

SET UP: $\omega_d = \sqrt{k/m}$ corresponds to resonance, and in this case $A = \frac{F_{\text{max}}}{\sqrt{\left(k - m\omega_d^2\right)^2 + b^2\omega_d^2}}$ reduces to $A = F_{\text{max}}/b\omega_d$.

EXECUTE: **(a)** $A_1/3$

(b) $2A_1$

EVALUATE: Note that the resonance frequency is independent of the value of b. (See Figure 14.28 in the textbook).

14.60. **IDENTIFY:** We are dealing with forced oscillations and resonance.

SET UP: Equation (14.46) gives $A = \dfrac{F_{\max}}{\sqrt{\left(k - m\omega_{\mathrm{d}}^2\right)^2 + b^2\omega_{\mathrm{d}}^2}}$, the amplitude A of a forced oscillator where $\omega = \sqrt{k/m}$ and $F_{\max}$ is the maximum value of the driving force. We want to investigate how varying the damping constant b affects the amplitude.

EXECUTE: **(a)** In this case, $b = 0.20\sqrt{km}$ and $\omega_{\mathrm{d}} = \omega = \sqrt{k/m}$, so A is

$$A = \frac{F_{\max}}{\sqrt{\left(k - m(k/m)\right)^2 + \left(0.20\sqrt{km}\right)^2\left(\sqrt{k/m}\right)^2}} = \frac{F_{\max}}{0.20k} = \frac{5F_{\max}}{k}.$$

(b) In this case, $b = 0.40\sqrt{km}$ and $\omega_{\mathrm{d}} = \omega = \sqrt{k/m}$, so A is

$$A = \frac{F_{\max}}{\sqrt{\left(0.40\sqrt{km}\right)^2 (k/m)}} = \frac{F_{\max}}{0.40k} = \frac{2.5F_{\max}}{k}.$$

(c) For $b = 0.20\sqrt{km}$ and $\omega_{\mathrm{d}} = \dfrac{\omega}{2} = \dfrac{1}{2}\sqrt{k/m}$, A is $A = \dfrac{F_{\max}}{\sqrt{\left(k - m(\omega^2/4)\right)^2 + \left(0.20\sqrt{km}\right)^2\left(\dfrac{1}{2}\sqrt{k/m}\right)^2}}$

$$= \frac{F_{\max}}{\sqrt{\left(k - m(k/4m)\right)^2 + (0.040km)(k/4m)}} = \frac{F_{\max}}{\sqrt{(3k/4)^2 + (0.010)k^2}} = \frac{F_{\max}}{0.20k} = \frac{1.3F_{\max}}{k}.$$

$$\frac{A_\omega}{A_{\omega/2}} = \frac{5F_{\max}/k}{1.32F_{\max}k} = 3.8.$$

For $b = 0.40\sqrt{km}$ and $\omega_{\mathrm{d}} = \dfrac{\omega}{2} = \dfrac{1}{2}\sqrt{k/m}$, $A = \dfrac{F_{\max}}{\sqrt{(3k/4)^2 + \left(0.40\sqrt{km}\right)^2\left(\dfrac{1}{2}\sqrt{k/m}\right)^2}} =$

$$\frac{F_{\max}}{\sqrt{(3k/4)^2 + (0.040)k^2}} = \frac{0.13F_{\max}}{k}.\quad \frac{A_\omega}{A_{\omega/2}} = \frac{2.5F_{\max}/k}{0.13F_{\max}k} = 1.9.$$

EVALUATE: The amplitude increases by a larger factor for $b = 0.20\sqrt{km}$ than for $b = 0.40\sqrt{km}$, which agrees with Fig. 14.28.

14.61. **IDENTIFY:** Two objects are in SHM on different springs, and we want to compare their maximum speed and maximum acceleration.

SET UP: We know that $v_{\max} = A\omega = A\sqrt{k/m}$ and $a_{\max} = \omega^2 A = (k/m)A.$

EXECUTE: **(a)** $\dfrac{v_{\max,A}}{v_{\max,B}} = \dfrac{\sqrt{\dfrac{k_A}{m_A}}A_A}{\sqrt{\dfrac{k_B}{m_B}}A_B} = \sqrt{\left(\dfrac{k_A}{k_B}\right)\left(\dfrac{m_B}{m_A}\right)}\left(\dfrac{A_A}{A_B}\right) = \sqrt{\left(\dfrac{9k_B}{k_B}\right)\left(\dfrac{4m_A}{m_A}\right)}\left(\dfrac{2A_B}{A_B}\right) = 12.$

(b) $\dfrac{a_{\max,A}}{a_{\max,B}} = \dfrac{\dfrac{k_A}{m_A}A_A}{\dfrac{k_B}{m_B}A_B} = \left(\dfrac{k_A}{k_B}\right)\left(\dfrac{m_B}{m_A}\right)\left(\dfrac{A_A}{A_B}\right) = \left(\dfrac{9k_B}{k_B}\right)\left(\dfrac{4m_A}{m_A}\right)\left(\dfrac{2A_B}{A_B}\right) = 72.$

EVALUATE: The ratio of the accelerations is considerably greater than that of the speeds because the acceleration depends on k/m while the speed depends on $\sqrt{k/m}$.

14.62. **IDENTIFY:** Apply $x(t) = A\cos(\omega t + \phi)$

SET UP: $x = A$ at $t = 0$, so $\phi = 0$. $A = 6.00$ cm. $\omega = \dfrac{2\pi}{T} = \dfrac{2\pi}{0.300 \text{ s}} = 20.9$ rad/s, so $x(t) = (6.00 \text{ cm})\cos[(20.9 \text{ rad/s})t]$.

EXECUTE: $t = 0$ at $x = 6.00$ cm. $x = -1.50$ cm when $-1.50 \text{ cm} = (6.00 \text{ cm})\cos[(20.9 \text{ rad/s})t]$.

$$t = \left(\frac{1}{20.9 \text{ rad/s}}\right)\arccos\left(\frac{1.50 \text{ cm}}{6.00 \text{ cm}}\right) = 0.0872 \text{ s}.$$ It takes 0.0872 s.

EVALUATE: It takes $t = T/4 = 0.075$ s to go from $x = 6.00$ cm to $x = 0$ and 0.150 s to go from $x = +6.00$ cm to $x = -6.00$ cm. Our result is between these values, as it should be.

14.63. IDENTIFY and **SET UP:** Calculate x using $x = A\cos(\omega t + \phi)$. Use T to find ω and x_0 to calculate ϕ.

EXECUTE: At $t = 0$, $x = 0$ and the object is traveling in the $-x$-direction, so $\phi = \pi/2$ rad.

Thus $x = A\cos(\omega t + \pi/2)$.

$T = 2\pi/\omega$ so $\omega = 2\pi/T = 2\pi/1.20 \text{ s} = 5.236$ rad/s

$x = (0.600 \text{ m})\cos[(5.236 \text{ rad/s})(0.480 \text{ s}) + \pi/2] = -0.353$ m.

The distance of the object from the equilibrium position is 0.353 m.

EVALUATE: It takes the object time $t = T/2 = 0.600$ s to return to $x = 0$, so at $t = 0.480$ s it is still at negative x.

14.64. IDENTIFY: $T = 2\pi\sqrt{\dfrac{m}{k}}$. The period changes when the mass changes.

SET UP: M is the mass of the empty car and the mass of the loaded car is $M + 250$ kg.

EXECUTE: The period of the empty car is $T_\text{E} = 2\pi\sqrt{\dfrac{M}{k}}$. The period of the loaded car is

$$T_\text{L} = 2\pi\sqrt{\frac{M + 250 \text{ kg}}{k}}. \quad k = \frac{(250 \text{ kg})(9.80 \text{ m/s}^2)}{4.00\times10^{-2} \text{ m}} = 6.125\times10^4 \text{ N/m}$$

$$M = \left(\frac{T_\text{L}}{2\pi}\right)^2 k - 250 \text{ kg} = \left(\frac{1.92 \text{ s}}{2\pi}\right)^2 (6.125\times10^4 \text{ N/m}) - 250 \text{ kg} = 5.469\times10^3 \text{ kg}.$$

$$T_\text{E} = 2\pi\sqrt{\frac{5.469\times10^3 \text{ kg}}{6.125\times10^4 \text{ N/m}}} = 1.88 \text{ s}.$$

EVALUATE: When the mass decreases, the period decreases.

14.65. IDENTIFY: An object is executing SHM on a spring.

SET UP: We want to change the spring so that the amplitude A_2 is half the original amplitude A_1 and the mechanical energy E_2 is 4 times its original value E_1. Our target variables are the new force constant k_2 and the new maximum speed $v_{2,\max}$ of the object. We know that $U_{\max} = \frac{1}{2}kA^2$, $E = K + U = K_{\max} = E_{\max}$, and $v_{\max} = A\omega = A\sqrt{k/m}$.

EXECUTE: (a) We want to relate k_2 to k_1. The original and final mechanical energies are $E_1 = \frac{1}{2}k_1A_1^2$ and $E_2 = \frac{1}{2}k_2A_2^2 = 4E_1 = 4\left(\frac{1}{2}k_1A_1^2\right)$, so $k_2 = 4\left(\dfrac{A_1}{A_2}\right)^2 k_1 = 4\left(\dfrac{2A_2}{A_2}\right)^2 k_1 = 16k_1$.

(b) Using $v_{\max} = A\omega = A\sqrt{k/m}$ and taking the ratio of the maximum speeds gives

$$\frac{v_{2,\max}}{v_{1,\max}} = \frac{\sqrt{\frac{k_2}{m}}A_2}{\sqrt{\frac{k_1}{m}}A_1} = \sqrt{\frac{k_2}{k_1}}\left(\frac{A_2}{A_1}\right) = \sqrt{\frac{16k_1}{k_1}}\left(\frac{A_2}{2A_2}\right) = 2,$$ so $v_{2,\max} = 2v_{1,\max}$.

EVALUATE: $E = \frac{1}{2}mv_{max}^2$, so if we increase E by a factor of 4, v_{max}^2 must increase by a factor of 4, so v_{max} must increase by a factor of 2, which is what we found in part (b).

14.66. IDENTIFY: In SHM, $a_{max} = \frac{k}{m_{tot}}A$. Apply $\sum \vec{F} = m\vec{a}$ to the top block.

SET UP: The maximum acceleration of the lower block can't exceed the maximum acceleration that can be given to the other block by the friction force.

EXECUTE: For block m, the maximum friction force is $f_s = \mu_s n = \mu_s mg$. $\sum F_x = ma_x$ gives $\mu_s mg = ma$ and $a = \mu_s g$. Then treat both blocks together and consider their simple harmonic motion. $a_{max} = \left(\frac{k}{M+m}\right)A$. Set $a_{max} = a$ and solve for A: $\mu_s g = \left(\frac{k}{M+m}\right)A$ and $A = \frac{\mu_s g(M+m)}{k}$.

EVALUATE: If A is larger than this the spring gives the block with mass M a larger acceleration than friction can give the other block, and the first block accelerates out from underneath the other block.

14.67. IDENTIFY: A block is moving with SHM on a spring. Using measurements of its maximum speed and mass, we will use graphical interpretation.

SET UP: $v_{max} = A\omega = A\sqrt{k/m}$. Our target variable is the force constant of the spring. The data is plotted as v_{max}^2 versus $1/m$, so we need to find a relation between these quantities to interpret the graph.

EXECUTE: Solving $v_{max} = A\omega = A\sqrt{k/m}$ gives $v_{max}^2 = (A^2k)(1/m)$, so a graph of v_{max}^2 versus $1/m$ should be a straight line having slope equal to A^2k. Therefore A^2k = slope = 8.62 $\text{N}\cdot\text{m}$, which gives k = (8.62 $\text{N}\cdot\text{m}$)/(0.120 m)^2 = 599 N/m.

EVALUATE: Converting 599 N/m to lb/in gives k = 3.42 lb/in. which is reasonable for a rather stiff spring.

14.68. IDENTIFY: Two blocks oscillate on a spring in SHM. One of them is accelerated only by static friction, so we'll need to use Newton's second law in addition to the principles of SHM.

SET UP: The maximum friction force on the upper block occurs when its acceleration is a maximum, and that occurs at $a_{max} = \omega^2 A$ for the SHM. For the block not to slip, $f_s = \mu_s n$. The target variable is the coefficient of static friction between the two blocks if the maximum distance that the spring can move from its equilibrium position without causing slipping is d = 8.8 cm. We know that $a_{max} = \omega^2 A$ and $T = 2\pi\sqrt{m/k}$ and will need to use $\sum F_x = ma_x$.

EXECUTE: **(a)** $T = 2\pi\sqrt{\frac{m}{k}} = 2\pi\sqrt{\frac{4.50\text{ kg}}{150\text{ N/m}}} = 1.09\text{ s}.$

(b) At d = 8.8 cm, f_s is at its maximum value, so $f_s = \mu_s n = \mu_s mg$. Only friction is accelerating the upper block, so $\sum F_x = ma_x$ gives $\mu_s mg = ma_x$. Now look at the system of two blocks (of total mass $m + M$) that are oscillating together. For the system, $\omega = \sqrt{k/m_{total}} = \sqrt{k/(m+M)}$, so $a_{max} = \omega^2 A = \left(\sqrt{k/(m+M)}\right)^2 d = \frac{kd}{m+M}$. Going back to $\sum F_x = ma_x$ gives $\mu_s mg = ma_{max} = m\left(\frac{kd}{m+M}\right)$. Which gives $\mu_s = \frac{kd}{g(m+M)} = \frac{(150\text{ N/m})(0.088\text{ m})}{(9.80\text{ m/s}^2)(4.50\text{ kg})} = 0.30.$

EVALUATE: According to Table 5.1, this value is about the same as for rubber on wet concrete, so it is reasonable.

14.69. IDENTIFY: The largest downward acceleration the ball can have is g whereas the downward acceleration of the tray depends on the spring force. When the downward acceleration of the tray is greater than g, then the ball leaves the tray. $y(t) = A\cos(\omega t + \phi)$.

SET UP: The downward force exerted by the spring is $F = kd$, where d is the distance of the object above the equilibrium point. The downward acceleration of the tray has magnitude $\frac{F}{m} = \frac{kd}{m}$, where m is the total mass of the ball and tray. $x = A$ at $t = 0$, so the phase angle ϕ is zero and $+x$ is downward.

EXECUTE: **(a)** $\frac{kd}{m} = g$ gives $d = \frac{mg}{k} = \frac{(1.775\text{ kg})(9.80\text{ m/s}^2)}{185\text{ N/m}} = 9.40\text{ cm}$. This point is 9.40 cm above the equilibrium point so is $9.40\text{ cm} + 15.0\text{ cm} = 24.4\text{ cm}$ above point A.

(b) $\omega = \sqrt{\frac{k}{m}} = \sqrt{\frac{185\text{ N/m}}{1.775\text{ kg}}} = 10.2\text{ rad/s}$. The point in (a) is above the equilibrium point so $x = -9.40\text{ cm}$.

$x = A\cos(\omega t)$ gives $\omega t = \arccos\left(\frac{x}{A}\right) = \arccos\left(\frac{-9.40\text{ cm}}{15.0\text{ cm}}\right) = 2.25\text{ rad}$. $t = \frac{2.25\text{ rad}}{10.2\text{ rad/s}} = 0.221\text{ s}$.

(c) $\frac{1}{2}kx^2 + \frac{1}{2}mv^2 = \frac{1}{2}kA^2$ gives $v = \sqrt{\frac{k}{m}(A^2 - x^2)} = \sqrt{\frac{185\text{ N/m}}{1.775\text{ kg}}([0.150\text{ m}]^2 - [-0.0940\text{ m}]^2)} = 1.19\text{ m/s}$.

EVALUATE: The period is $T = 2\pi\sqrt{\frac{m}{k}} = 0.615\text{ s}$. To go from the lowest point to the highest point takes time $T/2 = 0.308\text{ s}$. The time in (b) is less than this, as it should be.

14.70. **IDENTIFY:** Apply conservation of linear momentum to the collision and conservation of energy to the motion after the collision. $f = \frac{1}{2\pi}\sqrt{\frac{k}{m}}$ and $T = \frac{1}{f}$.

SET UP: The object returns to the equilibrium position in time $T/2$.

EXECUTE: **(a)** Momentum conservation during the collision: $mv_0 = (2m)V$.

$$V = \frac{1}{2}v_0 = \frac{1}{2}(2.00\text{ m/s}) = 1.00\text{ m/s}.$$

Energy conservation after the collision: $\frac{1}{2}MV^2 = \frac{1}{2}kx^2$.

$$x = \sqrt{\frac{MV^2}{k}} = \sqrt{\frac{(20.0\text{ kg})(1.00\text{ m/s})^2}{170.0\text{ N/m}}} = 0.343\text{ m (amplitude)}$$

$\omega = 2\pi f = \sqrt{k/M}$. $f = \frac{1}{2\pi}\sqrt{k/M} = \frac{1}{2\pi}\sqrt{\frac{170.0\text{ N/m}}{20.0\text{ kg}}} = 0.464\text{ Hz}$. $T = \frac{1}{f} = \frac{1}{0.464\text{ Hz}} = 2.16\text{ s}$.

(b) It takes $1/2$ period to first return: $\frac{1}{2}(2.16\text{ s}) = 1.08\text{ s}$.

EVALUATE: The total mechanical energy of the system determines the amplitude. The frequency and period depend only on the force constant of the spring and the mass that is attached to the spring.

14.71. **IDENTIFY** and **SET UP:** The bounce frequency is given by $f = \frac{1}{2\pi}\sqrt{\frac{k}{m}}$ and the pendulum frequency by $f = \frac{1}{2\pi}\sqrt{\frac{g}{L}}$. Use the relation between these two frequencies that is specified in the problem to calculate the equilibrium length L of the spring, when the apple hangs at rest on the end of the spring.

EXECUTE: Vertical SHM: $f_b = \frac{1}{2\pi}\sqrt{\frac{k}{m}}$

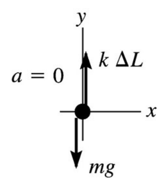
Pendulum motion (small amplitude): $f_p = \frac{1}{2\pi}\sqrt{\frac{g}{L}}$

The problem specifies that $f_{\text{p}} = \frac{1}{2} f_{\text{b}}$, so $\frac{1}{2\pi}\sqrt{\frac{g}{L}} = \frac{1}{2}\frac{1}{2\pi}\sqrt{\frac{k}{m}}$. Thus $g/L = k/4m$, which gives $L = 4gm/k = 4w/k = 4(1.00 \text{ N})/1.50 \text{ N/m} = 2.67 \text{ m}$.

EVALUATE: This is the *stretched* length of the spring, its length when the apple is hanging from it. (Note: Small angle of swing means *v* is small as the apple passes through the lowest point, so a_{rad} is small and the component of *mg* perpendicular to the spring is small. Thus the amount the spring is stretched changes very little as the apple swings back and forth.)

IDENTIFY: Use Newton's second law to calculate the distance the spring is stretched from its unstretched length when the apple hangs from it.

SET UP: The free-body diagram for the apple hanging at rest on the end of the spring is given in Figure 14.71.



EXECUTE: $\sum F_y = ma_y$

$k\Delta L - mg = 0$

$\Delta L = mg/k = w/k = 1.00 \text{ N}/1.50 \text{ N/m} = 0.667 \text{ m}$.

Thus the unstretched length of the spring is

$$2.67 \text{ m} - 0.67 \text{ m} = 2.00 \text{ m}.$$

Figure 14.71

EVALUATE: The spring shortens to its unstretched length when the apple is removed.

14.72. **IDENTIFY:** The vertical forces on the floating object must sum to zero. The buoyant force *B* applied to the object by the liquid is given by Archimedes's principle. The motion is SHM if the net force on the object is of the form $F_y = -ky$ and then $T = 2\pi\sqrt{m/k}$.

SET UP: Take $+y$ to be downward.

EXECUTE: **(a)** $V_{\text{submerged}} = LA$, where *L* is the vertical distance from the surface of the liquid to the bottom of the object. Archimedes's principle states $\rho gLA = Mg$, so $L = \frac{M}{\rho A}$.

(b) The buoyant force is $\rho gA(L + y) = Mg + F$, where *y* is the additional distance the object moves downward. Using the result of part (a) and solving for *y* gives $y = \frac{F}{\rho gA}$.

(c) The net force is $F_{\text{net}} = Mg - \rho gA(L + y) = -\rho gAy$. $k = \rho gA$, and the period of oscillation is

$$T = 2\pi\sqrt{\frac{M}{k}} = 2\pi\sqrt{\frac{M}{\rho gA}}.$$

EVALUATE: The force *F* determines the amplitude of the motion but the period does not depend on how much force was applied.

14.73. **IDENTIFY:** The object oscillates as a physical pendulum, so $f = \frac{1}{2\pi}\sqrt{\frac{m_{\text{object}} gd}{I}}$. Use the parallel-axis theorem, $I = I_{\text{cm}} + Md^2$, to find the moment of inertia of each stick about an axis at the hook.

SET UP: The center of mass of the square object is at its geometrical center, so its distance from the hook is $L\cos 45° = L/\sqrt{2}$. The center of mass of each stick is at its geometrical center. For each stick, $I_{\text{cm}} = \frac{1}{12} mL^2$.

EXECUTE: The parallel-axis theorem gives I for each stick for an axis at the center of the square to be $\frac{1}{12}mL^2 + m(L/2)^2 = \frac{1}{3}mL^2$ and the total I for this axis is $\frac{4}{3}mL^2$. For the entire object and an axis at the hook, applying the parallel-axis theorem again to the object of mass $4m$ gives
$I = \frac{4}{3}mL^2 + 4m(L/\sqrt{2})^2 = \frac{10}{3}mL^2$.

$$f = \frac{1}{2\pi}\sqrt{\frac{m_{\text{object}}gd}{I}} = \frac{1}{2\pi}\sqrt{\frac{4m_{\text{object}}gL/\sqrt{2}}{\frac{10}{3}m_{\text{object}}L^2}} = \sqrt{\frac{6}{5\sqrt{2}}}\left(\frac{1}{2\pi}\sqrt{\frac{g}{L}}\right) = 0.921\left(\frac{1}{2\pi}\sqrt{\frac{g}{L}}\right).$$

EVALUATE: Just as for a simple pendulum, the frequency is independent of the mass. A simple pendulum of length L has frequency $f = \frac{1}{2\pi}\sqrt{\frac{g}{L}}$ and this object has a frequency that is slightly less than this.

14.74. IDENTIFY: Conservation of energy says $K + U = E$.

SET UP: $U = \frac{1}{2}kx^2$ and $E = U_{\max} = \frac{1}{2}kA^2$.

EXECUTE: **(a)** The graph is given in Figure 14.74. The following answers are found algebraically, to be used as a check on the graphical method.

(b) $A = \sqrt{\frac{2E}{k}} = \sqrt{\frac{2(0.200\text{ J})}{(10.0\text{ N/m})}} = 0.200\text{ m}$.

(c) $\frac{E}{4} = 0.050\text{ J}$.

(d) $U = \frac{1}{2}E.\;\; x = \frac{A}{\sqrt{2}} = 0.141\text{ m}$.

(e) From Eq. (14.18), using $v_0 = \sqrt{\frac{2K_0}{m}}$ and $x_0 = -\sqrt{\frac{2U_0}{k}}$, $-\frac{v_0}{\omega x_0} = \frac{\sqrt{(2K_0/m)}}{\sqrt{(k/m)}\sqrt{(2U_0/k)}} = \sqrt{\frac{K_0}{U_0}} = \sqrt{0.429}$

and $\phi = \arctan(\sqrt{0.429}) = 3.72\text{ rad}$.

EVALUATE: The dependence of U on x is not linear and $U = \frac{1}{2}U_{\max}$ does not occur at $x = \frac{1}{2}x_{\max}$.

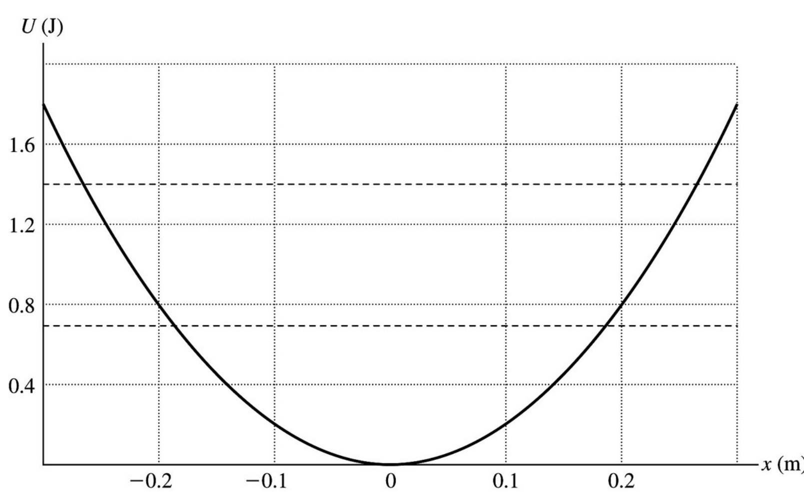


Figure 14.74

14.75. IDENTIFY: $T = 2\pi\sqrt{\frac{m}{k}}$ so the period changes because the mass changes.

SET UP: $\dfrac{dm}{dt} = -2.00\times10^{-3}$ kg/s. The rate of change of the period is $\dfrac{dT}{dt}$.

EXECUTE: **(a)** When the bucket is half full, $m = 7.00$ kg. $T = 2\pi\sqrt{\dfrac{7.00\text{ kg}}{450\text{ N/m}}} = 0.784$ s.

(b) $\dfrac{dT}{dt} = \dfrac{2\pi}{\sqrt{k}}\dfrac{d}{dt}(m^{1/2}) = \dfrac{2\pi}{\sqrt{k}}\tfrac{1}{2}m^{-1/2}\dfrac{dm}{dt} = \dfrac{\pi}{\sqrt{mk}}\dfrac{dm}{dt}$.

$\dfrac{dT}{dt} = \dfrac{\pi}{\sqrt{(7.00\text{ kg})(450\text{ N/m})}}(-2.00\times10^{-3}\text{ kg/s}) = -1.12\times10^{-4}$ s per s. $\dfrac{dT}{dt}$ is negative, so the period is getting shorter.

(c) The shortest period is when all the water has leaked out and $m = 2.00$ kg. In that case, $T = 2\pi\sqrt{m/k} = 0.419$ s.

EVALUATE: The rate at which the period changes is not constant but instead increases in time, even though the rate at which the water flows out is constant.

14.76. **IDENTIFY:** We are looking at molecular vibrations of the HI molecule.

SET UP: The classical frequency is $f = \dfrac{1}{2\pi}\sqrt{\dfrac{k}{m}}$, where $m \approx m_{\text{proton}} = 1.6726\times10^{-27}$ kg.

EXECUTE: **(a)** We want the force constant of the HI molecule, assuming that only the H atom moves significantly. Solve $f = \dfrac{1}{2\pi}\sqrt{\dfrac{k}{m}}$ for *k*, giving $k = 4\pi^2 mf^2$ from which we have

$k = 4\pi^2(1.6726\times10^{-27}\text{ kg})(7\times10^{13}\text{ Hz})^2$ = 300k N/m.

(b) $E_{\text{vibr}} = \dfrac{1}{2}mv^2$ so $v = \sqrt{\dfrac{2E_{\text{vibr}}}{m}} = \sqrt{\dfrac{2(5\times10^{-20}\text{ J})}{1.6726\times10^{-27}\text{ kg}}} = 7700\text{ m/s} - 8\text{ km/s}$.

(c) $E = \dfrac{1}{2}kA^2$ so $A = \sqrt{\dfrac{2E}{k}} = \sqrt{\dfrac{2(5\times10^{-20}\text{ J})}{300\text{ N/m}}} \approx 2\times10^{-11}$ m. This result is a little more than 1/10 the equilibrium distance.

EVALUATE: These results are not bad for a rough calculation.

14.77. **IDENTIFY** and **SET UP:** Measure *x* from the equilibrium position of the object, where the gravity and spring forces balance. Let $+x$ be downward.

(a) Use conservation of energy $\tfrac{1}{2}mv_x^2 + \tfrac{1}{2}kx^2 = \tfrac{1}{2}kA^2$ to relate v_x and *x*. Use $T = 2\pi\sqrt{\dfrac{m}{k}}$ to relate *T* to *k/m*.

EXECUTE: $\tfrac{1}{2}mv_x^2 + \tfrac{1}{2}kx^2 = \tfrac{1}{2}kA^2$

For $x = 0, \tfrac{1}{2}mv_x^2 = \tfrac{1}{2}kA^2$ and $v = A\sqrt{k/m}$, just as for horizontal SHM. We can use the period to calculate $\sqrt{k/m} : T = 2\pi\sqrt{m/k}$ implies $\sqrt{k/m} = 2\pi/T$. Thus $v = 2\pi A/T = 2\pi(0.100\text{ m})/4.20\text{ s} = 0.150\text{ m/s}$.

(b) **IDENTIFY** and **SET UP:** Use $a_x = -\dfrac{k}{m}x$ to relate a_x and *x*.

EXECUTE: $ma_x = -kx$ so $a_x = -(k/m)x$

+*x*-direction is downward, so here $x = -0.050$ m

$a_x = -(2\pi/T)^2(-0.050\text{ m}) = +(2\pi/4.20\text{ s})^2(0.050\text{ m}) = 0.112\text{ m/s}^2$ (positive, so direction is downward)

(c) **IDENTIFY** and **SET UP:** Use $x = A\cos(\omega t + \phi)$ to relate *x* and *t*. The time asked for is twice the time it takes to go from $x = 0$ to $x = +0.050$ m.

EXECUTE: $x(t) = A\cos(\omega t + \phi)$

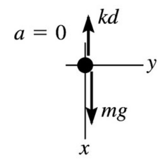
Let $\phi = -\pi/2$, so $x = 0$ at $t = 0$. Then $x = A\cos(\omega t - \pi/2) = A\sin\omega t = A\sin(2\pi t/T)$. Find the time t that gives $x = +0.050$ m: $0.050 \text{ m} = (0.100 \text{ m}) \sin(2\pi t/T)$

$2\pi t/T = \arcsin(0.50) = \pi/6$ and $t = T/12 = 4.20 \text{ s}/12 = 0.350$ s

The time asked for in the problem is twice this, 0.700 s.

(d) IDENTIFY: The problem is asking for the distance d that the spring stretches when the object hangs at rest from it. Apply Newton's second law to the object.

SET UP: The free-body diagram for the object is given in Figure 14.77.



EXECUTE: $\sum F_x = ma_x$

$mg - kd = 0$

$d = (m/k)g$

Figure 14.77

But $\sqrt{k/m} = 2\pi/T$ (part (a)) and $m/k = (T/2\pi)^2$

$$d = \left(\frac{T}{2\pi}\right)^2 g = \left(\frac{4.20 \text{ s}}{2\pi}\right)^2 (9.80 \text{ m/s}^2) = 4.38 \text{ m.}$$

EVALUATE: When the displacement is upward (part (b)), the acceleration is downward. The mass of the partridge is never entered into the calculation. We used just the ratio k/m, that is determined from T.

14.78. IDENTIFY: The rod is a physical pendulum. We will need to do graphical analysis.

SET UP: The period of a physical pendulum is $T = 2\pi\sqrt{\dfrac{I}{mgd}}$, where d is the distance from the rotation axis to the center of gravity of the rod. We want to find I_{cm} about the center of mass of the rod, which is at its center. Therefore we need to derive a relation between I_{cm} and d so we can interpret the graph.

EXECUTE: In the formula $T = 2\pi\sqrt{\dfrac{I}{mgd}}$, I is the moment of inertia of the rod about the rotation axis, which is a distance d from the center of the rod. But we want I_{cm} about the center of gravity of the rod. Using the parallel-axis theorem from Chapter 9, we have $I = I_{cm} + md^2$. Therefore the period is $T = 2\pi\sqrt{\dfrac{I_{cm} + md^2}{mgd}}$. Solving for T^2 gives $T^2 = 4\pi^2\left(\dfrac{I_{cm} + md^2}{mgd}\right) = \dfrac{4\pi^2 I_{cm}}{mgd} + \dfrac{4\pi^2 d}{g}$. Rearranging gives $T^2 - \dfrac{4\pi^2 d}{g} = \left(\dfrac{4\pi^2 I_{cm}}{mg}\right)\dfrac{1}{d}$. Now we can see that a graph of $T^2 - \dfrac{4\pi^2 d}{g}$ versus $1/d$ should be a straight line having slope equal to $\dfrac{4\pi^2 I_{cm}}{mg}$. Therefore $\dfrac{4\pi^2 I_{cm}}{mg} = \text{slope}$. Solving for I_{cm} gives us

$I_{cm} = mg(\text{slope})/4\pi^2 = (0.400 \text{ kg})(9.80 \text{ m/s}^2)(0.320 \text{ m}\cdot\text{s}^2)/(4\pi^2) = 0.0318 \text{ kg}\cdot\text{m}^2$.

EVALUATE: If this rod were uniform, its moment of inertia about its center of gravity would be $I = \dfrac{1}{12}ML^2 = \dfrac{1}{12}(0.400 \text{ kg})(0.800 \text{ m})^2 = 0.0213 \text{ kg}\cdot\text{m}^2$. This is less than we found above, so the nonuniform rod must have more mass toward its ends than a uniform rod. Its density must increase with distance from the center.

14.79. **IDENTIFY:** Apply conservation of linear momentum to the collision between the steak and the pan. Then apply conservation of energy to the motion after the collision to find the amplitude of the subsequent SHM. Use $T = 2\pi\sqrt{\frac{m}{k}}$ to calculate the period.

(a) SET UP: First find the speed of the steak just before it strikes the pan. Use a coordinate system with $+y$ downward.

$v_{0y} = 0$ (released from the rest); $y - y_0 = 0.40$ m; $a_y = +9.80\ \text{m/s}^2$; $v_y = ?$

$v_y^2 = v_{0_y}^2 + 2a_y(y - y_0)$

EXECUTE: $v_y = +\sqrt{2a_y(y - y_0)} = +\sqrt{2(9.80\ \text{m/s}^2)(0.40\ \text{m})} = +2.80\ \text{m/s}$

SET UP: Apply conservation of momentum to the collision between the steak and the pan. After the collision the steak and the pan are moving together with common velocity v_2. Let *A* be the steak and *B* be the pan. The system before and after the collision is shown in Figure 14.79.

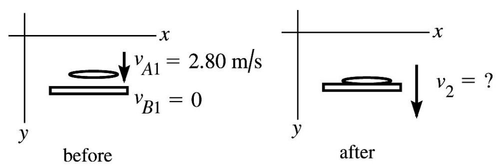


Figure 14.79

EXECUTE: P_y conserved: $m_A v_{A1y} + m_B v_{B1y} = (m_A + m_B)v_{2y}$

$m_A v_{A1} = (m_A + m_B)v_2$

$$v_2 = \left(\frac{m_A}{m_A + m_B}\right)v_{A1} = \left(\frac{2.2\ \text{kg}}{2.2\ \text{kg} + 0.20\ \text{kg}}\right)(2.80\ \text{m/s}) = 2.57\ \text{m/s}$$

(b) SET UP: Conservation of energy applied to the SHM gives: $\frac{1}{2}mv_0^2 + \frac{1}{2}kx_0^2 = \frac{1}{2}kA^2$ where v_0 and x_0 are the initial speed and displacement of the object and where the displacement is measured from the equilibrium position of the object.

EXECUTE: The weight of the steak will stretch the spring an additional distance *d* given by $kd = mg$ so $d = \frac{mg}{k} = \frac{(2.2\ \text{kg})(9.80\ \text{m/s}^2)}{400\ \text{N/m}} = 0.0539\ \text{m}.$ So just after the steak hits the pan, before the pan has had time to move, the steak plus pan is 0.0539 m above the equilibrium position of the combined object. Thus $x_0 = 0.0539$ m. From part (a) $v_0 = 2.57$ m/s, the speed of the combined object just after the collision. Then $\frac{1}{2}mv_0^2 + \frac{1}{2}kx_0^2 = \frac{1}{2}kA^2$ gives

$$A = \sqrt{\frac{mv_0^2 + kx_0^2}{k}} = \sqrt{\frac{2.4\ \text{kg}(2.57\ \text{m/s})^2 + (400\ \text{N/m})(0.0539\ \text{m})^2}{400\ \text{N/m}}} = 0.21\ \text{m}$$

(c) $T = 2\pi\sqrt{m/k} = 2\pi\sqrt{\frac{2.4\ \text{kg}}{400\ \text{N/m}}} = 0.49\ \text{s}$

EVALUATE: The amplitude is less than the initial height of the steak above the pan because mechanical energy is lost in the inelastic collision.

14.80. **IDENTIFY:** $F_x = -kx$ allows us to calculate *k*. $T = 2\pi\sqrt{m/k}$. $x(t) = A\cos(\omega t + \phi)$. $F_{\text{net}} = -kx$.

SET UP: Let $\phi = \pi/2$ so $x(t) = A\sin(\omega t)$. At $t = 0$, $x = 0$ and the object is moving downward. When the object is below the equilibrium position, F_{spring} is upward.

EXECUTE: **(a)** Solving $T = 2\pi\sqrt{m/k}$ for m, and using $k = \dfrac{F}{\Delta l}$ gives

$$m = \left(\frac{T}{2\pi}\right)^2 \frac{F}{\Delta l} = \left(\frac{1.00 \text{ s}}{2\pi}\right)^2 \frac{40.0 \text{ N}}{0.250 \text{ m}} = 4.05 \text{ kg}.$$

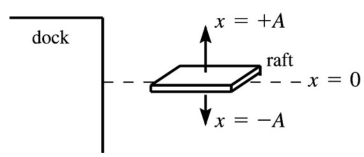
(b) $t = (0.35)T,$ and so $x = -A\sin[2\pi(0.35)] = -0.0405$ m. Since $t > T/4,$ the mass has already passed the lowest point of its motion, and is on the way up.

(c) Taking upward forces to be positive, $F_{\text{spring}} - mg = -kx,$ where x is the displacement from equilibrium, so $F_{\text{spring}} = -(160 \text{ N/m})(-0.030 \text{ m}) + (4.05 \text{ kg})(9.80 \text{ m/s}^2) = 44.5 \text{ N}.$

EVALUATE: When the object is below the equilibrium position the net force is upward and the upward spring force is larger in magnitude than the downward weight of the object.

14.81. **IDENTIFY**: Use $x = A\cos(\omega t + \phi)$ to relate x and t. $T = 3.5$ s.

SET UP: The motion of the raft is sketched in Figure 14.81.



Let the raft be at $x = +A$ when $t = 0.$ Then $\phi = 0$ and $x(t) = A\cos\omega t.$

Figure 14.81

EXECUTE: Calculate the time it takes the raft to move from $x = +A = +0.200$ m to $x =$ $A - 0.100 \text{ m} = 0.100$ m.

Write the equation for $x(t)$ in terms of T rather than ω: $\omega = 2\pi/T$ gives that $x(t) = A\cos(2\pi t/T)$

$x = A$ at $t = 0$

$x = 0.100$ m implies $0.100 \text{ m} = (0.200 \text{ m}) \cos(2\pi t/T)$

$\cos\ (2\pi t/T) = 0.500$ so $2\pi t/T = \arccos(0.500) = 1.047$ rad

$t = (T/2\pi)(1.047 \text{ rad}) = (3.5 \text{ s}/2\pi)(1.047 \text{ rad}) = 0.583$ s

This is the time for the raft to move down from $x = 0.200$ m to $x = 0.100$ m. But people can also get off while the raft is moving up from $x = 0.100$ m to $x = 0.200$ m, so during each period of the motion the time the people have to get off is $2t = 2(0.583 \text{ s}) = 1.17$ s.

EVALUATE: The time to go from $x = 0$ to $x = A$ and return is $T/2 = 1.75$ s. The time to go from $x = A/2$ to A and return is less than this.

14.82. **IDENTIFY**: $T = 2\pi/\omega.$ $F_r(r) = -kr$ to determine k.

SET UP: Example 13.10 derives $F_r(r) = -\dfrac{GM_{\text{E}}m}{R_{\text{E}}^3}r.$

EXECUTE: $F_r(r) = -\dfrac{GM_{\text{E}}m}{R_{\text{E}}^3}r$ is in the form of $F = -kx$, with x replaced by r, so the motion is simple harmonic. $k = \dfrac{GM_{\text{E}}m}{R_{\text{E}}^3}.$ $\omega^2 = \dfrac{k}{m} = \dfrac{GM_{\text{E}}}{R_{\text{E}}^3} = \dfrac{g}{R_{\text{E}}}.$ The period is then

$$T = \frac{2\pi}{\omega} = 2\pi\sqrt{\frac{R_{\text{E}}}{g}} = 2\pi\sqrt{\frac{6.37\times 10^6 \text{ m}}{9.80 \text{ m/s}^2}} = 5070 \text{ s, or } 84.5 \text{ min.}$$

EVALUATE: The period is independent of the mass of the object but does depend on R_{E}, which is also the amplitude of the motion.

14.83. **IDENTIFY**: During the collision, linear momentum is conserved. After the collision, mechanical energy is conserved and the motion is SHM.

SET UP: The linear momentum is $p_x = mv_x$, the kinetic energy is $\frac{1}{2}mv^2$, and the potential energy is $\frac{1}{2}kx^2$. The period is $T = 2\pi\sqrt{\frac{m}{k}}$, which is the target variable.

EXECUTE: Apply conservation of linear momentum to the collision:

$(8.00\times10^{-3}\text{ kg})(280\text{ m/s}) = (1.00\text{ kg})v.$ $v = 2.24\text{ m/s}.$ This is v_{max} for the SHM. $A = 0.150\text{ m}$ (given).So $\frac{1}{2}mv_{\text{max}}^2 = \frac{1}{2}kA^2.$ $k = \left(\frac{v_{\text{max}}}{A}\right)^2 m = \left(\frac{2.24\text{ m/s}}{0.150\text{ m}}\right)^2(1.00\text{ kg}) = 223.0\text{ N/m}.$

$T = 2\pi\sqrt{\frac{m}{k}} = 2\pi\sqrt{\frac{1.00\text{ kg}}{223.0\text{ N/m}}} = 0.421\text{ s}.$

EVALUATE: This block would weigh about 2 pounds, which is rather heavy, but the spring constant is large enough to keep the period within an easily observable range.

14.84. **IDENTIFY:** Newton's second law, in both its linear and rotational form, applies to this system. The motion is SHM.

SET UP: $\sum F = ma_{\text{cm}}$ and $\sum\tau = I\alpha$, where $I = \frac{2}{5}MR^2$ for a solid sphere, and $R\alpha = a_{\text{cm}}$ with no slipping.

EXECUTE: For each sphere, $f_s R = \left(\frac{2}{5}MR^2\right)\alpha.$ $R\alpha = a_{\text{cm}}.$ $f_s = \frac{2}{5}Ma_{\text{cm}}.$ For the system of two spheres,

$2f_s - kx = -2Ma_{\text{cm}}.$ $\frac{4}{5}Ma_{\text{cm}} - kx = -2Ma_{\text{cm}}.$ $kx = \frac{14}{5}Ma_{\text{cm}}$ and $a_{\text{cm}} = \frac{5}{14}\left(\frac{k}{M}\right)x.$ $a_x = -\frac{5}{14}\left(\frac{k}{M}\right)x.$

$a_x = -\omega^2 x$ so $\omega = \sqrt{\frac{5k}{14M}}.$ $T = \frac{2\pi}{\omega} = 2\pi\sqrt{\frac{14M}{5k}} = 2\pi\sqrt{\frac{14(0.800\text{ kg})}{5(160\text{ N/m})}} = 0.743\text{ s}.$

EVALUATE: If the surface were smooth, there would be no rolling, but the presence of friction provides the torque to cause the spheres to rotate.

14.85. **IDENTIFY**: Apply conservation of energy to the motion before and after the collision. Apply conservation of linear momentum to the collision. After the collision the system moves as a simple pendulum. If the maximum angular displacement is small, $f = \frac{1}{2\pi}\sqrt{\frac{g}{L}}.$

SET UP: In the motion before and after the collision there is energy conversion between gravitational potential energy mgh, where h is the height above the lowest point in the motion, and kinetic energy.

EXECUTE: Energy conservation during downward swing: $m_2gh_0 = \frac{1}{2}m_2v^2$ and

$v = \sqrt{2gh_0} = \sqrt{2(9.8\text{ m/s}^2)(0.100\text{ m})} = 1.40\text{ m/s}.$

Momentum conservation during collision: $m_2v = (m_2 + m_3)V$ and

$V = \frac{m_2v}{m_2 + m_3} = \frac{(2.00\text{ kg})(1.40\text{ m/s})}{5.00\text{ kg}} = 0.560\text{ m/s}.$

Energy conservation during upward swing: $Mgh_f = \frac{1}{2}MV^2$ and

$h_f = V^2/2g = \frac{(0.560\text{ m/s})^2}{2(9.80\text{ m/s}^2)} = 0.0160\text{ m} = 1.60\text{ cm}.$

Figure 14.85 shows how the maximum angular displacement is calculated from h_{f}. $\cos\theta = \dfrac{48.4 \text{ cm}}{50.0 \text{ cm}}$ and $\theta = 14.5°$. $f = \dfrac{1}{2\pi}\sqrt{\dfrac{g}{l}} = \dfrac{1}{2\pi}\sqrt{\dfrac{9.80 \text{ m/s}^2}{0.500 \text{ m}}} = 0.705 \text{ Hz}.$

EVALUATE: $14.5° = 0.253$ rad. $\sin(0.253 \text{ rad}) = 0.250$. $\sin\theta \approx \theta$ and the equation $f = \dfrac{1}{2\pi}\sqrt{\dfrac{g}{L}}$ is accurate.

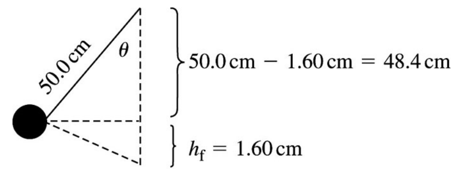


Figure 14.85

14.86. **IDENTIFY** and **SET UP:** $T = 2\pi\sqrt{\dfrac{I}{mgd}}$ gives the period for the bell and $T = 2\pi\sqrt{L/g}$ gives the period for the clapper.
EXECUTE: The bell swings as a physical pendulum so its period of oscillation is given by
$T = 2\pi\sqrt{I/mgd} = 2\pi\sqrt{18.0 \text{ kg}\cdot\text{m}^2/(34.0 \text{ kg})(9.80 \text{ m/s}^2)(0.60 \text{ m})} = 1.885 \text{ s}.$
The clapper is a simple pendulum so its period is given by $T = 2\pi\sqrt{L/g}$.
Thus $L = g(T/2\pi)^2 = (9.80 \text{ m/s}^2)(1.885 \text{ s}/2\pi)^2 = 0.88 \text{ m}.$
EVALUATE: If the cm of the bell were at the geometrical center of the bell, the bell would extend 1.20 m from the pivot, so the clapper is well inside the bell.

14.87. **IDENTIFY**: The motion is simple harmonic if the equation of motion for the angular oscillations is of the form $\dfrac{d^2\theta}{dt^2} = -\dfrac{\kappa}{I}\theta$, and in this case the period is $T = 2\pi\sqrt{I/\kappa}$.

SET UP: For a slender rod pivoted about its center, $I = \frac{1}{12}ML^2$.

EXECUTE: The torque on the rod about the pivot is $\tau = -\left(k\dfrac{L}{2}\theta\right)\dfrac{L}{2}$. $\tau = I\alpha = I\dfrac{d^2\theta}{dt^2}$ gives

$\dfrac{d^2\theta}{dt^2} = -k\dfrac{L^2/4}{I}\theta = -\dfrac{3k}{M}\theta.$ $\dfrac{d^2\theta}{dt^2}$ is proportional to θ and the motion is angular SHM. $\dfrac{\kappa}{I} = \dfrac{3k}{M}$,
$T = 2\pi\sqrt{\dfrac{M}{3k}}.$

EVALUATE: The expression we used for the torque, $\tau = -\left(k\dfrac{L}{2}\theta\right)\dfrac{L}{2}$, is valid only when θ is small enough for $\sin\theta \approx \theta$ and $\cos\theta \approx 1$.

14.88. **IDENTIFY**: The object oscillates as a physical pendulum, with $f = \dfrac{1}{2\pi}\sqrt{\dfrac{Mgd}{I}}$, where $M = 2m$ is the total mass of the object.
SET UP: The moment of inertia about the pivot is $2(1/3)ML^2 = (2/3)\,ML^2$, and the center of gravity when balanced is a distance $d = L/(2\sqrt{2})$ below the pivot.

EXECUTE: The frequency is $f = \dfrac{1}{T} = \dfrac{1}{2\pi}\sqrt{\dfrac{6g}{4\sqrt{2}L}} = \dfrac{1}{4\pi}\sqrt{\dfrac{6g}{\sqrt{2}L}}.$

EVALUATE: If $f_{\text{sp}} = \dfrac{1}{2\pi}\sqrt{\dfrac{g}{L}}$ is the frequency for a simple pendulum of length L,

$f = \dfrac{1}{2}\sqrt{\dfrac{6}{\sqrt{2}}} f_{\text{sp}} = 1.03 f_{\text{sp}}.$

14.89. IDENTIFY: The velocity is a sinusoidal function. From the graph we can read off the period and use it to calculate the other quantities.

SET UP: The period is the time for 1 cycle; after time T the motion repeats. The graph shows that $T = 1.60$ s and $v_{\max} = 20.0$ cm/s. Mechanical energy is conserved, so $\frac{1}{2}mv_x^2 + \frac{1}{2}kx^2 = \frac{1}{2}kA^2$, and Newton's second law applies to the mass.

EXECUTE: **(a)** $T = 1.60$ s (from the graph with the problem).

(b) $f = \dfrac{1}{T} = 0.625$ Hz.

(c) $\omega = 2\pi f = 3.93$ rad/s.

(d) $v_x = v_{\max}$ when $x = 0$ so $\frac{1}{2}kA^2 = \frac{1}{2}mv_{\max}^2$. $A = v_{\max}\sqrt{\dfrac{m}{k}}$. $f = \dfrac{1}{2\pi}\sqrt{\dfrac{k}{m}}$ so $A = v_{\max}/(2\pi f)$. From the graph in the problem, $v_{\max} = 0.20$ m/s, so $A = \dfrac{0.20\text{ m/s}}{2\pi(0.625\text{ Hz})} = 0.051\text{ m} = 5.1\text{ cm}$. The mass is at $x = \pm A$ when $v_x = 0$, and this occurs at $t = 0.4$ s, 1.2 s, and 1.8 s.

(e) Newton's second law gives $-kx = ma_x$, so

$a_{\max} = \dfrac{kA}{m} = (2\pi f)^2 A = (4\pi^2)(0.625\text{ Hz})^2(0.051\text{ m}) = 0.79\text{ m/s}^2 = 79\text{ cm/s}^2$. The acceleration is maximum when $x = \pm A$ and this occurs at the times given in (d).

(f) $T = 2\pi\sqrt{\dfrac{m}{k}}$ so $m = k\left(\dfrac{T}{2\pi}\right)^2 = (75\text{ N/m})\left(\dfrac{1.60\text{ s}}{2\pi}\right)^2 = 4.9$ kg.

EVALUATE: The speed is maximum at $x = 0$, when $a_x = 0$. The magnitude of the acceleration is maximum at $x = \pm A$, where $v_x = 0$.

14.90. IDENTIFY and SET UP: As stated in the problem, $T = 2\pi\sqrt{\dfrac{m + m_{\text{eff}}}{k}}$.

EXECUTE: **(a)** The graph of T^2 versus m is shown in Figure 14.90. Note that the times given in the table with the problem are for 10 oscillations, so we must divide each of them by 10 to get the period.

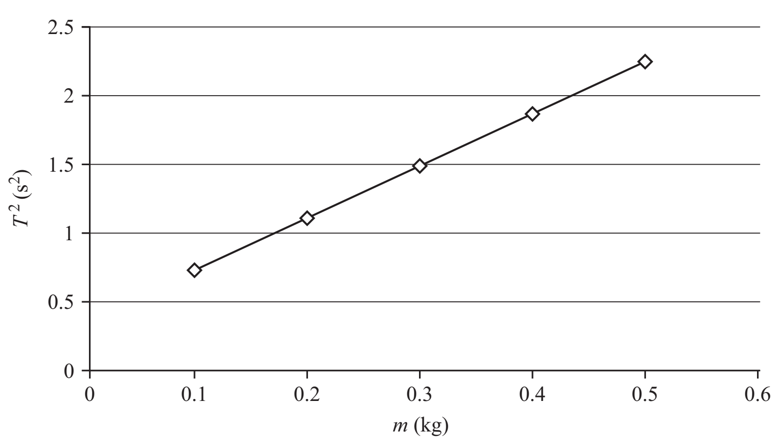

Figure 14.90

(b) Squaring the equation $T = 2\pi\sqrt{\frac{m+m_{\text{eff}}}{k}}$ and solving for T^2 in terms of m, we get

$$T^2 = \left(\frac{4\pi^2}{k}\right)m + \frac{4\pi^2 m_{\text{eff}}}{k}.$$

In the graph of T^2 versus m, the slope is $4\pi^2/k$ and the vertical intercept is $4\pi^2 m_{\text{eff}}/k$. The best-fit equation to our plotted points is $T^2 = (3.878\ \text{s}^2/\text{kg})m + 0.3492\ \text{s}^2$. Therefore we have
slope = $4\pi^2/k = 3.876\ \text{s}^2/\text{kg}$
$k = 4\pi^2/(3.876\ \text{s}^2/\text{kg}) = 10.19\ \text{kg/s}^2$ which rounds to $10.2\ \text{kg/s}^2 = 10.2$ N/m.
(c) Using the vertical intercept, we have
$4\pi^2 m_{\text{eff}}/k = 0.3492\ \text{s}^2$
$m_{\text{eff}} = (0.3492\ \text{s}^2)(10.19\ \text{kg/s}^2)/(4\pi^2) = 0.0901$ kg.
(d) The mass of the spring is 0.250 kg, so
$m_{\text{eff}}/m_{\text{spring}} = (0.0901\ \text{kg})/(0.250\ \text{kg}) = 0.360$.
Thus m_{eff} is 36% the mass of the spring.
(e) $T = 2\pi\sqrt{\frac{m+m_{\text{eff}}}{k}} = 2\pi\sqrt{\frac{0.450\ \text{kg} + 0.0901\ \text{kg}}{10.19\ \text{kg/s}^2}} = 1.45$ s.
$f = 1/T = 1/(1.45\ \text{s}) = 0.691$ Hz.
$\omega = 2\pi f = 2\pi(0.691\ \text{H}) = 4.34$ rad/s.
EVALUATE: If the mass of a spring is comparable to the mass of the object oscillating from it, the mass of the spring can have a significant effect on the period. The result we found, that the effective mass is 0.36 times the mass of the spring, is in very good agreement with the result of challenge problem 14.93(c), which shows that the effective mass is 1/3 the mass of the spring.

14.91. **IDENTIFY** and **SET UP**: For small-amplitude oscillations, the period of a simple pendulum is $T = 2\pi\sqrt{L/g}$.

EXECUTE: **(a)** The graph of T^2 versus L is shown in Figure 14.91a. Using $T = 2\pi\sqrt{L/g}$, we solve for T^2 in terms of L, which gives $T^2 = \left(\frac{4\pi^2}{g}\right)L$. The graph of T^2 versus L should be a straight line having slope $4\pi^2/g$. The best-fit line for our data has the equation $T^2 = (3.9795\ \text{s}^2/\text{m})L + 0.6674\ \text{s}^2$. The quantity $4\pi^2/g = 4\pi^2/(9.80\ \text{m/s}^2) = 4.03\ \text{s}^2/\text{m}$. Our line has slope 3.98 s^2/m, which is in very close agreement with the expected slope.

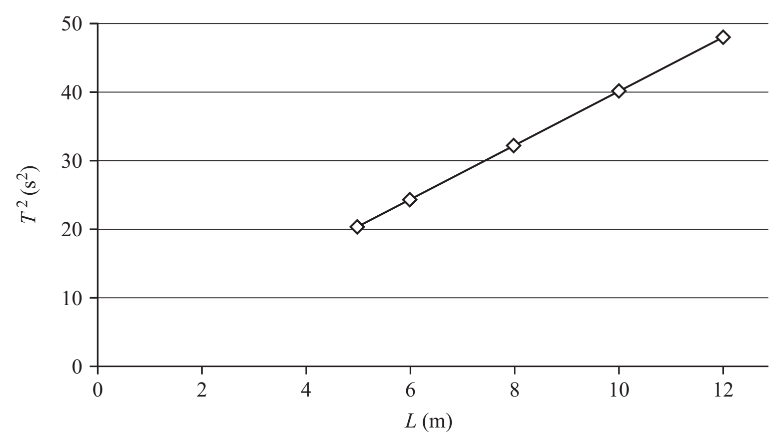

Figure 14.91a

(b) As L decreases, the angle the string makes with the vertical increases because the metal sphere is always released when it is touching the vertical wall. The formula $T = 2\pi\sqrt{L/g}$ is valid only for small angles. Figure 14.91b shows the graph of T/T_0 versus L.

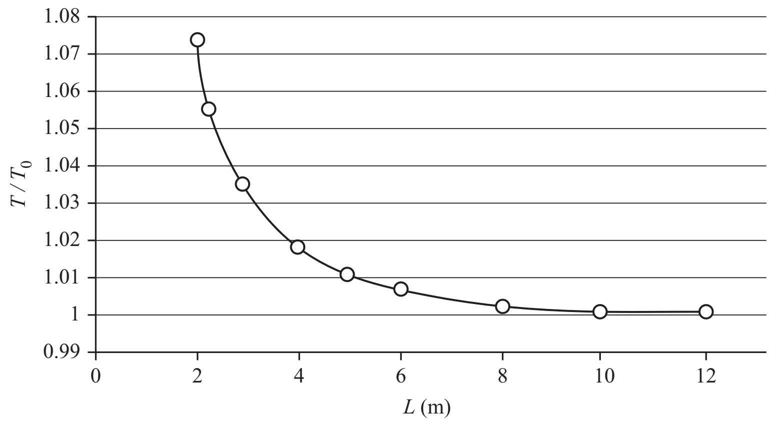

Figure 14.91b

(c) Since $T > T_0$, if T_0 is in error by 5%, $T/T_0 = 1.05$. From the graph in Figure 14.91b, that occurs for $L \approx 2.5$ m. In that case, $\sin\theta = (2.0\text{ m})/(2.5\text{ m}) = 0.80$, which gives $\theta = 53°$.

EVALUATE: Even for an angular amplitude of 53°, the error in using the formula $T = 2\pi\sqrt{L/g}$ is only 5%, so this formula is very useful in most situations. But for very large angular amplitudes it is not reliable.

14.92. **IDENTIFY**: In each situation, imagine the mass moves a distance Δx, the springs move distances Δx_1 and Δx_2, with forces $F_1 = -k_1\Delta x_1, F_2 = -k_2\Delta x_2$.

SET UP: Let Δx_1 and Δx_2 be positive if the springs are stretched, negative if compressed.

EXECUTE: **(a)** $\Delta x = \Delta x_1 = \Delta x_2, F = F_1 + F_2 = -(k_1 + k_2)\Delta x,$ so $k_{\text{eff}} = k_1 + k_2$.

(b) Despite the orientation of the springs, and the fact that one will be compressed when the other is extended, $\Delta x = \Delta x_1 - \Delta x_2$ and both spring forces are in the same direction. The above result is still valid; $k_{\text{eff}} = k_1 + k_2$.

(c) For massless springs, the force on the block must be equal to the tension in any point of the spring combination, and $F = F_1 = F_2$. $\Delta x_1 = -\dfrac{F}{k_1}, \Delta x_2 == -\dfrac{F}{k_2}$, $\Delta x = -\left(\dfrac{1}{k_1} + \dfrac{1}{k_2}\right)F = -\dfrac{k_1 + k_2}{k_1 k_2}F$ and

$$k_{\text{eff}} = \frac{k_1 k_2}{k_1 + k_2}.$$

(d) The result of part (c) shows that when a spring is cut in half, the effective spring constant doubles, and so the frequency increases by a factor of $\sqrt{2}$. Therefore $f_1/f_2 = 1/\sqrt{2}$.

EVALUATE: In cases (a) and (b) the effective force constant is greater than either k_1 or k_2 and in case (c) it is less.

14.93. **IDENTIFY:** Follow the procedure specified in the hint.
SET UP: Denote the position of a piece of the spring by l; $l=0$ is the fixed point and $l=L$ is the moving end of the spring. Then the velocity of the point corresponding to l, denoted u, is $u(l)=v\dfrac{l}{L}$ (when the spring is moving, l will be a function of time, and so u is an implicit function of time).

EXECUTE: **(a)** $dm=\dfrac{M}{L}dl$, and so $dK=\dfrac{1}{2}dm\,u^2=\dfrac{1}{2}\dfrac{Mv^2}{L^3}l^2\,dl$ and $K=\int dK=\dfrac{Mv^2}{2L^3}\int_0^L l^2\,dl=\dfrac{Mv^2}{6}$.

(b) $mv\dfrac{dv}{dt}+kx\dfrac{dx}{dt}=0$, or $ma+kx=0$, which is Eq. (14.4).

(c) m is replaced by $\dfrac{M}{3}$, so $\omega=\sqrt{\dfrac{3k}{M}}$ and $M'=\dfrac{M}{3}$.

EVALUATE: The effective mass of the spring is only one-third of its actual mass.

14.94. **IDENTIFY** and **SET UP**: The frequency is $f=\dfrac{1}{2\pi}\sqrt{\dfrac{k}{m}}$.

EXECUTE: Use $f=\dfrac{1}{2\pi}\sqrt{\dfrac{k}{m}}$ to solve for the mass:
$m = k/(2\pi f)^2 = (1000\text{ N/m})/[2\pi(100\times10^3\text{ Hz})]^2 = 2.5\times10^{-9}\text{ kg} = 2.5\times10^{-6}\text{ g} = 2.5\ \mu\text{g}$, which is choice (c).

EVALUATE: This is a much smaller mass than we've dealt with in the previous problems, but we are looking at vibrations at the molecular level.

14.95. **IDENTIFY** and **SET UP**: The energy is constant, so it is equal to the potential energy when the speed is zero, so $E=\frac{1}{2}kA^2$.

EXECUTE: $E=\frac{1}{2}(1000\text{ N/m})(0.050\times10^{-9}\text{ m})^2 = 1.25\times10^{-18}$ J, which is closest to choice (a).

EVALUATE: This is a much smaller energy than we've dealt with in the previous problems, but we are looking at vibrations at the molecular level.

14.96. **IDENTIFY** and **SET UP**: The frequency is $f=\dfrac{1}{2\pi}\sqrt{\dfrac{k}{m}}$, and we want $\dfrac{\Delta f}{f}$.

EXECUTE: $\dfrac{\Delta f}{f}=\dfrac{f-f_0}{f_0}$. Using $f=\dfrac{1}{2\pi}\sqrt{\dfrac{k}{m}}$ and calling k the new force constant, we have

$$\frac{\Delta f}{f}=\frac{(1/2\pi)\sqrt{k/m}-(1/2\pi)\sqrt{k_0/m}}{(1/2\pi)\sqrt{k_0/m}}=\frac{\sqrt{k}-\sqrt{k_0}}{\sqrt{k_0}}=\sqrt{\frac{k}{k_0}}-1=\sqrt{\frac{1005\text{ N/m}}{1000\text{ N/m}}}-1$$

$\dfrac{\Delta f}{f}=2.5\times10^{-3}=0.25\%$, which is choice (b).

EVALUATE: Since k_{surf} = 5 N/m is only 5/1000 = 0.5% of the original force constant, the effect on the frequency is even less, at 0.25%. This is reasonable because the frequency is proportional to the square root of the force constant.

15

MECHANICAL WAVES

VP15.3.1. **IDENTIFY:** We are dealing with general characteristics of waves.

SET UP: We know that $f = 1/T$, $v = f\lambda$, $\omega = 2\pi f$, and $k = 2\pi/\lambda$.

EXECUTE: **(a)** $f = 1/T = 1/(5.10\text{ s}) = 0.196\text{ Hz}$.

(b) $v = f\lambda = (0.196\text{ Hz})(30.5\text{ m}) = 5.98\text{ m/s}$.

(c) $\omega = 2\pi f = 2\pi(0.196\text{ Hz}) = 1.23\text{ rad/s}$.

(d) $k = 2\pi/\lambda = 2\pi/(0.206\text{ m}) = 0.206\text{ m}^{-1}$.

EVALUATE: Caution! The wave number k is *not* the number of waves. It is simply defined as $k = 2\pi/\lambda$.

VP15.3.2. **IDENTIFY:** This problem involves the characteristics of a sound wave on Mars.

SET UP: $T = 1/f$, $\omega = 2\pi f$, and $v = f\lambda$.

EXECUTE: **(a)** $T = 1/f = 1/(125\text{ Hz}) = 8.00\times 10^{-3}\text{ s}$.

Solve $v = f\lambda$ for λ: $\lambda = v/f = (245\text{ m/s})/(125\text{ Hz}) = 1.96\text{ m}$.

(b) Solve $v = f\lambda$ for f: $f = v/\lambda = (245\text{ m/s})/(3.00\text{ m}) = 81.7\text{ Hz}$.

$\omega = 2\pi f = 2\pi(81.7\text{ Hz}) = 513\text{ rad/s}$.

EVALUATE: On Earth the wavelength would be almost twice as long as on Mars for the same frequency because the speed of sound is about twice as great as on Mars.

VP15.3.3. **IDENTIFY:** We are dealing with a traveling wave on a string.

SET UP: $y(x,t) = A\cos(kx - \omega t)$, $\omega = 2\pi f$, $v = f\lambda$, $k = 2\pi/\lambda$, and $v = \sqrt{\dfrac{F}{\mu}}$. Call the $+x$-axis the direction in which the wave is traveling.

EXECUTE: **(a)** $v = \sqrt{\dfrac{F}{\mu}} = \sqrt{\dfrac{810\text{ N}}{0.0650\text{ kg/m}}} = 112\text{ m/s}$.

(b) Solve $v = f\lambda$ for λ: $\lambda = v/f = (112\text{ m/s})/(25.0\text{ Hz}) = 4.47\text{ m}$.

(c) Use $y(x,t) = A\cos(kx - \omega t)$ with $x = 2.50\text{ m}$, $k = 2\pi/\lambda = 2\pi/(4.47\text{ m}) = 1.41\text{ m}^{-1}$, $A = 5.00\text{ mm}$, and $\omega = 2\pi f = 2\pi(25.0\text{ Hz}) = 157\text{ rad/s}$. Using these numbers gives

$y(2.50\text{ m},t) = (5.00\text{ mm})\cos[3.52 - (157\text{ rad/s})t]$.

EVALUATE: This wave is traveling in the $+x$ direction. The equation for reflected waves having the same amplitude would be $y(2.50\text{ m},t) = (5.00\text{ mm})\cos[3.52 + (157\text{ rad/s})t]$.

VP15.3.4. **IDENTIFY:** We are dealing with a traveling wave on a string.

SET UP: $v = f\lambda$, $v = \sqrt{\dfrac{F}{\mu}}$. The 0.400 m is the distance from a crest to the adjacent trough, which is one-half of a complete wave. Therefore $\lambda = 2(0.400\text{ m}) = 0.800\text{ m}$.

EXECUTE: **(a)** $v = f\lambda$ = (45.0 Hz)(0.800 m) = 36.0 m/s.

(b) Solve $v = \sqrt{\dfrac{F}{\mu}}$ for μ: $v = \sqrt{\dfrac{F}{\mu}}$ = 0.193 kg/m.

EVALUATE: A linear mass density of 0.193 kg/m is a bit large but not unreasonable for a string.

VP15.5.1. **IDENTIFY:** We are dealing with a traveling wave on a rope and the average power it transfers.

SET UP: $P_{\text{av}} = \dfrac{1}{2}\sqrt{\mu F}\,\omega^2 A^2$, $\omega = 2\pi f$, and $f = 1/T$. The target variable is the average power delivered by the wave.

EXECUTE: **(a)** $\omega = 2\pi f$ = 2π/T = 2π/(0.575 s) = 10.9 rad/s.

(b) $P_{\text{av}} = \dfrac{1}{2}\sqrt{\mu F}\,\omega^2 A^2 = \dfrac{1}{2}\sqrt{\dfrac{m}{L}F}\,\omega^2 A^2 = \dfrac{1}{2}\sqrt{\left(\dfrac{2.50\text{ kg}}{50.0\text{ m}}\right)(600\text{ N})}\,(10.9\text{ rad/s})^2(0.0300\text{ m})^2 = 0.294\text{ W}.$

EVALUATE: Note that the power depends on the *square* of the frequency and the amplitude. This power is much less than that of an ordinary 60 W light bulb.

VP15.5.2. **IDENTIFY:** We are dealing with the maximum power carried by a traveling wave on a piano wire.

SET UP: $P_{\max} = \sqrt{\mu F}\,\omega^2 A^2$, $\omega = 2\pi f$. We know all the quantities except the amplitude, and our target variable is the amplitude of the wave.

EXECUTE: Solve $P_{\max} = \sqrt{\mu F}\,\omega^2 A^2$ for A: $A = \sqrt{\dfrac{P_{\max}}{\omega^2\sqrt{\mu F}}}$. Using $P_{\max}$ = 5.20 W, F = 185 N, μ = 5.55×10^{-4} kg/m, and $\omega = 2\pi f$ = 2π(256 Hz) = 512π Hz, we get $A = 2.50\times 10^{-3}$ m = 2.50 mm.

EVALUATE: An amplitude of 2.50 mm on a piano string is large enough to see readily.

VP15.5.3. **IDENTIFY:** We are investigating the power output of a sound speaker.

SET UP: $I = P/A$ where $A = 4\pi r^2$.

EXECUTE: **(a)** $I = P/A$ = (8.00 W)/[4π(2.00 m)^2] = 0.159 W/m^2.

(b) Solve $I = P/(4\pi r^2)$ for r: $r = \sqrt{\dfrac{P}{4\pi I}} = \sqrt{\dfrac{8.00\text{ W}}{4\pi(0.045\text{ W/m}^2)}} = 3.76$ m.

EVALUATE: The distance from the speaker in part (b) is nearly twice as great as in part (a), which is reasonable because the intensity in (b) is considerably less than in (a).

VP15.5.4. **IDENTIFY:** We are dealing with the sonic power received by a frog's "ears."

SET UP: $I = P/4\pi r^2$ and the energy E received by an area A during a time t is $E = IAt$. Our target variable is the amount of energy the frog's membrane receives in one second.

EXECUTE: $I = P/4\pi r^2$ where r is the distance from the source of sound and P is the power the source is emitting. The area A is $A = \pi R^2$, where R is the radius of the membrane. Combining these quantities gives $E = IAt = \left(\dfrac{P}{4\pi r^2}\right)\left(\pi R^2\right)t$. Using $P = 2.00\times 10^{-6}$ W, r = 1.50 m, t = 1.00 s, and $R = 5.00\times 10^{-3}$ m, we get $E = 5.56\times 10^{-12}$ J.

EVALUATE: This is a very small amount of energy, so the frog must have very sensitive "ears"!

VP15.8.1. **IDENTIFY:** We are dealing with a standing wave on a string.

SET UP: The equation for the standing wave is $y(x,t) = A_{\text{SW}}\sin k_n x \cos \omega_n t$, where $\omega = 2\pi f$. The speed of the wave is $v = f\lambda$; it is a constant and directed along the string. The transverse velocity is $v_y(x,t) = \dfrac{\partial y}{\partial t}$; it is different for different points on the string and is directed perpendicular to the string.

EXECUTE: **(a)** The distance of 0.125 m between nodes is one-half a wavelength, so λ = 0.250 m. Therefore $v = f\lambda$ = (256 Hz)(0.250 m) = 64.0 m/s.

(b) $v_y = \dfrac{\partial y}{\partial t} = \dfrac{\partial\left((A_{SW}\sin k_n x)\sin\omega_n t\right)}{\partial t} = A_{SW}\omega_n \sin k_n x\,\cos\omega_n t$. The maximum speed is $A_{SW}\omega_n$, so $v_{y\text{-max}}$ $= (1.40\times10^{-3}\text{ m})[2\pi(256\text{ Hz})] = 2.25\text{ m/s}$.

(c) $a_y = \dfrac{\partial v_y}{\partial t} = -A_{SW}\omega_n^2 \sin k_n x\,\sin\omega_n t$. The $= 2L$ maximum acceleration is $A_{SW}\omega_n^2$, so

$a_{y\text{-max}} = (1.40\times10^{-3}\text{ m})[2\pi(256\text{ Hz})]^2 = 3620\text{ m/s}^2$.

EVALUATE: For a very taut string or wire, the maximum acceleration can be extremely large.

VP15.8.2. **IDENTIFY:** This problem involves a standing wave on the G string of a guitar string.

SET UP: $v = \sqrt{\dfrac{F}{\mu}}$, $v = f\lambda$, $\lambda_n = \dfrac{2L}{n}$, and for the fundamental mode $n = 1$ so $\lambda_1 = \dfrac{2L}{1} = 2L$.

EXECUTE: **(a)** We want the wave speed. $v = f_1\lambda_1 = f_1(2L) = (196\text{ Hz})(2)(0.641\text{ m}) = 251\text{ m/s}$.

(b) We want the tension in the string, so solve $v = \sqrt{\dfrac{F}{\mu}}$ for F, giving $F = \mu v^2$. Therefore

$F = (2.29\times10^{-3}\text{ kg/m})(251\text{ m/s})^2 = 145\text{ N}$.

EVALUATE: This is a very fast wave since the tension is large.

VP15.8.3. **IDENTIFY:** Standing waves form on the cable that is fixed at both ends.

SET UP: $\lambda_n = \dfrac{2L}{n}$, $v = f\lambda$, $v = \sqrt{\dfrac{F}{\mu}}$. Since there are 5 antinodes on the cable, it is vibrating in its 5th harmonic, so $n = 5$. We want to know the wavelength and frequency of the waves and the linear mass density of the cable.

EXECUTE: **(a)** $\lambda_n = \dfrac{2L}{n}$ so $\lambda_5 = \dfrac{2L}{5} = \dfrac{6.00\text{ m}}{5} = 1.20\text{ m}$.

(b) Solve $v = f\lambda$ for f, giving $f = \dfrac{v}{\lambda} = \dfrac{96.0\text{ m/s}}{1.20\text{ m}} = 80.0\text{ Hz}$.

(c) Solve $v = \sqrt{\dfrac{F}{\mu}}$ for μ giving $\mu = \dfrac{F}{v^2} = \dfrac{175\text{ N}}{(96.0\text{ m/s})^2} = 1.90\times10^{-2}\text{ kg/m}$.

EVALUATE: This density is 19 kg/m, which is not unreasonable for a thin cable.

VP15.8.4. **IDENTIFY:** A string fixed at both ends is vibrating in its second harmonic of a standing wave pattern. This vibration produces a sound wave.

SET UP: $v = \sqrt{\dfrac{F}{\mu}}$, $\lambda_n = \dfrac{2L}{n}$, $f_n = nf_1$, $v = f\lambda$. For the second harmonic, $n = 2$. The target variables are the tension in the string and the wavelength of the sound wave the vibrating string produces.

EXECUTE: **(a)** We want the tension in the string. First find the wavelength and use it to find the speed of the wave. Then use $v = \sqrt{\dfrac{F}{\mu}}$ to find the tension. For the string in the second harmonic,

$\lambda_2 = 2L/2 = L = 0.500\text{ m}$. The wave speed is $v = f\lambda = (512\text{ Hz})(0.500\text{ m}) = 256\text{ m/s}$. Now solve

$v = \sqrt{\dfrac{F}{\mu}}$ for F giving $F = \mu v^2 = (1.17\times10^{-3}\text{ kg/m})(256\text{ m/s})^2 = 76.7\text{ N}$.

(b) We want the wavelength of the sound wave this string produces when vibrating in its fundamental harmonic. Each cycle of the string produces a cycle of sound waves, so the frequency of the sound will be the same as the frequency of the string. The string is now vibrating in its *fundamental* frequency, not its second harmonic. Using $f_n = nf_1$, we have $f_2 = 2f_1 = 512$ Hz, so its frequency is $f_1 = (512\text{ Hz})/2 = 256$ Hz. Now solve $v_s = f\lambda$ for λ, where v_s is the speed of sound. This gives $\lambda = \dfrac{v_s}{f} = \dfrac{344\text{ m/s}}{256\text{ Hz}} = 1.34\text{ m}$.

EVALUATE: The wavelength of the sound wave is very different from the wavelength of the waves on the string, even though both have the same frequency. This difference is due to the difference in the speeds of the two waves.

15.1. IDENTIFY: $v = f\lambda$. $T = 1/f$ is the time for one complete vibration.

SET UP: The frequency of the note one octave higher is 1568 Hz.

EXECUTE: **(a)** $\lambda = \dfrac{v}{f} = \dfrac{344\text{ m/s}}{784\text{ Hz}} = 0.439\text{ m}$. $T = \dfrac{1}{f} = 1.28\text{ ms}$.

(b) $\lambda = \dfrac{v}{f} = \dfrac{344\text{ m/s}}{1568\text{ Hz}} = 0.219\text{ m}$.

EVALUATE: When f is doubled, λ is halved.

15.2. IDENTIFY: $f\lambda = v$.

SET UP: $1.0\text{ mm} = 0.0010\text{ m}$.

EXECUTE: $f = \dfrac{v}{\lambda} = \dfrac{1500\text{ m/s}}{0.0010\text{ m}} = 1.5\times10^6\text{ Hz}$.

EVALUATE: The frequency is much higher than the upper range of human hearing.

15.3. IDENTIFY: $v = f\lambda = \lambda/T$.

SET UP: $1.0\text{ h} = 3600\text{ s}$. The crest to crest distance is λ.

EXECUTE: $v = \dfrac{800\times10^3\text{ m}}{3600\text{ s}} = 220\text{ m/s}$. $v = \dfrac{800\text{ km}}{1.0\text{ h}} = 800\text{ km/h}$.

EVALUATE: Since the wave speed is very high, the wave strikes with very little warning.

15.4. IDENTIFY: The fisherman observes the amplitude, wavelength, and period of the waves.

SET UP: The time from the highest displacement to lowest displacement is $T/2$. The distance from highest displacement to lowest displacement is $2A$. The distance between wave crests is λ, and the speed of the waves is $v = f\lambda = \lambda/T$.

EXECUTE: **(a)** $T = 2(2.5\text{ s}) = 5.0\text{ s}$. $\lambda = 4.8\text{ m}$. $v = \dfrac{4.8\text{ m}}{5.0\text{ s}} = 0.96\text{ m/s}$.

(b) $A = (0.53\text{ m})/2 = 0.265\text{ m}$ which rounds to 0.27 m.

(c) The amplitude becomes 0.15 m but the wavelength, period and wave speed are unchanged.

EVALUATE: The wavelength, period and wave speed are independent of the amplitude of the wave.

15.5. IDENTIFY: We want to relate the wavelength and frequency for various waves.

SET UP: For waves $v = f\lambda$.

EXECUTE: **(a)** $v = 344\text{ m/s}$. For $f = 20{,}000\text{ Hz}$, $\lambda = \dfrac{v}{f} = \dfrac{344\text{ m/s}}{20{,}000\text{ Hz}} = 1.7\text{ cm}$. For $f = 20\text{ Hz}$,

$\lambda = \dfrac{v}{f} = \dfrac{344\text{ m/s}}{20\text{ Hz}} = 17\text{ m}$. The range of wavelengths is 1.7 cm to 17 m.

(b) $v = c = 3.00\times10^8\text{ m/s}$. For $\lambda = 700\text{ nm}$, $f = \dfrac{c}{\lambda} = \dfrac{3.00\times10^8\text{ m/s}}{700\times10^{-9}\text{ m}} = 4.3\times10^{14}\text{ Hz}$. For $\lambda = 400\text{ nm}$,

$f = \dfrac{c}{\lambda} = \dfrac{3.00\times10^8\text{ m/s}}{400\times10^{-9}\text{ m}} = 7.5\times10^{14}\text{ Hz}$. The range of frequencies for visible light is $4.3\times10^{14}\text{ Hz}$ to $7.5\times10^{14}\text{ Hz}$.

(c) $v = 344\text{ m/s}$. $\lambda = \dfrac{v}{f} = \dfrac{344\text{ m/s}}{23\times10^3\text{ Hz}} = 1.5\text{ cm}$.

(d) $v = 1480\text{ m/s}$. $\lambda = \dfrac{v}{f} = \dfrac{1480\text{ m/s}}{23\times10^3\text{ Hz}} = 6.4\text{ cm}$.

EVALUATE: For a given v, a larger f corresponds to smaller λ. For the same f, λ increases when v increases.

15.6. **IDENTIFY:** The string is vibrating in SHM. The maximum force occurs when the acceleration of the bead is a maximum.

SET UP: The equation for the wave is $y(x,t) = A\cos(kx - \omega t)$. The maximum force on the bead occurs when the transverse acceleration is a maximum, so use $\sum F_y = ma_y$, where $a_y = \dfrac{\partial^2 y}{\partial t^2}$. The target variable is the maximum force on the bead.

EXECUTE: Find $a_y = \dfrac{\partial^2 y}{\partial t^2}$ for $y(x,t) = A\cos(kx - \omega t)$. $\dfrac{\partial y}{\partial t} = A\omega \sin(kx - \omega t)$, so $a_y = \dfrac{\partial^2 y}{\partial t^2} = -A\omega^2 \cos(kx - \omega t)$. The maximum magnitude acceleration of the bead is $a_{\max} = A\omega^2$, so the maximum force on the bead is $F_{\max} = ma_{\max} = mA\omega^2$. Putting in the numbers gives $F_{\max} = (0.00400\ \text{kg})(8.00 \times 10^{-3}\ \text{m})[2\pi(20.0\ \text{Hz})]^2 = 0.505\ \text{N}$.

EVALUATE: The weight of the bead is (0.00400 kg)(9.80 m/s^2) = 0.0392 N, so it is small enough to be neglected with reasonable accuracy.

15.7. **IDENTIFY:** Use $v = f\lambda$ to calculate v. $T = 1/f$ and k is defined by $k = 2\pi/\lambda$. The general form of the wave function is given by $y(x, t) = A\cos 2\pi(x/\lambda + t/T)$, which is the equation for the transverse displacement.

SET UP: $v = 8.00\ \text{m/s}$, $A = 0.0700\ \text{m}$, $\lambda = 0.320\ \text{m}$

EXECUTE: **(a)** $v = f\lambda$ so $f = v/\lambda = (8.00\ \text{m/s})/(0.320\ \text{m}) = 25.0\ \text{Hz}$

$T = 1/f = 1/25.0\ \text{Hz} = 0.0400\ \text{s}$

$k = 2\pi/\lambda = 2\pi\ \text{rad}/0.320\ \text{m} = 19.6\ \text{rad/m}$

(b) For a wave traveling in the $-x$-direction,

$y(x, t) = A\cos 2\pi(x/\lambda + t/T)$

At $x = 0$, $y(0, t) = A\cos 2\pi(t/T)$, so $y = A$ at $t = 0$. This equation describes the wave specified in the problem.

Substitute in numerical values:

$y(x, t) = (0.0700\ \text{m})\cos\left[2\pi\left(x/(0.320\ \text{m}) + t/(0.0400\ \text{s})\right)\right]$.

Or, $y(x, t) = (0.0700\ \text{m})\cos\left[(19.6\ \text{m}^{-1})x + (157\ \text{rad/s})t\right]$.

(c) From part (b), $y = (0.0700\ \text{m})\cos[2\pi(x/0.320\ \text{m} + t/0.0400\ \text{s})]$.

Plug in $x = 0.360\ \text{m}$ and $t = 0.150\ \text{s}$:

$y = (0.0700\ \text{m})\cos[2\pi(0.360\ \text{m}/0.320\ \text{m} + 0.150\ \text{s}/0.0400\ \text{s})]$

$y = (0.0700\ \text{m})\cos[2\pi(4.875\ \text{rad})] = +0.0495\ \text{m} = +4.95\ \text{cm}$

(d) In part (c) $t = 0.150\ \text{s}$.

$y = A$ means $\cos[2\pi(x/\lambda + t/T)] = 1$

$\cos\theta = 1$ for $\theta = 0, 2\pi, 4\pi, \ldots = n(2\pi)$ or $n = 0, 1, 2, \ldots$

So $y = A$ when $2\pi(x/\lambda + t/T) = n(2\pi)$ or $x/\lambda + t/T = n$

$t = T(n - x/\lambda) = (0.0400\ \text{s})(n - 0.360\ \text{m}/0.320\ \text{m}) = (0.0400\ \text{s})(n - 1.125)$

For $n = 4$, $t = 0.1150\ \text{s}$ (before the instant in part (c))

For $n = 5$, $t = 0.1550\ \text{s}$ (the first occurrence of $y = A$ after the instant in part (c)). Thus the elapsed time is $0.1550\ \text{s} - 0.1500\ \text{s} = 0.0050\ \text{s}$.

EVALUATE: Part (d) says $y = A$ at 0.115 s and next at 0.155 s; the difference between these two times is 0.040 s, which is the period. At $t = 0.150\ \text{s}$ the particle at $x = 0.360\ \text{m}$ is at $y = 4.95\ \text{cm}$ and traveling upward. It takes $T/4 = 0.0100$ s for it to travel from $y = 0$ to $y = A$, so our answer of 0.0050 s is reasonable.

15.8. **IDENTIFY:** Compare $y(x, t)$ given in the problem to the general form $y(x,t) = A\cos 2\pi\left(\frac{x}{\lambda} - \frac{t}{T}\right)$. $f = 1/T$ and $v = f\lambda$

SET UP: The comparison gives $A = 6.50$ mm, $\lambda = 28.0$ cm and $T = 0.0360$ s.

EXECUTE: **(a)** 6.50 mm

(b) 28.0 cm

(c) $f = \frac{1}{0.0360\text{ s}} = 27.8\text{ Hz}$

(d) $v = (0.280\text{ m})(27.8\text{ Hz}) = 7.78\text{ m/s}$

(e) Since there is a minus sign in front of the t/T term, the wave is traveling in the $+x$-direction.

EVALUATE: The speed of propagation does not depend on the amplitude of the wave.

15.9. **IDENTIFY:** Evaluate the partial derivatives and see if the wave equation $\frac{\partial^2 y(x,t)}{\partial x^2} = \frac{1}{v^2}\frac{\partial^2 y(x,t)}{\partial t^2}$ is satisfied.

SET UP: $\frac{\partial}{\partial x}\cos(kx + \omega t) = -k\sin(kx + \omega t)$. $\frac{\partial}{\partial t}\cos(kx + \omega t) = -\omega\sin(kx + \omega t)$. $\frac{\partial}{\partial x}\sin(kx + \omega t) = k\cos(kx + \omega t)$. $\frac{\partial}{\partial t}\sin(kx + \omega t) = \omega\cos(kx + \omega t)$.

EXECUTE: **(a)** $\frac{\partial^2 y}{\partial x^2} = -Ak^2\cos(kx + \omega t)$. $\frac{\partial^2 y}{\partial t^2} = -A\omega^2\cos(kx + \omega t)$. The wave equation is satisfied, if $v = \omega/k$.

(b) $\frac{\partial^2 y}{\partial x^2} = -Ak^2\sin(kx + \omega t)$. $\frac{\partial^2 y}{\partial t^2} = -A\omega^2\sin(kx + \omega t)$. The wave equation is satisfied, if $v = \omega/k$.

(c) $\frac{\partial y}{\partial x} = -kA\sin(kx)$. $\frac{\partial^2 y}{\partial x^2} = -k^2A\cos(kx)$. $\frac{\partial y}{\partial t} = -\omega A\sin(\omega t)$. $\frac{\partial^2 y}{\partial t^2} = -\omega^2 A\cos(\omega t)$. The wave equation is not satisfied.

(d) $v_y = \frac{\partial y}{\partial t} = \omega A\cos(kx + \omega t)$. $a_y = \frac{\partial^2 y}{\partial t^2} = -A\omega^2\sin(kx + \omega t)$

EVALUATE: The functions $\cos(kx + \omega t)$ and $\sin(kx + \omega t)$ differ only in phase.

15.10. **IDENTIFY:** The general form of the wave function for a wave traveling in the $-x$-direction is given by $y(x,t) = A\cos 2\pi\left(\frac{x}{\lambda} + \frac{t}{T}\right)$. The time for one complete cycle to pass a point is the period T and the number that pass per second is the frequency f. The speed of a crest is the wave speed v and the maximum speed of a particle in the medium is $v_{max} = \omega A$.

SET UP: Comparison to $y(x,t) = A\cos(kx + \omega t)$ gives $A = 2.75$ cm, $k = 0.410$ rad/cm and $\omega = 6.20$ rad/s.

EXECUTE: **(a)** $T = \frac{2\pi\text{ rad}}{\omega} = \frac{2\pi\text{ rad}}{6.20\text{ rad/s}} = 1.0134\text{ s}$ which rounds to 1.01 s. In one cycle a wave crest travels a distance $\lambda = \frac{2\pi\text{ rad}}{k} = \frac{2\pi\text{ rad}}{0.410\text{ rad/cm}} = 15.325\text{ cm} = 0.153\text{ m}$.

(b) $k = 0.410$ rad/cm. $f = 1/T = 0.9868\text{ Hz} = 0.987$ waves/second.

(c) $v = f\lambda = (0.9868\text{ Hz})(0.15325\text{ m}) = 0.151\text{ m/s}$.

$v_{max} = \omega A = (6.20\text{ rad/s})(2.75\text{ cm}) = 17.1\text{ cm/s} = 0.171\text{ m/s}$.

EVALUATE: The transverse velocity of the particles in the medium (water) is not the same as the velocity of the wave.

15.11. **IDENTIFY and SET UP:** Read A and T from the graph. Apply $y(x,t) = A\cos 2\pi\left(\dfrac{x}{\lambda} - \dfrac{t}{T}\right)$ to determine λ and then use $v = f\lambda$ to calculate v.

EXECUTE: **(a)** The maximum y is 4 mm (read from graph).
(b) For either x the time for one full cycle is 0.040 s; this is the period.
(c) Since $y = 0$ for $x = 0$ and $t = 0$ and since the wave is traveling in the $+x$-direction then $y(x, t) = A\sin[2\pi(t/T - x/\lambda)]$. (The phase is different from the wave described by $y(x,t) = A\cos 2\pi\left(\dfrac{x}{\lambda} - \dfrac{t}{T}\right)$; for that wave $y = A$ for $x = 0,\ t = 0$.) From the graph, if the wave is traveling in the $+x$-direction and if $x = 0$ and $x = 0.090$ m are within one wavelength the peak at $t = 0.01$ s for $x = 0$ moves so that it occurs at $t = 0.035$ s (read from graph so is approximate) for $x = 0.090$ m. The peak for $x = 0$ is the first peak past $t = 0$ so corresponds to the first maximum in $\sin[2\pi(t/T - x/\lambda)]$ and hence occurs at $2\pi(t/T - x/\lambda) = \pi/2$. If this same peak moves to $t_1 = 0.035$ s at $x_1 = 0.090$ m, then

$2\pi(t/T - x/\lambda) = \pi/2.$

Solve for λ: $t_1/T - x_1/\lambda = 1/4$

$x_1/\lambda = t_1/T - 1/4 = 0.035\text{ s}/0.040\text{ s} - 0.25 = 0.625$

$\lambda = x_1/0.625 = 0.090\text{ m}/0.625 = 0.14\text{ m}.$

Then $v = f\lambda = \lambda/T = 0.14\text{ m}/0.040\text{ s} = 3.5\text{ m/s}.$

(d) If the wave is traveling in the $-x$-direction, then $y(x, t) = A\sin(2\pi(t/T + x/\lambda))$ and the peak at $t = 0.050$ s for $x = 0$ corresponds to the peak at $t_1 = 0.035$ s for $x_1 = 0.090$ m. This peak at $x = 0$ is the second peak past the origin so corresponds to $2\pi(t/T + x/\lambda) = 5\pi/2$. If this same peak moves to $t_1 = 0.035$ s for $x_1 = 0.090$ m, then $2\pi(t_1/T + x_1/\lambda) = 5\pi/2.$

$t_1/T + x_1/\lambda = 5/4$

$x_1/\lambda = 5/4 - t_1/T = 5/4 - 0.035\text{ s}/0.040\text{ s} = 0.375$

$\lambda = x_1/0.375 = 0.090\text{ m}/0.375 = 0.24\text{ m}.$

Then $v = f\lambda = \lambda/T = 0.24\text{ m}/0.040\text{ s} = 6.0\text{ m/s}.$

EVALUATE: **(e)** No. Wouldn't know which point in the wave at $x = 0$ moved to which point at $x = 0.090$ m.

15.12. **IDENTIFY:** $v_y = \dfrac{\partial y}{\partial t}$. $v = f\lambda = \lambda/T.$

SET UP: $\dfrac{\partial}{\partial t}A\cos\left(\dfrac{2\pi}{\lambda}(x - vt)\right) = +A\left(\dfrac{2\pi v}{\lambda}\right)\sin\left(\dfrac{2\pi}{\lambda}(x - vt)\right)$

EXECUTE: **(a)** $A\cos 2\pi\left(\dfrac{x}{\lambda} - \dfrac{t}{T}\right) = +A\cos\dfrac{2\pi}{\lambda}\left(x - \dfrac{\lambda}{T}t\right) = +A\cos\dfrac{2\pi}{\lambda}(x - vt)$ where $\dfrac{\lambda}{T} = \lambda f = v$ has been used.

(b) $v_y = \dfrac{\partial y}{\partial t} = \dfrac{2\pi v}{\lambda}A\sin\dfrac{2\pi}{\lambda}(x - vt).$

(c) The speed is the greatest when the sine is 1, and that speed is $2\pi vA/\lambda$. This will be equal to v if $A = \lambda/2\pi$, less than v if $A < \lambda/2\pi$ and greater than v if $A > \lambda/2\pi$.

EVALUATE: The propagation speed applies to all points on the string. The transverse speed of a particle of the string depends on both x and t.

15.13. **IDENTIFY:** Follow the procedure specified in the problem.

SET UP: For λ and x in cm, v in cm/s and t in s, the argument of the cosine is in radians.

EXECUTE: **(a)** $t = 0$:

x(cm)	0.00	1.50	3.00	4.50	6.00	7.50	9.00	10.50	12.00
y(cm)	0.300	0.212	0	–0.212	–0.300	–0.212	0	0.212	0.300

The graph is shown in Figure 15.13a.

(b) (i) $t = 0.400$ s:

x(cm)	0.00	1.50	3.00	4.50	6.00	7.50	9.00	10.50	12.00
y(cm)	–0.221	–0.0131	0.203	0.300	0.221	0.0131	–0.203	–0.300	–0.221

The graph is shown in Figure 15.13b.

(ii) $t = 0.800$ s:

x(cm)	0.00	1.50	3.00	4.50	6.00	7.50	9.00	10.50	12.00
y(cm)	0.0262	–0.193	–0.300	–0.230	–0.0262	0.193	0.300	0.230	0.0262

The graph is shown in Figure 15.13c.

(iii) The graphs show that the wave is traveling in the $+x$-direction.

EVALUATE: We know that $y(x,t) = A\cos 2\pi f\left(\dfrac{x}{v} - t\right)$ is for a wave traveling in the $+x$-direction, and $y(x, t)$ is derived from this. This is consistent with the direction of propagation we deduced from our graph.

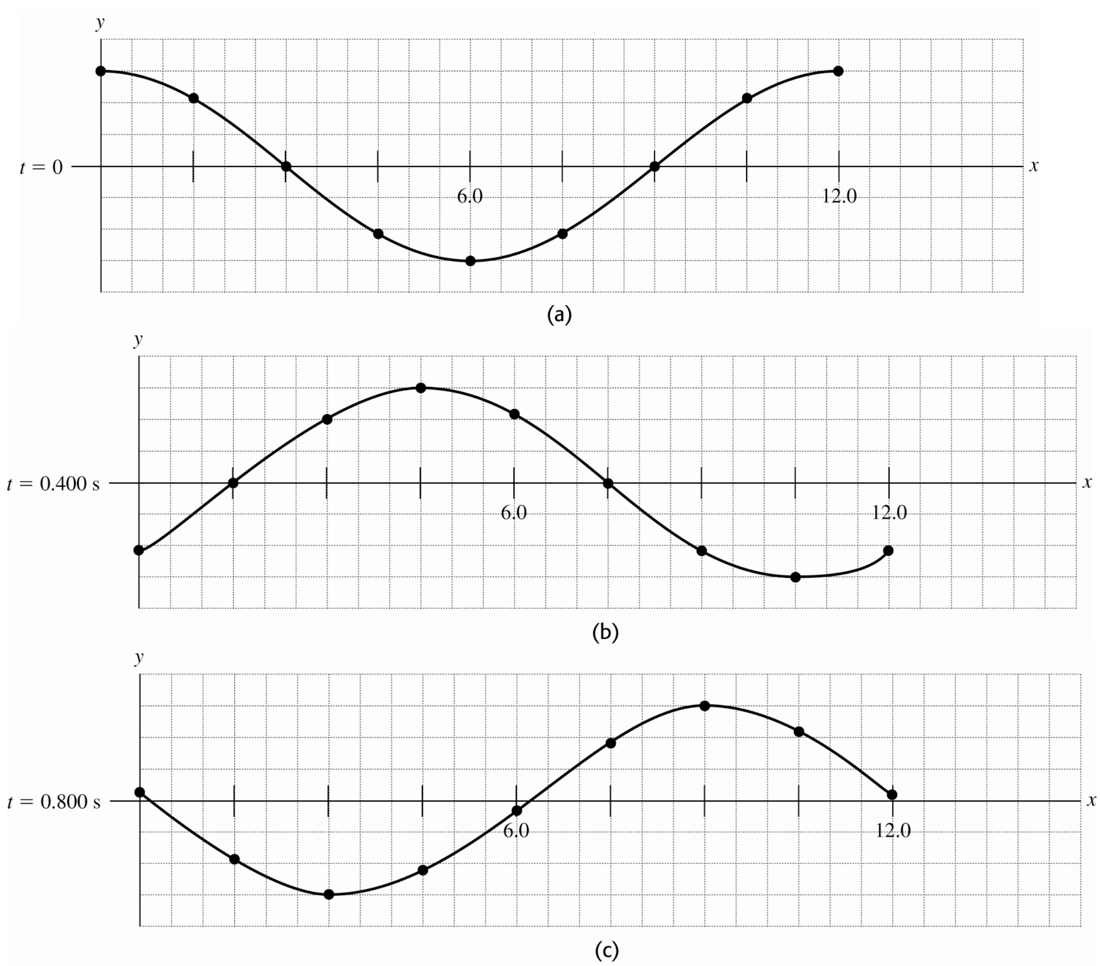

Figure 15.13

15.14. **IDENTIFY:** We are dealing the tension in a taut vibrating string.

SET UP: $v=\sqrt{\dfrac{F}{\mu}}$ and $v=f\lambda$. We want to know what change in the tension is required to double the frequency of the fundamental mode.

EXECUTE: Combining $v=\sqrt{\dfrac{F}{\mu}}$ and $v=f\lambda$ gives $f\lambda = \sqrt{\dfrac{F}{\mu}}$. Solving for F gives $F=\mu\lambda^2 f^2$. From this result we see that to double the frequency, F we would have to increase by a factor of 4.

EVALUATE: This is *not* a good idea because such a large increase in tension could damage the instrument or cause the spring to break.

15.15. **IDENTIFY** and **SET UP:** Use $v=\sqrt{F/\mu}$ to calculate the wave speed. Then use $v=f\lambda$ to calculate the wavelength.

EXECUTE: **(a)** The tension F in the rope is the weight of the hanging mass:

$F=mg=(1.50\ \text{kg})(9.80\ \text{m/s}^2)=14.7\ \text{N}$

$v=\sqrt{F/\mu}=\sqrt{14.7\ \text{N}/(0.0480\ \text{kg/m})}=17.5\ \text{m/s}.$

(b) $v=f\lambda$ so $\lambda=v/f=(17.5\ \text{m/s})/120\ \text{Hz}=0.146\ \text{m}.$

(c) EVALUATE: $v=\sqrt{F/\mu}$, where $F=mg$. Doubling m increases v by a factor of $\sqrt{2}$. $\lambda=v/f$. f remains 120 Hz and v increases by a factor of $\sqrt{2}$, so λ increases by a factor of $\sqrt{2}$.

15.16. **IDENTIFY:** The frequency and wavelength determine the wave speed and the wave speed depends on the tension.

SET UP: $v=\sqrt{\dfrac{F}{\mu}}$. $\mu=m/L$. $v=f\lambda$.

EXECUTE: $F=\mu v^2=\mu(f\lambda)^2=\dfrac{0.120\ \text{kg}}{2.50\ \text{m}}([40.0\ \text{Hz}][0.750\ \text{m}])^2=43.2\ \text{N}$

EVALUATE: If the frequency is held fixed, increasing the tension will increase the wavelength.

15.17. **IDENTIFY:** The speed of the wave depends on the tension in the wire and its mass density. The target variable is the mass of the wire of known length.

SET UP: $v=\sqrt{\dfrac{F}{\mu}}$ and $\mu=m/L$.

EXECUTE: First find the speed of the wave: $v=\dfrac{3.80\ \text{m}}{0.0492\ \text{s}}=77.24\ \text{m/s}$. $v=\sqrt{\dfrac{F}{\mu}}$. $\mu=\dfrac{F}{v^2}=$

$\dfrac{(54.0\ \text{kg})(9.8\ \text{m/s}^2)}{(77.24\ \text{m/s})^2}=0.08870\ \text{kg/m}$. The mass of the wire is

$m=\mu L=(0.08870\ \text{kg/m})(3.80\ \text{m})=0.337\ \text{kg}.$

EVALUATE: This mass is 337 g, which is a bit large for a wire 3.80 m long. It must be fairly thick.

15.18. **IDENTIFY:** For transverse waves on a string, $v=\sqrt{F/\mu}$. The general form of the equation for waves traveling in the $+x$-direction is $y(x,t)=A\cos(kx-\omega t)$. For waves traveling in the $-x$-direction it is $y(x,t)=A\cos(kx+\omega t)$. $v=\omega/k$.

SET UP: Comparison to the general equation gives $A=8.50\ \text{mm}$, $k=172\ \text{rad/m}$ and $\omega=4830\ \text{rad/s}$. The string has mass 0.00128 kg and $\mu=m/L=0.000850\ \text{kg/m}$.

EXECUTE: **(a)** $v=\dfrac{\omega}{k}=\dfrac{4830\ \text{rad/s}}{172\ \text{rad/m}}=28.08\ \text{m/s}$. $t=\dfrac{d}{v}=\dfrac{1.50\ \text{m}}{28.08\ \text{m/s}}=0.0534\ \text{s} = 53.4\ \text{ms}.$

(b) $W=F=\mu v^2=(0.000850\ \text{kg/m})(28.08\ \text{m/s})^2=0.670\ \text{N}.$

(c) $\lambda = \dfrac{2\pi \text{ rad}}{k} = \dfrac{2\pi \text{ rad}}{172 \text{ rad/m}} = 0.0365 \text{ m}$. The number of wavelengths along the length of the string is $\dfrac{1.50 \text{ m}}{0.0365 \text{ m}} = 41.1.$

(d) For a wave traveling in the opposite direction, $y(x,t) = (8.50 \text{ mm})\cos([172 \text{ rad/m}]x + [4830 \text{ rad/s}]t).$

EVALUATE: We have assumed that the tension in the string is constant and equal to W. This is reasonable since $W \gg 0.0125$ N, so the weight of the string has a negligible effect on the tension.

15.19. **IDENTIFY:** For transverse waves on a string, $v = \sqrt{F/\mu}$. $v = f\lambda$.

SET UP: The wire has $\mu = m/L = (0.0165 \text{ kg})/(0.750 \text{ m}) = 0.0220 \text{ kg/m}$.

EXECUTE: **(a)** $v = f\lambda = (625 \text{ Hz})(3.33\times 10^{-2} \text{ m}) = 20.813 \text{ m/s}$. The tension is $F = \mu v^2 = (0.0220 \text{ kg/m})(20.813 \text{ m/s})^2 = 9.53 \text{ N}$.

(b) $v = 20.8$ m/s

EVALUATE: If λ is kept fixed, the wave speed and the frequency increase when the tension is increased.

15.20. **IDENTIFY:** The rope is heavy, so the tension at any point in it must support not only the weight attached but the weight of the rope below that point. Assume that the rope is uniform.

SET UP: $v = \sqrt{F/\mu}$ and $\mu = m/L$ = [(29.4 N)/(9.80 m/s^2)]/(6.00 m) = 0.500 kg/m.

EXECUTE: **(a)** At the bottom, the rope supports only the 0.500-kg object, so $T = mg$ = (0.500 kg)(9.80 m/s^2) = 4.90 N. Now use $v = \sqrt{F/\mu}$ find v.

v = [(4.90 N)/(0.500 kg/m)]$^{1/2}$ = 3.13 m/s.

(b) At the middle, the tension supports the 0.500-kg object plus half the weight of the rope, so T = (29.4 N)/2 + 4.90 N = 19.6 N. Therefore v = [(19.6 N)/(0.500 kg/m)]$^{1/2}$ = 6.26 m/s.

(c) At the top, the tension supports the entire rope plus the object, so T = 29.4 N + 4.90 N = 34.3 N. Therefore v = [(34.3 N)/(0.500 kg/m)]$^{1/2}$ = 8.28 m/s.

(d) T_{middle}= 19.6 N. $T_{\text{av}} = (T_{\text{top}} + T_{\text{bot}})/2$ = (34.3 N + 4.90 N)/2 = 19.6 N, which is equal to T_{middle}. v_{middle} = 6.26 m/s. v_{av} = (8.28 m/s + 3.13 m/s)/2 = 5.71 m/s, which is not equal to v_{middle}.

EVALUATE: The average speed is not equal to the speed at the middle because the speed depends on the square root of the tension. So even though the tension at the middle is the average of the top and bottom tensions, that is not true of the wave speed.

15.21. **IDENTIFY:** We are dealing with the power carried by a wave on a vibrating string.

SET UP: Estimates: The amplitude is the length of an arm ≈ 65 cm = 0.65 m. The maximum tension is $T_{\max}$ ≈ 25 lb ≈ 110 N. The time to complete each pulse: do about 2 per second, so the time per pulse is about 0.50 s. We want to know about the power we supply. Use $\omega = 2\pi / T$ and $P_{\text{av}} = \frac{1}{2}\sqrt{\mu F}\,\omega^2 A^2$.

EXECUTE: **(a)** $\omega = 2\pi / T$ = 2π/(0.50 s) = 4π rad/s. The average power is given by $P_{\text{av}} = \frac{1}{2}\sqrt{\mu F}\,\omega^2 A^2$

$= \frac{1}{2}\sqrt{(0.500 \text{ kg/m})(110 \text{ N})}(4\pi \text{ rad/s})^2(0.65 \text{ m})^2 = 250 \text{ W}.$

(b) $P_{\text{av}} \propto (A\omega)^2$, so if we halve A and double ω, the effects cancel out so there is no change in the average power.

EVALUATE: With this power you could keep around four 60-W light bulbs burning, but it would be difficult to keep it up for very long!

15.22. **IDENTIFY:** Apply $P_{\text{av}} = \frac{1}{2}\sqrt{\mu F}\,\omega^2 A^2$. d

SET UP: $\omega = 2\pi f$. $\mu = m/L$.

EXECUTE: **(a)** Using $P_{av} = \frac{1}{2}\sqrt{\mu F}\omega^2 A^2$, we get $P_{av} = \frac{1}{2}\sqrt{\left(\frac{3.00\times10^{-3}\text{ kg}}{0.80\text{ m}}\right)(25.0\text{ N})}\left[2\pi(120.0\text{ Hz})\right]^2$ $(1.6\times10^{-3}\text{ m})^2 = 0.223\text{ W}$ or 0.22 W to two significant figures.

(b) P_{av} is proportional to A^2, so halving the amplitude quarters the average power, to 0.056 W.

EVALUATE: The average power is also proportional to the square of the frequency.

15.23. **IDENTIFY:** The average power carried by the wave depends on the mass density of the wire and the tension in it, as well as on the square of both the frequency and amplitude of the wave (the target variable).

SET UP: $P_{av} = \frac{1}{2}\sqrt{\mu F}\omega^2 A^2$, $v = \sqrt{\frac{F}{\mu}}$.

EXECUTE: Solving $P_{av} = \frac{1}{2}\sqrt{\mu F}\omega^2 A^2$ for A gives $A = \left(\frac{2P_{av}}{\omega^2\sqrt{\mu F}}\right)^{1/2}$. $P_{av} = 0.365$ W. $\omega = 2\pi f =$ $2\pi(69.0\text{ Hz}) = 433.5\text{ rad/s}$. The tension is $F = 94.0$ N and $v = \sqrt{\frac{F}{\mu}}$ so $\mu = \frac{F}{v^2} = \frac{94.0\text{ N}}{(406\text{ m/s})^2} =$ 5.703×10^{-4} kg/m. $A = \left(\frac{2(0.365\text{ W})}{(433.5\text{ rad/s})^2\sqrt{(5.703\times10^{-4}\text{ kg/m})(94.0\text{ N})}}\right)^{1/2} = 4.10\times10^{-3}\text{ m} = 4.10\text{ mm}$.

EVALUATE: Vibrations of strings and wires normally have small amplitudes, which this wave does.

15.24. **IDENTIFY:** Apply $\frac{I_1}{I_2} = \frac{r_2^2}{r_1^2}$.

SET UP: $I_1 = 0.11\text{ W/m}^2$. $r_1 = 7.5$ m. Set $I_2 = 1.0\text{ W/m}^2$ and solve for r_2.

EXECUTE: $r_2 = r_1\sqrt{\frac{I_1}{I_2}} = (7.5\text{ m})\sqrt{\frac{0.11\text{ W/m}^2}{1.0\text{ W/m}^2}} = 2.5$ m, so it is possible to move $r_1 - r_2 = 7.5\text{ m} - 2.5\text{ m} = 5.0$ m closer to the source.

EVALUATE: I increases as the distance r of the observer from the source decreases.

15.25. **IDENTIFY:** For a point source, $I = \frac{P}{4\pi r^2}$ and $\frac{I_1}{I_2} = \frac{r_2^2}{r_1^2}$.

SET UP: $1\,\mu\text{W} = 10^{-6}$ W

EXECUTE: **(a)** $r_2 = r_1\sqrt{\frac{I_1}{I_2}} = (30.0\text{ m})\sqrt{\frac{10.0\text{ W/m}^2}{1\times10^{-6}\text{ W/m}^2}} = 95$ km

(b) $\frac{I_2}{I_3} = \frac{r_3^2}{r_2^2}$, with $I_2 = 1.0\,\mu\text{W/m}^2$ and $r_3 = 2r_2$. $I_3 = I_2\left(\frac{r_2}{r_3}\right)^2 = I_2/4 = 0.25\,\mu\text{W/m}^2$.

(c) $P = I(4\pi r^2) = (10.0\text{ W/m}^2)(4\pi)(30.0\text{ m})^2 = 1.1\times10^5$ W

EVALUATE: These are approximate calculations, that assume the sound is emitted uniformly in all directions and that ignore the effects of reflection, for example reflections from the ground.

15.26. **IDENTIFY:** The tension and mass per unit length of the rope determine the wave speed. Compare $y(x,t)$ given in the problem to the general form given in $y(x,t) = A\cos 2\pi\left(\frac{x}{\lambda} + \frac{t}{T}\right)$. $v = \omega/k$. The average power is given by $P_{\text{av}} = \frac{1}{2}\sqrt{\mu F}\omega^2 A^2$.

SET UP: Comparison with $y(x,t) = A\cos(kx - \omega t)$ gives $A = 2.30$ mm, $k = 6.98$ rad/m and $\omega = 742$ rad/s.

EXECUTE: **(a)** $A = 2.30$ mm

(b) $f = \frac{\omega}{2\pi} = \frac{742 \text{ rad/s}}{2\pi} = 118 \text{ Hz}$

(c) $\lambda = \frac{2\pi}{k} = \frac{2\pi}{6.98 \text{ rad/m}} = 0.90 \text{ m}$

(d) $v = \frac{\omega}{k} = \frac{742 \text{ rad/s}}{6.98 \text{ rad/m}} = 106 \text{ m/s}$

(e) The wave is traveling in the $-x$-direction because the phase of $y(x, t)$ has the form $kx + \omega t$.

(f) The linear mass density is $\mu = (3.38\times10^{-3} \text{ kg})/(1.35 \text{ m}) = 2.504\times10^{-3} \text{ kg/m}$, so the tension is $F = \mu v^2 = (2.504\times10^{-3} \text{ kg/m})(106.3 \text{ m/s})^2 = 28.3 \text{ N}$.

(g) $P_{\text{av}} = \frac{1}{2}\sqrt{\mu F}\omega^2 A^2 = \frac{1}{2}\sqrt{(2.50\times10^{-3} \text{ kg/m})(28.3 \text{ N})}(742 \text{ rad/s})^2(2.30\times10^{-3} \text{ m})^2 = 0.39 \text{ W}$

EVALUATE: In part (d) we could also calculate the wave speed as $v = f\lambda$ and we would obtain the same result.

15.27. **IDENTIFY** and **SET UP:** Apply $\frac{I_1}{I_2} = \frac{r_2^2}{r_1^2}$ and $I = \frac{P}{4\pi r^2}$ to relate I and r.

Power is related to intensity at a distance r by $P = I(4\pi r^2)$. Energy is power times time.

EXECUTE: **(a)** $I_1 r_1^2 = I_2 r_2^2$

$I_2 = I_1(r_1/r_2)^2 = (0.026 \text{ W/m}^2)(4.3 \text{ m}/3.1 \text{ m})^2 = 0.050 \text{ W/m}^2$

(b) $P = 4\pi r^2 I = 4\pi(4.3 \text{ m})^2(0.026 \text{ W/m}^2) = 6.04 \text{ W}$

$\text{Energy} = Pt = (6.04 \text{ W})(3600 \text{ s}) = 2.2\times10^4 \text{ J}$

EVALUATE: We could have used $r = 3.1$ m and $I = 0.050 \text{ W/m}^2$ in $P = 4\pi r^2 I$ and would have obtained the same P. Intensity becomes less as r increases because the radiated power spreads over a sphere of larger area.

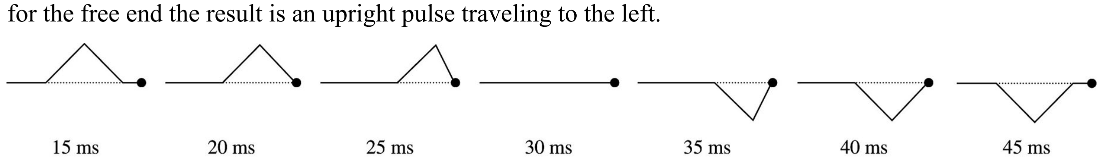
15.28. **IDENTIFY:** The distance the wave shape travels in time t is vt. The wave pulse reflects at the end of the string, at point O.

SET UP: The reflected pulse is inverted when O is a fixed end and is not inverted when O is a free end.

EXECUTE: **(a)** The wave form for the given times, respectively, is shown in Figure 15.28(a).

(b) The wave form for the given times, respectively, is shown in Figure 15.28(b).

EVALUATE: For the fixed end the result of the reflection is an inverted pulse traveling to the left and for the free end the result is an upright pulse traveling to the left.



(a)

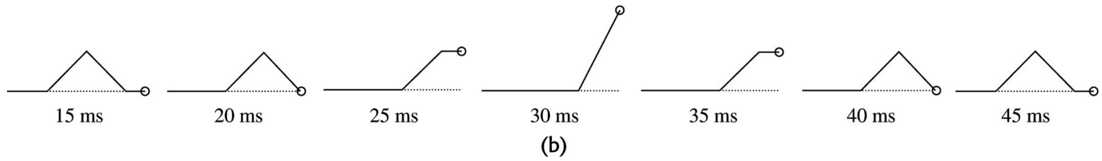


Figure 15.28

15.29. **IDENTIFY:** The distance the wave shape travels in time t is vt. The wave pulse reflects at the end of the string, at point O.

SET UP: The reflected pulse is inverted when O is a fixed end and is not inverted when O is a free end.

EXECUTE: **(a)** The wave form for the given times, respectively, is shown in Figure 15.29(a).

(b) The wave form for the given times, respectively, is shown in Figure 15.29(b).

EVALUATE: For the fixed end the result of the reflection is an inverted pulse traveling to the right and for the free end the result is an upright pulse traveling to the right.

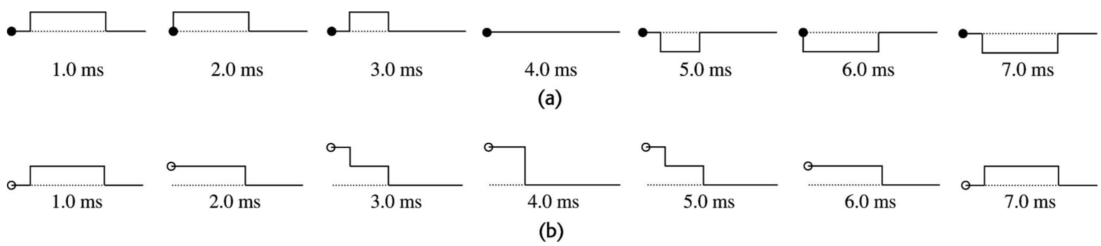

Figure 15.29

15.30. **IDENTIFY:** Apply the principle of superposition.

SET UP: The net displacement is the algebraic sum of the displacements due to each pulse.

EXECUTE: The shape of the string at each specified time is shown in Figure 15.30.

EVALUATE: The pulses interfere when they overlap but resume their original shape after they have completely passed through each other.

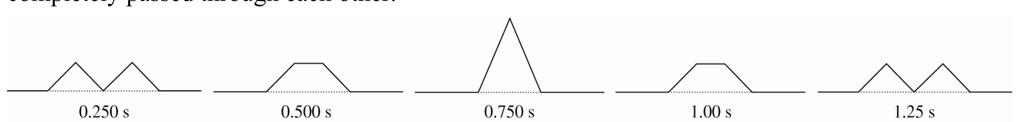

Figure 15.30

15.31. **IDENTIFY:** Apply the principle of superposition.

SET UP: The net displacement is the algebraic sum of the displacements due to each pulse.

EXECUTE: The shape of the string at each specified time is shown in Figure 15.31.

EVALUATE: The pulses interfere when they overlap but resume their original shape after they have completely passed through each other.

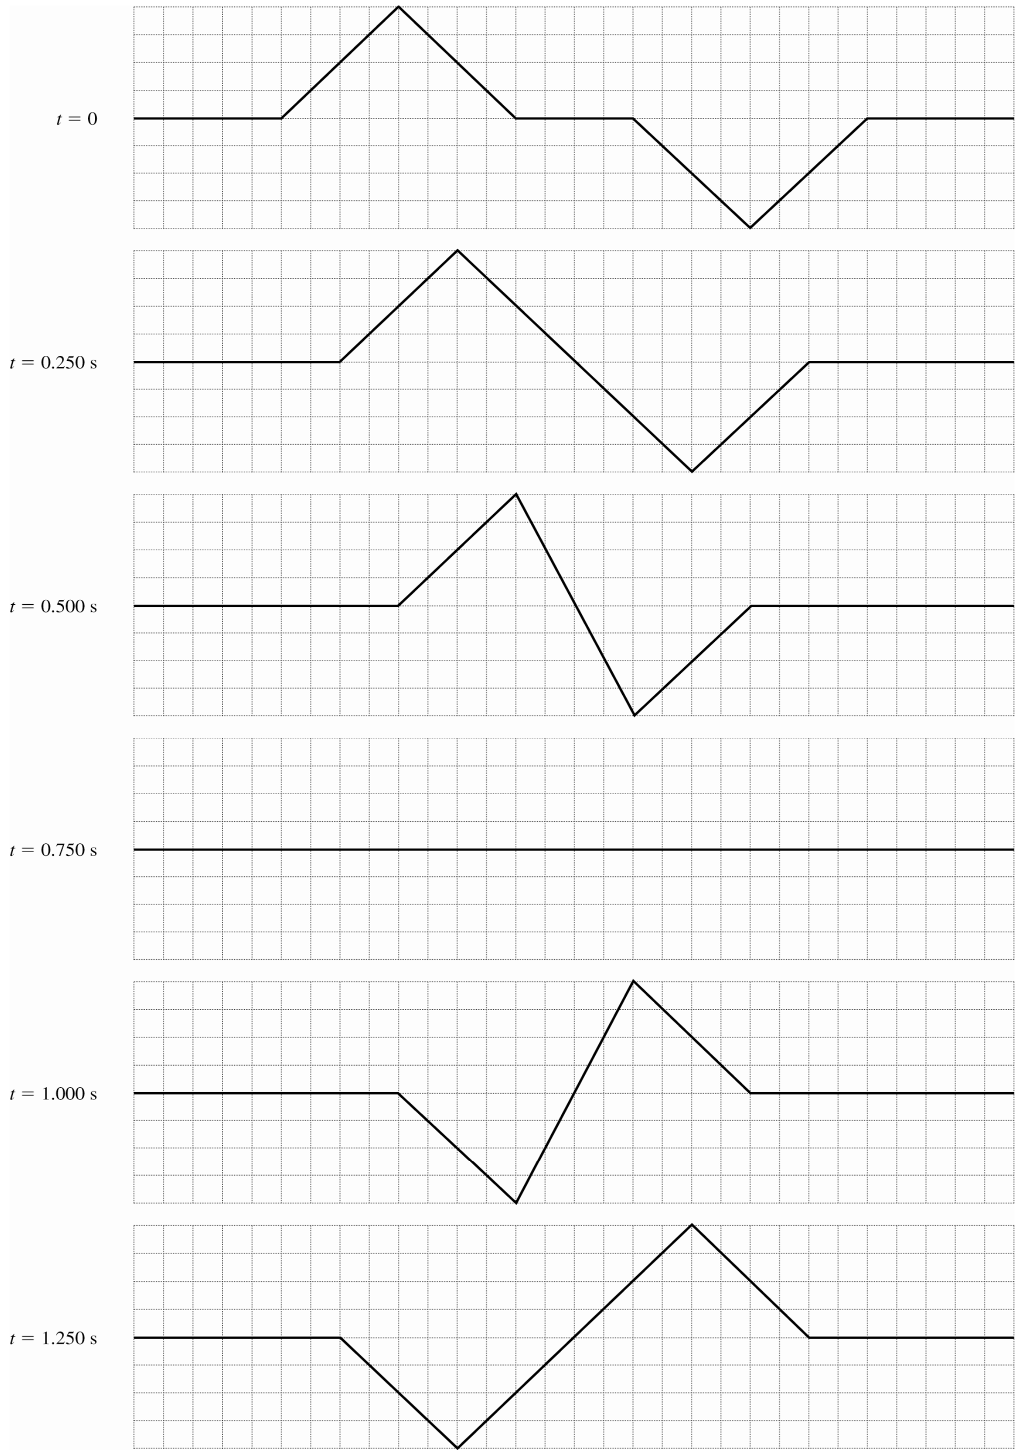

Figure 15.31

15.32. IDENTIFY: Apply the principle of superposition.

SET UP: The net displacement is the algebraic sum of the displacements due to each pulse.

EXECUTE: The shape of the string at each specified time is shown in Figure 15.32.

EVALUATE: The pulses interfere when they overlap but resume their original shape after they have completely passed through each other.

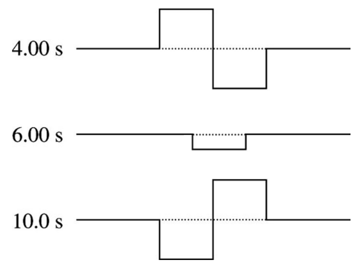

Figure 15.32

15.33. **IDENTIFY:** We are investigating standing waves on a violin string that is fixed at both ends.

SET UP: Estimate: The portion of the violin string that is free to vibrate is about 30 cm = 0.30 m long. For the bass viol, the free portion is 1.0 m long. We use $v = \sqrt{\dfrac{F}{\mu}}$ and $v = f\lambda$.

EXECUTE: **(a)** We want the speed of the wave, so $v = f\lambda$ = (659 Hz)(0.30 m) = 200 m/s.

(b) We want to compare the wavelength of the wave on the string to the wavelength of the sound wave it produces. Both waves have the same frequency but different speeds. In air we have $\lambda_{air} = v_{air}/f$ = (344 m/s)/(659 Hz) = 0.522 m. On the string λ_{string} = 0.30 m, so $\lambda_{air} > \lambda_{string}$.

(c) $v = f\lambda$ = (98 Hz)(1.0 m) = 98 m/s (on the string).

$\lambda_{air} = v_{air}/f$ = (344 m/s)/(98 Hz) = 3.5 m (in air).

So $\lambda_{air} > \lambda_{string}$.

EVALUATE: Each cycle of vibration of the string produces one cycle of sound, so the frequency is the same for the sound and for the string. But the sound wave travels at a different speed than the wave on the string, so the wavelength of the sound is not the same as the wavelength of the wave on the string.

15.34. **IDENTIFY:** Apply $y(x,t) = (A_{SW} \sin kx)\sin \omega t$ and $v = f\lambda$. At an antinode, $y(t) = A_{SW} \sin \omega t$. k and ω for the standing wave have the same values as for the two traveling waves.

SET UP: $A_{SW} = 0.850$ cm. The antinode to antinode distance is $\lambda/2$, so $\lambda = 30.0$ cm. $v_y = \partial y/\partial t$.

EXECUTE: **(a)** The node to node distance is $\lambda/2 = 15.0$ cm.

(b) λ is the same as for the standing wave, so $\lambda = 30.0$ cm. $A = \frac{1}{2}A_{SW} = 0.425$ cm.

$$v = f\lambda = \frac{\lambda}{T} = \frac{0.300\text{ m}}{0.0750\text{ s}} = 4.00\text{ m/s}.$$

(c) $v_y = \dfrac{\partial y}{\partial t} = A_{SW}\,\omega \sin kx \cos \omega t$. At an antinode $\sin kx = 1$, so $v_y = A_{SW}\,\omega \cos \omega t$. $v_{max} = A_{SW}\omega$.

$$\omega = \frac{2\pi\text{ rad}}{T} = \frac{2\pi\text{ rad}}{0.0750\text{ s}} = 83.8\text{ rad/s}.\quad v_{max} = (0.850\times10^{-2}\text{ m})(83.8\text{ rad/s}) = 0.712\text{ m/s}.\quad v_{min} = 0.$$

(d) The distance from a node to an adjacent antinode is $\lambda/4 = 7.50$ cm.

EVALUATE: The maximum transverse speed for a point at an antinode of the standing wave is twice the maximum transverse speed for each traveling wave, since $A_{SW} = 2A$.

15.35. **IDENTIFY** and **SET UP:** Nodes occur where $\sin kx = 0$ and antinodes are where $\sin kx = \pm 1$.

EXECUTE: Use $y = (A_{SW} \sin kx)\sin \omega t$:

(a) At a node $y = 0$ for all t. This requires that $\sin kx = 0$ and this occurs for $kx = n\pi$, $n = 0, 1, 2, \ldots$

$$x = n\pi/k = \frac{n\pi}{0.750\pi\text{ rad/m}} = (1.33\text{ m})n,\ n = 0,\ 1,\ 2, \ldots$$

(b) At an antinode $\sin kx = \pm 1$ so y will have maximum amplitude. This occurs when $kx = (n+\frac{1}{2})\pi$, $n = 0, 1, 2, \ldots$

$$x = (n+\tfrac{1}{2})\pi/k = (n+\tfrac{1}{2})\frac{\pi}{0.750\pi \text{ rad/m}} = (1.33 \text{ m})(n+\tfrac{1}{2}), n = 0, 1, 2, \ldots$$

EVALUATE: $\lambda = 2\pi/k = 2.66$ m. Adjacent nodes are separated by $\lambda/2$, adjacent antinodes are separated by $\lambda/2$, and the node to antinode distance is $\lambda/4$.

15.36. **IDENTIFY:** For a string fixed at both ends, $\lambda_n = \dfrac{2L}{n}$ and $f_n = n\left(\dfrac{v}{2L}\right)$.

SET UP: For the fundamental, $n = 1$. For the second overtone, $n = 3$. For the fourth harmonic, $n = 4$.

EXECUTE: **(a)** $\lambda_1 = 2L = 3.00$ m. $f_1 = \dfrac{v}{2L} = \dfrac{(62.0 \text{ m/s})}{2(1.50 \text{ m})} = 20.7$ Hz.

(b) $\lambda_3 = \lambda_1/3 = 1.00$ m. $f_3 = 3f_1 = 62.0$ Hz.

(c) $\lambda_4 = \lambda_1/4 = 0.75$ m. $f_4 = 4f_1 = 82.7$ Hz.

EVALUATE: As n increases, λ decreases and f increases.

15.37. **IDENTIFY:** Use $v = f\lambda$ for v and $v = \sqrt{F/\mu}$ for the tension F. $v_y = \partial y/\partial t$ and $a_y = \partial v_y/\partial t$.

(a) SET UP: The fundamental standing wave is sketched in Figure 15.37.

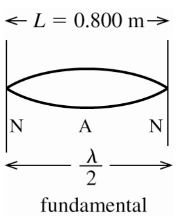

Figure 15.37

$f = 60.0$ Hz

From the sketch,
$\lambda/2 = L$ so
$\lambda = 2L = 1.60$ m

EXECUTE: $v = f\lambda = (60.0 \text{ Hz})(1.60 \text{ m}) = 96.0$ m/s

(b) The tension is related to the wave speed by $v = \sqrt{F/\mu}$:

$v = \sqrt{F/\mu}$ so $F = \mu v^2$.

$\mu = m/L = 0.0400 \text{ kg}/0.800 \text{ m} = 0.0500$ kg/m

$F = \mu v^2 = (0.0500 \text{ kg/m})(96.0 \text{ m/s})^2 = 461$ N.

(c) $\omega = 2\pi f = 377$ rad/s and $y(x, t) = A_{SW} \sin kx \sin \omega t$

$v_y = \omega A_{SW} \sin kx \cos \omega t$; $a_y = -\omega^2 A_{SW} \sin kx \sin \omega t$

$(v_y)_{max} = \omega A_{SW} = (377 \text{ rad/s})(0.300 \text{ cm}) = 1.13$ m/s.

$(a_y)_{max} = \omega^2 A_{SW} = (377 \text{ rad/s})^2(0.300 \text{ cm}) = 426 \text{ m/s}^2$.

EVALUATE: The transverse velocity is different from the wave velocity. The wave velocity and tension are similar in magnitude to the values in the examples in the text. Note that the transverse acceleration is quite large.

15.38. **IDENTIFY:** The fundamental frequency depends on the wave speed, and that in turn depends on the tension.

SET UP: $v = \sqrt{\dfrac{F}{\mu}}$ where $\mu = m/L$. $f_1 = \dfrac{v}{2L}$. The nth harmonic has frequency $f_n = nf_1$.

EXECUTE: **(a)** $v = \sqrt{\dfrac{F}{m/L}} = \sqrt{\dfrac{FL}{m}} = \sqrt{\dfrac{(800 \text{ N})(0.400 \text{ m})}{3.00\times10^{-3} \text{ kg}}} = 327$ m/s. $f_1 = \dfrac{v}{2L} = \dfrac{327 \text{ m/s}}{2(0.400 \text{ m})} = 409$ Hz.

(b) $n = \dfrac{10{,}000 \text{ Hz}}{f_1} = 24.4.$ The 24th harmonic is the highest that could be heard.

EVALUATE: In part (b) we use the fact that a standing wave on the wire produces a sound wave in air of the same frequency.

15.39. IDENTIFY: Compare $y(x,t)$ given in the problem to $y(x,t) = (A_{SW} \sin kx)\sin \omega t$. From the frequency and wavelength for the third harmonic find these values for the eighth harmonic.

(a) SET UP: The third harmonic standing wave pattern is sketched in Figure 15.39.

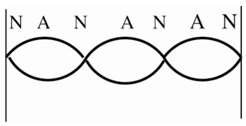

Figure 15.39

EXECUTE: **(b)** Use the general equation for a standing wave on a string:

$y(x,t) = (A_{SW} \sin kx)\sin \omega t$

$A_{SW} = 2A$, so $A = A_{SW}/2 = (5.60 \text{ cm})/2 = 2.80 \text{ cm}$

(c) The sketch in part (a) shows that $L = 3(\lambda/2)$. $k = 2\pi/\lambda$, $\lambda = 2\pi/k$

Comparison of $y(x,t)$ given in the problem to $y(x,t) = (A_{SW} \sin kx)\sin \omega t$ gives $k = 0.0340 \text{ rad/cm}$.

So, $\lambda = 2\pi/(0.0340 \text{ rad/cm}) = 184.8 \text{ cm}$

$L = 3(\lambda/2) = 277 \text{ cm}$

(d) $\lambda = 185 \text{ cm}$, from part (c)

$\omega = 50.0 \text{ rad/s}$ so $f = \omega/2\pi = 7.96 \text{ Hz}$

period $T = 1/f = 0.126 \text{ s}$ $v = f\lambda = 1470 \text{ cm/s}$

(e) $v_y = \partial y/\partial t = \omega A_{SW} \sin kx \cos \omega t$

$v_{y,\,\max} = \omega A_{SW} = (50.0 \text{ rad/s})(5.60 \text{ cm}) = 280 \text{ cm/s}$

(f) $f_3 = 7.96 \text{ Hz} = 3f_1$, so $f_1 = 2.65 \text{ Hz}$ is the fundamental

$f_8 = 8f_1 = 21.2 \text{ Hz}$; $\omega_8 = 2\pi f_8 = 133 \text{ rad/s}$

$\lambda = v/f = (1470 \text{ cm/s})/(21.2 \text{ Hz}) = 69.3 \text{ cm}$ and $k = 2\pi/\lambda = 0.0906 \text{ rad/cm}$

$y(x,t) = (5.60 \text{ cm})\sin\left[(0.0906 \text{ rad/cm})x\right]\sin[(133 \text{ rad/s})t]$.

EVALUATE: The wavelength and frequency of the standing wave equals the wavelength and frequency of the two traveling waves that combine to form the standing wave. In the eighth harmonic the frequency and wave number are larger than in the third harmonic.

15.40. IDENTIFY: Compare the $y(x,t)$ specified in the problem to the general form of $y(x,t) = (A_{SW} \sin kx)\sin \omega t$.

SET UP: The comparison gives $A_{SW} = 4.44 \text{ mm}$, $k = 32.5 \text{ rad/m}$ and $\omega = 754 \text{ rad/s}$.

EXECUTE: **(a)** $A = \frac{1}{2}A_{SW} = \frac{1}{2}(4.44 \text{ mm}) = 2.22 \text{ mm}$.

(b) $\lambda = \dfrac{2\pi}{k} = \dfrac{2\pi}{32.5 \text{ rad/m}} = 0.193 \text{ m}$.

(c) $f = \dfrac{\omega}{2\pi} = \dfrac{754 \text{ rad/s}}{2\pi} = 120 \text{ Hz}$.

(d) $v = \dfrac{\omega}{k} = \dfrac{754 \text{ rad/s}}{32.5 \text{ rad/m}} = 23.2 \text{ m/s}$.

(e) If the wave traveling in the +x-direction is written as $y_1(x,t) = A\cos(kx - \omega t)$, then the wave traveling in the $-x$-direction is $y_2(x,t) = -A\cos(kx + \omega t)$, where $A = 2.22 \text{ mm}$ from part (a), $k = 32.5 \text{ rad/m}$ and $\omega = 754 \text{ rad/s}$.

(f) The harmonic cannot be determined because the length of the string is not specified.
EVALUATE: The two traveling waves that produce the standing wave are identical except for their direction of propagation.

15.41. **IDENTIFY:** Standing waves are formed on a string fixed at both ends.
SET UP: The distance between adjacent nodes is one-half of a wavelength. The second overtone is the third harmonic ($n = 3$). $\lambda_n = 2L/n$.
EXECUTE: **(a)** We want the length of the string. In the third harmonic $\lambda_3 = 2L/3$, so $L = 3\lambda_3/2$. The distance between adjacent nodes is $\lambda/2$ = 8.00 cm, so λ = 16.0 cm. Therefore $L = 3\lambda_3/2$ = 24.0 cm = 0.240 m.
(b) For the 4th harmonic, $n = 4$, so $\lambda_4 = 2L/4$ = (48.0 cm)/4 = 12.0 cm = 0.120 m. The node-to-node distance is $\lambda/2$ = (12.0 cm)/2 = 6.00 cm = 0.0600 m.
EVALUATE: The node-to-node distance decreases with higher harmonics because the wavelength decreases, which is consistent with your results.

15.42. **IDENTIFY:** $v = \sqrt{F/\mu}$. $v = f\lambda$. The standing waves have wavelengths $\lambda_n = \dfrac{2L}{n}$ and frequencies $f_n = nf_1$. The standing wave on the string and the sound wave it produces have the same frequency.
SET UP: For the fundamental $n = 1$ and for the second overtone $n = 3$. The string has $\mu = m/L = (8.75\times10^{-3}\text{ kg})/(0.750\text{ m}) = 1.17\times10^{-2}\text{ kg/m}$.
EXECUTE: **(a)** $\lambda = 2L/3 = 2(0.750\text{ m})/3 = 0.500\text{ m}$. The sound wave has frequency

$$f = \frac{v}{\lambda} = \frac{344\text{ m/s}}{0.765\text{ m}} = 449.7\text{ Hz}.$$ For waves on the string,

$v = f\lambda = (449.7\text{ Hz})(0.500\text{ m}) = 224.8\text{ m/s}$. The tension in the string is

$F = \mu v^2 = (1.17\times10^{-2}\text{ kg/m})(224.8\text{ m/s})^2 = 591\text{ N}$.

(b) $f_1 = f_3/3 = (449.7\text{ Hz})/3 = 150\text{ Hz}$.

EVALUATE: The waves on the string have a much longer wavelength than the sound waves in the air because the speed of the waves on the string is much greater than the speed of sound in air.

15.43. **IDENTIFY** and **SET UP:** Use the information given about the A_4 note to find the wave speed that depends on the linear mass density of the string and the tension. The wave speed isn't affected by the placement of the fingers on the bridge. Then find the wavelength for the D_5 note and relate this to the length of the vibrating portion of the string.
EXECUTE: **(a)** $f = 440\text{ Hz}$ when a length $L = 0.600\text{ m}$ vibrates; use this information to calculate the speed v of waves on the string. For the fundamental $\lambda/2 = L$ so $\lambda = 2L = 2(0.600\text{ m}) = 1.20\text{ m}$. Then $v = f\lambda = (440\text{ Hz})(1.20\text{ m}) = 528\text{ m/s}$. Now find the length $L = x$ of the string that makes $f = 587\text{ Hz}$.

$$\lambda = \frac{v}{f} = \frac{528\text{ m/s}}{587\text{ Hz}} = 0.900\text{ m}$$

$L = \lambda/2 = 0.450\text{ m}$, so $x = 0.450\text{ m} = 45.0\text{ cm}$.

(b) No retuning means same wave speed as in part (a). Find the length of vibrating string needed to produce $f = 392\text{ Hz}$.

$$\lambda = \frac{v}{f} = \frac{528\text{ m/s}}{392\text{ Hz}} = 1.35\text{ m}$$

$L = \lambda/2 = 0.675\text{ m}$; string is shorter than this. No, not possible.

EVALUATE: Shortening the length of this vibrating string increases the frequency of the fundamental.

15.44. **IDENTIFY:** $y(x,t) = (A_{\text{SW}}\sin kx)\sin\omega t$. $v_y = \partial y/\partial t$. $a_y = \partial^2 y/\partial t^2$.

SET UP: $v_{\text{max}} = (A_{\text{SW}}\sin kx)\omega$. $a_{\text{max}} = (A_{\text{SW}}\sin kx)\omega^2$.

EXECUTE: (a) (i) $x = \dfrac{\lambda}{2}$ is a node, and there is no motion.

(ii) $x = \dfrac{\lambda}{4}$ is an antinode, and $v_{\text{max}} = \omega A = 2\pi fA$, $a_{\text{max}} = \omega v_{\text{max}} = (2\pi f)v_{\text{max}} = 4\pi^2 f^2 A.$

(iii) $\cos\dfrac{\pi}{4} = \dfrac{1}{\sqrt{2}}$ and this factor multiplies the results of (ii), so $v_{\text{max}} = \sqrt{2}\pi fA$, $a_{\text{max}} = 2\sqrt{2}\pi^2 f^2 A.$

(b) The amplitude is $2A\sin kx$, or (i) 0, (ii) $2A$, (iii) $2A/\sqrt{2}$.

(c) The time between the extremes of the motion is the same for any point on the string (although the period of the zero motion at a node might be considered indeterminate) and is $1/2f$.

EVALUATE: Any point in a standing wave moves in SHM. All points move with the same frequency but have different amplitude.

15.45. IDENTIFY: We are dealing with a traveling sinusoidal wave on a string.
SET UP: The equation $y(x,t) = A\cos(kx - \omega t)$ describes this wave. We know the maximum transverse speed and acceleration. We use $v_{y\text{-max}} = A\omega$, $a_{y\text{-max}} = A\omega^2$, and $v = f\lambda$. The target variables are the speed v of the wave and its amplitude A.
EXECUTE: Take the ratio of the maximum acceleration to the maximum speed, giving $\dfrac{a_{y\text{-max}}}{v_{y\text{-max}}} = \dfrac{A\omega^2}{A\omega} = \omega$. Using the known values gives $\omega = \dfrac{8.50\times10^4 \text{ m/s}^2}{3.00 \text{ m/s}} = 2.8333\times10^4$ rad/s. Now use

$$v = f\lambda = (\omega/2\pi)\lambda = \left(\frac{2.8333\times10^4 \text{ rad/s}}{2\pi}\right)(0.400 \text{ m}) = 1.80\times10^3 \text{ m/s}.$$

From the velocity equation $v_{y\text{-max}} = A\omega$ we have $A = \dfrac{v_{y\text{-max}}}{\omega}$, which gives

$$A = \frac{3.00 \text{ m/s}}{2.8333\times10^4 \text{ rad/s}} = 1.06\times10^{-4} \text{ m}.$$

EVALUATE: The propagation speed v is constant. But the transverse speed $v_y = \dfrac{\partial y}{\partial t}$ is *not* constant; it varies with time and from place to place on the string.

15.46. IDENTIFY: Compare $y(x,t)$ given in the problem to the general form $y(x,t) = A\cos(kx - \omega t)$.
SET UP: The comparison gives $A = 0.750$ cm, $k = 0.400\pi$ rad/cm and $\omega = 250\pi$ rad/s.

EXECUTE: (a) $A = 0.750$ cm, $\lambda = \dfrac{2}{0.400 \text{ rad/cm}} = 5.00$ cm, $f = 125$ Hz, $T = \frac{1}{f} = 0.00800$ s and $v = \lambda f = 6.25$ m/s.

(b) The sketches of the shape of the rope at each time are given in Figure 15.46.
(c) To stay with a wavefront as t increases, x decreases and so the wave is moving in the $-x$-direction.
(d) From $v = \sqrt{F/\mu}$, the tension is $F = \mu v^2 = (0.050 \text{ kg/m})(6.25 \text{ m/s})^2 = 1.95$ N.

(e) $P_{\text{av}} = \frac{1}{2}\sqrt{\mu F}\omega^2 A^2 = 5.42$ W.

EVALUATE: The argument of the cosine is $(kx + \omega t)$ for a wave traveling in the $-x$-direction, and that is the case here.

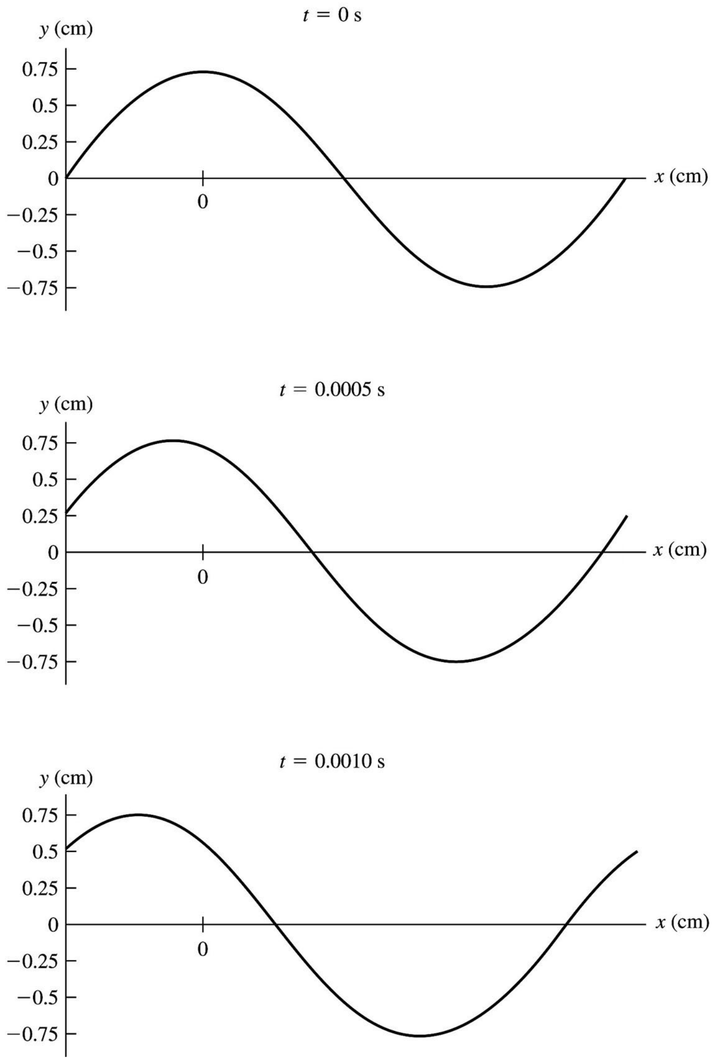

Figure 15.46

15.47. **IDENTIFY** and **SET UP:** Calculate v, ω, and k from $v = f\lambda$, $\omega = vk$, $k = 2\pi/\lambda$. Then apply $y(x,t) = A\cos(kx - \omega t)$ to obtain $y(x,t)$.

$A = 2.50\times10^{-3}$ m, $\lambda = 1.80$ m, $v = 36.0$ m/s

EXECUTE: **(a)** $v = f\lambda$ so $f = v/\lambda = (36.0 \text{ m/s})/1.80 \text{ m} = 20.0 \text{ Hz}$

$\omega = 2\pi f = 2\pi(20.0 \text{ Hz}) = 126 \text{ rad/s}$

$k = 2\pi/\lambda = 2\pi \text{ rad}/1.80 \text{ m} = 3.49 \text{ rad/m}$

(b) For a wave traveling to the right, $y(x,t) = A\cos(kx - \omega t)$. This equation gives that the $x = 0$ end of the string has maximum upward displacement at $t = 0$.

Put in the numbers: $y(x,t) = (2.50\times10^{-3} \text{ m})\cos[(3.49 \text{ rad/m})x - (126 \text{ rad/s})t]$.

(c) The left-hand end is located at $x = 0$. Put this value into the equation of part (b):

$y(0,t) = +(2.50\times10^{-3} \text{ m})\cos((126 \text{ rad/s})t)$.

(d) Put $x = 1.35$ m into the equation of part (b):

$y(1.35 \text{ m}, t) = (2.50\times10^{-3} \text{ m})\cos((3.49 \text{ rad/m})(1.35 \text{ m}) - (126 \text{ rad/s})t)$.

$y(1.35 \text{ m}, t) = (2.50\times10^{-3} \text{ m})\cos(4.71 \text{ rad} - (126 \text{ rad/s})t)$

$4.71 \text{ rad} = 3\pi/2$ and $\cos(\theta) = \cos(-\theta)$, so $y(1.35 \text{ m}, t) = (2.50\times 10^{-3} \text{ m})\cos((126 \text{ rad/s})t - 3\pi/2 \text{ rad})$

(e) $y = A\cos(kx - \omega t)$ (part (b))

The transverse velocity is given by $v_y = \dfrac{\partial y}{\partial t} = A\dfrac{\partial}{\partial t}\cos(kx - \omega t) = +A\omega\sin(kx - \omega t)$.

The maximum v_y is $A\omega = (2.50\times 10^{-3} \text{ m})(126 \text{ rad/s}) = 0.315 \text{ m/s}$.

(f) $y(x,t) = (2.50\times 10^{-3} \text{ m})\cos((3.49 \text{ rad/m})x - (126 \text{ rad/s})t)$

$t = 0.0625$ s and $x = 1.35$ m gives

$y = (2.50\times 10^{-3} \text{ m})\cos((3.49 \text{ rad/m})(1.35 \text{ m}) - (126 \text{ rad/s})(0.0625 \text{ s})) = -2.50\times 10^{-3}$ m.

$v_y = +A\omega\sin(kx - \omega t) = +(0.315 \text{ m/s})\sin((3.49 \text{ rad/m})x - (126 \text{ rad/s})t)$

$t = 0.0625$ s and $x = 1.35$ m gives

$v_y = (0.315 \text{ m/s})\sin((3.49 \text{ rad/m})(1.35 \text{ m}) - (126 \text{ rad/s})(0.0625 \text{ s})) = 0.0$

EVALUATE: The results of part (f) illustrate that $v_y = 0$ when $y = \pm A$, as we saw from SHM in Chapter 14.

15.48. **IDENTIFY:** Apply $\Sigma\tau_z = 0$ to find the tension in each wire. Use $v = \sqrt{F/\mu}$ to calculate the wave speed for each wire and then $t = L/v$ is the time for each pulse to reach the ceiling, where $L = 1.25$ m.

SET UP: The wires have $\mu = \dfrac{m}{L} = \dfrac{0.290 \text{ N}}{(9.80 \text{ m/s}^2)(1.25 \text{ m})} = 0.02367 \text{ kg/m}$. The free-body diagram for the beam is given in Figure 15.48. Take the axis to be at the end of the beam where wire A is attached.

EXECUTE: $\Sigma\tau_z = 0$ gives $T_B L = w(L/3)$ and $T_B = w/3 = 583$ N. $T_A + T_B = 1750$ N, so $T_A = 1167$ N.

$v_A = \sqrt{\dfrac{T_A}{\mu}} = \sqrt{\dfrac{1167 \text{ N}}{0.02367 \text{ kg/m}}} = 222$ m/s. $t_A = \dfrac{1.25 \text{ m}}{222 \text{ m/s}} = 0.00563 \text{ s} = 5.63$ ms.

$v_B = \sqrt{\dfrac{583 \text{ N}}{0.02367 \text{ kg/m}}} = 156.9$ m/s. $t_B = \dfrac{1.25 \text{ m}}{156.9 \text{ m/s}} = 0.007965 \text{ s} = 7.965$ ms.

$\Delta t = t_B - t_A = 7.965 \text{ ms} - 5.63 \text{ ms} = 2.34$ ms.

EVALUATE: The wave pulse travels faster in wire A, since that wire has the greater tension, so the pulse in wire A arrives first.

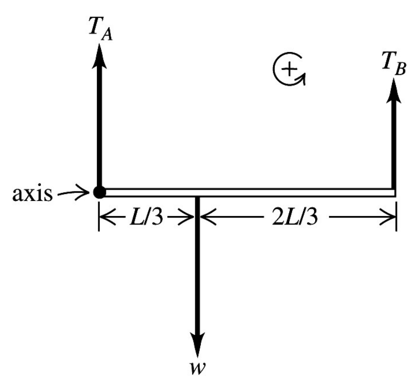

Figure 15.48

15.49. **IDENTIFY:** The block causes tension in the wire supporting the rod. A standing wave pattern exists on the wire, and the torques on the rod balance.

SET UP: The graph is a plot of the square of the frequency f versus the mass m hanging from the rod. The target variable is the mass of the wire. To interpret the graph, we need to find a relationship between f^2 and m. We apply $\sum\tau_z = 0$ about the hinge and use $v = \sqrt{\dfrac{F}{\mu}}$ and $v = f\lambda$.

EXECUTE: $\sum\tau_z = 0$: $TL\sin\theta - mg\dfrac{L}{2} = 0$ gives $T = \dfrac{mg}{2\sin\theta}$. Now use $v = \sqrt{\dfrac{F}{\mu}}$ and $v = f\lambda$. Equating these velocity equations gives $f\lambda = \sqrt{\dfrac{F}{\mu}}$, so $f^2 = \dfrac{1}{\lambda^2}\left(\dfrac{F}{\mu}\right)$. Using the result for the tension gives $f^2 = \dfrac{1}{\mu\lambda^2}\left(\dfrac{mg}{2\sin\theta}\right) = \left(\dfrac{g}{2\mu\lambda^2\sin\theta}\right)m$. The wire is vibrating in its fundamental mode so $\lambda = 2L$. The linear mass density of the wire is $\mu = \dfrac{m_w}{L}$. Therefore the final equation becomes $f^2 = \left(\dfrac{g}{8m_w L\sin\theta}\right)m$. From this we see that a graph of f^2 versus m should be a straight line with slope equal to $\dfrac{g}{8m_w L\sin\theta}$.

Thus $m_w = \dfrac{g}{(\text{slope})8L\sin\theta}$ which gives

$$m_w = \frac{9.80\ \text{m/s}^2}{(20.4\ \text{kg}^{-1}\cdot\text{s}^{-2})(8)(2.00\ \text{m})(\sin 30.0°)} = 0.0600\ \text{kg} = 60.0\ \text{g}.$$

EVALUATE: A mass of 60 g for a 2.00-m wire is not unreasonable.

15.50. IDENTIFY: The maximum vertical acceleration must be at least g.

SET UP: $a_{max} = \omega^2 A$

EXECUTE: $g = \omega^2 A_{min}$ and thus $A_{min} = g/\omega^2$. Using $\omega = 2\pi f = 2\pi v/\lambda$ and $v = \sqrt{F/\mu}$, this becomes $A_{min} = \dfrac{g\lambda^2\mu}{4\pi^2 F}$.

EVALUATE: When the amplitude of the motion increases, the maximum acceleration of a point on the rope increases.

15.51. IDENTIFY: Calculate the speed of the wave and use that to find the length of the wire since we know how long it takes the wave to travel the length of the wire.

SET UP: $v = \sqrt{F/\mu}$, $x = v_x t$, and $\mu = m/L$.

EXECUTE: **(a)** $\mu = m/L = (14.5\times10^{-9}\ \text{kg})/(0.0200\ \text{m}) = 7.25\times10^{-7}\ \text{kg/m}$. Now combine $v = \sqrt{F/\mu}$ and $x = v_x t$: $vt = L$, so $L = t\sqrt{F/\mu} = (26.7\times10^{-3}\ \text{s})\sqrt{\dfrac{(0.400\ \text{kg})(9.80\ \text{m/s}^2)}{7.25\times10^{-7}\ \text{kg/m}}} = 62.1\ \text{m}$.

(b) The mass of the wire is $m = \mu L = (7.25\times10^{-7}\ \text{kg/m})(62.1\ \text{m}) = 4.50\times10^{-5}\ \text{kg} = 0.0450\ \text{g}$.

EVALUATE: The mass of the wire is negligible compared to the 0.400-kg object hanging from the wire.

15.52. IDENTIFY: The frequencies at which a string vibrates depend on its tension, mass density and length.

SET UP: $f_1 = \dfrac{v}{\lambda_1} = \dfrac{v}{2L}$, where $v = \sqrt{\dfrac{F}{\mu}} = \sqrt{\dfrac{FL}{m}}$. F is the tension in the string, L is its length and m is its mass.

EXECUTE: **(a)** $f_1 = \dfrac{v}{2L} = \dfrac{1}{2L}\sqrt{\dfrac{FL}{m}} = \dfrac{1}{2}\sqrt{\dfrac{F}{Lm}}$. Solving for F gives

$$F = (2f_1)^2 Lm = 4(262\ \text{Hz})^2(0.350\ \text{m})(8.00\times10^{-3}\ \text{kg}) = 769\ \text{N}.$$

(b) $m = \dfrac{F}{L(2f_1)^2} = \dfrac{769 \text{ N}}{(0.350 \text{ m})(4)(466 \text{ Hz})^2} = 2.53 \text{ g}.$

(c) For S_1, $\mu = \dfrac{8.00\times10^{-3} \text{ kg}}{0.350 \text{ m}} = 0.0229 \text{ kg/m}$. $F = 769 \text{ N}$ and $v = \sqrt{F/\mu} = 183 \text{ m/s}$. $f_1 = \dfrac{v}{2L}$ gives $L = \dfrac{v}{2f_1} = \dfrac{183 \text{ m/s}}{2(277 \text{ Hz})} = 33.0 \text{ cm}$. $x = 35.0 \text{ cm} - 33.0 \text{ cm} = 2.00 \text{ cm}$.

(d) For S_2, $\mu = \dfrac{2.53\times10^{-3} \text{ kg}}{0.350 \text{ m}} = 7.23\times10^{-3} \text{ kg/m}$. $F = 769 \text{ N}$ and $v = \sqrt{F/\mu} = 326 \text{ m/s}$. $L = 0.330 \text{ m}$ and $f_1 = \dfrac{v}{2L} = \dfrac{326 \text{ m/s}}{2(0.330 \text{ m})} = 494 \text{ Hz}$.

EVALUATE: If the tension is the same in the strings, the mass densities must be different to produce sounds of different pitch.

15.53. **IDENTIFY:** Apply $\Sigma\tau_z = 0$ to one post and calculate the tension in the wire. $v = \sqrt{F/\mu}$ for waves on the wire. $v = f\lambda$. The standing wave on the wire and the sound it produces have the same frequency. For standing waves on the wire, $\lambda_n = \dfrac{2L}{n}$.

SET UP: For the fifth overtone, $n = 6$. The wire has $\mu = m/L = (0.732 \text{ kg})/(5.00 \text{ m}) = 0.146 \text{ kg/m}$. The free-body diagram for one of the posts is given in Figure 15.53. Forces at the pivot aren't shown. We take the rotation axis to be at the pivot, so forces at the pivot produce no torque.

EXECUTE: $\Sigma\tau_z = 0$ gives $w\left(\dfrac{L}{2}\cos 57.0°\right) - T(L\sin 57.0°) = 0$. $T = \dfrac{w}{2\tan 57.0°} = \dfrac{235 \text{ N}}{2\tan 57.0°} = 76.3 \text{ N}$.

For waves on the wire, $v = \sqrt{\dfrac{F}{\mu}} = \sqrt{\dfrac{76.3 \text{ N}}{0.146 \text{ kg/m}}} = 22.9 \text{ m/s}$. For the fifth overtone standing wave on the wire, $\lambda = \dfrac{2L}{6} = \dfrac{2(5.00 \text{ m})}{6} = 1.67 \text{ m}$. $f = \dfrac{v}{\lambda} = \dfrac{22.9 \text{ m/s}}{1.67 \text{ m}} = 13.7 \text{ Hz}$. The sound waves have frequency 13.7 Hz and wavelength $\lambda = \dfrac{344 \text{ m/s}}{13.7 \text{ Hz}} = 25.0 \text{ m}$.

EVALUATE: The frequency of the sound wave is just below the lower limit of audible frequencies. The wavelength of the standing wave on the wire is much less than the wavelength of the sound waves, because the speed of the waves on the wire is much less than the speed of sound in air.

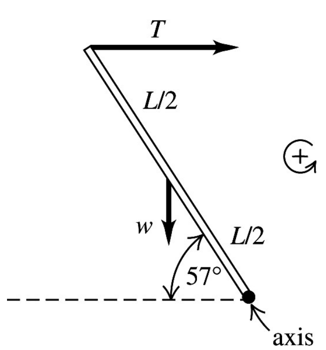

Figure 15.53

15.54. **IDENTIFY:** The mass of the planet (the target variable) determines g at its surface, which in turn determines the weight of the lead object hanging from the string. The weight is the tension in the string, which determines the speed of a wave pulse on that string.

SET UP: At the surface of the planet $g = G\dfrac{m_{\rm p}}{R_{\rm p}^2}$. The pulse speed is $v = \sqrt{\dfrac{F}{\mu}}$.

EXECUTE: On earth, $v = \dfrac{4.00\ \text{m}}{0.0390\ \text{s}} = 1.0256\times 10^2\ \text{m/s}$. $\mu = \dfrac{0.0280\ \text{kg}}{4.00\ \text{m}} = 7.00\times 10^{-3}\ \text{kg/m}^3$. $F = Mg$, so $v = \sqrt{\dfrac{Mg}{\mu}}$ and the mass of the lead weight is

$M = \left(\dfrac{\mu}{g}\right)v^2 = \left(\dfrac{7.00\times 10^{-3}\ \text{kg/m}}{9.8\ \text{m/s}^2}\right)(1.0256\times 10^2\ \text{m/s})^2 = 7.513\ \text{kg}$. On the planet,

$v = \dfrac{4.00\ \text{m}}{0.0685\ \text{s}} = 58.394\ \text{m/s}$. Therefore $g = \left(\dfrac{\mu}{M}\right)v^2 = \left(\dfrac{7.00\times 10^{-3}\ \text{kg/m}}{7.513\ \text{kg}}\right)(58.394\ \text{m/s})^2 = 3.1770\ \text{m/s}^2$.

$g = G\dfrac{m_{\rm p}}{R_{\rm p}^2}$ and $m_{\rm p} = \dfrac{gR_{\rm p}^2}{G} = \dfrac{(3.1770\ \text{m/s}^2)(7.20\times 10^7\ \text{m})^2}{6.6743\times 10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2} = 2.47\times 10^{26}\ \text{kg}$.

EVALUATE: This mass is about 41 times that of earth, but its radius is about 10 times that of earth, so the result is reasonable.

15.55. **IDENTIFY:** The wavelengths of standing waves depend on the length of the string (the target variable), which in turn determine the frequencies of the waves.

SET UP: $f_n = nf_1$ where $f_1 = \dfrac{v}{2L}$.

EXECUTE: $f_n = nf_1$ and $f_{n+1} = (n+1)f_1$. We know the wavelengths of two adjacent modes, so $f_1 = f_{n+1} - f_n = 630\ \text{Hz} - 525\ \text{Hz} = 105\ \text{Hz}$. Solving $f_1 = \dfrac{v}{2L}$ for L gives $L = \dfrac{v_1}{2f} = \dfrac{384\ \text{m/s}}{2(105\ \text{Hz})} = 1.83\ \text{m}$.

EVALUATE: The observed frequencies are both audible which is reasonable for a string that is about a half meter long.

15.56. **IDENTIFY:** A standing wave exists on a string fixed at both ends.

SET UP: The graph plots the number n of nodes (*not* antinodes) versus the frequency f_n. Therefore we look for a relationship between f_n and n so we can interpret the slope of the graph. The target variable is the speed v of waves on the string. We use $v = f\lambda$.

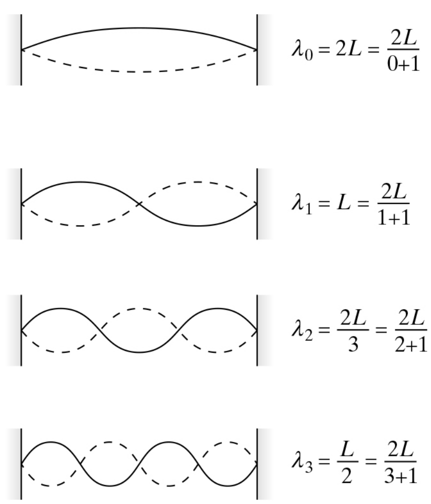

Figure 15.56

EXECUTE: We cannot use $\lambda_n = 2L/n$ because in that formula n is the number of *antinodes* and we need a relationship involving the number of *nodes* (not counting the nodes at the ends of the string). Fig. 15.56 helps to find this relationship. We already know that the wavelengths of the harmonics are $2L$, L, $2L/3$, $L/2$, … . Letting n be the number of antinodes between the ends, from the figure we see that $\lambda_0 = 2L$, $\lambda_1 = L = 2L/2$, $\lambda_2 = 2L/3$, $\lambda_3 = L/2 = 2L/4$, … . Notice that the denominator is 1 more than n, so the general formula is $\lambda_n = \dfrac{2L}{n+1}$, where n = 0, 1, 2, … . Now we need to relate this result to the frequency f_n. Using $v = f\lambda$ gives $f_n\lambda_n = v$. Using $\lambda_n = \dfrac{2L}{n+1}$, we get $f_n\left(\dfrac{2L}{n+1}\right) = v$. Solving for n gives $n = \dfrac{2L}{v}f_n - 1$. From this equation we see that a graph of n versus f_n should be a straight line having slope $2L/v$, so $v = \dfrac{2L}{\text{slope}} = \dfrac{2(0.800\text{ m})}{7.30\times10^{-3}\text{ s}} = 219\text{ m/s}$.

EVALUATE: The method used here would be useful if the string could not be removed to measure its mass and length to use $v = \sqrt{\dfrac{F}{\mu}}$.

15.57. **IDENTIFY:** The tension in the wires along with their lengths determine the fundamental frequency in each one (the target variables). These frequencies are different because the wires have different linear mass densities. The bar is in equilibrium, so the forces and torques on it balance.

SET UP: $T_a + T_c = w$, $\Sigma\tau_z = 0$, $v = \sqrt{\dfrac{F}{\mu}}$, $f_1 = v/2L$ and $\mu = \dfrac{m}{L}$, where $m = \rho V = \rho\pi r^2 L$. The densities of copper and aluminum are given in a table in the text.

EXECUTE: Using the subscript "a" for aluminum and "c" for copper, we have $T_a + T_c = w = 638\text{ N}$. $\Sigma\tau_z = 0$, with the axis at left-hand end of bar, gives $T_c(1.40\text{ m}) = w(0.90\text{ m})$, so $T_c = 410.1\text{ N}$.

$T_a = 638\text{ N} - 410.1\text{ N} = 227.9\text{ N}$. $f_1 = \dfrac{v}{2L}$. $\mu = \dfrac{m}{L} = \dfrac{\rho\pi r^2 L}{L} = \rho\pi r^2$.

<u>For the copper wire</u>: $F = 410.1\text{ N}$ and $\mu = (8.90\times10^3\text{ kg/m}^3)\pi(0.280\times10^{-3}\text{ m})^2 = 2.19\times10^{-3}\text{ kg/m}$, so

$v = \sqrt{\dfrac{F}{\mu}} = \sqrt{\dfrac{410.1\text{ N}}{2.19\times10^{-3}\text{ kg/m}}} = 432.7\text{ m/s}$. $f_1 = \dfrac{v}{2L} = \dfrac{432.7\text{ m/s}}{2(0.600\text{ m})} = 361\text{ Hz}$.

<u>For the aluminum wire</u>: $F = 227.9\text{ N}$ and

$\mu = (2.70\times10^3\text{ kg/m}^3)\pi(0.280\times10^{-3}\text{ m})^2 = 6.65\times10^{-4}\text{ kg/m}$, so

$v = \sqrt{\dfrac{F}{\mu}} = \sqrt{\dfrac{227.9\text{ N}}{6.65\times10^{-4}\text{ kg/m}}} = 585.4\text{ m/s}$, which gives $f_1 = \dfrac{585.4\text{ m/s}}{2(0.600\text{ m})} = 488\text{ Hz}$.

EVALUATE: The wires have different fundamental frequencies because they have different tensions and different linear mass densities.

15.58. **IDENTIFY:** We are dealing with a standing wave on a string fixed at both ends.

SET UP: We want to know the maximum transverse speed at two points on the string. The equation for the displacement $y(x,t)$ of the string is $y(x,t) = A_{SW}\sin kx \sin\omega t$. The transverse velocity is $v_y = \dfrac{\partial y}{\partial t}$, $v = f\lambda$, $k = 2\pi/\lambda$, and $\omega = 2\pi f$. The first antinode occurs at x = 0.150 m, which is ¼ of a wavelength from the end, so λ = 0.600 m.

EXECUTE: **(a)** The maximum transverse speed occurs at the antinodes. Using $v_y = \dfrac{\partial y}{\partial t}$, we get $v_y = \omega A_{SW}\sin kx\cos\omega t$. The maximum speed is ωA_{SW}. Now use $v = f\lambda$ and $\omega = 2\pi f$ to find ω:

$v = f\lambda = (\omega / 2\pi)\lambda$, so $\omega = 2\pi v / \lambda$. Thus $v_{y,\max} = \omega A_{\rm SW} = \dfrac{2\pi v A_{\rm SW}}{\lambda}$. Putting in the numbers gives

$v_{y,\max} = \dfrac{2\pi(260 \text{ m/s})(0.00180 \text{ m})}{0.600 \text{ m}} = 4.90 \text{ m/s}.$

(b) Use $v_y = \omega A_{\rm SW} \sin kx \cos \omega t$ at $x = 0.075$ m. The maximum speed occurs when $\cos \omega t = \pm 1$, so

$v_{y,\max} = (4.90 \text{ m/s}) \sin\left[(10.472 \text{ m}^{-1})(0.075 \text{ m})\right] = 3.5 \text{ m/s}.$

EVALUATE: Notice that the wave speed (260 m/s) moves much faster than any point on the string.

15.59. IDENTIFY: The distance between adjacent nodes is one-half the wavelength. The second overtone is the third harmonic ($n = 3$).

SET UP: The wavelengths are $\lambda_n = 2L/n$, $f = 1/T$, $v = \sqrt{F/\mu}$, $v = f\lambda$, and $\mu = m/L$.

EXECUTE: **(a)** The node-to-node distance is $\lambda/2$, so $\lambda = 2(6.28 \text{ cm}) = 12.56 \text{ cm} = 0.1256$ m. In the third harmonic, $\lambda_n = 2L/n$ gives $0.1256 \text{ m} = 2L/3$, so $L = 0.1884$ m which rounds to 0.188 m.

(b) The time to go from top to bottom is one-half the period, $T/2$, so $T = 2(8.40 \text{ ms}) = 16.8 \text{ ms} = 0.0168$ s.

$f = 1/T = 1/(0.0168 \text{ s}) = 59.52$ Hz. Combining $v = \sqrt{F/\mu}$, $\mu = m/L$, and $v = f\lambda$ gives

$(f\lambda)^2 = \dfrac{F}{\mu} \to \mu = \dfrac{F}{(f\lambda)^2} = \dfrac{m}{L} \to m = \dfrac{FL}{(f\lambda)^2}$. Putting in the numbers gives

$m = (5.00 \text{ N})(0.1884 \text{ m})/[(59.52 \text{ Hz})(0.1256 \text{ m})]^2 = 0.0169 \text{ kg} = 16.9$ g.

EVALUATE: In a standing wave pattern, the nodes, we well as the antinodes, are spaced one-half a wavelength apart.

15.60. IDENTIFY: The wavelengths of the standing waves on the wire are given by $\lambda_n = \dfrac{2L}{n}$. When the ball is changed the wavelength changes because the length of the wire changes; $\Delta l = \dfrac{Fl_0}{AY}$.

SET UP: For the third harmonic, $n = 3$. For copper, $Y = 11 \times 10^{10}$ Pa. The wire has cross-sectional area $A = \pi r^2 = \pi(0.512 \times 10^{-3} \text{ m})^2 = 8.24 \times 10^{-7} \text{ m}^2$.

EXECUTE: **(a)** $\lambda_3 = \dfrac{2(1.20 \text{ m})}{3} = 0.800 \text{ m}$

(b) The increase in length when the 100.0 N ball is replaced by the 500.0 N ball is given by

$\Delta l = \dfrac{(\Delta F)l_0}{AY}$, where $\Delta F = 400.0$ N is the increase in the force applied to the end of the wire.

$\Delta l = \dfrac{(400.0 \text{ N})(1.20 \text{ m})}{(8.24 \times 10^{-7} \text{ m}^2)(11 \times 10^{10} \text{ Pa})} = 5.30 \times 10^{-3}$ m. The change in wavelength is $\Delta\lambda = \frac{2}{3}\Delta l = 3.5$ mm.

EVALUATE: The change in tension changes the wave speed and that in turn changes the frequency of the standing wave, but the problem asks only about the wavelength.

15.61. IDENTIFY and SET UP: The average power is given by $P_{\rm av} = \frac{1}{2}\sqrt{\mu F}\,\omega^2 A^2$. Rewrite this expression in terms of v and λ in place of F and ω.

EXECUTE: **(a)** $P_{\rm av} = \frac{1}{2}\sqrt{\mu F}\,\omega^2 A^2$

$v = \sqrt{F/\mu}$ so $\sqrt{F} = v\sqrt{\mu}$

$\omega = 2\pi f = 2\pi(v/\lambda)$

Using these two expressions to replace $\sqrt{F}$ and ω gives $P_{\rm av} = 2\mu\pi^2 v^3 A^2/\lambda^2$;

$\mu = (6.00 \times 10^{-3} \text{ kg})/(8.00 \text{ m})$

$$A=\left(\frac{2\lambda^2 P_{av}}{4\pi^2 v^3 \mu}\right)^{1/2}=7.07\text{ cm}$$

(b) EVALUATE: $P_{av}\sim v^3$ so doubling v increases P_{av} by a factor of 8.

$P_{av}=8(50.0\text{ W})=400.0\text{ W}$

15.62. **IDENTIFY:** The time between positions 1 and 5 is equal to $T/2$. $v=f\lambda$. The velocity of points on the string is given by $v_y(x,t)=\omega A\sin(kx-\omega t)$.

SET UP: Four flashes occur from position 1 to position 5, so the elapsed time is $4\left(\frac{60\text{ s}}{5000}\right)=0.048\text{ s}$.

The figure in the problem shows that $\lambda=L=0.500\text{ m}$. At point P the amplitude of the standing wave is 1.5 cm.

EXECUTE: **(a)** $T/2=0.048\text{ s}$ and $T=0.096\text{ s}$. $f=1/T=10.4\text{ Hz}$. $\lambda=0.500\text{ m}$.

(b) The fundamental standing wave has nodes at each end and no nodes in between. This standing wave has one additional node. This is the first overtone and second harmonic.

(c) $v=f\lambda=(10.4\text{ Hz})(0.500\text{ m})=5.20\text{ m/s}$.

(d) In position 1, point P is at its maximum displacement and its speed is zero. In position 3, point P is passing through its equilibrium position and its speed is

$v_{max}=\omega A=2\pi fA=2\pi(10.4\text{ Hz})(0.015\text{ m})=0.980\text{ m/s}$.

(e) $v=\sqrt{\frac{F}{\mu}}=\sqrt{\frac{FL}{m}}$ and $m=\frac{FL}{v^2}=\frac{(1.00\text{ N})(0.500\text{ m})}{(5.20\text{ m/s})^2}=18.5\text{ g}$.

EVALUATE: The standing wave is produced by traveling waves moving in opposite directions. Each point on the string moves in SHM, and the amplitude of this motion varies with position along the string.

15.63. **IDENTIFY:** The chain of beads vibrates in a standing wave pattern.

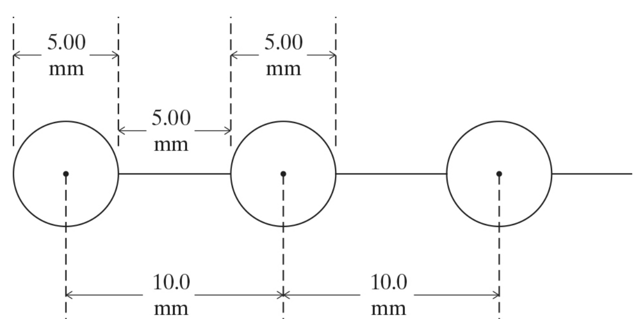

Figure 15.63

SET UP: First find the number of beads on a string 1.005 m long. Fig. 15.63 shows the first few beads. Starting at the left end, the string is made up of units each consisting of one bead of diameter 5.00 mm plus a space of 5.00 mm, so each unit is 10.0 mm long. To make a chain 1.005 m long, we need 100 of these units plus 5.00 mm for the end bead on the right. So the total mass of the 101 beads is 101 g = 0.101 kg. We use $y(x,t)=A_{SW}\sin kx\sin\omega t$, $v=\sqrt{\frac{F}{\mu}}$, $v=f\lambda$, $v_y=\frac{\partial y}{\partial t}$, $\lambda_n=2L/n$, $k=2\pi/\lambda$, $\omega=2\pi f$, and $F=kx$ (this k is the force constant).

EXECUTE: **(a)** $\mu=m/L$ = (0.101 kg)/(1.50 m) = 0.0673 kg/m.

(b) $T=kx$ = (28.8 N/m)(1.50 m – 1.005 m) = 14.3 N.

(c) $v=\sqrt{\dfrac{F}{\mu}}=\sqrt{\dfrac{14.3\text{ N}}{0.0673\text{ kg/m}}}=14.6\text{ m/s}.$

(d) We want the wave speed v. The wave pattern has 4 antinodes, so the chain is vibrating in its 4th harmonic, so $n = 4$. $\lambda_n = 2L/n$ = (3.00 m)/4 = 0.750 m. Using $v = f\lambda$ gives $f = v/\lambda$ = (14.6 m/s)/(0.750 m) = 19.5 Hz.

(e) The motionless beads are at the nodes. In the 4th harmonic, nodes occur at the ends of the chain, in the middle, and ¼ and ¾ of the way along the chain. The beads at these locations are #1, 26, 51, 76, and 101.

(f) Bead #26 is at a node, so bead #13 is at an antinode, so its maximum speed is $v_{y,\max} = A\omega$. Using $\omega = 2\pi f$, we get $A=\dfrac{v_{y,\max}}{\omega}=\dfrac{v_{y,\max}}{2\pi f}=\dfrac{7.54\text{ m/s}}{2\pi(19.5\text{ Hz})}=0.0615\text{ m}=6.15\text{ cm}.$

(g) When the chain is stretched, the beads are 15.0 mm apart center-to-center, with the origin at the center of the first bead. The first few coordinates are:

x_1 = 0 mm = (1 – 1)(15.0 mm)

x_2 = 10.0 mm = (2 – 1)(15.0 mm)

x_3 = 20.0 mm = (3 – 1)(15.0 mm)

x_4 = 30.0 mm = (4 – 1)(15.0 mm)

From this pattern we recognize that the n^{th} bead is at $x_n = (n - 1)(15.0\text{ mm})$, where n = 1, 2, … .

(h) The 30th bead is at x_{30} = (30 – 1)(15.0 mm) = 435 mm = 0.435 m. The standing wave equation is $y(x,t) = A_{\text{SW}}\sin kx \sin\omega t$. Thus $v_y=\dfrac{\partial y}{\partial t}=\omega A_{\text{SW}}\sin kx\cos\omega t$, so at any position x, $v_{y\text{-max}} = \omega A_{\text{SW}}\sin kx = 2\pi f A_{\text{SW}}\sin kx$. From part (f) A_{SW} = 0.0615 m, and $k = 2\pi/\lambda$ = 2π/(0.750 m) = 8.378 m^{-1}. Therefore $v_{y,\max}$ = 2π(19.5 Hz)(0.0615 m) sin[(8.3778 m^{-1})(0.435 m)] = –3.63 m/s, so the maximum *speed* is 3.63 m/s.

EVALUATE: The 30th bead has a smaller maximum speed than the 13th bead. This is reasonable since the 13th bead is at an antinode but the 30th bead is not.

15.64. **IDENTIFY** and **SET UP:** $v=\sqrt{F/\mu}$ is the wave speed and $v_y=\dfrac{\partial y}{\partial t}$ is the transverse speed of a point on the string. $v = f\lambda$, $\lambda_n = 2L/n$, $\mu = m/L$, $v_{\max} = \omega A$ (maximum v_y), $a_{\max} = \omega^2 A$ (maximum a_y).

EXECUTE: **(a)** $\mu = m/L$ = (0.00300 kg)/(2.20 m) = 0.0013636 kg/m. In the fundamental mode, n = 1, so $\lambda_n = 2L/n$ = 2L. Combining $v = f\lambda$ and $v=\sqrt{F/\mu}$, we get $f\lambda=\sqrt{F/\mu}$. Putting in the numbers get f(2)(2.20 m) = [(330 N)/(0.0013636 kg/m)]$^{1/2}$, which gives f = 111.8 Hz. Now use $v_{\max} = \omega A$ to get $A = v_{\max}/(2\pi f)$ = (9.00 m/s)/[2π(111.8 Hz)] = 0.0128 m = 1.28 cm.

(b) $a_{\max} = \omega^2 A = (2\pi f)^2 A$ = [2π(111.8 Hz)]^2(0.0128 m) = 6320 m/s^2.

EVALUATE: It is important to distinguish between the transverse velocity of a point on the string, $v_y=\dfrac{\partial y}{\partial t}$, and speed of the wave, $v=\sqrt{F/\mu}$. The wave speed is constant in time, but the transverse speed is not. The maximum acceleration of a point on the string is 645g!

15.65. **IDENTIFY** and **SET UP:** $v=\sqrt{F/\mu}$ is the wave speed and $v_y=\dfrac{\partial y}{\partial t}$ is the transverse speed of a point on the string. $v = f\lambda$, $\lambda_n = 2L/n$, $\mu = m/L$, $v_{\max} = \omega A$ (maximum v_y), $a_{\max} = \omega^2 A$ (maximum a_y). The first overtone is the second harmonic (n = 2).

EXECUTE: **(a)** $v_{\max} = \omega A = 2\pi f A$, which gives 28.0 m/s = (0.0350 m)(2πf), so f = 127.32 Hz. $\lambda_n = 2L/n = 2L/2 = L$ = 2.50 m. Using these results to get v gives $v = f\lambda$ = (127.32 Hz)(2.50 m) = 318.3 m/s. Now combine $v=\sqrt{F/\mu}$ and $\mu = m/L$ to find m, giving

$m = LF/v^2 = (2.50\text{ m})(90.0\text{ N})/(318.3\text{ m/s})^2 = 0.00222\text{ kg} = 2.22\text{ g}.$

(b) $a_{\max} = \omega^2 A = A(2\pi f)^2 = (0.0350\text{ m})[2\pi(127.32\text{ Hz})]^2 = 22{,}400\text{ m/s}^2.$

EVALUATE: It is important to distinguish between the transverse velocity of a point on the string, $v_y = \dfrac{\partial y}{\partial t}$, and speed of the wave, $v = \sqrt{F/\mu}$. The wave speed is constant in time, but the transverse speed is not. The maximum acceleration of a point on the string is about 2300g!

15.66. **IDENTIFY:** The displacement of the string at any point is $y(x,t) = (A_{\text{SW}} \sin kx)\sin \omega t$. For the fundamental mode $\lambda = 2L$, so at the midpoint of the string $\sin kx = \sin(2\pi/\lambda)(L/2) = 1$, and $y = A_{\text{SW}} \sin \omega t$. The transverse velocity is $v_y = \partial y/\partial t$ and the transverse acceleration is $a_y = \partial v_y/\partial t$.

SET UP: Taking derivatives gives $v_y = \dfrac{\partial y}{\partial t} = \omega A_{\text{SW}} \cos \omega t$, with maximum value $v_{y,\max} = \omega A_{\text{SW}}$, and $a_y = \dfrac{\partial v_y}{\partial t} = -\omega^2 A_{\text{SW}} \sin \omega t$, with maximum value $a_{y,\max} = \omega^2 A_{\text{SW}}$.

EXECUTE: **(a)** $\omega = a_{y,\max}/v_{y,\max} = (8.40\times10^3\text{ m/s}^2)/(3.80\text{ m/s}) = 2.21\times10^3\text{ rad/s}$, and then $A_{\text{SW}} = v_{y,\max}/\omega = (3.80\text{ m/s})/(2.21\times10^3\text{ rad/s}) = 1.72\times10^{-3}\text{ m}$.

(b) $v = \lambda f = (2L)(\omega/2\pi) = L\omega/\pi = (0.386\text{ m})(2.21\times10^3\text{ rad/s})/\pi = 272\text{ m/s}$.

EVALUATE: The maximum transverse velocity and acceleration will have different (smaller) values at other points on the string.

15.67. **IDENTIFY:** The standing wave frequencies are given by $f_n = n\left(\dfrac{v}{2L}\right)$. $v = \sqrt{F/\mu}$. Use the density of steel to calculate μ for the wire.

SET UP: For steel, $\rho = 7.8\times10^3\text{ kg/m}^3$. For the first overtone standing wave, $n = 2$.

EXECUTE: $v = \dfrac{2Lf_2}{2} = (0.550\text{ m})(311\text{ Hz}) = 171\text{ m/s}$. The volume of the wire is $V = (\pi r^2)L$. $m = \rho V$ so $\mu = \dfrac{m}{L} = \dfrac{\rho V}{L} = \rho\pi r^2 = (7.8\times10^3\text{ kg/m}^3)\pi(0.57\times10^{-3}\text{ m})^2 = 7.96\times10^{-3}\text{ kg/m}$. The tension is $F = \mu v^2 = (7.96\times10^{-3}\text{ kg/m})(171\text{ m/s})^2 = 233\text{ N}$.

EVALUATE: The tension is not large enough to cause much change in length of the wire.

15.68. **IDENTIFY:** The standing wave is given by $y(x,t) = (A_{\text{SW}} \sin kx)\sin \omega t$.

SET UP: At an antinode, $\sin kx = 1$. $v_{y,\max} = \omega A$. $a_{y,\max} = \omega^2 A$.

EXECUTE: **(a)** $\lambda = v/f = (192.0\text{ m/s})/(240.0\text{ Hz}) = 0.800\text{ m}$, and the wave amplitude is $A_{\text{SW}} = 0.400\text{ cm}$. The amplitude of the motion at the given points is

(i) $(0.400\text{ cm})\sin(\pi) = 0$ (a node) (ii) $(0.400\text{ cm})\sin(\pi/2) = 0.400\text{ cm}$ (an antinode)

(iii) $(0.400\text{ cm})\sin(\pi/4) = 0.283\text{ cm}$

(b) The time is half of the period, or $1/(2f) = 2.08\times10^{-3}\text{ s}$.

(c) In each case, the maximum velocity is the amplitude multiplied by $\omega = 2\pi f$ and the maximum acceleration is the amplitude multiplied by $\omega^2 = 4\pi^2 f^2$:

(i) 0, 0; (ii) 6.03 m/s, $9.10\times10^3\text{ m/s}^2$; (iii) 4.27 m/s, $6.43\times10^3\text{ m/s}^2$.

EVALUATE: The amplitude, maximum transverse velocity, and maximum transverse acceleration vary along the length of the string. But the period of the simple harmonic motion of particles of the string is the same at all points on the string.

15.69. **IDENTIFY:** When the rock is submerged in the liquid, the buoyant force on it reduces the tension in the wire supporting it. This in turn changes the frequency of the fundamental frequency of the vibrations of the wire. The buoyant force depends on the density of the liquid (the target variable). The vertical forces on the rock balance in both cases, and the buoyant force is equal to the weight of the liquid displaced by the rock (Archimedes's principle).

SET UP: The wave speed is $v = \sqrt{\dfrac{F}{\mu}}$ and $v = f\lambda$. $B = \rho_{\text{liq}} V_{\text{rock}} g$. $\Sigma F_y = 0$.

EXECUTE: $\lambda = 2L = 6.00$ m. In air, $v = f\lambda = (42.0\text{ Hz})(6.00\text{ m}) = 252$ m/s. $v = \sqrt{\dfrac{F}{\mu}}$ so

$\mu = \dfrac{F}{v^2} = \dfrac{164.0\text{ N}}{(252\text{ m/s})^2} = 0.002583$ kg/m. In the liquid, $v = f\lambda = (28.0\text{ Hz})(6.00\text{ m}) = 168$ m/s.

$F = \mu v^2 = (0.002583\text{ kg/m})(168\text{ m/s})^2 = 72.90$ N. $F + B - mg = 0$.

$B = mg - F = 164.0\text{ N} - 72.9\text{ N} = 91.10$ N. For the rock,

$V = \dfrac{m}{\rho} = \dfrac{(164.0\text{ N}/9.8\text{ m/s}^2)}{3200\text{ kg/m}^3} = 5.230 \times 10^{-3}\text{ m}^3$. $B = \rho_{\text{liq}} V_{\text{rock}} g$ and

$\rho_{\text{liq}} = \dfrac{B}{V_{\text{rock}} g} = \dfrac{91.10\text{ N}}{(5.230 \times 10^{-3}\text{ m}^3)(9.8\text{ m/s}^2)} = 1.78 \times 10^3\text{ kg/m}^3$.

EVALUATE: This liquid has a density 1.78 times that of water, which is rather dense but not impossible.

15.70. **IDENTIFY:** We model a vibrating stretched rubber band as a standing wave pattern, fixed at both ends.

SET UP: **(a)** Estimate: Tension is about 1 lb ≈ 4.5 N. We use $v = \sqrt{\dfrac{F}{\mu}}$ and $v = f\lambda$. Our target variable is the frequency of vibration.

EXECUTE: **(b)** $\mu = m/L = (0.10\text{ g})/10\text{ cm}) = 1.0 \times 10^{-3}$ kg/m.

(c) If we simply pluck the rubber band, it vibrates in its fundamental mode, so $\lambda = 2L = 0.20$ m.

Combining $v = \sqrt{\dfrac{F}{\mu}}$ and $v = f\lambda$ gives $f = \dfrac{1}{\lambda}\sqrt{\dfrac{F}{\mu}} = \dfrac{1}{0.20\text{ m}}\sqrt{\dfrac{4.5\text{ N}}{1.0 \times 10^{-3}\text{ kg/m}}} = 340$ Hz.

EVALUATE: This result seems somewhat high, but our model is just a rough approximation.

15.71. **IDENTIFY:** Compute the wavelength from the length of the string. Use $v = f\lambda$ to calculate the wave speed and then apply $v = \sqrt{F/\mu}$ to relate this to the tension.

(a) SET UP: The tension F is related to the wave speed by $v = \sqrt{F/\mu}$, so use the information given to calculate v.

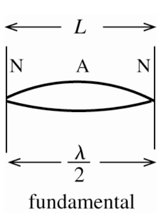

Figure 15.71

EXECUTE: $\lambda/2 = L$

$\lambda = 2L = 2(0.600\text{ m}) = 1.20$ m

$v = f\lambda = (65.4\text{ Hz})(1.20\text{ m}) = 78.5$ m/s

$\mu = m/L = 14.4 \times 10^{-3}\text{ kg}/0.600\text{ m} = 0.024$ kg/m

Then $F = \mu v^2 = (0.024\text{ kg/m})(78.5\text{ m/s})^2 = 148$ N.

(b) SET UP: $F = \mu v^2$ and $v = f\lambda$ give $F = \mu f^2 \lambda^2$.

μ is a property of the string so is constant.

λ is determined by the length of the string so stays constant.

μ, λ constant implies $F/f^2 = \mu\lambda^2 = \text{constant}$, so $F_1/f_1^2 = F_2/f_2^2$.

EXECUTE: $F_2 = F_1\left(\dfrac{f_2}{f_1}\right)^2 = (148\text{ N})\left(\dfrac{73.4\text{ Hz}}{65.4\text{ Hz}}\right)^2 = 186\text{ N}.$

The percent change in F is $\dfrac{F_2 - F_1}{F_1} = \dfrac{186\text{ N} - 148\text{ N}}{148\text{ N}} = 0.26 = 26\%.$

EVALUATE: The wave speed and tension we calculated are similar in magnitude to values in the examples. Since the frequency is proportional to $\sqrt{F}$, a 26% increase in tension is required to produce a 13% increase in the frequency.

15.72. IDENTIFY: The mass and breaking stress determine the length and radius of the string. $f_1 = \dfrac{v}{2L}$, with $v = \sqrt{\dfrac{F}{\mu}}$.

SET UP: The tensile stress is $F/\pi r^2$.

EXECUTE: **(a)** The breaking stress is $\dfrac{F}{\pi r^2} = 7.0\times 10^8\text{ N/m}^2$ and the maximum tension is $F = 900$ N, so solving for r gives the minimum radius $r = \sqrt{\dfrac{900\text{ N}}{\pi(7.0\times 10^8\text{ N/m}^2)}} = 6.4\times 10^{-4}$ m. The mass and density are fixed, $\rho = \dfrac{M}{\pi r^2 L}$. so the minimum radius gives the maximum length

$$L = \frac{M}{\pi r^2 \rho} = \frac{4.0\times 10^{-3}\text{ kg}}{\pi(6.4\times 10^{-4}\text{ m})^2(7800\text{ kg/m}^3)} = 0.40\text{ m}.$$

(b) The fundamental frequency is $f_1 = \dfrac{1}{2L}\sqrt{\dfrac{F}{\mu}} = \dfrac{1}{2L}\sqrt{\dfrac{F}{M/L}} = \dfrac{1}{2}\sqrt{\dfrac{F}{ML}}$. Assuming the maximum length of the string is free to vibrate, the highest fundamental frequency occurs when $F = 900$ N and

$$f_1 = \frac{1}{2}\sqrt{\frac{900\text{ N}}{(4.0\times 10^{-3}\text{ kg})(0.40\text{ m})}} = 375\text{ Hz}.$$

EVALUATE: If the radius was any smaller the breaking stress would be exceeded. If the radius were greater, so the stress was less than the maximum value, then the length would be less to achieve the same total mass.

15.73. IDENTIFY and SET UP: Assume that the mass M is large enough so that there no appreciable motion of the string at the pulley or at the oscillator. For a string fixed at both ends, $\lambda_n = 2L/n$. The node-to-node distance d is $\lambda/2$, so $d = \lambda/2$. $v = f\lambda = \sqrt{F/\mu}$.

EXECUTE: **(a)** Because it is essentially fixed at its ends, the string can vibrate in only wavelengths for which $\lambda_n = 2L/n$, so $d = \lambda/2 = L/n$, where $n = 1, 2, 3, \ldots$.

(b) $f\lambda = \sqrt{F/\mu}$ and $\lambda = 2d$. Combining these two conditions and squaring gives $f^2(4d^2) = T/\mu = Mg/\mu$. Solving for μd^2 gives $\mu d^2 = \left(\dfrac{g}{4f^2}\right)M$. Therefore the graph of μd^2 versus M should be a straight line having slope equal to $g/4f^2$. Figure 15.73 shows this graph.

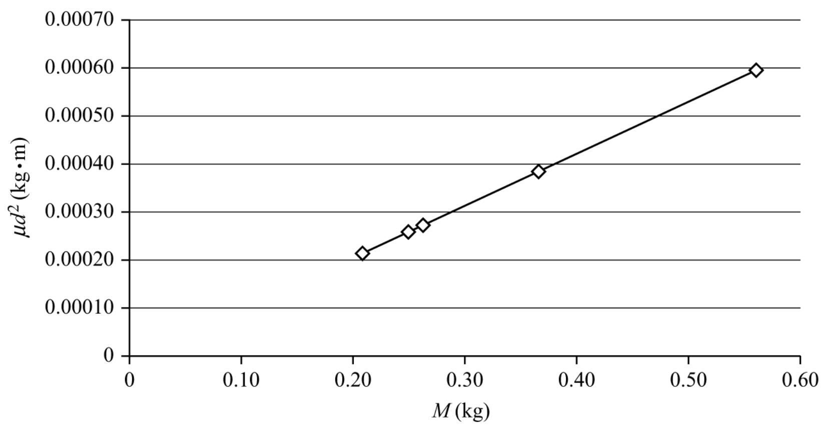

Figure 15.73

(c) The best fit straight line for the data has the equation μd^2 = (0.001088 m)M – 0.00009074 kg·m. The slope is $g/4f^2$, so $g/4f^2$ = 0.001088 m. Solving for f gives f = 47.5 Hz.

(d) For string A, μ = 0.0260 g/cm = 0.00260 kg/m. We want the mass M for λ = 48.0 cm. Using $f\lambda = \sqrt{F/\mu}$ where $F = Mg$, squaring and solving for M, we get $M = \dfrac{\mu(f\lambda)^2}{g}$. Putting in the numbers gives M = (0.00260 kg/m)[(47.5 Hz)(0.480 m)]^2/(9.80 m/s^2) = 0.138 kg = 138 g.

EVALUATE: In part (d), if the string is vibrating in its fundamental mode, n = 1, so $d = L$ = 48.0 cm. The mass of the string in that case would be $m = \mu L$ = (0.00260 kg/m)(0.48 m) = 0.00125 kg = 1.25 g, so the string would be much lighter than the 138-g weight attached to it.

15.74. **IDENTIFY** and **SET UP:** We have a standing wave in its fundamental mode on each string of the guitar. $v = \sqrt{F/\mu}$, $v = f\lambda$, $\lambda_n = 2L/n$, 25.5 in. = 64.77 cm = 0.6477 m.

EXECUTE: **(a)** Each string has the same length, so the wavelength in the fundamental mode is $\lambda_n = 2L/n$ = $2L$ = 2(0.6477 m) = 1.2954 m.

Combining $v = \sqrt{F/\mu}$ and $v = f\lambda$ and solving for μ gives $\mu = F/(f\lambda)^2$.

For the E2 string, we have μ_{E2} = (78.0 N)/[(82.4 Hz)(1.2954 m)]^2 = 0.006846 kg/m = 0.0685 g/cm. Using similar calculations for the other strings, we get μ_{G3} = 0.0121 g/cm and μ_{E4} = 0.00428 g/cm.

(b) From $f\lambda = \sqrt{F/\mu}$, we get $F = \mu(f\lambda)^2$ = (0.006846 kg/m)[(196.0 Hz)(1.2954 m)]^2 = 441 N.

EVALUATE: A tension of 441 N is nearly 100 lb, which is why a string will snap violently if it happens to break.

15.75. **IDENTIFY** and **SET UP:** $P_{av} = \dfrac{1}{2}\sqrt{\mu F}\,\omega^2 A^2$, $v = \sqrt{F/\mu}$, and $\omega = 2\pi f$.

EXECUTE: Combining $P_{av} = \dfrac{1}{2}\sqrt{\mu F}\,\omega^2 A^2$ and $\omega = 2\pi f$ gives $P_{av} = 2\pi^2\sqrt{\mu F}\,A^2 f^2$. Therefore a graph of P_{av} versus f^2 should be a straight line having slope $2\pi^2\sqrt{\mu F}\,A^2$.

(b) Calculate the slope from the graph shown in the problem. Estimating the points (40,000 Hz^2, 12.2 W) and (10,000 Hz^2, 3 W), we get a slope of (9.2 W)/(30,000 Hz^2) = 3.07×10^{-4} W/Hz^2. (Answers here will vary, depending on the accuracy in reading the graph.) We can get F from the slope of the graph and then use $v = \sqrt{F/\mu}$ to calculate v. Using our measured slope, we have $2\pi^2\sqrt{\mu F}\,A^2$ = slope = 3.07×10^{-4} W/Hz^2. Solving for F gives $F = \dfrac{(\text{slope})^2}{4\pi^4 A^4 \mu}$. Putting this result into $v = \sqrt{F/\mu}$ gives us

$v = \sqrt{\dfrac{F}{\mu}} = \sqrt{\dfrac{(\text{slope})^2}{4\pi^4 A^4 \mu^2}} = \dfrac{\text{slope}}{2\pi^2 A^2 \mu}$. This gives $v = (3.07\times 10^{-4}\ \text{W/Hz}^2)/[2\pi^2(0.0040\ \text{m})^2(0.0035\ \text{kg/m})] =$ 280 m/s.

(c) From the graph, $P = 10.0$ W corresponds to $f^2 = 33{,}000\ \text{Hz}^2$, so

$\omega = 2\pi f = 2\pi\sqrt{33{,}000\ \text{Hz}^2} = 1100\ \text{rad/s}.$

EVALUATE: At 280 m/s and with an angular frequency of 1100 rad/s, the string is moving too fast to follow individual waves.

15.76. IDENTIFY: The membrane is stretched and caused to vibrate in a standing wave pattern. We can visualize this membrane as n tiny strings, each of length L, vibrating together.

SET UP: We want to investigate the characteristics of its vibrational motion. We use $v = \sqrt{\dfrac{F}{\mu}}$, $v = f\lambda$, $k = 2\pi/\lambda$, $P = \sqrt{\mu F}\,\omega^2 A^2 \sin^2(kx - \omega t)$, and $P_{\text{av}} = \dfrac{1}{2}\sqrt{\mu F}\,\omega^2 A^2$.

EXECUTE: **(a)** The tension F is equally divided among the n tiny strings, as is the mass M. Therefore the speed of the wave on each string is $v = \sqrt{\dfrac{F/n}{\mu/n}} = \sqrt{\dfrac{F}{\mu}}$. Using $\mu = M/L$, we get $v = \sqrt{\dfrac{FL}{M}}$. For the values here, we have $v = \sqrt{\dfrac{(81.0\ \text{N})(4.00\ \text{m})}{4.00\ \text{kg}}} = 9.00\ \text{m/s}$.

(b) We want k, so first find λ. Solving $v = f\lambda$ for λ gives $\lambda = v/f$. Therefore we get

$k = \dfrac{2\pi}{\lambda} = \dfrac{2\pi}{v/f} = \dfrac{2\pi f}{v} = \dfrac{2\pi(1.00\ \text{Hz})}{9.00\ \text{m/s}} = 0.698\ \text{m}^{-1}.$

(c) $P = \sqrt{\mu F}\,\omega^2 A^2 \sin^2(kx - \omega t) = \sqrt{(M/L)F}\,(2\pi f)^2 A^2 \sin^2(kx - \omega t)$, which we can write as

$P = \sqrt{\dfrac{MF}{L}}\,4\pi^2 f^2 A^2 \sin^2(kx - \omega t).$

(d) $E = P_{\text{av}} t = \dfrac{1}{2}\sqrt{\dfrac{MF}{L}}\,4\pi^2 f^2 A^2 t = 2\pi^2 f^2 A^2 \sqrt{\dfrac{MF}{L}}\,t.$ For the numbers here, we get

$E = 2\pi^2(1.0\ \text{Hz})^2(0.100\ \text{m})^2\sqrt{\dfrac{(4.00\ \text{kg})(81.0\ \text{N})}{4.00\ \text{m}}}(1.00\ \text{s}) = 1.78\ \text{J}.$

EVALUATE: Think of the membrane as a very wide string.

15.77. IDENTIFY: Apply $\Sigma F_y = 0$ to segments of the cable. The forces are the weight of the diver, the weight of the segment of the cable, the tension in the cable and the buoyant force on the segment of the cable and on the diver.

SET UP: The buoyant force on an object of volume V that is completely submerged in water is $B = \rho_{\text{water}} V g$.

EXECUTE: **(a)** The tension is the difference between the diver's weight and the buoyant force,

$F = (m - \rho_{\text{water}} V)g = \left[120\ \text{kg} - (1000\ \text{kg/m}^3)(0.0800\ \text{m}^3)\right](9.80\ \text{m/s}^2) = 392\ \text{N}.$

(b) The increase in tension will be the weight of the cable between the diver and the point at x, minus the buoyant force. This increase in tension is then

$\left[\mu x - \rho(Ax)\right]g = \left[1.10\ \text{kg/m} - (1000\ \text{kg/m}^3)\pi(1.00\times 10^{-2}\ \text{m})^2\right](9.80\ \text{m/s}^2)x = (7.70\ \text{N/m})x.$ The tension as a function of x is then $F(x) = (392\ \text{N}) + (7.70\ \text{N/m})x.$

(c) Denote the tension as $F(x)=F_0+ax$, where $F_0=392$ N and $a=7.70$ N/m. Then the speed of transverse waves as a function of x is $v=\dfrac{dx}{dt}=\sqrt{(F_0+ax)/\mu}$ and the time t needed for a wave to reach the surface is found from $t=\int dt=\int \dfrac{dx}{dx/dt}=\int \dfrac{\sqrt{\mu}}{\sqrt{F_0+ax}}\,dx.$

Let the length of the cable be L, so $t=\sqrt{\mu}\int_0^L \dfrac{dx}{\sqrt{F_0+ax}}=\sqrt{\mu}\dfrac{2}{a}\sqrt{F_0+ax}\Big|_0^L=\dfrac{2\sqrt{\mu}}{a}\left(\sqrt{F_0+aL}-\sqrt{F_0}\right).$

$$t=\frac{2\sqrt{1.10\text{ kg/m}}}{7.70\text{ N/m}}(\sqrt{392\text{ N}+(7.70\text{ N/m})(100\text{ m})}-\sqrt{392\text{ N}})=3.89\text{ s}.$$

EVALUATE: If the weight of the cable and the buoyant force on the cable are neglected, then the tension would have the constant value calculated in part (a). Then $v=\sqrt{\dfrac{F}{\mu}}=\sqrt{\dfrac{392\text{ N}}{1.10\text{ kg/m}}}=18.9\text{ m/s}$ and $t=\dfrac{L}{v}=5.29$ s. The weight of the cable increases the tension along the cable and the time is reduced from this value.

15.78. IDENTIFY and **SET UP:** Apply $v=f\lambda$.

EXECUTE: $v=f\lambda$ gives (125 Hz) λ = 3.75 m/s, so λ = 0.030 m = 3 cm, which is choice (d).

EVALUATE: These are waves on the vocal cords, not sound waves in air.

15.79. IDENTIFY and **SET UP:** Using the figure shown with the problem in the text, the wave is traveling in the +z-direction, so it must be of the form $A\sin(kz-\omega t)$.

EXECUTE: The required wave is of the form $A\sin(kz-\omega t)$. Putting this in terms of f and v gives

$$A\sin(kz-\omega t)=\sin[-(\omega t-kz)]=\sin[-(2\pi ft-2\pi z/\lambda)]=\sin[-2\pi f(t-z/f\lambda)]=-\sin[2\pi f(t-z/v)],$$

which is of the form of choice (b).

EVALUATE: A wave traveling in the opposite direction would be of the form $\sin[2\pi f(t+z/v)]$.

15.80. IDENTIFY and **SET UP:** The graph of v versus f is a straight line that appears to pass through the origin, so v is directly proportional to v. $v=f\lambda$.

EXECUTE: $v=f\lambda$ gives λ = v/f. From the graph of v versus f, v is proportional to f, so $v = Kf$, where K is a constant. Thus λ = v/f = Kf/f = K = constant, which is choice (c).

EVALUATE: Normally we expect the wavelength to decrease as the frequency increases, but that is only true if the wave speed is consant. In this case the speed depends on the frequency, so it is possible for the wavelength to remain constant.

16

SOUND AND HEARING

VP16.9.1. **IDENTIFY:** We want to know the pressure amplitude of a sound wave.

SET UP: $I = \dfrac{p_{\max}^2}{2\rho v}$

EXECUTE: **(a)** Solve for $p_{\max}$ giving $p_{\max} = \sqrt{2\rho v I}$. Putting in the numbers we get $p_{\max} = \sqrt{2(1.20 \text{ kg/m}^3)(344 \text{ m/s})(5.50\times10^{-8} \text{ W/m}^2)} = 6.74\times10^{-3}$ Pa.

(b) Neither ρ nor v is affected by the frequency change, so $p_{\max}$ remain unchanged.

EVALUATE: Changing the air density would affect the pressure amplitude.

VP16.9.2. **IDENTIFY:** This problem deals with sound intensity and intensity level.

SET UP: $\beta = (10 \text{ dB}) \log\dfrac{I}{I_0}$

EXECUTE: **(a)** We know the sound level is 85.0 dB and want the sound intensity. Using $\beta = (10 \text{ dB}) \log\dfrac{I}{I_0}$ gives $85.0\,\text{dB} = (10 \text{ dB}) \log\dfrac{I}{I_0}$. Solving for I gives

$I = 10^{8.5} I_0 = 10^{8.5}10^{-12} \text{ W/m}^2 = 10^{-3.50} \text{ W/m}^2 = 3.16\times10^{-4} \text{ W/m}^2$.

(b) Solve $\beta = (10 \text{ dB}) \log\dfrac{I}{I_0}$ for I, giving $I = I_0 10^{\beta/(10 \text{ dB})}$. Now take the ratio of the two intensities.

$\dfrac{I_{85}}{I_{67}} = \dfrac{I_0 10^{(85.0\,\text{dB})/(10 \text{ dB})}}{I_0 10^{(67.0\,\text{dB})/(10 \text{ dB})}} = \dfrac{10^{8.50}}{10^{6.70}} = 63.1$, so I_{85} is 63.1 times greater than I_{67}.

EVALUATE: The ratio of the sound intensity levels is 85/67 = 1.27, but the intensity ratio is *much* greater.

VP16.9.3. **IDENTIFY:** This problem involves sound intensity and intensity level.

SET UP: We know the sound intensity level of the lion's roar is 114 at 1.00 m, and we want to know what it is at 4.00 m and 15.8 m from the lion. The sound intensity obeys an inverse-square law, but the sound intensity level does not. We use $\beta = (10 \text{ dB}) \log\dfrac{I}{I_0}$ and $I_2 = I_1\left(\dfrac{r_1}{r_2}\right)^2$.

EXECUTE: **(a)** <u>At 1.00 m</u>: $\beta_1 = (10 \text{ dB}) \log\dfrac{I_1}{I_0} = 114$ dB. Solve for I_1: $I_1 = 10^{11.4} I_0$.

<u>At 4.00 m</u>: $I_2 = I_1\left(\dfrac{r_1}{r_2}\right)^2$ gives $I_4 = I_1\left(\dfrac{1.00 \text{ m}}{4.00 \text{ m}}\right)^2 = \dfrac{I_1}{16.0} = \dfrac{10^{11.4} I_0}{16.0}$. Now find the sound intensity level:

$\beta_4 = (10 \text{ dB}) \log\dfrac{I_4}{I_0} = (10 \text{ dB}) \log\left(\dfrac{10^{11.4} I_0}{16.0 I_0}\right) = 102$ dB.

(b) At 15.8 m we follow the same procedure as above, giving

$$\beta_{15.8} = (10\text{ dB})\log\frac{I_{16}}{I_0} = (10\text{ dB})\log\left(\frac{10^{11.4}I_0}{(15.8)^2 I_0}\right) = 90.0\text{ dB}.$$

EVALUATE: The sound intensity obeys an inverse-square law, but sound intensity level does not.

VP16.9.4. **IDENTIFY:** We are investigating the relationship between sound intensity level and the pressure amplitude of a sound wave.

SET UP: We know that $I = \dfrac{p_{\max}^2}{2\rho v}$, $\beta = (10\text{ dB})\log\dfrac{I}{I_0}$, and $I_0 = 10^{-12}$ W/m^2. We want to find the pressure amplitude of the sound wave and then see how changing it would affect the sound intensity level.

EXECUTE: **(a)** First use $\beta = (10\text{ dB})\log\dfrac{I}{I_0}$ to find the intensity I. $\beta = (10\text{ dB})\log\dfrac{I}{I_0}$ = 66.0 dB, so

$I = 10^{6.60} I_0 = 3.9811\times10^{-6}$ W/m^2. Now use I to find $p_{\max}$. Solving $I = \dfrac{p_{\max}^2}{2\rho v}$ for $p_{\max}$ gives

$p_{\max} = \sqrt{2\rho v I}$, which gives $p_{\max} = \sqrt{2(0.920\text{ kg/m}^3)(344\text{ m/s})(3.9811\times10^{-6}\text{ W/m}^2)} = 5.02\times10^{-2}$ Pa.

(b) Since $I \propto p_{\max}^2$, increasing $p_{\max}$ by a factor of 10.0 will increase I by a factor of $10.0^2 = 100$, so $I_2 = 100I_1$. Taking the ratio of the sound intensity levels gives

$\dfrac{\beta_2}{\beta_1} = \dfrac{(10\text{ dB})\log(I_2/I_0)}{(10\text{ dB})\log(I_1/I_0)} = \dfrac{\log(100I_1/I_0)}{\log(I_1/I_0)} = \dfrac{2+\log(I_1/I_0)}{\log(I_1/I_0)}$. But $\beta_1 = (10\text{ dB})\log(I_1/I_0)$, so

$\log(I_1/I_0) = \dfrac{\beta_1}{10} = \dfrac{66.0\text{ dB}}{10} = 6.60$. Therefore $\dfrac{\beta_2}{\beta_1} = \dfrac{2+\dfrac{\beta_1}{10}}{\dfrac{\beta_1}{10}} = \dfrac{2+6.60}{6.60} = 1.303$. So we have

$\beta_2 = 1.303\beta_1 = (1.303)(66.0\text{ dB}) = 86.0$ dB.

EVALUATE: Careful in handling logarithms because $\log(100I_1/I_0)$ is *not* equal to $100\log I_1/I_0$.

VP16.12.1. **IDENTIFY:** We are dealing with standing sound waves in open and stopped pipes.

SET UP: For an open pipe, $f_n = nv/2L$ (n = 1, 2, 3, …), and for a stopped pipe $f_n = nv/4L$ (n = 1, 3, 5, …).

EXECUTE: **(a)** We want the length L of this open pipe. For the fundamental frequency, $f_1 = v/2L$, so the length is L = (344 m/s)/[2(220 Hz)] = 0.782 m.

(b) For the open pipe in its 3rd harmonic, n = 3, so $f_3 = \dfrac{3v}{2L_3}$.

For the stopped pipe in its fundamental frequency, $f_1 = \dfrac{v}{4L_1}$.

The two frequencies are the same, so $\dfrac{3v}{2L_3} = \dfrac{v}{4L_1}$, so $L_1 = L_3/6$ = (0.782 m)/6 = 0.130 m.

EVALUATE: Careful on stopped pipes: n must be an *odd* integer, but on open pipes n can be odd and even integers.

VP16.12.2. **IDENTIFY:** We are investigating the harmonics of a stopped and an open organ pipe. We want to find what harmonics of a stopped pipe will resonate at the same frequency as the third harmonic of an open pipe.

SET UP: For an open pipe $f_n = nv/2L$ (n = 1, 2, 3, …), and for a stopped pipe $f_n = nv/4L$ (n = 1, 3, 5, …). We know that $f_3 = 3v/2L_o$ for the open pipe. We want to find values of n for the stopped pipe so that it will have the same frequency as the third harmonic of the open pipe. That is f_n(stopped) = f_3(open), where we want to find n for the stopped pipe. Equating the frequencies gives $\frac{nv}{4L_s} = \frac{3v}{2L_o}$, so $n = 6\frac{L_s}{L_o}$.

EXECUTE: **(a)** In this case $L_s = L_o/6$ so $n = 6\frac{L_s}{L_o} = 6\left(\frac{L_o}{6L_o}\right) = 1$.

(b) In this case, $L_s = L_o/2$, so $n = 6\frac{L_s}{L_o} = 6\left(\frac{L_o}{2L_o}\right) = 3$.

(c) In this case, $L_s = L_o/3$, so $n = 6\frac{L_s}{L_o} = 6\left(\frac{L_o}{3L_o}\right) = 2$. But n is only *odd* for a stopped pipe, so there are no harmonics of the stopped pipe having a frequency that is equal to the 3rd harmonic frequency of the open pipe.

EVALUATE: We cannot always make two pipes resonate at a given frequency.

VP16.12.3. **IDENTIFY:** A string vibrating in its fundamental frequency causes a nearby stopped organ pipe to vibrate in its fundamental frequency. So we are dealing with standing waves on a string and in a stopped pipe.

SET UP: For a string fixed at its ends, $f_n = nv_{str}/2L$ and $\lambda_n = 2L/n$ (n = 1, 2, 3, …), and for a stopped pipe $f_n = nv/4L$ (n = 1, 3, 5, …). For any wave $v = f\lambda$.

EXECUTE: **(a)** For the fundamental mode of the string, $\lambda_1 = 2L$ so $v_{str} = f\lambda = f(2L) =$ (165 Hz)(2)(0.680 m) = 224 m/s.

(b) The organ pipe in its fundamental mode is vibrating at the same frequency as the string. Using $f_n = nv/4L$ and solving for L gives $L = \frac{v}{4f_1} = \frac{344 \text{ m/s}}{4(165 \text{ Hz})} = 0.521$ m.

EVALUATE: The frequency of the sound wave is the same as the frequency at which the string is vibrating, but the wavelengths of the two waves are *not* the same because they have different speeds.

VP16.12.4. **IDENTIFY:** A stopped pipe 1.00 m long that is filled with helium is vibrating in its third harmonic, which causes a nearby open pipe to vibrate in its fifth harmonic.

SET UP: We want to know the frequency and wavelength of the sound in both pipes and the length of the open pipe. The speed of sound in the helium is v_{He} = 999 m/s, $v = f\lambda$, $\lambda_n = 4L/n$ (n = 1, 3, 4, …) for a stopped pipe, and $f_n = nv/2L$ (n = 1, 2, 3 …) for an open pipe.

EXECUTE: **(a)** In the stopped pipe, $\lambda_3 = 4L/3$ = 4(1.00 m)/3 = 1.33 m.

Using $v = f\lambda$ gives $f_3 = \frac{v_{He}}{\lambda_3} = \frac{999 \text{ m/s}}{1.33 \text{ m}} =$ 749 Hz.

(b) In the open pipe, we know that f_5 = 749 Hz.

Using $v = f\lambda$ gives $\lambda_5 = \frac{v_{air}}{f_5} = \frac{344 \text{ m/s}}{749 \text{ Hz}} =$ 0.459 m.

(c) Using $f_n = nv/2L$ in the open pipe gives $f_5 = \frac{5v_{air}}{2L}$. Solving for L gives

$$L = \frac{5v_{air}}{2f_5} = \frac{5(344 \text{ m/s})}{2(749 \text{ Hz})} = 1.15 \text{ m}.$$

EVALUATE: The speed of sound is different in the helium than it is in air because the density of the helium is not the same as that of air.

VP16.18.1. **IDENTIFY:** You do not hear the same frequency that the siren is emitting due to the motion of the ambulance. This is due to the Doppler effect.

SET UP: We have a moving source of sound and a stationary listener. The target variables are the frequency and wavelength of the sound heard by the listener, so use $f_{\text{L}} = \left(\dfrac{v+v_{\text{L}}}{v+v_{\text{S}}}\right) f_{\text{S}}$ and $v = f\lambda$.

EXECUTE: **(a)** Listener in front of source: v_{S} = –26.0 m/s. $f_{\text{L}} = \left(\dfrac{v+v_{\text{L}}}{v+v_{\text{S}}}\right) f_{\text{S}}$ gives

$$f_{\text{L}} = \left(\frac{340\text{ m/s} + 0}{340\text{ m/s} - 26.0\text{ m/s}}\right)(2.80\times10^3\text{ Hz}) = 3.03\times10^3\text{ Hz}.$$

The wavelength is $\lambda = \dfrac{v}{f} = \dfrac{340\text{ m/s}}{3.03\times10^3\text{ Hz}} = 0.112\text{ m}.$

(b) Listener behind source: v_{S} = +26.0 m/s. $f_{\text{L}} = \left(\dfrac{340\text{ m/s} + 0}{340\text{ m/s} + 26.0\text{ m/s}}\right)(2.80\times10^3\text{ Hz}) = 2.60\times10^3\text{ Hz}.$

The wavelength is $\lambda = \dfrac{v}{f} = \dfrac{340\text{ m/s}}{2.60\times10^3\text{ Hz}} = 0.131\text{ m}.$

EVALUATE: When the source moves toward the listener, the wave crests are closer together so the frequency is increased. When the source moves away from the listener, the distance between wave crests is greater so the frequency is decreased.

VP16.18.2. **IDENTIFY:** The bike rider hears a sound different from what the bagpiper is emitting due to the bike's motion. This is due to the Doppler effect.

SET UP: The bagpiper is the stationary source and the bike rider is the moving observer. We want the frequency and wavelength of the sound the bike rider hears, so we use $v = f\lambda$ and $f_{\text{L}} = \left(\dfrac{v+v_{\text{L}}}{v+v_{\text{S}}}\right) f_{\text{S}}$ with $v_{\text{S}} = 0$.

EXECUTE: **(a)** $\lambda = \dfrac{v}{f} = \dfrac{340\text{ m/s}}{440\text{ Hz}} = 0.773\text{ m}.$

(b) <u>Biker approaching source</u>: v_{L} = +10.0 m/s. Using $f_{\text{L}} = \left(\dfrac{v+v_{\text{L}}}{v+v_{\text{S}}}\right) f_{\text{S}}$ gives

$$f_{\text{L}} = \left(\frac{340\text{ m/s} + 10.0\text{ m/s}}{340\text{ m/s} + 0}\right)(440\text{ Hz}) = 453\text{ Hz}.$$

Now use $v = f\lambda$, but v is the speed of sound relative to the listener, which is 340 m/s + 10.0 m/s = 350 m/s. Therefore $\lambda = \dfrac{v}{f} = \dfrac{350\text{ m/s}}{453\text{ Hz}} = 0.773\text{ m}.$

<u>Biker moving away from source</u>: v_{L} = –10.0 m/s. Now we get

$$f_{\text{L}} = \left(\frac{340\text{ m/s} - 10.0\text{ m/s}}{340\text{ m/s}}\right)(440\text{ Hz}) = 427\text{ Hz}.$$

Now use $v = f\lambda$, where v = 340 m/s – 10.0 m/s = 330 m/s. $\lambda = \dfrac{v}{f} = \dfrac{330\text{ m/s}}{453\text{ Hz}} = 0.773\text{ m}.$

EVALUATE: The frequency varies due to the speed of the listener because she runs into the waves at a higher (or lower) rate due to her motion. But the wavelength is just the distance between wave crests, so it is not affected by her motion and we get the same answer in both cases.

VP16.18.3. **IDENTIFY:** The police car and the sports car are both moving, so both of their motions affect the frequency that the listener receives. We need to use the Doppler effect.

SET UP: Our target variable is the frequency f_{L} of sound that the listener receives. We use $f_{\text{L}} = \left(\dfrac{v+v_{\text{L}}}{v+v_{\text{S}}}\right) f_{\text{S}}$. Figure VP16.18.3 shows both situations.

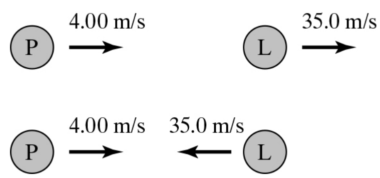

Figure VP16.18.3

EXECUTE: **(a)** The police car is moving in the direction of the listener and the listener is moving away from the police car, so $v_S = -40.0$ m/s and $v_L = -35.0$ m/s. $f_L = \left(\dfrac{v+v_L}{v+v_S}\right)f_S$ gives

$$f_L = \left(\frac{340\text{ m/s} - 35.0\text{ m/s}}{340\text{ m/s} - 40.0\text{ m/s}}\right)(1200\text{ Hz}) = 1220\text{ Hz}.$$

(b) The police car is moving in the direction of the listener and the listener is in the direction of the police car, so $v_S = -40.0$ m/s and $v_L = +35.0$ m/s. $f_L = \left(\dfrac{v+v_L}{v+v_S}\right)f_S$ gives

$$f_L = \left(\frac{340\text{ m/s} + 35.0\text{ m/s}}{340\text{ m/s} - 40.0\text{ m/s}}\right)(1200\text{ Hz}) = 1500\text{ Hz}.$$

EVALUATE: In part (a), the motion of the police car causes a higher frequency but the motion of the sports car causes a lower frequency, so there is a small change in the frequency heard by the listener compared to the emitted frequency. In part (b) both of their motions increase the frequency, so there is a large frequency change.

VP16.18.4. **IDENTIFY:** The motion of the car increases the sound frequency in front of it, and this motion also increases the frequency of the sound the driver hears reflected from the wall. There are two Doppler effects to consider.

SET UP: We need to break this problem into two steps: (1) the car is a moving source and the wall is a stationary listener and (2) the wall is a stationary source and the car is a moving listener. The wall reflects the same frequency it receives from the car. $f_L = \left(\dfrac{v+v_L}{v+v_S}\right)f_S$. In part (a) we want to find the frequency that the driver receives reflected from the wall. In part (b) we want to find how fast he most drive to hear sound of frequency 495 Hz coming from the wall.

EXECUTE: **(a)** Car as moving source and wall as stationary listener: $v_L = 0$ (the wall), $v_S = -25.0$ m/s. Use $f_L = \left(\dfrac{v+v_L}{v+v_S}\right)f_S$ to find the frequency f_w that the wall receives.

$$f_w = \left(\frac{340\text{ m/s}}{340\text{ m/s} - 25.0\text{ m/s}}\right)(415\text{ Hz}) = 447.94\text{ Hz}.$$

Car as moving listener and wall as stationary source: $v_S = 0$ (the wall), $v_L = +25.0$ m/s, and $f_S = 447.94$ Hz. Use $f_L = \left(\dfrac{v+v_L}{v+v_S}\right)f_S$ to find the frequency f_d that the driver receives coming back from the wall.

$$f_d = \left(\frac{340\text{ m/s} + 25.0\text{ m/s}}{340\text{ m/s}}\right)(447.94\text{ Hz}) = 481\text{ Hz}.$$

(b) We want to find v_S so that $f_c = 495$ Hz. We follow the same steps as in part (a).

Car as listener and wall as source: $v_L = v_c = ?$ (where v_c is the *magnitude* of the car's speed), $f_S = f_w = ?$, $f_L = f_c = 495$ Hz, $v_S = 0$ (wall). Using $f_L = \left(\frac{v+v_L}{v+v_S}\right) f_S$ gives $495\text{ Hz} = \left(\frac{340\text{ m/s} + v_c}{340\text{ m/s}}\right) f_w$, so $f_w = \frac{(495\text{ Hz})(340\text{ m/s})}{340\text{ m/s} + v_c}$.

Car as source and wall as listener: $v_S = -v_c$, $v_L = 0$, $f_S = 415$ Hz, $f_L = f_w = ?$ so $f_L = \left(\frac{v+v_L}{v+v_S}\right) f_S$ gives $f_w = \left(\frac{340\text{ m/s}}{340\text{ m/s} - v_c}\right)(415\text{ Hz})$. Now use the result for f_w that we just found in the previous step.

Equating these two equations for f_w and solving for v_c gives us $\frac{(495\text{ Hz})(340\text{ m/s})}{340\text{ m/s} + v_c} = \left(\frac{340\text{ m/s}}{340\text{ m/s} - v_c}\right)(415\text{ Hz})$, so $v_c = 29.9$ m/s.

EVALUATE: Our result in part (b) gives $v_c = 29.9$ m/s which is greater than the speed of 25.0 m/s in part (a). This result is reasonable because the frequency change in (b) is greater than the one in (a).

16.1. **IDENTIFY** and **SET UP:** $v = f\lambda$ gives the wavelength in terms of the frequency. Use $p_{\text{max}} = BkA$ to relate the pressure and displacement amplitudes.

EXECUTE: **(a)** $\lambda = v/f = (344\text{ m/s})/1000\text{ Hz} = 0.344\text{ m}$.

(b) $p_{\text{max}} = BkA$ and Bk is constant gives $p_{\text{max}1}/A_1 = p_{\text{max}2}/A_2$

$$A_2 = A_1\left(\frac{p_{\text{max}2}}{p_{\text{max}1}}\right) = 1.2\times10^{-8}\text{ m}\left(\frac{30\text{ Pa}}{3.0\times10^{-2}\text{ Pa}}\right) = 1.2\times10^{-5}\text{ m}.$$

(c) $p_{\text{max}} = BkA = 2\pi BA/\lambda$

$$p_{\text{max}}\lambda = 2\pi BA = \text{constant so } p_{\text{max}1}\lambda_1 = p_{\text{max}2}\lambda_2 \text{ and } \lambda_2 = \lambda_1\left(\frac{p_{\text{max}1}}{p_{\text{max}2}}\right) = (0.344\text{ m})\left(\frac{3.0\times10^{-2}\text{ Pa}}{1.5\times10^{-3}\text{ Pa}}\right)$$

$= 6.9$ m

$f = v/\lambda = (344\text{ m/s})/6.9\text{ m} = 50\text{ Hz}$.

EVALUATE: The pressure amplitude and displacement amplitude are directly proportional. For the same displacement amplitude, the pressure amplitude decreases when the frequency decreases and the wavelength increases.

16.2. **IDENTIFY:** Apply $p_{\text{max}} = BkA$. $k = \frac{2\pi}{\lambda} = \frac{2\pi f}{v}$, so $p_{\text{max}} = \frac{2\pi fBA}{v}$.

SET UP: $v = 344$ m/s

EXECUTE: $f = \frac{vp_{\text{max}}}{2\pi BA} = \frac{(344\text{ m/s})(10.0\text{ Pa})}{2\pi(1.42\times10^5\text{ Pa})(1.00\times10^{-6}\text{ m})} = 3.86\times10^3\text{ Hz}$

EVALUATE: Audible frequencies range from about 20 Hz to about 20,000 Hz, so this frequency is audible.

16.3. **IDENTIFY:** Use $p_{\text{max}} = BkA$ to relate the pressure and displacement amplitudes.

SET UP: As stated in Example 16.1 the adiabatic bulk modulus for air is $B = 1.42\times10^5$ Pa. Use $v = f\lambda$ to calculate λ from f, and then $k = 2\pi/\lambda$.

EXECUTE: **(a)** $f = 150$ Hz

Need to calculate k: $\lambda = v/f$ and $k = 2\pi/\lambda$ so $k = 2\pi f/v = (2\pi\text{ rad})(150\text{ Hz})/344\text{ m/s} = 2.74\text{ rad/m}$.

Then $p_{\text{max}} = BkA = (1.42\times10^5\text{ Pa})(2.74\text{ rad/m})(0.0200\times10^{-3}\text{ m}) = 7.78\text{ Pa}$. This is below the pain threshold of 30 Pa.

(b) *f* is larger by a factor of 10 so $k = 2\pi f/v$ is larger by a factor of 10, and $p_{\text{max}} = BkA$ is larger by a factor of 10. $p_{\text{max}} = 77.8\text{ Pa},$ above the pain threshold.

(c) There is again an increase in *f*, *k*, and p_{max} of a factor of 10, so $p_{\text{max}} = 778\text{ Pa},$ far above the pain threshold.

EVALUATE: When *f* increases, λ decreases so *k* increases and the pressure amplitude increases.

16.4. **IDENTIFY** and **SET UP:** Use the relation $v = f\lambda$ to find the wavelength or frequency of various sounds.

EXECUTE: **(a)** $\lambda = \dfrac{v}{f} = \dfrac{1531\text{ m/s}}{17\text{ Hz}} = 90\text{ m}.$

(b) $f = \dfrac{v}{\lambda} = \dfrac{1531\text{ m/s}}{0.015\text{ m}} = 102\text{ kHz}.$

(c) $\lambda = \dfrac{v}{f} = \dfrac{344\text{ m/s}}{25\times10^3\text{ Hz}} = 1.4\text{ cm}.$

(d) For $f = 78\text{ kHz},$ $\lambda = \dfrac{v}{f} = \dfrac{344\text{ m/s}}{78\times10^3\text{ Hz}} = 4.4\text{ mm}.$ For $f = 39\text{ kHz},$ $\lambda = \dfrac{v}{f} = \dfrac{344\text{ m/s}}{39\times10^3\text{ Hz}} = 8.8\text{ mm}.$

The range of wavelengths is 4.4 mm to 8.8 mm.

(e) $\lambda = 0.25\text{ mm}$ so $f = \dfrac{v}{\lambda} = \dfrac{1550\text{ m/s}}{0.25\times10^{-3}\text{m}} = 6.2\text{ MHz}.$

EVALUATE: Nonaudible (to human) sounds cover a wide range of frequencies and wavelengths.

16.5. **IDENTIFY** and **SET UP:** Use $t = \text{distance/speed}.$ Calculate the time it takes each sound wave to travel the $L = 60.0\text{ m}$ length of the pipe. Use $v = \sqrt{\dfrac{Y}{\rho}}$ to calculate the speed of sound in the brass rod.

EXECUTE: Wave in air: $t = (60.0\text{ m})/(344\text{ m/s}) = 0.1744\text{ s}.$

Wave in the metal: $v = \sqrt{\dfrac{Y}{\rho}} = \sqrt{\dfrac{9.0\times10^{10}\text{ Pa}}{8600\text{ kg/m}^3}} = 3235\text{ m/s},$ so $t = \dfrac{60.0\text{ m}}{3235\text{ m/s}} = 0.01855\text{ s}.$

The time interval between the two sounds is $\Delta t = 0.1744\text{ s} - 0.01855\text{ s} = 0.156\text{ s}.$

EVALUATE: The restoring forces that propagate the sound waves are much greater in solid brass than in air, so *v* is much larger in brass.

16.6. **IDENTIFY:** $v = f\lambda.$ Apply $v = \sqrt{\dfrac{B}{\rho}}$ for the waves in the liquid and $v = \sqrt{\dfrac{Y}{\rho}}$ for the waves in the metal bar.

SET UP: In part (b) the wave speed is $v = \dfrac{d}{t} = \dfrac{1.50\text{ m}}{3.90\times10^{-4}\text{ s}}.$

EXECUTE: **(a)** Using $v = \sqrt{\dfrac{B}{\rho}},$ we have $B = v^2\rho = (\lambda f)^2\rho,$ so

$B = [(8\text{ m})(400\text{ Hz})]^2(1300\text{ kg/m}^3) = 1.33\times10^{10}\text{ Pa}.$

(b) Using $v = \sqrt{\dfrac{Y}{\rho}},$ we have

$Y = v^2\rho = (L/t)^2\rho = [(1.50\text{ m})/(3.90\times10^{-4}\text{ s})]^2(6400\text{ kg / m}^3) = 9.47\times10^{10}\text{ Pa}.$

EVALUATE: In the liquid, $v = 3200\text{ m/s}$ and in the metal, $v = 3850\text{ m/s}.$ Both these speeds are much greater than the speed of sound in air.

16.7. **IDENTIFY:** $d = vt$ for the sound waves in air and in water.

SET UP: Use $v_{\text{water}} = 1482\text{ m/s}$ at $20°\text{C},$ as given in Table 16.1. In air, $v = 344\text{ m/s}.$

EXECUTE: Since along the path to the diver the sound travels 1.2 m in air, the sound wave travels in water for the same time as the wave travels a distance $22.0\text{ m} - 1.20\text{ m} = 20.8\text{ m}$ in air. The depth of the diver is $(20.8\text{ m})\dfrac{v_{\text{water}}}{v_{\text{air}}} = (20.8\text{ m})\dfrac{1482\text{ m/s}}{344\text{ m/s}} = 89.6\text{ m}.$ This is the depth of the diver; the distance from the horn is $90.8\text{ m}.$

EVALUATE: The time it takes the sound to travel from the horn to the person on shore is $t_1 = \dfrac{22.0\text{ m}}{344\text{ m/s}} = 0.0640\text{ s}.$ The time it takes the sound to travel from the horn to the diver is $t_2 = \dfrac{1.2\text{ m}}{344\text{ m/s}} + \dfrac{89.6\text{ m}}{1482\text{ m/s}} = 0.0035\text{ s} + 0.0605\text{ s} = 0.0640\text{ s}.$ These times are indeed the same. For three figure accuracy the distance of the horn above the water can't be neglected.

16.8. IDENTIFY: Apply $v = \sqrt{\dfrac{\gamma RT}{M}}$ to each gas.

SET UP: In each case, express M in units of kg/mol. For H_2, $\gamma = 1.41.$ For He and Ar, $\gamma = 1.67.$

EXECUTE: **(a)** $v_{H_2} = \sqrt{\dfrac{(1.41)(8.3145\text{ J/mol}\cdot\text{K})(300.15\text{ K})}{(2.02\times10^{-3}\text{ kg/mol})}} = 1.32\times10^3\text{ m/s}$

(b) . $v_{\text{He}} = \sqrt{\dfrac{(1.67)(8.3145\text{ J/mol}\cdot\text{K})(300.15\text{ K})}{(4.00\times10^{-3}\text{ kg/mol})}} = 1.02\times10^3\text{ m/s}$.

(c) $v_{\text{Ar}} = \sqrt{\dfrac{(1.67)(8.3145\text{ J/mol}\cdot\text{K})(300.15\text{ K})}{(39.9\times10^{-3}\text{ kg/mol})}} = 323\text{ m/s}.$

(d) Repeating the calculation of Example 16.4 at $T = 300.15\text{ K}$ gives $v_{\text{air}} = 348\text{ m/s},$ and so $v_{H_2} = 3.80 v_{\text{air}}$, $v_{\text{He}} = 2.94 v_{\text{air}}$ and $v_{\text{Ar}} = 0.928 v_{\text{air}}$.

EVALUATE: v is larger for gases with smaller M.

16.9. IDENTIFY: $v = f\lambda.$ The relation of v to gas temperature is given by $v = \sqrt{\dfrac{\gamma RT}{M}}.$

SET UP: Let $T = 22.0°\text{C} = 295.15\text{ K}.$

EXECUTE: At $22.0°\text{C}$, $\lambda = \dfrac{v}{f} = \dfrac{325\text{ m/s}}{1250\text{ Hz}} = 0.260\text{ m} = 26.0\text{ cm}.$ $\lambda = \dfrac{v}{f} = \dfrac{1}{f}\sqrt{\dfrac{\gamma RT}{M}}.$ $\dfrac{\lambda}{\sqrt{T}} = \dfrac{1}{f}\sqrt{\dfrac{\gamma R}{M}},$ which is constant, so $\dfrac{\lambda_1}{\sqrt{T_1}} = \dfrac{\lambda_2}{\sqrt{T_2}}.$ $T_2 = T_1\left(\dfrac{\lambda_2}{\lambda_1}\right)^2 = (295.15\text{ K})\left(\dfrac{28.5\text{ cm}}{26.0\text{ cm}}\right)^2 = 354.6\text{ K} = 81.4°\text{C}.$

EVALUATE: When T increases v increases and for fixed f, λ increases. Note that we did not need to know either γ or M for the gas.

16.10. IDENTIFY: $v = \sqrt{\dfrac{\gamma RT}{M}}.$ Take the derivative of v with respect to T. In part (b) replace dv by Δv and dT by ΔT in the expression derived in part (a).

SET UP: $\dfrac{d(x^{1/2})}{dx} = \tfrac{1}{2}x^{-1/2}.$ In $v = \sqrt{\dfrac{\gamma RT}{M}},$ T must be in kelvins. $20°\text{C} = 293\text{ K}.$ $\Delta T = 1\text{ C}° = 1\text{ K}.$

EXECUTE: **(a)** $\dfrac{dv}{dT} = \sqrt{\dfrac{\gamma R}{M}}\dfrac{dT^{1/2}}{dT} = \sqrt{\dfrac{\gamma R}{M}}\tfrac{1}{2}T^{-1/2} = \dfrac{1}{2T}\sqrt{\dfrac{\gamma RT}{M}} = \dfrac{v}{2T}.$ Rearranging gives $\dfrac{dv}{v} = \dfrac{1}{2}\dfrac{dT}{T},$ the desired result.

(b) $\dfrac{\Delta v}{v} = \dfrac{1}{2}\dfrac{\Delta T}{T}.$ $\Delta v = \dfrac{v}{2}\dfrac{\Delta T}{T} = \left(\dfrac{344\text{ m/s}}{2}\right)\left(\dfrac{1\text{ K}}{293\text{ K}}\right) = 0.59\text{ m/s}.$

EVALUATE: Since $\frac{\Delta T}{T} = 3.4\times10^{-3}$ and $\frac{\Delta v}{v}$ is one-half this, replacing dT by ΔT and dv by Δv is accurate. Using the result from part (a) is much simpler than calculating v for $20°\text{C}$ and for $21°\text{C}$ and subtracting, and is not subject to round-off errors.

16.11. IDENTIFY and **SET UP:** Sound delivers energy (and hence power) to the ear. For a whisper, $I = 1\times10^{-10}\ \text{W/m}^2$. The area of the tympanic membrane is $A = \pi r^2$, with $r = 4.2\times10^{-3}\ \text{m}$. Intensity is energy per unit time per unit area.

EXECUTE: **(a)** $E = IAt = (1\times10^{-10}\ \text{W/m}^2)\pi(4.2\times10^{-3}\ \text{m})^2(1\ \text{s}) = 5.5\times10^{-15}\ \text{J}$.

(b) $K = \frac{1}{2}mv^2$ so $v = \sqrt{\frac{2K}{m}} = \sqrt{\frac{2(5.5\times10^{-15}\ \text{J})}{2.0\times10^{-6}\ \text{kg}}} = 7.4\times10^{-5}\ \text{m/s} = 0.074\ \text{mm/s}$.

EVALUATE: Compared to the energy of ordinary objects, it takes only a very small amount of energy for hearing. As part (b) shows, a mosquito carries a lot more energy than is needed for hearing.

16.12. IDENTIFY: The sound intensity level decreases by 13.0 dB, and from this we can find the change in the intensity.

SET UP: $\beta = 10\log(I/I_0)$. $\Delta\beta = 13.0$ dB.

EXECUTE: **(a)** $\Delta\beta = \beta_2 - \beta_1 = 10\ \text{dB}\log(I_2/I_0) - 10\ \text{dB}\log(I_1/I_0) = 10\ \text{dB}\log(I_2/I_1) = 13.0\ \text{dB}$, so $1.3 = \log(I_2/I_1)$ which gives $I_2/I_1 = 20.0$.

(b) EVALUATE: According to the equation in part (a) the difference in two sound intensity levels is determined by the ratio of the sound intensities. So you don't need to know I_1, just the ratio I_2/I_1.

16.13. IDENTIFY and **SET UP:** We want the sound intensity level to increase from 20.0 dB to 60.0 dB. The previous problem showed that $\beta_2 - \beta_1 = (10\ \text{dB})\log\left(\frac{I_2}{I_1}\right)$. We also know that $\frac{I_2}{I_1} = \frac{r_1^2}{r_2^2}$.

EXECUTE: Using $\beta_2 - \beta_1 = (10\ \text{dB})\log\left(\frac{I_2}{I_1}\right)$, we have $\Delta\beta = +40.0\ \text{dB}$. Therefore $\log\left(\frac{I_2}{I_1}\right) = 4.00$, so $\frac{I_2}{I_1} = 1.00\times10^4$. Using $\frac{I_2}{I_1} = \frac{r_1^2}{r_2^2}$ and solving for r_2, we get $r_2 = r_1\sqrt{\frac{I_1}{I_2}} = (15.0\ \text{m})\sqrt{\frac{1}{1.00\times10^4}} = 15.0\ \text{cm}$.

EVALUATE: A change of 10^2 in distance gives a change of 10^4 in intensity. Our analysis assumes that the sound spreads from the source uniformly in all directions.

16.14. IDENTIFY: This problem deals with sound intensity and intensity level.

SET UP: The sound intensity level is $\beta = (10\ \text{dB})\log\frac{I}{I_0}$ and the intensity is $I = \frac{P}{A} = \frac{P}{4\pi r^2}$. We want to know by what factor the power P should increase so that β will increase by 5.00 dB at 20.0 m from the source. We know that $\beta_2 - \beta_1 = 5.00\ \text{dB}$ and we want to find P_2/P_1.

EXECUTE: $\beta_1 = (10\ \text{dB})\log\frac{I_1}{I_0}$ and $\beta_2 = (10\ \text{dB})\log\frac{I_2}{I_0}$. We know that $\beta_2 - \beta_1 = 5.00\ \text{dB}$, so we have $\beta_2 - \beta_1 = (10\ \text{dB})\log(I_2/I_0) - (10\ \text{dB})\log(I_1/I_0)$. Using the properties of logarithms gives $\beta_2 - \beta_1 = (10\ \text{dB})\left[\log I_2 - \log I_0 - (\log I_1 - \log I_0)\right] = (10\ \text{dB})\log(I_2/I_1)$. Now use $I = \frac{P}{4\pi r^2}$, giving $\beta_2 - \beta_1 = (10\ \text{dB})\log\left(\frac{P_2/4\pi r^2}{P_1/4\pi r^2}\right) = (10\ \text{dB})\log(P_2/P_1)$. This gives us $5.00\ \text{dB} = (10\ \text{dB})\log(P_2/P_1)$, so $P_2/P_1 = 10^{1/2} = \sqrt{10} = 3.16$.

EVALUATE: Our result does not depend on the distance from the source, since the r divided out. Therefore the sound intensity level at all points would increase by 5.00 dB if the power of the source increased by a factor of 3.16.

16.15. IDENTIFY and SET UP: Apply $p_{\max} = BkA$, $I = \frac{1}{2}B\omega kA^2$, and $\beta = (10\text{ dB})\log\left(\frac{I}{I_0}\right)$.

EXECUTE: (a) $\omega = 2\pi f = (2\pi\text{ rad})(320\text{ Hz}) = 2011\text{ rad/s}$

$$k = \frac{2\pi}{\lambda} = \frac{2\pi f}{v} = \frac{\omega}{v} = \frac{2011\text{ rad/s}}{344\text{ m/s}} = 5.84\text{ rad/m}$$

$B = 1.42\times10^5\text{ Pa}$ (Example 16.1)

Then $p_{\max} = BkA = (1.42\times10^5\text{ Pa})(5.84\text{ rad/m})(5.00\times10^{-6}\text{ m}) = 4.14\text{ Pa}$.

(b) Using $I = \frac{1}{2}\omega BkA^2$ gives

$I = \frac{1}{2}(2011\text{ rad/s})(1.42\times10^5\text{ Pa})(5.84\text{ rad/m})(5.00\times10^{-6}\text{ m})^2 = 2.08\times10^{-2}\text{ W/m}^2$.

(c) $\beta = (10\text{ dB})\log\left(\frac{I}{I_0}\right)$: $\beta = (10\text{ dB})\log(I/I_0)$, with $I_0 = 1\times10^{-12}\text{ W/m}^2$.

$\beta = (10\text{ dB})\log[(2.08\times10^{-2}\text{ W/m}^2)/(1\times10^{-12}\text{ W/m}^2)] = 103\text{ dB}$.

EVALUATE: Even though the displacement amplitude is very small, this is a very intense sound. Compare the sound intensity level to the values in Table 16.2.

16.16. IDENTIFY: Changing the sound intensity level will decrease the rate at which energy reaches the ear.

SET UP: Example 16.9 shows that $\beta_2 - \beta_1 = (10\text{ dB})\log\left(\frac{I_2}{I_1}\right)$.

EXECUTE: (a) $\Delta\beta = -30\text{ dB}$ so $\log\left(\frac{I_2}{I_1}\right) = -3$ and $\frac{I_2}{I_1} = 10^{-3} = 1/1000$.

(b) $I_2/I_1 = \frac{1}{2}$ so $\Delta\beta = 10\log\left(\frac{1}{2}\right) = -3.0\text{ dB}$.

EVALUATE: Because of the logarithmic relationship between the intensity and intensity level of sound, a small change in the intensity level produces a large change in the intensity.

16.17. IDENTIFY: Use $I = \frac{vp_{\max}^2}{2B}$ to relate I and $p_{\max}$. $\beta = (10\text{ dB})\log(I/I_0)$. The equation $p_{\max} = BkA$ says the pressure amplitude and displacement amplitude are related by $p_{\max} = BkA = B\left(\frac{2\pi f}{v}\right)A$.

SET UP: At $20°\text{C}$ the bulk modulus for air is $1.42\times10^5\text{ Pa}$ and $v = 344\text{ m/s}$. $I_0 = 1\times10^{-12}\text{ W/m}^2$.

EXECUTE: (a) $I = \frac{vp_{\max}^2}{2B} = \frac{(344\text{ m/s})(6.0\times10^{-5}\text{ Pa})^2}{2(1.42\times10^5\text{ Pa})} = 4.4\times10^{-12}\text{ W/m}^2$

(b) $\beta = (10\text{ dB})\log\left(\frac{4.4\times10^{-12}\text{ W/m}^2}{1\times10^{-12}\text{ W/m}^2}\right) = 6.4\text{ dB}$

(c) $A = \frac{vp_{\max}}{2\pi fB} = \frac{(344\text{ m/s})(6.0\times10^{-5}\text{ Pa})}{2\pi(400\text{ Hz})(1.42\times10^5\text{ Pa})} = 5.8\times10^{-11}\text{ m}$

EVALUATE: This is a very faint sound and the displacement and pressure amplitudes are very small. Note that the displacement amplitude depends on the frequency but the pressure amplitude does not.

16.18. IDENTIFY and SET UP: Apply the relation $\beta_2 - \beta_1 = (10\text{ dB})\log(I_2/I_1)$ that is derived in Example 16.9.

EXECUTE: (a) $\Delta\beta = (10\text{ dB})\log\left(\frac{4I}{I}\right) = 6.0\text{ dB}$

(b) The total number of crying babies must be multiplied by four, for an increase of 12 kids.
EVALUATE: For $I_2 = \alpha I_1$, where α is some factor, the increase in sound intensity level is $\Delta\beta = (10\text{ dB})\log\alpha$. For $\alpha = 4$, $\Delta\beta = 6.0$ dB.

16.19. **IDENTIFY** and **SET UP:** Let 1 refer to the mother and 2 to the father. Use the result derived in Example 16.9 for the difference in sound intensity level for the two sounds. Relate intensity to distance from the source using $I_1/I_2 = r_2^2/r_1^2$.
EXECUTE: From Example 16.9, $\beta_2 - \beta_1 = (10\text{ dB})\log(I_2/I_1)$
Using $I_1/I_2 = r_2^2/r_1^2$ gives us
$\Delta\beta = \beta_2 - \beta_1 = (10\text{ dB})\log(I_2/I_1) = (10\text{ dB})\log(r_1/r_2)^2 = (20\text{ dB})\log(r_1/r_2)$
$\Delta\beta = (20\text{ dB})\log(1.50\text{ m}/0.30\text{ m}) = 14.0\text{ dB}.$
EVALUATE: The father is 5 times closer so the intensity at his location is 25 times greater.

16.20. **IDENTIFY:** We must use the relationship between intensity and sound level.
SET UP: Example 16.9 shows that $\beta_2 - \beta_1 = (10\text{ dB})\log\left(\dfrac{I_2}{I_1}\right)$.
EXECUTE: **(a)** $\Delta\beta = 5.00$ dB gives $\log\left(\dfrac{I_2}{I_1}\right) = 0.5$ and $\dfrac{I_2}{I_1} = 10^{0.5} = 3.16.$
(b) $\dfrac{I_2}{I_1} = 100$ gives $\Delta\beta = 10\log(100) = 20$ dB.
(c) $\dfrac{I_2}{I_1} = 2$ gives $\Delta\beta = 10\log 2 = 3.0$ dB.
EVALUATE: Every doubling of the intensity increases the decibel level by 3.0 dB.

16.21. **IDENTIFY:** The intensity of sound obeys an inverse square law.
SET UP: $\dfrac{I_2}{I_1} = \dfrac{r_1^2}{r_2^2}$. $\beta = (10\text{ dB})\log\left(\dfrac{I}{I_0}\right)$, with $I_0 = 1\times10^{-12}\text{ W/m}^2$.
EXECUTE: **(a)** $\beta = 53$ dB gives $5.3 = \log\left(\dfrac{I}{I_0}\right)$ and $I = (10^{5.3})I_0 = 2.0\times10^{-7}\text{ W/m}^2$.
(b) $r_2 = r_1\sqrt{\dfrac{I_1}{I_2}} = (3.0\text{ m})\sqrt{\dfrac{4}{1}} = 6.0$ m.
(c) $\beta = \dfrac{53\text{ dB}}{4} = 13.25$ dB gives $1.325 = \log\left(\dfrac{I}{I_0}\right)$ and $I = 2.1\times10^{-11}\text{ W/m}^2$.
$r_2 = r_1\sqrt{\dfrac{I_1}{I_2}} = (3.0\text{ m})\sqrt{\dfrac{2.0\times10^{-7}\text{ W/m}^2}{2.1\times10^{-11}\text{ W/m}^2}} = 290\text{ m}.$
EVALUATE: **(d)** Intensity obeys the inverse square law but noise level does not.

16.22. **IDENTIFY:** We are looking at the standing wave pattern in a pipe. The pattern has displacement antinodes at both ends of the pipe.
SET UP: For an open pipe, $\lambda_n = 2L/n$, and for any wave $v = f\lambda$. Table 16.1 tells us that at 20°C v_{air} = 344 m/s and v_{He} = 999 m/s.
EXECUTE: **(a)** The fact that displacement nodes occur at both ends of the pipe tells us that it must be an open pipe.
(b) The pattern shows 5 nodes, so it is the 5th harmonic.
(c) $\lambda_n = 2L/n$, so $\lambda_5 = 2L/5$, which gives $L = 5\lambda_5/2$. Now get λ_5 which we can use to find L.
$\lambda_5 = v/f_5 = (344\text{ m/s})/(1710\text{ Hz}) = 0.2012$ m. Therefore $L = 5\lambda_5/2 = 5(0.2012\text{ m})/2 = 0.503$ m.

(d) L remains the same, so $\lambda_1 = 2L$. $f_1\lambda_1 = v_{\text{He}}$, so $f_1 = \dfrac{v_{\text{He}}}{\lambda_1} = \dfrac{v_{\text{He}}}{2L} = \dfrac{999\text{ m/s}}{2(0.503\text{ m})} = 993\text{ Hz}.$

EVALUATE: Replacing the air with helium changes the harmonic frequencies. But it does not change the wavelengths because they are determined by the length of the pipe.

16.23. **IDENTIFY** and **SET UP:** An open end is a displacement antinode and a closed end is a displacement node. Sketch the standing wave pattern and use the sketch to relate the node-to-antinode distance to the length of the pipe. A displacement node is a pressure antinode and a displacement antinode is a pressure node.

EXECUTE: **(a)** The placement of the displacement nodes and antinodes along the pipe is as sketched in Figure 16.23a. The open ends are displacement antinodes.

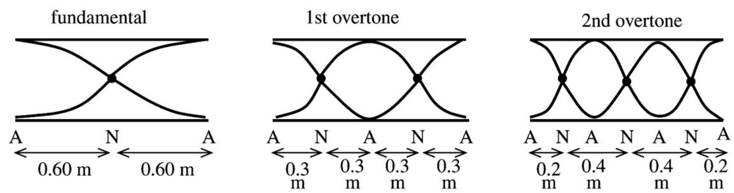

Figure 16.23a

Location of the displacement nodes (N) measured from the left end:
fundamental 0.60 m
1st overtone 0.30 m, 0.90 m
2nd overtone 0.20 m, 0.60 m, 1.00 m

Location of the pressure nodes (displacement antinodes (A)) measured from the left end:
fundamental 0, 1.20 m
1st overtone 0, 0.60 m, 1.20 m
2nd overtone 0, 0.40 m, 0.80 m, 1.20 m

(b) The open end is a displacement antinode and the closed end is a displacement node. The placement of the displacement nodes and antinodes along the pipe is sketched in Figure 16.23b.

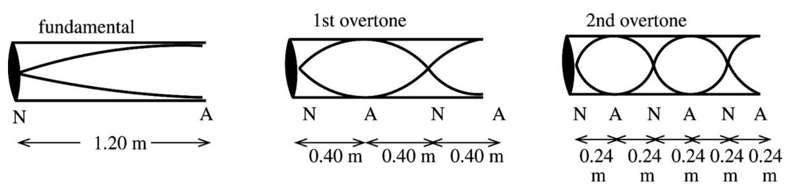

Figure 16.23b

Location of the displacement nodes (N) measured from the closed end:
fundamental 0
1st overtone 0, 0.80 m
2nd overtone 0, 0.48 m, 0.96 m

Location of the pressure nodes (displacement antinodes (A)) measured from the closed end:
fundamental 1.20 m
1st overtone 0.40 m, 1.20 m
2nd overtone 0.24 m, 0.72 m, 1.20 m

EVALUATE: The node-to-node or antinode-to-antinode distance is $\lambda/2$. For the higher overtones the frequency is higher and the wavelength is smaller.

16.24. **IDENTIFY:** For an open pipe, $f_1 = \frac{v}{2L}$. For a stopped pipe, $f_1 = \frac{v}{4L}$. $v = f\lambda$.

SET UP: $v = 344$ m/s. For a pipe, there must be a displacement node at a closed end and an antinode at the open end.

EXECUTE: **(a)** $L = \frac{v}{2f_1} = \frac{344 \text{ m/s}}{2(524 \text{ Hz})} = 0.328$ m.

(b) There is a node at one end, an antinode at the other end and no other nodes or antinodes in between, so $\frac{\lambda_1}{4} = L$ and $\lambda_1 = 4L = 4(0.328 \text{ m}) = 1.31$ m.

(c) $f_1 = \frac{v}{4L} = \frac{1}{2}\left(\frac{v}{2L}\right) = \frac{1}{2}(524 \text{ Hz}) = 262$ Hz.

EVALUATE: We could also calculate f_1 for the stopped pipe as $f_1 = \frac{v}{\lambda_1} = \frac{344 \text{ m/s}}{1.31 \text{ m}} = 262$ Hz, which agrees with our result in part (c).

16.25. **IDENTIFY:** For a stopped pipe, the standing wave frequencies are given by $f_n = nv/4L$.
SET UP: The first three standing wave frequencies correspond to $n = 1$, 3, and 5.

EXECUTE: $f_1 = \frac{(344 \text{ m/s})}{4(0.17 \text{ m})} = 506$ Hz, $f_3 = 3f_1 = 1517$ Hz, $f_5 = 5f_1 = 2529$ Hz.

EVALUATE: All three of these frequencies are in the audible range, which is about 20 Hz to 20,000 Hz.

16.26. **IDENTIFY:** The vocal tract is modeled as a stopped pipe, open at one end and closed at the other end, so we know the wavelength of standing waves in the tract.

SET UP: For a stopped pipe, $\lambda_n = 4L/n$ $(n = 1, 3, 5, \ldots)$ and $v = f\lambda$, so $f_1 = \frac{v}{4L}$ with $f_1 = 220$ Hz.

EXECUTE: $L = \frac{v}{4f_1} = \frac{344 \text{ m/s}}{4(220 \text{ Hz})} = 39.1$ cm. This result is a reasonable value for the mouth to diaphragm distance for a typical adult.
EVALUATE: 1244 Hz is not an integer multiple of the fundamental frequency of 220 Hz; it is 5.65 times the fundamental. The production of sung notes is more complicated than harmonics of an air column of fixed length.

16.27. **IDENTIFY:** A pipe open at one end and closed at the other is a stopped pipe.
SET UP: For an open pipe, the fundamental is $f_1 = v/2L$, and for a stopped pipe, it is $f_1 = v/4L$.

EXECUTE: **(a)** For an open pipe, $f_1 = \frac{v}{2L} = \frac{344 \text{ m/s}}{2(4.88 \text{ m})} = 35.2$ Hz.

(b) For a stopped pipe, $f_1 = \frac{v}{4L} = \frac{35.2 \text{ Hz}}{2} = 17.6$ Hz.

EVALUATE: Even though the pipes both have the same length, their fundamental frequencies are very different, depending on whether they are open or closed at their ends.

16.28. **IDENTIFY:** There must be a node at each end of the pipe. For the fundamental there are no additional nodes and each successive overtone has one additional node. $v = f\lambda$.

SET UP: $v = 344$ m/s. The node to node distance is $\lambda/2$.

EXECUTE: **(a)** $\frac{\lambda_1}{2} = L$ so $\lambda_1 = 2L$. Each successive overtone adds an additional $\lambda/2$ along the pipe, so $n\left(\frac{\lambda_n}{2}\right) = L$ and $\lambda_n = \frac{2L}{n}$, where $n = 1, 2, 3, \ldots$ $f_n = \frac{v}{\lambda_n} = \frac{nv}{2L}$.

(b) $f_1 = \dfrac{v}{2L} = \dfrac{344\text{ m/s}}{2(2.50\text{ m})} = 68.8\text{ Hz}.$ $f_2 = 2f_1 = 138\text{ Hz}.$ $f_3 = 3f_1 = 206\text{ Hz}.$ All three of these frequencies are audible.

EVALUATE: A pipe of length L closed at both ends has the same standing wave wavelengths, frequencies and nodal patterns as for a string of length L that is fixed at both ends.

16.29. **IDENTIFY:** We are looking at the standing wave pattern in a pipe. The pattern has a displacement node at one end and a displacement antinode at the other end of the pipe.

SET UP: For a stopped pipe $\lambda_n = 4L/n$ (n an odd integer). $v = f\lambda$

EXECUTE: **(a)** With a displacement node at one end and an antinode at the other, this must be a stopped pipe.

(b) The n^{th} harmonic has $\dfrac{n+1}{2}$ nodes, so for 5 nodes, $5 = \dfrac{n+1}{2}$, which gives $n = 5$. This pipe is resonating in its 5^{th} harmonic.

(c) Using $v = f\lambda$ gives $\lambda_9 = \dfrac{v}{f_9} = \dfrac{344\text{ m/s}}{1710\text{ Hz}} = 0.20117\text{ m}.$ Using $\lambda_n = 4L/n$ gives

$$L = \frac{n\lambda_n}{4} = \frac{9(0.20117\text{ m})}{4} = 0.453\text{ m}.$$

(d) $f_9 = 9f_1$, so $f_1 = (1710\text{ Hz})/9 = 190\text{ Hz}$.

EVALUATE: A stopped pipe does not have even harmonics because it has a displacement node at the closed end and an antinode at the open end.

16.30. **IDENTIFY:** The wire will vibrate in its second overtone with frequency f_3^{wire} when $f_3^{\text{wire}} = f_1^{\text{pipe}}$. For a stopped pipe, $f_1^{\text{pipe}} = \dfrac{v}{4L_{\text{pipe}}}$. The second overtone standing wave frequency for a wire fixed at both ends is $f_3^{\text{wire}} = 3\left(\dfrac{v_{\text{wire}}}{2L_{\text{wire}}}\right)$. $v_{\text{wire}} = \sqrt{F/\mu}$.

SET UP: The wire has $\mu = \dfrac{m}{L_{\text{wire}}} = \dfrac{7.25\times10^{-3}\text{ kg}}{0.620\text{ m}} = 1.169\times10^{-2}\text{ kg/m}$. The speed of sound in air is $v = 344\text{ m/s}$.

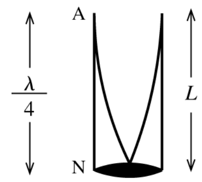
EXECUTE: $v_{\text{wire}} = \sqrt{\dfrac{4110\text{ N}}{1.169\times10^{-2}\text{ kg/m}}} = 592.85\text{ m/s}.$ $f_3^{\text{wire}} = f_1^{\text{pipe}}$ gives $3\dfrac{v_{\text{wire}}}{2L_{\text{wire}}} = \dfrac{v}{4L_{\text{pipe}}}$.

$$L_{\text{pipe}} = \frac{2L_{\text{wire}}v}{12v_{\text{wire}}} = \frac{2(0.620\text{ m})(344\text{ m/s})}{12(592.85\text{ m/s})} = 0.0600\text{ m} = 6.00\text{ cm}.$$

EVALUATE: The fundamental for the pipe has the same frequency as the third harmonic of the wire. But the wave speeds for the two objects are different and the two standing waves have different wavelengths.

16.31. **IDENTIFY** and **SET UP:** Use the standing wave pattern to relate the wavelength of the standing wave to the length of the air column and then use $v = f\lambda$ to calculate f. There is a displacement antinode at the top (open) end of the air column and a node at the bottom (closed) end, as shown in Figure 16.31.

EXECUTE: **(a)**



$$\lambda / 4 = L$$
$$\lambda = 4L = 4(0.140 \text{ m}) = 0.560 \text{ m}$$
$$f = \frac{v}{\lambda} = \frac{344 \text{ m/s}}{0.560 \text{ m}} = 614 \text{ Hz}$$

Figure 16.31

(b) Now the length L of the air column becomes $\frac{1}{2}(0.140 \text{ m}) = 0.070 \text{ m}$ and $\lambda = 4L = 0.280 \text{ m}$.

$$f = \frac{v}{\lambda} = \frac{344 \text{ m/s}}{0.280 \text{ m}} = 1230 \text{ Hz}$$

EVALUATE: Smaller L means smaller λ which in turn corresponds to larger *f*.

16.32. **IDENTIFY** and **SET UP:** The path difference for the two sources is *d*. For destructive interference, the path difference is a half-integer number of wavelengths. For constructive interference, the path difference is an integer number of wavelengths. $v = f\lambda$.

EXECUTE: **(a)** $\lambda = \dfrac{v}{f} = \dfrac{344 \text{ m/s}}{725 \text{ Hz}} = 0.474 \text{ m}$. Destructive interference will first occur when $d = \lambda/2 = 0.237 \text{ m}$.

(b) Destructive interference will next occur when $d = 3\lambda/2 = 0.711 \text{ m}$.

(c) Constructive interference will first occur when $d = \lambda = 0.474 \text{ m}$.

EVALUATE: Constructive interference should first occur midway between the first two points where destructive interference occurs. This midpoint is (0.237 m + 0.711 m)/2 = 0.474 m, which is just what we found in part (c).

16.33. **(a) IDENTIFY** and **SET UP:** Path difference from points *A* and *B* to point *Q* is $3.00 \text{ m} - 1.00 \text{ m} = 2.00 \text{ m}$, as shown in Figure 16.33. Constructive interference implies path difference $= n\lambda$, $n = 1, 2, 3, \ldots$

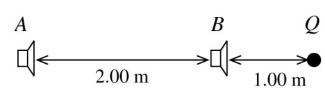


Figure 16.33

EXECUTE: $2.00 \text{ m} = n\lambda$ so $\lambda = 2.00 \text{ m}/n$

$$f = \frac{v}{\lambda} = \frac{nv}{2.00 \text{ m}} = \frac{n(344 \text{ m/s})}{2.00 \text{ m}} = n(172 \text{ Hz}), \quad n = 1, 2, 3, \ldots$$

The lowest frequency for which constructive interference occurs is 172 Hz.

(b) IDENTIFY and **SET UP:** Destructive interference implies path difference $= (n/2)\lambda$, $n = 1, 3, 5, \ldots$

EXECUTE: $2.00 \text{ m} = (n/2)\lambda$ so $\lambda = 4.00 \text{ m}/n$

$$f = \frac{v}{\lambda} = \frac{nv}{4.00 \text{ m}} = \frac{n(344 \text{ m/s})}{(4.00 \text{ m})} = n(86 \text{ Hz}), \quad n = 1, 3, 5, \ldots.$$

The lowest frequency for which destructive interference occurs is 86 Hz.

EVALUATE: As the frequency is slowly increased, the intensity at *Q* will fluctuate, as the interference changes between destructive and constructive.

16.34. **IDENTIFY:** Constructive interference occurs when the difference of the distances of each source from point *P* is an integer number of wavelengths. The interference is destructive when this difference of path lengths is a half integer number of wavelengths.

SET UP: The wavelength is $\lambda = v/f = (344\text{ m/s})/(206\text{ Hz}) = 1.67\text{ m}$. Since P is between the speakers, x must be in the range 0 to L, where $L = 2.00\text{ m}$ is the distance between the speakers.
EXECUTE: The difference in path length is $\Delta l = (L - x) - x = L - 2x$, or $x = (L - \Delta l)/2$. For destructive interference, $\Delta l = (n + (1/2))\lambda$, and for constructive interference, $\Delta l = n\lambda$.
(a) Destructive interference: $n = 0$ gives $\Delta l = 0.835\text{ m}$ and $x = 0.58\text{ m}$. $n = -1$ gives $\Delta l = -0.835\text{ m}$ and $x = 1.42\text{ m}$. No other values of n place P between the speakers.
(b) Constructive interference: $n = 0$ gives $\Delta l = 0$ and $x = 1.00\text{ m}$. $n = 1$ gives $\Delta l = 1.67\text{ m}$ and $x = 0.17\text{ m}$. $n = -1$ gives $\Delta l = -1.67\text{ m}$ and $x = 1.83\text{ m}$. No other values of n place P between the speakers.
(c) Treating the speakers as point sources is a poor approximation for these dimensions, and sound reaches these points after reflecting from the walls, ceiling and floor.
EVALUATE: Points of constructive interference are a distance $\lambda/2$ apart, and the same is true for the points of destructive interference.

16.35. **IDENTIFY:** For constructive interference the path difference is an integer number of wavelengths and for destructive interference the path difference is a half-integer number of wavelengths.
SET UP: $\lambda = v/f = (344\text{ m/s})/(688\text{ Hz}) = 0.500\text{ m}$
EXECUTE: To move from constructive interference to destructive interference, the path difference must change by $\lambda/2$. If you move a distance x toward speaker B, the distance to B gets shorter by x and the distance to A gets longer by x so the path difference changes by $2x$. $2x = \lambda/2$ and $x = \lambda/4 = 0.125\text{ m}$.
EVALUATE: If you walk an additional distance of 0.125 m farther, the interference again becomes constructive.

16.36. **IDENTIFY:** Destructive interference occurs when the path difference is a half integer number of wavelengths.
SET UP: $v = 344\text{ m/s}$, so $\lambda = v/f = (344\text{ m/s})/(172\text{ Hz}) = 2.00\text{ m}$. If $r_A = 8.00\text{ m}$ and r_B are the distances of the person from each is $r_B - r_A = \left(n + \tfrac{1}{2}\right)\lambda$, where n is any integer.
EXECUTE: Requiring $r_B = r_A + \left(n + \tfrac{1}{2}\right)\lambda > 0a$ gives $n + \tfrac{1}{2} > -r_A/\lambda = 0 - (8.00\text{ m})/(2.00\text{ m}) = -4$, so the smallest value of r_B occurs when $n = -4$, and the closest distance to B is
$r_B = 8.00\text{ m} + \left(-4 + \tfrac{1}{2}\right)(2.00\text{ m}) = 1.00\text{ m}$.
EVALUATE: For $r_B = 1.00\text{ m}$, the path difference is $r_A - r_B = 7.00\text{ m}$. This is 3.5λ.

16.37. **IDENTIFY:** For constructive interference, the path difference is an integer number of wavelengths. For destructive interference, the path difference is a half-integer number of wavelengths.
SET UP: One speaker is 4.50 m from the microphone and the other is 4.92 m from the microphone, so the path difference is 0.42 m. $f = v/\lambda$.
EXECUTE: **(a)** $\lambda = 0.42\text{ m}$ gives $f = \dfrac{v}{\lambda} = 820\text{ Hz}$; $2\lambda = 0.42\text{ m}$ gives $\lambda = 0.21\text{ m}$ and $f = \dfrac{v}{\lambda} = 1640\text{ Hz}$; $3\lambda = 0.42\text{ m}$ gives $\lambda = 0.14\text{ m}$ and $f = \dfrac{v}{\lambda} = 2460\text{ Hz}$, and so on. The frequencies for constructive interference are $n(820\text{ Hz})$, $n = 1, 2, 3, \ldots$.
(b) $\lambda/2 = 0.42\text{ m}$ gives $\lambda = 0.84\text{ m}$ and $f = \dfrac{v}{\lambda} = 410\text{ Hz}$; $3\lambda/2 = 0.42\text{ m}$ gives $\lambda = 0.28\text{ m}$ and $f = \dfrac{v}{\lambda} = 1230\text{ Hz}$; $5\lambda/2 = 0.42\text{ m}$ gives $\lambda = 0.168\text{ m}$ and $f = \dfrac{v}{\lambda} = 2050\text{ Hz}$, and so on. The frequencies for destructive interference are $(2n+1)(410\text{ Hz})$, $n = 0, 1, 2, \ldots$.
EVALUATE: The frequencies for constructive interference lie midway between the frequencies for destructive interference.

16.38. **IDENTIFY:** $f_{\text{beat}} = |f_1 - f_2|$. $v = f\lambda$.

SET UP: $v = 344$ m/s. Let $\lambda_1 = 64.8$ cm and $\lambda_2 = 65.2$ cm. $\lambda_2 > \lambda_1$ so $f_1 > f_2$.

EXECUTE: $f_1 - f_2 = v\left(\dfrac{1}{\lambda_1} - \dfrac{1}{\lambda_2}\right) = \dfrac{v(\lambda_2 - \lambda_1)}{\lambda_1\lambda_2} = \dfrac{(344\text{ m/s})(0.04\times10^{-2}\text{ m})}{(0.648\text{ m})(0.652\text{ m})} = 0.33$ beats/s, which rounds to 0.3 beats/s.

EVALUATE: We could have calculated f_1 and f_2 and subtracted, but doing it this way we would have to be careful to retain enough figures in intermediate calculations to avoid round-off errors.

16.39. **IDENTIFY:** The beat is due to a difference in the frequencies of the two sounds.

SET UP: $f_{\text{beat}} = f_1 - f_2$. Tightening the string increases the wave speed for transverse waves on the string and this in turn increases the frequency.

EXECUTE: **(a)** If the beat frequency increases when she raises her frequency by tightening the string, it must be that her frequency is 433 Hz, 3 Hz above concert *A*.

(b) She needs to lower her frequency by loosening her string.

EVALUATE: The beat would only be audible if the two sounds are quite close in frequency. A musician with a good sense of pitch can come very close to the correct frequency just from hearing the tone.

16.40. **IDENTIFY:** $f_{\text{beat}} = |f_a - f_b|$. For a stopped pipe, $f_1 = \dfrac{v}{4L}$.

SET UP: $v = 344$ m/s. Let $L_a = 1.14$ m and $L_b = 1.16$ m. $L_b > L_a$ so $f_{1a} > f_{1b}$.

EXECUTE: $f_{1a} - f_{1b} = \dfrac{v}{4}\left(\dfrac{1}{L_a} - \dfrac{1}{L_b}\right) = \dfrac{v(L_b - L_a)}{4L_aL_b} = \dfrac{(344\text{ m/s})(2.00\times10^{-2}\text{ m})}{4(1.14\text{ m})(1.16\text{ m})} = 1.3$ Hz. There are 1.3 beats per second.

EVALUATE: Increasing the length of the pipe increases the wavelength of the fundamental and decreases the frequency.

16.41. **IDENTIFY:** Apply the Doppler shift equation $f_{\text{L}} = \left(\dfrac{v + v_{\text{L}}}{v + v_{\text{S}}}\right)f_{\text{S}}$.

SET UP: The positive direction is from listener to source. $f_{\text{S}} = 1200$ Hz. $f_{\text{L}} = 1240$ Hz.

EXECUTE: $v_{\text{L}} = 0$. $v_{\text{S}} = -25.0$ m/s. $f_{\text{L}} = \left(\dfrac{v}{v + v_{\text{S}}}\right)f_{\text{S}}$ gives

$$v = \frac{v_{\text{S}}f_{\text{L}}}{f_{\text{S}} - f_{\text{L}}} = \frac{(-25\text{ m/s})(1240\text{ Hz})}{1200\text{ Hz} - 1240\text{ Hz}} = 780\text{ m/s}.$$

EVALUATE: $f_{\text{L}} > f_{\text{S}}$ since the source is approaching the listener.

16.42. **IDENTIFY** and **SET UP:** Apply $\lambda = \dfrac{v - v_{\text{S}}}{f_{\text{S}}}$ and $\lambda = \dfrac{v + v_{\text{S}}}{f_{\text{S}}}$ for the wavelengths in front of and behind the source. Then $f = v/\lambda$. When the source is at rest $\lambda = \dfrac{v}{f_{\text{S}}} = \dfrac{344\text{ m/s}}{400\text{ Hz}} = 0.860$ m.

EXECUTE: **(a)** $\lambda = \dfrac{v - v_{\text{S}}}{f_{\text{S}}} = \dfrac{344\text{ m/s} - 25.0\text{ m/s}}{400\text{ Hz}} = 0.798$ m

(b) $\lambda = \dfrac{v + v_{\text{S}}}{f_{\text{S}}} = \dfrac{344\text{ m/s} + 25.0\text{ m/s}}{400\text{ Hz}} = 0.922$ m

(c) $f_{\text{L}} = v/\lambda$ (since $v_{\text{L}} = 0$), so $f_{\text{L}} = (344\text{ m/s})/0.798\text{ m} = 431$ Hz

(d) $f_{\text{L}} = v/\lambda = (344\text{ m/s})/0.922\text{ m} = 373$ Hz

EVALUATE: In front of the source (source moving toward listener) the wavelength is decreased and the frequency is increased. Behind the source (source moving away from listener) the wavelength is increased and the frequency is decreased.

16.43. IDENTIFY: Apply the Doppler shift equation $f_L = \left(\frac{v+v_L}{v+v_S}\right)f_S$.

SET UP: The positive direction is from listener to source. $f_S = 392$ Hz.

EXECUTE: **(a)** $v_S = 0$. $v_L = -15.0$ m/s. $f_L = \left(\frac{v+v_L}{v+v_S}\right)f_S = \left(\frac{344 \text{ m/s} - 15.0 \text{ m/s}}{344 \text{ m/s}}\right)(392 \text{ Hz}) = 375 \text{ Hz}$

(b) $v_S = +35.0$ m/s. $v_L = +15.0$ m/s. $f_L = \left(\frac{v+v_L}{v+v_S}\right)f_S = \left(\frac{344 \text{ m/s} + 15.0 \text{ m/s}}{344 \text{ m/s} + 35.0 \text{ m/s}}\right)(392 \text{ Hz}) = 371 \text{ Hz}$

(c) $f_{beat} = f_1 - f_2 = 4$ Hz

EVALUATE: The distance between whistle A and the listener is increasing, and for whistle A $f_L < f_S$. The distance between whistle B and the listener is also increasing, and for whistle B $f_L < f_S$.

16.44. IDENTIFY: Apply $f_L = \left(\frac{v+v_L}{v+v_S}\right)f_S$.

SET UP: $f_S = 1000$ Hz. The positive direction is from the listener to the source. $v = 344$ m/s.

EXECUTE: **(a)** $v_S = -(344 \text{ m/s})/2 = -172$ m/s, $v_L = 0$.

$$f_L = \left(\frac{v+v_L}{v+v_S}\right)f_S = \left(\frac{344 \text{ m/s}}{344 \text{ m/s} - 172 \text{ m/s}}\right)(1000 \text{ Hz}) = 2000 \text{ Hz}$$

(b) $v_S = 0$, $v_L = +172$ m/s. $f_L = \left(\frac{v+v_L}{v+v_S}\right)f_S = \left(\frac{344 \text{ m/s} + 172 \text{ m/s}}{344 \text{ m/s}}\right)(1000 \text{ Hz}) = 1500 \text{ Hz}$

EVALUATE: The answer in (b) is much less than the answer in (a). It is the velocity of the source and listener relative to the air that determines the effect, not the relative velocity of the source and listener relative to each other.

16.45. IDENTIFY: The distance between crests is λ. In front of the source $\lambda = \frac{v - v_S}{f_S}$ and behind the source $\lambda = \frac{v + v_S}{f_S}$. $f_S = 1/T$.

SET UP: $T = 1.6$ s. $v = 0.32$ m/s. The crest to crest distance is the wavelength, so $\lambda = 0.12$ m.

EXECUTE: **(a)** $f_S = 1/T = 0.625$ Hz. $\lambda = \frac{v - v_S}{f_S}$ gives

$v_S = v - \lambda f_S = 0.32 \text{ m/s} - (0.12 \text{ m})(0.625 \text{ Hz}) = 0.25 \text{ m/s}$.

(b) $\lambda = \frac{v + v_S}{f_S} = \frac{0.32 \text{ m/s} + 0.25 \text{ m/s}}{0.625 \text{ Hz}} = 0.91 \text{ m}$

EVALUATE: If the duck was held at rest but still paddled its feet, it would produce waves of wavelength $\lambda = \frac{0.32 \text{ m/s}}{0.625 \text{ Hz}} = 0.51$ m. In front of the duck the wavelength is decreased and behind the duck the wavelength is increased. The speed of the duck is 78% of the wave speed, so the Doppler effects are large.

16.46. **IDENTIFY:** Apply the Doppler effect formula $f_L = \left(\frac{v + v_L}{v + v_S}\right) f_S$.

(a) SET UP: The positive direction is from the listener toward the source, as shown in Figure 16.46a.

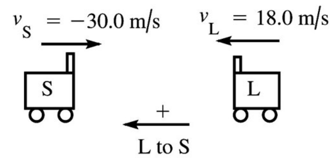

Figure 16.46a

EXECUTE: $f_L = \left(\frac{v+v_L}{v+v_S}\right) f_S = \left(\frac{344\text{ m/s}+18.0\text{ m/s}}{344\text{ m/s}-30.0\text{ m/s}}\right)(352\text{ Hz}) = 406\text{ Hz}.$

EVALUATE: Listener and source are approaching and $f_L > f_S$.

(b) SET UP: See Figure 16.46b.

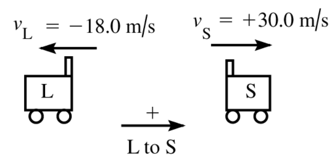

Figure 16.46b

EXECUTE: $f_L = \left(\frac{v+v_L}{v+v_S}\right) f_S = \left(\frac{344\text{ m/s}-18.0\text{ m/s}}{344\text{ m/s}+30.3\text{ m/s}}\right)(352\text{ Hz}) = 307\text{ Hz}.$

EVALUATE: Listener and source are moving away from each other and $f_L < f_S$.

16.47. **IDENTIFY:** Apply $f_L = \left(\frac{v+v_L}{v+v_S}\right) f_S$.

SET UP: The positive direction is from the motorcycle toward the car. The car is stationary, so $v_S = 0$.

EXECUTE: $f_L = \frac{v+v_L}{v+v_S} f_S = (1 + v_L/v) f_S$, which gives

$v_L = v\left(\frac{f_L}{f_S} - 1\right) = (344\text{ m/s})\left(\frac{490\text{ Hz}}{520\text{ Hz}} - 1\right) = -19.8\text{ m/s}.$ You must be traveling at 19.8 m/s.

EVALUATE: $v_L < 0$ means that the listener is moving away from the source.

16.48. **IDENTIFY:** We have a moving source and a stationary observer. The beat frequency is due to interference between the Doppler-shifted sound from the horn in the moving car and the horn in the stationary car. The beat frequency is equal to the difference between these two frequencies.

SET UP: Apply $f_L = \left(\frac{v + v_L}{v + v_S}\right) f_S = \left(\frac{v}{v + v_S}\right) f_S$, where $f_S = 260$ Hz. Since the source is moving toward you, you will hear the moving car horn at a higher pitch than your horn, and the beat frequency will be given by $f_{beat} = f_L - f_S$.

EXECUTE: We can determine f_L from the beat frequency: $f_{beat} = 6.0 \text{ Hz} = f_L - f_S = f_L - 260 \text{ Hz}$; thus, $f_L = 266 \text{ Hz}$. Assuming that $v = 344 \text{ m/s}$, we obtain $266 \text{ Hz} = \left(\dfrac{344 \text{ m/s}}{344 \text{ m/s} + v_S}\right)(260 \text{ Hz})$. Solving for v_S we obtain $v_S = \left(\dfrac{260 \text{ Hz}}{266 \text{ Hz}} - 1\right)(344 \text{ m/s}) = -7.8 \text{ m/s}$. Thus, your friend is moving at 7.8 m/s toward you.

EVALUATE: What frequency will your friend hear? In this case, you have a stationary source (your horn) and a moving observer (your friend). The positive direction points from listener to source. Thus, we have $f_L = \left(\dfrac{344 \text{ m/s} + 7.8 \text{ m/s}}{344 \text{ m/s}}\right)(260 \text{ Hz}) = 265.8 \text{ Hz} \approx 266 \text{ Hz}$. At low speeds, there is little difference in the Doppler shift of a moving source or that of a moving observer.

16.49. **IDENTIFY:** The source of sound is moving and so is the listener, so we are dealing with the Doppler effect.

SET UP: We use $v = f\lambda$, where v is the speed relative to the listener, and $f_L = \left(\dfrac{v + v_L}{v + v_S}\right)f_S$.

EXECUTE: **(a)** You and the sound waves are moving toward each other, so the speed of sound that you measure is $v = 340 \text{ m/s} + 15 \text{ m/s} = 355 \text{ m/s}$.
(b) The wavelength of the sound that you receive is the same as the wavelength that the police car would measure behind the car. The speed of those waves relative to the police car is $v = 340 \text{ m/s} + 15 \text{ m/s} = 355 \text{ m/s}$ because the sound and police car are moving away from each other. The wavelength of those waves is $\lambda = \dfrac{v}{f} = \dfrac{355 \text{ m/s}}{500 \text{ Hz}} = 0.710 \text{ m}$, which is also the wavelength you observe.
(c) The speed of the sound waves relative to you is $v = 340 \text{ m/s} + 15 \text{ m/s} = 355 \text{ m/s}$ since you are moving toward the waves, and the wavelength you measure is 0.710 m. So the frequency you measure is $f = \dfrac{v}{\lambda} = \dfrac{355 \text{ m/s}}{0.710 \text{ m}} = 500 \text{ Hz}$. This is the same frequency the police siren is emitting.

EVALUATE: We can check using the Doppler effect formula $f_L = \left(\dfrac{v + v_L}{v + v_S}\right)f_S$, where $v_L = +15 \text{ m/s}$ and $v_S = +15 \text{ m/s}$. Doing so gives $f_L = f_S = 500 \text{ Hz}$.

16.50. **IDENTIFY:** There is a Doppler shift due to the motion of the fire engine as well as due to the motion of the truck, which reflects the sound waves.

SET UP: We use the Doppler shift equation $f_L = \left(\dfrac{v + v_L}{v + v_S}\right)f_S$.

EXECUTE: **(a)** First consider the truck as the listener, as shown in Figure 16.50(a).

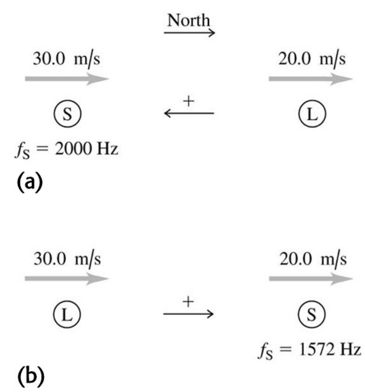

Figure 16.50

$f_L = \left(\frac{v+v_L}{v+v_S}\right)f_S = \left(\frac{344\text{ m/s} - 20.0\text{ m/s}}{344\text{ m/s} - 30.0\text{ m/s}}\right)(2000\text{ Hz}) = 2064\text{ Hz}.$ Now consider the truck as a source, with $f_S = 2064\text{ Hz},$ and the fire engine driver as the listener, as shown in Figure 16.50(b). $f_L = \left(\frac{v+v_L}{v+v_S}\right)f_S = \left(\frac{344\text{ m/s} + 30.0\text{ m/s}}{344\text{ m/s} + 20.0\text{ m/s}}\right)(2064\text{ Hz}) = 2120\text{ Hz}.$ The objects are getting closer together so the frequency is increased.

(b) The driver detects a frequency of 2120 Hz and the waves returning from the truck move past him at 344 m/s + 30.0 m/s, so the wavelength he measures is $\lambda = \frac{344\text{ m/s} + 30\text{ m/s}}{2120\text{ Hz}} = 0.176\text{ m}.$ The wavelength of waves emitted by the fire engine when it is stationary is $\lambda = \frac{344\text{ m/s}}{2000\text{ Hz}} = 0.172\text{ m}.$

EVALUATE: In (a) the objects are getting closer together so the frequency is increased. In (b), the quantities to use in the equation $v = f\lambda$ are measured *relative to the observer*.

16.51. **IDENTIFY:** Apply the Doppler shift formulas. We first treat the stationary police car as the source and then as the observer as he receives his own sound reflected from the on-coming car.

SET UP: $f_L = \left(\frac{v+v_L}{v+v_S}\right)f_S.$

EXECUTE: (a) Since the frequency is increased the moving car must be approaching the police car. Let v_c be the speed of the moving car. The speed v_p of the police car is zero. First consider the moving car as the listener, as shown in Figure 16.51(a).

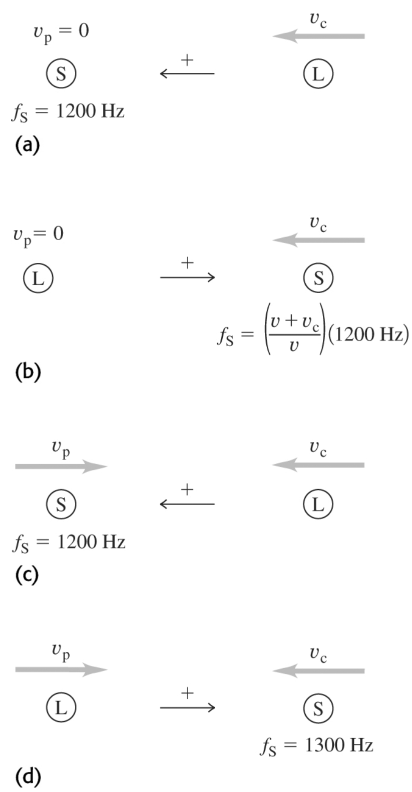

Figure 16.51

$$f_L = \left(\frac{v+v_L}{v+v_S}\right)f_S = \left(\frac{v+v_c}{v}\right)(1200\ \text{Hz})$$

Then consider the moving car as the source and the police car as the listener, as shown in Figure 16.51(b):

$$f_L = \left(\frac{v+v_L}{v+v_S}\right)f_S \text{ gives } 1250\ \text{Hz} = \left(\frac{v}{v-v_c}\right)\left(\frac{v+v_c}{v}\right)(1200\ \text{Hz}).$$

Solving for v_c gives

$$v_c = \left(\frac{50}{2450}\right)v = \left(\frac{50}{2450}\right)(344\ \text{m/s}) = 7.02\ \text{m/s}$$

(**b**) Repeat the calculation of part (a), but now $v_p = 20.0\ \text{m/s},$ toward the other car.

Waves received by the car (Figure 16.51(c)):

$$f_L = \left(\frac{v+v_c}{v-v_p}\right)f_S = \left(\frac{344\ \text{m/s}+7\ \text{m/s}}{344\ \text{m/s}-20\ \text{m/s}}\right)(1200\ \text{Hz}) = 1300\ \text{Hz}$$

Waves reflected by the car and received by the police car (Figure 16.51(d)):

$$f_L = \left(\frac{v+v_p}{v-v_c}\right)f_S = \left(\frac{344\ \text{m/s}+20\ \text{m/s}}{344\ \text{m/s}-7\ \text{m/s}}\right)(1300\ \text{Hz}) = 1404\ \text{Hz}$$

EVALUATE: The cars move toward each other with a greater relative speed in (b) and the increase in frequency is much larger there.

16.52. **IDENTIFY:** A sound detector is moving toward a stationary source, so we are dealing with the Doppler effect.

SET UP: The graph we must interpret plots f_L versus v_L, so we need to find a relationship between those quantities to be able to interpret the graph. We use $f_L = \left(\dfrac{v+v_L}{v+v_S}\right)f_S$.

EXECUTE: Solve $f_L = \left(\dfrac{v+v_L}{v+v_S}\right)f_S$ for f_L explicitly in terms of v_L, giving $f_L = \dfrac{f_S v_L}{v+v_S} + \dfrac{v f_S}{v+v_S}$. From this equation, we see that the graph should be a straight line having slope $\dfrac{f_S}{v+v_S}$ and y-intercept $\dfrac{v f_S}{v+v_S}$.

From this we see that (y-intercept) = (slope)v. Solving for v gives

$v = \dfrac{y\text{-intercept}}{\text{slope}} = \dfrac{600.0\ \text{Hz}}{1.75\ \text{m}^{-1}} = 3.43\,\text{m/s}.$

EVALUATE: This result is very close to the value v = 344 m/s in Table 16.1.

16.53. **IDENTIFY:** Apply $\sin\alpha = v/v_S$ to calculate α. Use the method of Example 16.19 to calculate t.

SET UP: Mach 1.70 means $v_S/v = 1.70$.

EXECUTE: **(a)** In $\sin\alpha = v/v_S$, $v/v_S = 1/1.70 = 0.588$ and $\alpha = \arcsin(0.588) = 36.0°$.

(b) As in Example 16.19, $t = \dfrac{1250\ \text{m}}{(1.70)(344\ \text{m/s})(\tan\ 36.0°)} = 2.94\ \text{s}.$

EVALUATE: The angle α decreases when the speed v_S of the plane increases.

16.54. **IDENTIFY:** Apply $\sin\alpha = v/v_S$.

SET UP: The Mach number is the value of v_S/v, where v_S is the speed of the shuttle and v is the speed of sound at the altitude of the shuttle.

EXECUTE: **(a)** $\dfrac{v}{v_S} = \sin\alpha = \sin 58.0° = 0.848$. The Mach number is $\dfrac{v_S}{v} = \dfrac{1}{0.848} = 1.18.$

(b) $v_S = \dfrac{v}{\sin\alpha} = \dfrac{331\ \text{m/s}}{\sin 58.0°} = 390\ \text{m/s}$

(c) $\dfrac{v_S}{v} = \dfrac{390\ \text{m/s}}{344\ \text{m/s}} = 1.13$. The Mach number would be 1.13. $\sin\alpha = \dfrac{v}{v_S} = \dfrac{344\ \text{m/s}}{390\ \text{m/s}}$ and $\alpha = 61.9°$.

EVALUATE: The smaller the Mach number, the larger the angle of the shock-wave cone.

16.55. **IDENTIFY:** This problem involves the speed of sound in a gas.

SET UP: Eq. 16.10: $v = \sqrt{\dfrac{\gamma RT}{M}}$. Information from Example 16.4: M = 0.0288 kg/mol, γ = 1.40. If T is in K, $T_C = T - 273$, so $T = T_C + 273$. We want to determine the speed of sound at 20°C.

EXECUTE: **(a)** $v = \sqrt{\dfrac{\gamma RT}{M}} = \sqrt{\dfrac{\gamma R(T_C+273)}{M}} = \sqrt{\dfrac{\gamma R}{M}}\sqrt{T_C+273} = \sqrt{\dfrac{273\gamma R}{M}}\sqrt{\dfrac{T_C}{273}+1}$. If T_C is much less than 273°C, $T_C/273 \ll 1$, so we can use the approximation $\sqrt{1+x} \approx 1+\dfrac{x}{2}$, which gives

$v \approx \sqrt{\dfrac{273\gamma R}{M}}\left[1+\dfrac{T_C}{2(273)}\right] = \sqrt{\dfrac{273\gamma R}{M}}\left[1+\dfrac{T_C}{546}\right]$. Putting in M = 0.0288 kg/mol, γ = 1.40, and R = 8.314 J/mol·K gives v = (332 m/s)(1 + T_C/546).

(b) At 20°C we have v = (332 m/s)(1 + 20/546) = 344 m/s.

(c) When T_C = 120°C, T_C/273 = 0.440 is not much much greater than 1, so the approximation is less valid. So the answer is no.

EVALUATE: For part (c), compare the second and third terms of the power series. The second term is $\frac{1}{2}\left(\frac{120}{273}\right) = 0.220$. The third term is $\frac{\frac{1}{2}\left(\frac{1}{2}-1\right)}{2}\left(\frac{120}{273}\right)^2 = -0.024$, which is large enough to affect the sum.

16.56. IDENTIFY: Use the equations that relate intensity level and intensity, intensity and pressure amplitude, pressure amplitude and displacement amplitude, and intensity and distance.

(a) SET UP: Use the intensity level β to calculate I at this distance. $\beta = (10\text{ dB})\log(I/I_0)$

EXECUTE: $52.0\text{ dB} = (10\text{ dB})\log[I/(10^{-12}\text{ W/m}^2)]$

$\log[I/(10^{-12}\text{ W/m}^2)] = 5.20$ implies $I = 1.585\times10^{-7}\text{ W/m}^2$

SET UP: Then use $I = \dfrac{p_{\max}^2}{2\rho v}$ to calculate $p_{\max}$:

$I = \dfrac{p_{\max}^2}{2\rho v}$ so $p_{\max} = \sqrt{2\rho v I}$

From Example 16.5, $\rho = 1.20\text{ kg/m}^3$ for air at $20°\text{C}$.

EXECUTE: $p_{\max} = \sqrt{2\rho v I} = \sqrt{2(1.20\text{ kg/m}^3)(344\text{ m/s})(1.585\times10^{-7}\text{ W/m}^2)} = 0.0114\text{ Pa}$

(b) SET UP: Use $p_{\max} = BkA$ so $A = \dfrac{p_{\max}}{Bk}$

For air $B = 1.42\times10^5\text{ Pa}$ (Example 16.1).

EXECUTE: $k = \dfrac{2\pi}{\lambda} = \dfrac{2\pi f}{v} = \dfrac{(2\pi\text{ rad})(587\text{ Hz})}{344\text{ m/s}} = 10.72\text{ rad/m}$

$A = \dfrac{p_{\max}}{Bk} = \dfrac{0.0114\text{ Pa}}{(1.42\times10^5\text{ Pa})(10.72\text{ rad/m})} = 7.49\times10^{-9}\text{ m}$

(c) SET UP: $\beta_2 - \beta_1 = (10\text{ dB})\log(I_2/I_1)$ (Example 16.9).

Inverse-square law: $I_1/I_2 = r_2^2/r_1^2$ so $I_2/I_1 = r_1^2/r_2^2$

EXECUTE: $\beta_2 - \beta_1 = (10\text{ dB})\log(r_1/r_2)^2 = (20\text{ dB})\log(r_1/r_2)$.

$\beta_2 = 52.0\text{ dB}$ and $r_2 = 5.00\text{ m}$. Then $\beta_1 = 30.0\text{ dB}$ and we need to calculate r_1.

$52.0\text{ dB} - 30.0\text{ dB} = (20\text{ dB})\log(r_1/r_2)$

$22.0\text{ dB} = (20\text{ dB})\log(r_1/r_2)$

$\log(r_1/r_2) = 1.10$ so $r_1 = 12.6r_2 = 63.0\text{ m}$.

EVALUATE: The decrease in intensity level corresponds to a decrease in intensity, and this means an increase in distance. The intensity level uses a logarithmic scale, so simple proportionality between r and β doesn't apply.

16.57. IDENTIFY: We are investigating how the speed of sound depends on the air temperature as we look at higher and higher altitudes.

SET UP: Eq. 16.10: $v = \sqrt{\dfrac{\gamma RT}{M}}$, where $M = 0.0288$ kg/mol and $\gamma = 1.40$. First use the given information to sketch the graph of T versus y, as in Fig. 16.57. We use the slope-intercept equation of a straight line $T = my + b$. For this graph, $m = -\dfrac{20.0\text{ K}}{300.0\text{ m}} = -0.06667$ K/m and $b = 278$ K. Using these results, the speed v of sound as a function of altitude y is $v = \sqrt{\dfrac{\gamma R}{M}(my+b)}$. We want to find the time for the sound to travel 300.0 m straight upward, and we know $v_y = dy/dt$.

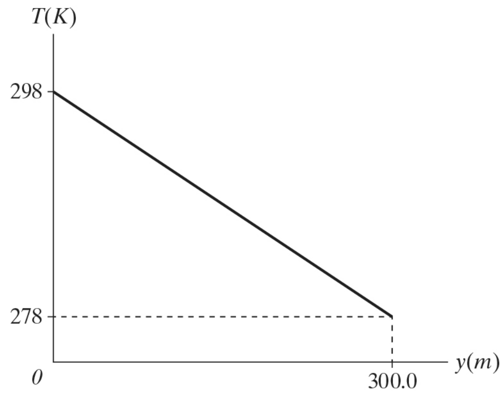

Figure 16.57

EXECUTE: **(a)** $v_y = dy/dt$ gives $dt = \dfrac{dy}{v}$, so we integrate, giving $\int_0^{t_{300}} dt = \int_0^{300\text{ m}} \dfrac{dy}{v}$. The time integral gives simply t_{300}, but the y integral requires a bit more effort. Using our equation for v from above, the y integral becomes $\int_0^{300\text{ m}} \dfrac{dy}{v} = \int_0^{300\text{ m}} \dfrac{dy}{\sqrt{\dfrac{\gamma R}{M}}\sqrt{my+b}} = \sqrt{\dfrac{M}{\gamma R}} \int_0^{300\text{ m}} \dfrac{dy}{(my+b)^{1/2}}$. To do the integral, let $u = my + b$, so $du = m\,dy$. The integral now becomes $\int \dfrac{(1/m)du}{u^{1/2}} = \dfrac{2}{m}u^{1/2}$. Returning to the original variables, the integral is $\sqrt{\dfrac{M}{\gamma R}} \int_0^{300\text{ m}} \dfrac{dy}{(my+b)^{1/2}} = \sqrt{\dfrac{M}{\gamma R}} \dfrac{2}{m}(my+b)^{1/2}\Big|_0^{300\text{ m}} = t_{300}$. Putting in the numbers for m, b, M, R, and γ gives $t_{300} = 0.879$ s.

(b) At 300.0 m, $T = 5.00°\text{C} = 298$ K, so using these numbers gives $v = \sqrt{\dfrac{\gamma RT}{M}} = 335.2$ m/s. The horizontal distance the sound travels is $x = vt_{300} = (335.2\text{ m/s})(0.879\text{ s}) = 295$ m.

EVALUATE: Since $v \propto \sqrt{T}$ (with T in K units), there is not much difference between the surface temperature and the temperature at 300 m, so v at 300 m is not very much different from v at the surface, as we see.

16.58. IDENTIFY: $f_{\text{beat}} = |f_A - f_B|$. $f_1 = \dfrac{v}{2L}$ and $v = \sqrt{\dfrac{FL}{m}}$ gives $f_1 = \dfrac{1}{2}\sqrt{\dfrac{F}{mL}}$. Apply $\Sigma\tau_z = 0$ to the bar to find the tension in each wire.

SET UP: For $\Sigma\tau_z = 0$ take the pivot at wire A and let counterclockwise torques be positive. The free-body diagram for the bar is given in Figure 16.58. Let L be the length of the bar.

EXECUTE: $\Sigma\tau_z = 0$ gives $F_B L - w_{\text{lead}}(3L/4) - w_{\text{bar}}(L/2) = 0$.

$F_B = 3w_{\text{lead}}/4 + w_{\text{bar}}/2 = 3(185\text{ N})/4 + (165\text{ N})/2 = 221\text{ N}$. $F_A + F_B = w_{\text{bar}} + w_{\text{lead}}$ so

$F_A = w_{\text{bar}} + w_{\text{lead}} - F_B = 165\text{ N} + 185\text{ N} - 221\text{ N} = 129\text{ N}$.

$f_{1A} = \dfrac{1}{2}\sqrt{\dfrac{129\text{ N}}{(5.50\times10^{-3}\text{ kg})(0.750\text{ m})}} = 88.4\text{ Hz}$. $f_{1B} = f_{1A}\sqrt{\dfrac{221\text{ N}}{129\text{ N}}} = 115.7\text{ Hz}$.

$f_{\text{beat}} = f_{1B} - f_{1A} = 27.3\text{ Hz}$.

EVALUATE: The frequency increases when the tension in the wire increases.

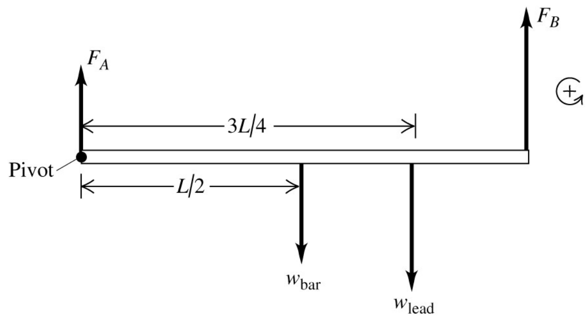

Figure 16.58

16.59. **IDENTIFY** and **SET UP:** The frequency of any harmonic is an integer multiple of the fundamental. For a stopped pipe only odd harmonics are present. For an open pipe, all harmonics are present. See which pattern of harmonics fits to the observed values in order to determine which type of pipe it is. Then solve for the fundamental frequency and relate that to the length of the pipe.

EXECUTE: **(a)** For an open pipe the successive harmonics are $f_n = nf_1,\ n = 1, 2, 3, \ldots$ For a stopped pipe the successive harmonics are $f_n = nf_1,\ n = 1, 3, 5, \ldots.$ If the pipe is open and these harmonics are successive, then $f_n = nf_1 = 1372\text{ Hz}$ and $f_{n+1} = (n+1)f_1 = 1764\text{ Hz}.$ Subtract the first equation from the second: $(n+1)f_1 - nf_1 = 1764\text{ Hz} - 1372\text{ Hz}.$ This gives $f_1 = 392\text{ Hz}.$ Then $n = \dfrac{1372\text{ Hz}}{392\text{ Hz}} = 3.5.$ But n must be an integer, so the pipe can't be open. If the pipe is stopped and these harmonics are successive, then $f_n = nf_1 = 1372\text{ Hz}$ and $f_{n+2} = (n+2)f_1 = 1764\text{ Hz}$ (in this case successive harmonics differ in n by 2). Subtracting one equation from the other gives $2f_1 = 392\text{ Hz}$ and $f_1 = 196\text{ Hz}.$ Then $n = 1372\text{ Hz}/f_1 = 7$ so $1372\text{ Hz} = 7f_1$ and $1764\text{ Hz} = 9f_1.$ The solution gives integer n as it should; the pipe is stopped.

(b) From part (a) these are the seventh and ninth harmonics.

(c) From part (a) $f_1 = 196\text{ Hz}.$

For a stopped pipe $f_1 = \dfrac{v}{4L}$ and $L = \dfrac{v}{4f_1} = \dfrac{344\text{ m/s}}{4(196\text{ Hz})} = 0.439\text{ m}.$

EVALUATE: It is essential to know that these are successive harmonics and to realize that 1372 Hz is not the fundamental. There are other lower frequency standing waves; these are just two successive ones.

16.60. **IDENTIFY:** This problem involves standing waves in a tube and the dependence of the speed of sound on temperature.

SET UP: A Kundt's tube is a stopped pipe, and the node-to-node distance is $\lambda/2$, so $\dfrac{\lambda}{2} = 47.0\text{ cm}$ which gives $\lambda = 0.940\text{ m}.$ We know that $v = f\lambda$, $f = 1200\text{ Hz}$, and $v = \sqrt{\dfrac{\gamma RT}{M}}.$ At 20°C the speed of sound in helium is 999 m/s. Our target variable is the temperature T of the helium in the tube.

EXECUTE: First find v_T in the tube at temperature T: $v_T = f\lambda = (1200\text{ Hz})(0.940\text{ m}) = 1128\text{ m/s}.$ Now solve $v_T = \sqrt{\dfrac{\gamma RT}{M}}$ for T, which gives $T = \dfrac{Mv_T^2}{\gamma R}.$ We don't know M and γ, but we do know that at 20°C (which is 293 K), $v_{293} = 999\text{ m/s}$ for helium. Using $v = \sqrt{\dfrac{\gamma RT}{M}}$ and solving for T_{293} gives $T_{293} = \dfrac{Mv_{293}^2}{\gamma R}.$

Now take the ratio T/T_{293}, which gives $\dfrac{T}{T_{293}} = \dfrac{\dfrac{Mv_{\text{T}}^2}{\gamma R}}{\dfrac{Mv_{293}^2}{\gamma R}} = \left(\dfrac{v_{\text{T}}}{v_{293}}\right)^2 = \left(\dfrac{1128\text{ m/s}}{999\text{ m/s}}\right)^2 = 1.275.$ This gives T = (293 K)(1.275) = 374 K = 101°C.

EVALUATE: This type of experiment relies on very simple measurements: the frequency of the tuning fork (or electronic oscillator) and the visible node-to-node distance of the standing wave pattern in the tube. We do not to know anything about the gas since γ and M divide out.

16.61. IDENTIFY: Destructive interference occurs when the path difference is a half-integer number of wavelengths. Constructive interference occurs when the path difference is an integer number of wavelengths.

SET UP: $\lambda = \dfrac{v}{f} = \dfrac{344\text{ m/s}}{784\text{ Hz}} = 0.439\text{ m}$

EXECUTE: **(a)** If the separation of the speakers is denoted h, the condition for destructive interference is $\sqrt{x^2 + h^2} - x = \beta\lambda$, where β is an odd multiple of one-half. Adding x to both sides, squaring, canceling the x^2 term from both sides, and solving for x gives $x = \dfrac{h^2}{2\beta\lambda} - \dfrac{\beta}{2}\lambda.$ Using $\lambda = 0.439$ m and $h = 2.00$ m yields 9.01 m for $\beta = \frac{1}{2}$, 2.71 m for $\beta = \frac{3}{2}$, 1.27 m for $\beta = \frac{5}{2}$, 0.53 m for $\beta = \frac{7}{2}$, and 0.026 m for $\beta = \frac{9}{2}$. These are the only allowable values of β that give positive solutions for x.

(b) Repeating the above for integral values of β, constructive interference occurs at 4.34 m, 1.84 m, 0.86 m, 0.26 m. Note that these are between, but not midway between, the answers to part (a).

(c) If $h = \lambda/2$, there will be destructive interference at speaker *B*. If $\lambda/2 > h$, the path difference can never be as large as $\lambda/2$. (This is also obtained from the above expression for x, with $x = 0$ and $\beta = \frac{1}{2}$.) The minimum frequency is then $v/2h = (344\text{ m/s})/(4.0\text{ m}) = 86\text{ Hz}$.

EVALUATE: When f increases, λ is smaller and there are more occurrences of points of constructive and destructive interference.

16.62. IDENTIFY: Apply $f_{\text{L}} = \left(\dfrac{v + v_{\text{L}}}{v + v_{\text{S}}}\right) f_{\text{S}}$. The wall first acts as a listener and then as a source.

SET UP: The positive direction is from listener to source. The bat is moving toward the wall so the Doppler effect increases the frequency and the final frequency received, f_{L2}, is greater than the original source frequency, f_{S1}. $f_{\text{S1}} = 1700$ Hz. $f_{\text{L2}} - f_{\text{S1}} = 8.00$ Hz.

EXECUTE: The wall receives the sound: $f_{\text{S}} = f_{\text{S1}}$. $f_{\text{L}} = f_{\text{L1}}$. $v_{\text{S}} = -v_{\text{bat}}$ and $v_{\text{L}} = 0$. $f_{\text{L}} = \left(\dfrac{v + v_{\text{L}}}{v + v_{\text{S}}}\right) f_{\text{S}}$ gives $f_{\text{L1}} = \left(\dfrac{v}{v - v_{\text{bat}}}\right) f_{\text{S1}}$. The wall receives the sound: $f_{\text{S2}} = f_{\text{L1}}$. $v_{\text{S}} = 0$ and $v_{\text{L}} = +v_{\text{bat}}$.

$$f_{\text{L2}} = \left(\frac{v + v_{\text{bat}}}{v}\right) f_{\text{S2}} = \left(\frac{v + v_{\text{bat}}}{v}\right)\left(\frac{v}{v - v_{\text{bat}}}\right) f_{\text{S1}} = \left(\frac{v + v_{\text{bat}}}{v - v_{\text{bat}}}\right) f_{\text{S1}}.$$

$$f_{\text{L2}} - f_{\text{S1}} = \Delta f = \left(\frac{v + v_{\text{bat}}}{v - v_{\text{bat}}} - 1\right) f_{\text{S1}} = \left(\frac{2v_{\text{bat}}}{v - v_{\text{bat}}}\right) f_{\text{S1}}.$$

$$v_{\text{bat}} = \frac{v\Delta f}{2f_{\text{S1}} + \Delta f} = \frac{(344\text{ m/s})(8.00\text{ Hz})}{2(1700\text{ Hz}) + 8.00\text{ Hz}} = 0.808\text{ m/s}.$$

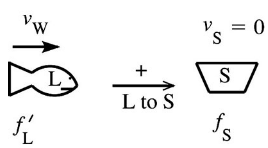
EVALUATE: $f_{S1} < \Delta f$, so we can write our result as the approximate but accurate expression $\Delta f = \left(\dfrac{2v_{bat}}{v}\right) f_{S1}$.

16.63. **(a) IDENTIFY** and **SET UP:** Use $v = f\lambda$ to calculate λ.

EXECUTE: $\lambda = \dfrac{v}{f} = \dfrac{1482 \text{ m/s}}{18.0\times10^3 \text{ Hz}} = 0.0823 \text{ m}.$

(b) IDENTIFY: Apply the Doppler effect equation, $f_L = \left(\dfrac{v+v_L}{v}\right) f_S = \left(1+\dfrac{v_L}{v}\right) f_S$. The frequency of the directly radiated waves is $f_S = 18{,}000$ Hz. The moving whale first plays the role of a moving listener, receiving waves with frequency f_L'. The whale then acts as a moving source, emitting waves with the same frequency, $f_S' = f_L'$ with which they are received. Let the speed of the whale be v_W.

SET UP: Whale receives waves: (Figure 16.63a)

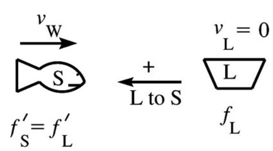


EXECUTE: $v_L = +v_W$

$$f_L' = f_S\left(\frac{v+v_L}{v+v_S}\right) = f_S\left(\frac{v+v_W}{v}\right)$$

Figure 16.63a

SET UP: Whale re-emits the waves: (Figure 16.63b)



EXECUTE: $v_S = -v_W$

$$f_L = f_S\left(\frac{v+v_L}{v+v_S}\right) = f_S'\left(\frac{v}{v-v_W}\right)$$

Figure 16.63b

But $f_S' = f_L'$ so $f_L = f_S\left(\dfrac{v+v_W}{v}\right)\left(\dfrac{v}{v-v_W}\right) = f_S\left(\dfrac{v+v_W}{v-v_W}\right)$.

Then $\Delta f = f_S - f_L = f_S\left(1-\dfrac{v+v_W}{v-v_W}\right) = f_S\left(\dfrac{v-v_W-v-v_W}{v-v_W}\right) = \dfrac{-2f_S v_W}{v-v_W}$.

$$\Delta f = \frac{-2(1.80\times10^4 \text{ Hz})(4.95 \text{ m/s})}{1482 \text{ m/s} - 4.95 \text{ m/s}} = -120 \text{ Hz}.$$

EVALUATE: Δf is negative, which means that $f_L > f_S$. This is reasonable because the listener and source are moving toward each other so the frequency is raised.

16.64. **IDENTIFY:** This problem deals with sound intensity and sound intensity level.

SET UP and EXECUTE: **(a)** Estimate: 5.0 s delay between the flash and sound of thunder.

(b) $x = vt = (344 \text{ m/s})(5.0 \text{ s}) = 1700$ m.

(c) Estimate: 70 dB. $\beta = (10 \text{ dB})\log\dfrac{I}{I_0} = 70$ dB, so $I = 10^7 I_0 = 10^7\ 10^{-12} \text{ W/m}^2 = 10^{-5} \text{ W/m}^2$.

(d) $I = P/A$, so $P_{av} = IA = I(4\pi r^2) = (10^{-5} \text{ W/m}^2)(4\pi)(1700 \text{ m})^2 = 370$ W.

(e) Estimate: 4.0 s duration. $E = P_{av}t = (370 \text{ W})(4.0 \text{ s}) = 1500$ J.

EVALUATE: The power due to a lightning strike is much greater than 370 W because the strike lasts only a fraction of a second and can create a great deal of heat. We are looking only at the *sound* energy.

16.65. **IDENTIFY:** This problem deals with sound intensity and sound intensity level.

SET UP and EXECUTE: **(a)** Estimate: Somewhere between busy traffic and an elevated train, so use 85 dB. $\beta = (10\text{ dB})\log\dfrac{I}{I_0} = 85$ dB, so $I = 10^{8.5}I_0 = 10^{8.5}\ 10^{-12}\ \text{W/m}^2 = 3.2\times10^{-4}\ \text{W/m}^2$.

(b) $I = P/A$, so $P_{av} = IA = I(4\pi r^2) = (3.2\times10^{-4}\ \text{W/m}^2)(4\pi)(18\text{ m})^2 = 1.3$ W.

(c) Estimate: 2.0 s for the crashing sound. $E = P_{av}t = (1.3\text{ W})(2.0\text{ s}) = 2.6$ J.

(d) Estimate: 4.0 s to travel down the alley. $v = x/t = (18\text{ m})/(4.0\text{ s}) = 4.5$ m/s.

(e) $K = \dfrac{1}{2}mv_{cm}^2 + \dfrac{1}{2}I\omega^2$, with $\omega = v_{cm}/R$ for rolling and $I = \dfrac{2}{5}MR^2$. Using these gives

$$K = \frac{1}{2}mv_{cm}^2 + \frac{1}{2}\left(\frac{2}{5}mR^2\right)\left(\frac{v_{cm}}{R}\right)^2 = \frac{7}{10}mv_{cm}^2 = \frac{7}{10}(6.4\text{ kg})(4.5\text{ m/s})^2 = 91\text{ J}.$$

(f) $\dfrac{2.6\text{ J}}{91\text{ J}} = 0.029 \approx 3\%$.

EVALUATE: Just from watching the heavy pins scatter, it is clear that most of the ball's kinetic energy is transferred to them, with little left over for sound energy. The 3% is not unreasonable.

16.66. **IDENTIFY:** Apply $f_L = \left(\dfrac{v+v_L}{v+v_S}\right)f_S$. The heart wall first acts as the listener and then as the source.

SET UP: The positive direction is from listener to source. The heart wall is moving toward the receiver so the Doppler effect increases the frequency and the final frequency received, f_{L2}, is greater than the source frequency, f_{S1}. $f_{L2} - f_{S1} = 72$ Hz.

EXECUTE: Heart wall receives the sound: $f_S = f_{S1}$. $f_L = f_{L1}$. $v_S = 0$. $v_L = -v_{wall}$. $f_L = \left(\dfrac{v+v_L}{v+v_S}\right)f_S$ gives $f_{L1} = \left(\dfrac{v-v_{wall}}{v}\right)f_{S1}$.

Heart wall emits the sound: $f_{S2} = f_{L1}$. $v_S = +v_{wall}$. $v_L = 0$.

$$f_{L2} = \left(\frac{v}{v+v_{wall}}\right)f_{S2} = \left(\frac{v}{v+v_{wall}}\right)\left(\frac{v-v_{wall}}{v}\right)f_{S1} = \left(\frac{v-v_{wall}}{v+v_{wall}}\right)f_{S1}.$$

$f_{L2} - f_{S1} = \left(1 - \dfrac{v-v_{wall}}{v+v_{wall}}\right)f_{S1} = \left(\dfrac{2v_{wall}}{v+v_{wall}}\right)f_{S1}$. $v_{wall} = \dfrac{(f_{L2}-f_{S1})v}{2f_{S1} - (f_{L2}-f_{S1})}$. $f_{S1} \gg f_{L2} - f_{S1}$ and

$$v_{wall} = \frac{(f_{L2}-f_{S1})v}{2f_{S1}} = \frac{(72\text{ Hz})(1500\text{ m/s})}{2(2.00\times10^6\text{ Hz})} = 0.0270\text{ m/s} = 2.70\text{ cm/s}.$$

EVALUATE: $f_{S1} = 2.00\times10^6$ Hz and $f_{L2} - f_{S1} = 72$ Hz, so the approximation we made is very accurate. Within this approximation, the frequency difference between the reflected and transmitted waves is directly proportional to the speed of the heart wall.

16.67. **IDENTIFY:** Follow the method of Example 16.18 and apply the Doppler shift formula twice, once with the insect as the listener and again with the insect as the source.

SET UP: Let v_{bat} be the speed of the bat, v_{insect} be the speed of the insect, and f_i be the frequency with which the sound waves both strike and are reflected from the insect. The positive direction in each application of the Doppler shift formula is from the listener to the source.

EXECUTE: The frequencies at which the bat sends and receives the signals are related by $f_L = f_i\left(\dfrac{v+v_{bat}}{v-v_{insect}}\right) = f_S\left(\dfrac{v+v_{insect}}{v-v_{bat}}\right)\left(\dfrac{v+v_{bat}}{v-v_{insect}}\right)$. Solving for v_{insect},

$$v_{\text{insect}} = v\left[\frac{1-\dfrac{f_S}{f_L}\left(\dfrac{v+v_{\text{bat}}}{v-v_{\text{bat}}}\right)}{1+\dfrac{f_S}{f_L}\left(\dfrac{v+v_{\text{bat}}}{v-v_{\text{bat}}}\right)}\right] = v\left[\frac{f_L(v-v_{\text{bat}})-f_S(v+v_{\text{bat}})}{f_L(v-v_{\text{bat}})+f_S(v+v_{\text{bat}})}\right].$$

Letting $f_L = f_{\text{refl}}$ and $f_S = f_{\text{bat}}$ gives the result.

(b) If $f_{\text{bat}} = 80.7$ kHz, $f_{\text{refl}} = 83.5$ kHz, and $v_{\text{bat}} = 3.9$ m/s, then $v_{\text{insect}} = 2.0$ m/s.

EVALUATE: $f_{\text{refl}} > f_{\text{bat}}$ because the bat and insect are approaching each other.

16.68. IDENTIFY: Apply the Doppler effect formula $f_L = \left(\dfrac{v+v_L}{v+v_S}\right)f_S$. In the SHM the source moves toward and away from the listener, with maximum speed $\omega_p A_p$.

SET UP: The direction from listener to source is positive.

EXECUTE: **(a)** The maximum velocity of the siren is $\omega_P A_P = 2\pi f_P A_P$. You hear a sound with frequency $f_L = f_{\text{siren}} v/(v+v_S)$, where v_S varies between $+2\pi f_P A_P$ and $-2\pi f_P A_P$.

$f_{L-\max} = f_{\text{siren}} v/(v-2\pi f_P A_P)$ and $f_{L-\min} = f_{\text{siren}} v/(v+2\pi f_P A_P)$.

(b) The maximum (minimum) frequency is heard when the platform is passing through equilibrium and moving up (down).

EVALUATE: When the platform is moving upward the frequency you hear is greater than f_{siren} and when it is moving downward the frequency you hear is less than f_{siren}. When the platform is at its maximum displacement from equilibrium its speed is zero and the frequency you hear is f_{siren}.

16.69. IDENTIFY: The sound from the speaker moving toward the listener will have an increased frequency, while the sound from the speaker moving away from the listener will have a decreased frequency. The difference in these frequencies will produce a beat.

SET UP: The greatest frequency shift from the Doppler effect occurs when one speaker is moving away and one is moving toward the person. The speakers have speed $v_0 = r\omega$, where $r = 0.75$ m.

$f_L = \left(\dfrac{v+v_L}{v+v_S}\right)f_S$, with the positive direction from the listener to the source. $v = 344$ m/s.

EXECUTE: **(a)** $f = \dfrac{v}{\lambda} = \dfrac{344\text{ m/s}}{0.313\text{ m}} = 1100$ Hz. $\omega = (75\text{ rpm})\left(\dfrac{2\pi\text{ rad}}{1\text{ rev}}\right)\left(\dfrac{1\text{ min}}{60\text{ s}}\right) = 7.85$ rad/s and

$v_0 = (0.75\text{ m})(7.85\text{ rad/s}) = 5.89$ m/s.

For speaker A, moving toward the listener: $f_{LA} = \left(\dfrac{v}{v-5.89\text{ m/s}}\right)(1100\text{ Hz}) = 1119$ Hz.

For speaker B, moving toward the listener: $f_{LB} = \left(\dfrac{v}{v+5.89\text{ m/s}}\right)(1100\text{ Hz}) = 1081$ Hz.

$f_{\text{beat}} = f_1 - f_2 = 1119\text{ Hz} - 1081\text{ Hz} = 38$ Hz.

(b) A person can hear individual beats only up to about 7 Hz and this beat frequency is much larger than that.

EVALUATE: As the turntable rotates faster the beat frequency at this position of the speakers increases.

16.70. IDENTIFY and SET UP: Assuming that the gas is nearly ideal, the speed of sound in it is given by $v = \sqrt{\dfrac{\gamma RT}{M}}$, where T is in absolute (Kelvin) units and M is the molar mass of the gas.

EXECUTE: **(a)** Squaring $v=\sqrt{\dfrac{\gamma RT}{M}}$, gives $v^2=\left(\dfrac{\gamma R}{M}\right)T$. On a graph of v^2 versus T, we would expect a straight line with slope equal to $\dfrac{\gamma R}{M}$. Figure 16.70 shows the graph of the data given in the problem.

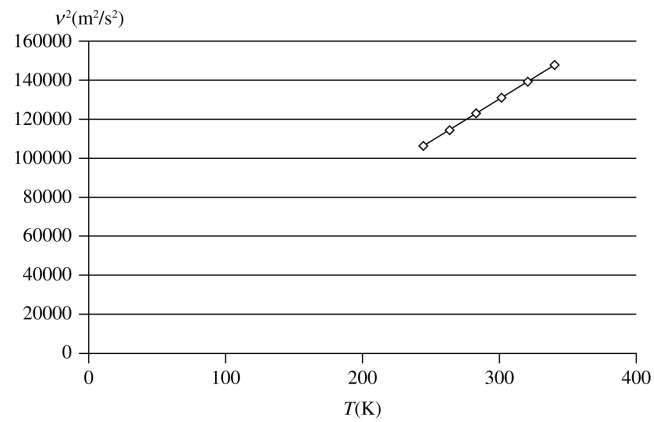


Figure 16.70

(b) The best-fit equation for the graph in Figure 16.70 is $v^2 = (416.47\ \text{m}^2/\text{K}\cdot\text{s}^2)\,T + 296.65\ \text{m}^2/\text{s}^2$. Solving our expression for the slope for M gives $M = \gamma R$ /slope. Putting in the numbers gives $M = (1.40)(8.3145\ \text{J/mol}\cdot\text{K})/(416.47\ \text{m}^2/\text{K}\cdot\text{s}^2) = 0.0279$ kg/mol = 27.9 g/mol.

EVALUATE: Nitrogen N_2 is a diatomic gas with a molecular mass of 28.0 g/mol, so the gas is probably nitrogen.

16.71. **IDENTIFY** and **SET UP:** There is a node at the piston, so the distance the piston moves is the node to node distance, $\lambda/2$. Use $v = f\lambda$ to calculate v and $v=\sqrt{\dfrac{\gamma RT}{M}}$ to calculate γ from v.

EXECUTE: **(a)** $\lambda/2 = 37.5$ cm, so $\lambda = 2(37.5\text{ cm}) = 75.0\text{ cm} = 0.750$ m.
$v = f\lambda = (500\text{ Hz})(0.750\text{ m}) = 375$ m/s

(b) Solve $v=\sqrt{\gamma RT/M}$ for γ: $\gamma = \dfrac{Mv^2}{RT} = \dfrac{(28.8\times10^{-3}\ \text{kg/mol})(375\ \text{m/s})^2}{(8.3145\ \text{J/mol}\cdot\text{K})(350\ \text{K})} = 1.39.$

(c) EVALUATE: There is a node at the piston so when the piston is 18.0 cm from the open end the node is inside the pipe, 18.0 cm from the open end. The node to antinode distance is $\lambda/4 = 18.8$ cm, so the antinode is 0.8 cm beyond the open end of the pipe.
The value of γ we calculated agrees with the value given for air in Example 16.4.

16.72. **IDENTIFY** and **SET UP:** We know from the problem that $f_R = f_S\left(1-\dfrac{v}{c}\right)^{1/2}\left(1+\dfrac{v}{c}\right)^{1/2}$. The radius of the nebula is $R = vt$, where t is the time since the supernova explosion. When the source and receiver are moving toward each other, v is negative and $f_R > f_S$. The light from the explosion reached earth 960 years ago, so that is the amount of time the nebula has expanded. $1\text{ ly} = 9.461\times10^{15}$ m.

EXECUTE: **(a)** According to the binomial theorem, $(1 \pm x)^n \approx 1 \pm nx$ if $|x| << 1$. Applying this to the two square roots, where $n = \pm\dfrac{1}{2}$ and $x = v/c$, the equation $f_R = f_S\left(1-\dfrac{v}{c}\right)^{1/2}\left(1+\dfrac{v}{c}\right)^{1/2}$ becomes

$$f_R \approx f_S\left(1-\frac{1}{2}\frac{v}{c}\right)\left(1-\frac{1}{2}\frac{v}{c}\right) \approx f_S\left(1-\frac{1}{2}\frac{v}{c}\right)^2 \approx f_S\left[1-2\left(\frac{1}{2}\frac{v}{c}\right)\right] \approx f_S\left(1-\frac{v}{c}\right).$$

(b) Solving the equation we derived in part (a) for v gives

$v = c\dfrac{f_S - f_R}{f_S} = (3.00\times10^8\text{ m/s})\dfrac{-0.018\times10^{14}\text{ Hz}}{4.568\times10^{14}\text{ Hz}} = -1.2\times10^6\text{ m/s},$ with the minus sign indicating that the gas is approaching the earth, as is expected since $f_R > f_S$.

(c) As of 2014, the supernova occurred 960 years ago. The diameter D is therefore

$D = 2(960\text{ y})(3.156\times10^7\text{ s/y})(1.2\times10^6\text{ m/s}) = 7.15\times10^{16}\text{ m} = 7.6\text{ ly}.$

(d) The ratio of the width of the nebula to 2π times the distance from the earth is the ratio of the angular width (taken as 5 arc minutes) to an entire circle, which is 60×360 arc minutes. The distance to the nebula is then $\left(\dfrac{2}{2\pi}\right)(3.75\text{ ly})\dfrac{(60)(360)}{5} = 5.2\times10^3$ ly. The time it takes light to travel this distance is 5200 yr, so the explosion actually took place 5200 yr before 1054 C.E., or about 4100 B.C.E.

EVALUATE: $\left|\dfrac{v}{c}\right| = 4.0\times10^{-3}$, so even though $|v|$ is very large the approximation required for $v = c\dfrac{\Delta f}{f}$ is accurate.

16.73. **IDENTIFY:** The wire vibrating in its fundamental causes the tube to resonate with the same frequency in its fundamental. We are dealing with standing waves on a string and in an open pipe.

SET UP: Fig. 16.73a illustrates the information in the problem. The information we have is as follows:

<u>wire</u>: μ = 1.40 g/m = 0.00140 kg/m, vibrating in its fundamental f_1.

<u>pole</u>: M = 8.00 kg, L = 1.56 m

<u>tube</u>: 39.0 cm long, m = 4.00 kg, hollow (open pipe), vibrating in its fundamental f_1

We want to find the frequency f_1 at which the wire and tube are vibrating and the height h in Fig. 16.73a. The equations we use for the tube are $f_n = nv_s/2L_t$, $\lambda_n = 2L_t/n$, $\lambda_1 = 2L_t$ and for the wire $f_n = nv/2L_w$, $\lambda_n = 2L_w/n$, $\lambda_1 = 2L_w$. We also use $v = f\lambda$.

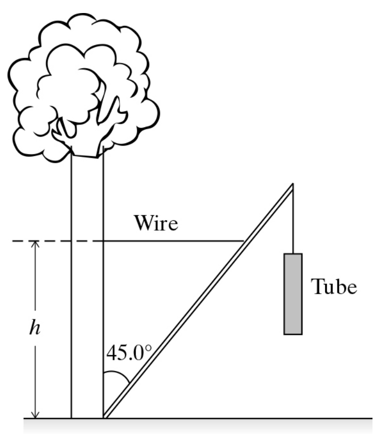

Figure 16.73a

EXECUTE: **(a)** For the tube in its fundamental mode, we have $\lambda_1 = 2L_t$ = 2(0.390 m) = 0.780 m. The frequency is $f_1 = \dfrac{v_s}{\lambda_t} = \dfrac{344\text{ m/s}}{0.780\text{ m}} = 441$ Hz. This is the frequency at which the wire and the tube are resonating.

(b) We want to find h in Fig. 16.73a. Now look at the wire. $f_w \lambda_w = v_w = \sqrt{\frac{F}{\mu}}$. In its fundamental mode $\lambda_1 = 2L_w$. From Fig. 16.73a we see that $L_w = h\tan 45.0° = h$, so $\lambda_1 = 2h$. From part (a) we know that f_1 = 441 Hz, so $f_w \lambda_w = v_w = \sqrt{\frac{F}{\mu}}$ gives $f_1(2h) = (441\text{ Hz})(2h) = \sqrt{\frac{F}{\mu}}$, which becomes

$(882\text{ Hz})h = \sqrt{\frac{F}{\mu}}$. (Eq. 1)

We need to find F in order to find h. Make a free-body diagram of the pole as in Fig. 16.73b and apply $\sum \tau_z = 0$ about the hinge. Using Fig. 16.73 as a guide, we get

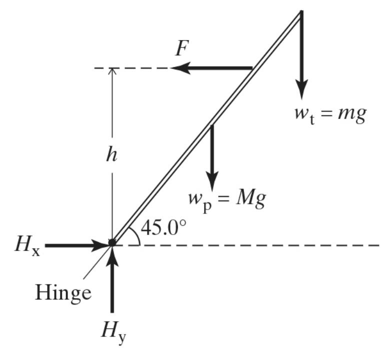

Figure 16.73b

$Fh - Mg\frac{L}{2}\cos 45.0° - mgL\cos 45.0° = 0,$ which simplifies to $Fh = \left(\frac{M}{2} + m\right)gL\cos 45.0°.$ Putting in M =8.00 kg, m = 4.00 kg, and L = 1.56 m, and solving for F, we get $F = \frac{86.48\text{ N}\cdot\text{m}}{h}$. Now return to Eq. 1. Square the equation and substitute for F, giving $(882\text{ Hz})^2 h^2 = \frac{F}{\mu} = \frac{86.48\text{ N}\cdot\text{m}}{h(0.00140\text{ kg/m})}$. Solving for h gives h = 0.430 m.

EVALUATE: Changing h would change the length of the wire as well as the tension in it. These changes would affect the fundamental frequency of the wire.

16.74. **IDENTIFY:** The sound from the two speakers travels different distances to reach the aisle. Therefore interference occurs along the aisle.

SET UP: Start with a figure to illustrate the information given, as in Fig. 16.74. The path difference d between sound from speakers A and B is $d = r - x$. For destructive interference to occur, the path difference must be $d = \frac{\lambda}{2}, \frac{3\lambda}{2}, \frac{5\lambda}{2}, \cdots = (2n-1)\frac{\lambda}{2}$ $(n = 1,2,3,...)$. From the figure, we can see that $d = \sqrt{x^2 + (15.0\text{ m})^2} - x$, so $d = \sqrt{x^2 + (15.0\text{ m})^2} - x = (2n-1)\frac{\lambda}{2}$ $(n = 1,2,3,...)$. The wavelength of the sound from both speakers is $\lambda = \frac{v}{f} = \frac{344\text{ m/s}}{440\text{ Hz}} = 0.7818\text{ m}.$

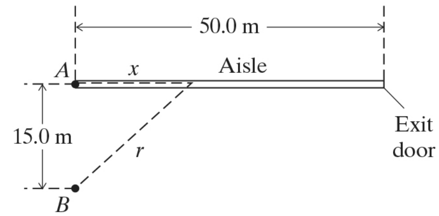

Figure 16.74

EXECUTE: **(a)** The path difference d increases as we get closer to speaker A in the figure. The limit would be right at the speaker, in which case $x = 0$, $r = 15.0$ m, and $d = 15.0$ m. Therefore we have $d = 15.0\text{ m} = (2n-1)\dfrac{\lambda}{2} = (2n-1)\dfrac{0.7818\text{ m}}{2}$. Solving for n gives $n = 19.69$. But n must be an integer and cannot exceed 19.69, so $n = 19$. This is the total number of points along the aisle where the waves from the two speakers would cancel each other. But aisle is only 50.0 m long, so the theater may not be deep enough for all these points to occur. The smallest path difference would occur at the back door 50.0 m from the stage. The path difference at that point is d_{min} which is $d_{\text{min}} = \sqrt{(50.0\text{ m})^2 + (15.0\text{ m})^2} - 50.0\text{ m} = 2.2015\text{ m}$. Now use this distance to find out how may points of cancellation will fit inside the theater. $2.2015\text{ m} = (2n-1)\left(\dfrac{0.7818\text{ m}}{2}\right) = (0.3909\text{ m})(2n-1)$. Solving for n gives $n = 3.316$, which suggests $n = 3$. However for $n = 3$, $d = (2n-1)\dfrac{\lambda}{2} = \dfrac{5\lambda}{2} = \dfrac{5(0.7818\text{ m})}{2} = 1.955\text{ m}$. But this distance is shorter than the minimum path difference of 2.2015 m that we calculated earlier. So we would have to be farther than 50.0 m from the stage to experience it, which is outside the theater. Thus the $n = 3$ point does not occur, and neither do the $n = 2$ and $n = 1$ points. Therefore we have found that a total of 19 cancellation points are possible, but 3 of them would occur outside the theater, so the number that occur inside the theater are 19 – 3 = 16.

(b) We have just seen that the $n = 3$ interference point does not occur, so the farthest point at which cancellation does occur would be for the $n = 4$ point for which $d = \dfrac{7}{2}\lambda = \dfrac{7}{2}(0.7818\text{ m}) = 2.7363\text{ m}$. Using this value of d and solving for the distance x from the stage gives $\sqrt{x^2 + (15.0\text{ m})^2} - x = 2.7363\text{ m}$. Squaring and solving for x gives $x = 39.746$ m. The distance from the exit door is 50.0 m – 39.746 m = 10.3 m.

(c) The second frequency must be such that it cancels at the same points as the original frequency (and it may cancel at other points also). This frequency must be some multiple of the original frequency. Call the original wavelength λ and the second frequency λ', and realize that λ' must be less than λ, so we can write it as $\lambda' = \lambda / k$. For cancellation of the sound at both frequencies to occur, d must be odd multiples of a half wavelength for each frequency f and f'. That is, $d = N(\lambda/2)$ and $d = N'(\lambda'/2)$, where both N and N' must be odd integers. Substituting $\lambda' = \lambda / k$ into $d = N(\lambda/2)$ gives $d = N\left(\dfrac{k\lambda'}{2}\right) = Nk\dfrac{\lambda'}{2}$. This result tells us that Nk must be an odd integer. Since N is already an odd integer, k must also be an odd integer for the product Nk to be odd. The frequency f' of the second sound is $f' = \dfrac{v}{\lambda'} = \dfrac{v}{\lambda/k} = k(v/\lambda) = kf$, where k is an odd integer. We want the smallest possible frequency for f', so k must have its smallest possible value. The smallest is $k = 1$, but in that case the second frequency is the same as the first one, which is not what we want. So k must be 3, which makes the second wavelength $\lambda' = \frac{\lambda}{3} = \frac{0.7818\text{ m}}{3} = 0.2606\text{ m}$ and the second frequency $f' = 3f = 3(440\text{ Hz}) = 1320\text{ Hz}.$

(d) We follow the same procedure as in part (a), but this time for f' and λ'. For destructive interference, the path difference must be $d = (2N-1)\frac{\lambda'}{2}$, N = 1, 2, 3, … . The greatest path difference occurs closest to speaker *A*, with the limit being d = 15.0 m. In this case we have $15.0\text{ m} = (2N-1)\frac{\lambda'}{2} = (2N-1)\frac{0.2606\text{ m}}{2}$. Solving for N gives N = 58. This means that destructive interference can occur at a maximum of 58 points. However the hall may not be deep enough for all of them to occur. As we saw in part (a), the minimum path difference d_{min} that can occur in the hall is at the back door, and at that point d_{min} = 2.2015 m. Using this information to find the minimum value of N for points inside the hall gives $2.2015\text{ m} = (2N-1)\frac{\lambda'}{2} = (2N-1)\frac{0.2606\text{ m}}{2}$. Solving for N we get N = 8.95, so we use N = 8. But first check to see if d is shorter than d_{min} for this result. Doing so gives $d = (2N-1)\frac{\lambda'}{2} = (15)\frac{0.2606\text{ m}}{2} = 1.955\text{ m}$, which is less than 2.2015 m. Therefore the N = 8 point does not occur within the hall, and neither do all the others for N = 7, 6, etc. So the total number of points within the hall at which destructive interference occurs is 58 – 8 = 50. But 16 of those points occur at the same places as the 440-Hz sound, so the *additional* number of points is 50 – 16 = 34 points.

(e) At the point closest to the speaker, N = 58 from part (d). The path difference at this point is $d = (2N-1)\frac{\lambda'}{2} = (115)\frac{0.2606\text{ m}}{2} = 14.9845\text{ m}.$ Using $\sqrt{x^2 + (15.0\text{ m})^2} - x = 14.9845\text{ m}$, we solve for x, giving x = 0.0155 m = 1.55 cm.

EVALUATE: The sound cannot cancel completely at the points of destructive interference because the intensity from the two speakers is different due to the difference in distance from them. But the loudness will definitely reach a minimum at the points of destructive interference.

16.75. **IDENTIFY:** The phase of the wave is determined by the value of $x - vt$, so t increasing is equivalent to x decreasing with t constant. The pressure fluctuation and displacement are related by the equation $p(x,t) = -B\frac{\partial y(x,t)}{\partial x}$.

SET UP: $y(x,t) = -\frac{1}{B}\int p(x,t)dx.$ If $p(x,t)$ versus x is a straight line, then $y(x,t)$ versus x is a parabola. For air, $B = 1.42\times10^5\text{ Pa}.$

EXECUTE: **(a)** The graph is sketched in Figure 16.75a.

(b) From $p(x,t) = BkA\sin(kx - \omega t)$, the function that has the given $p(x,0)$ at $t = 0$ is given graphically in Figure 16.75b. Each section is a parabola, not a portion of a sine curve. The period is $\lambda/v = (0.200\text{ m})/(344\text{ m/s}) = 5.81\times10^{-4}\text{ s}$ and the amplitude is equal to the area under the p versus x curve between $x = 0$ and $x = 0.0500$ m divided by B, or 7.04×10^{-6} m.

(c) Assuming a wave moving in the $+x$-direction, $y(0,t)$ is as shown in Figure 16.75c.

(d) The maximum velocity of a particle occurs when a particle is moving through the origin, and the particle speed is $v_y = -\frac{\partial y}{\partial x}v = \frac{pv}{B}$. The maximum velocity is found from the maximum pressure, and $v_{y\text{max}} = (40\text{ Pa})(344\text{ m/s})/(1.42\times10^5\text{ Pa}) = 9.69\text{ cm/s}.$ The maximum acceleration is the maximum pressure gradient divided by the density,

$$a_{\text{max}} = \frac{(80.0\text{ Pa})/(0.100\text{ m})}{(1.20\text{ kg/m}^3)} = 6.67\times10^2\text{ m/s}^2.$$

(e) The speaker cone moves with the displacement as found in part (c); the speaker cone alternates between moving forward and backward with constant magnitude of acceleration (but changing sign). The acceleration as a function of time is a square wave with amplitude $667\ \text{m/s}^2$ and frequency $f = v/\lambda = (344\ \text{m/s})/(0.200\ \text{m}) = 1.72\ \text{kHz}$.

EVALUATE: We can verify that $p(x,t)$ versus x has a shape proportional to the slope of the graph of $y(x,t)$ versus x. The same is also true of the graphs versus t.

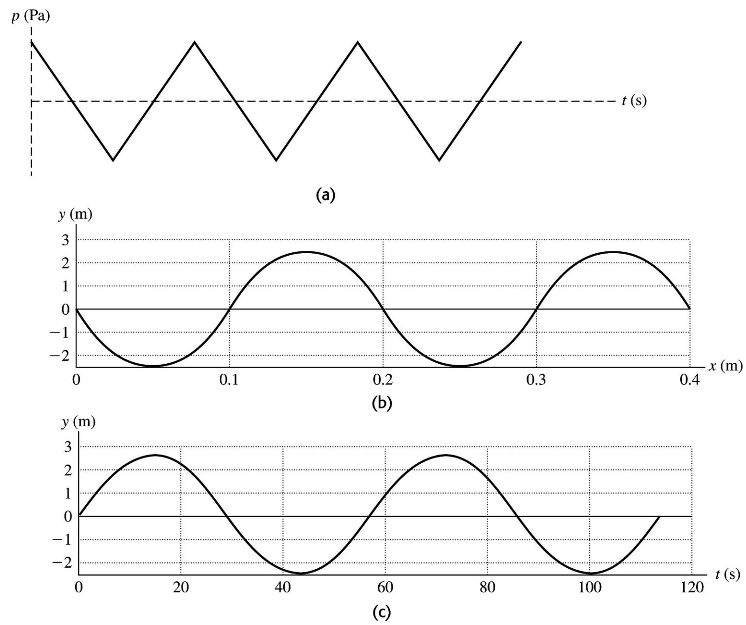

Figure 16.75

16.76. **IDENTIFY** and **SET UP:** Consider the derivation of the speed of a longitudinal wave in Section 16.2.
EXECUTE: **(a)** The quantity of interest is the change in force per fractional length change. The force constant k' is the change in force per length change, so the force change per fractional length change is $k'L$, the applied force at one end is $F = (k'L)(v_y/v)$ and the longitudinal impulse when this force is applied for a time t *is* $k'Ltv_y/v$. The change in longitudinal momentum is $((vt)m/L)v_y$ and equating the expressions, canceling a factor of t and solving for v gives $v^2 = L^2k'/m$.
(b) $v = (2.00\ \text{m})\sqrt{(1.50\ \text{N/m})/(0.250\ \text{kg})} = 4.90\ \text{m/s}$
EVALUATE: *A* larger k' corresponds to a stiffer spring and for a stiffer spring the wave speed is greater.

16.77. **IDENTIFY** and **SET UP:** The time between pulses is limited by the time for the wave to travel from the transducer to the structure and then back again. Use $x = v_xt$ and $f = 1/T$.
EXECUTE: **(a)** The wave travels 10 cm in and 10 cm out, so $t = x/v_x = (0.20\ \text{m})/(1540\ \text{m/s}) = 0.13 \times 10^{-3}\ \text{s} = 0.13\ \text{ms}$. The period can be no shorter than this, so the highest pulse frequency is $f = 1/t = 1/(0.13\ \text{ms}) = 7700\ \text{Hz}$, which is choice (b).
EVALUATE: The pulse frequency is not the same thing as the frequency of the ultrasound waves, which is around 1.0 MHz.

16.78. **IDENTIFY** and **SET UP:** Call S the intensity level of the beam. The beam attenuates by 100 dB per meter, so in 10 cm (0.10 m) it would attenuate by 1/10 of this amount. Therefore $\Delta S = -10$ dB. $S = 10\ \text{dB}\log(I/I_0)$.

EXECUTE: **(a)** $\Delta S = S_2 - S_1 = 10 \text{ dB} \log(I_2/I_0) - 10 \text{ dB} \log(I_1/I_0) = 10 \text{ dB} \log(I_2/I_0)$ since $I_1 = I_0$. Therefore $-10 \text{ dB} = 10 \text{ dB} \log(I_2/I_0)$, which gives $I_2/I_0 = 10^{-1}$, so $I_2 = 1/10\ I_0$, which is choice (d).
EVALUATE: In the next 10 cm, the beam would attenuate by another factor of 1/10, so it would be 1/100 of the initial intensity.

16.79. **IDENTIFY** and **SET UP:** The beam goes through 5.0 cm of tissue and 2.0 cm of bone. Use $d = vt$ to calculate the total time in this case and compare it with the time to travel 7.0 cm through only tissue.
EXECUTE: $d = vt$ gives $t = x/v$. Calculate the time to go through 2.0 cm of bone and 5.0 cm of tissue and then get the total time t_{tot}. $t_T = x_T/v_T$ and $t_B = x_B/v_B$, so $t_{tot} = x_T/v_T + x_B/v_B$. Putting in the numbers gives
$t_{tot} = (0.050 \text{ m})/(1540 \text{ m/s}) + (0.020 \text{ m})/(3080 \text{ m/s}) = 3.896 \times 10^{-5}$ s. If the wave went through only tissue during this time, it would have traveled $x = v_T t_{tot} = (1540 \text{ m/s})(3.896 \times 10^{-5} \text{ s}) = 6.0 \times 10^{-2} \text{ m} =$ 6.0 cm. So the beam traveled 7.0 cm, but you think it traveled 6.0 cm, so the structure is actually 1.0 cm deeper than you think, which makes choice (a) the correct one.
EVALUATE: A difference of 1.0 cm when a structure is 7.0 below the surface can be very significant.

16.80. **IDENTIFY** and **SET UP:** In a standing wave pattern, the distance between antinodes is one-half the wavelength of the waves. Use $v = f\lambda$ to find the wavelength.
EXECUTE: $\lambda = v/f = (1540 \text{ m/s})/(1.00 \text{ MHz}) = 1.54 \times 10^{-3} \text{ m} = 1.54$ mm. The distance D between antinodes is $D = \lambda/2 = (1.54 \text{ mm})/2 = 0.77 \text{ mm} \approx 0.75$ mm, which is choice (b).
EVALUATE: Decreasing the frequency could reduce the distance between antinodes if this is desired.

16.81. **IDENTIFY** and **SET UP:** The antinode spacing is $\lambda/2$. Use $v = f\lambda$.
EXECUTE: **(a)** The antinode spacing d is $\lambda/2$. Using $v = f\lambda$, we have $d = \lambda/2 = v/2f$. For the numbers in this problem, we have $d = (1540 \text{ m/s})/[2(1.0 \text{ kHz})] = 0.77 \text{ m} = 77$ cm. The cranium is much smaller than 77 cm, so there will be no standing waves within it at 1.0 kHz, which is choice (b).
EVALUATE: Using 1.0 MHz waves, the distance between antinodes would be 1000 times smaller, or 0.077 cm, so there could certainly be standing waves within the cranium.

17

TEMPERATURE AND HEAT

VP17.4.1. **IDENTIFY:** The rods expand (or contract) when their temperature is changed, so we are dealing with thermal expansion.

SET UP: $\Delta L = \alpha L_0 \Delta T$

EXECUTE: **(a)** We want to find α, the coefficient of linear expansion. Using $\Delta L = \alpha L_0 \Delta T$ gives $2.20\times10^{-4}\ \text{m} = \alpha(0.500\ \text{m})(37.0°\text{C} - 15.0°\text{C})$, so $\alpha = 2.00\times10^{-5}\ (\text{C}°)^{-1} = 2.00\times10^{-5}\ \text{K}^{-1}$.

(b) We want the change in length. Using $\Delta L = \alpha L_0 \Delta T$ gives

$\Delta L = \left[2.00\times10^{-5}\ (\text{C}°)^{-1}\right](0.300\ \text{m})(-20.0°\text{C} - 25.0°\text{C}) = -2.7\times10^{-4}\ \text{m} = -0.27\ \text{mm}$. Its length would *decrease* by 0.27 mm.

EVALUATE: Increasing temperature causes thermal expansion, while decreasing temperature causes thermal contraction. In both cases, the relative change in length is normally very small.

VP17.4.2. **IDENTIFY:** The mug and ethanol both decrease in volume as their temperature is decreased, so we are dealing with thermal contraction.

SET UP: We are dealing with volume contraction, so we use $\Delta V = \beta V_0 \Delta T$. If the volume of the ethanol and the mug decreased by the same amount, the ethanol would continue to fill the mug. In that case we could not add any additional ethanol to the mug. But $\beta_{\text{ethanol}} > \beta_{\text{mug}}$, so the ethanol contracts more than the mug, leaving room to add additional ethanol. The amount of empty space after the contraction will be $V_{\text{empy}} = \Delta V_{\text{ethanol}} - \Delta V_{\text{mug}}$, which is what we want to find. Table 17.2 tells us that $\beta_{\text{Cu}} = 5.1\times10^{-5}(\text{C}°)^{-1}$ and $\beta_{\text{ethanol}} = 75\times10^{-5}(\text{C}°)^{-1}$.

EXECUTE: $V_{\text{empy}} = \Delta V_{\text{ethanol}} - \Delta V_{\text{mug}} = \beta_{\text{e}} V_0 \Delta T - \beta_{\text{c}} V_0 \Delta T = (\beta_{\text{e}} - \beta_{\text{c}}) V_0 \Delta T$. Using the coefficients of volume expansion from Table 17.2, $V_0 = 250\ \text{cm}^3$, and $\Delta T = -70.0°\text{C}$, we get $V_{\text{empty}} = -12\ \text{cm}^3$. This is the net change in volume, and it is negative since the volumes have decreased. The available volume is $12\ \text{cm}^3$.

EVALUATE: If β_{ethanol} were less than β_{mug}, ethanol would spill out of the mug as the temperature fell because the mug would contract more than the ethanol.

VP17.4.3. **IDENTIFY:** The thermal stress is due to the contraction of the brass rod as its temperature is decreased.

SET UP: Thermal stress is $\dfrac{F}{A} = -Y\alpha\Delta T$. Table 17.1 gives $\alpha_{\text{brass}} = 2.0\times10^{-5}(\text{C}°)^{-1}$ and Y_{brass} is given in the problem. The target variable is the thermal stress.

EXECUTE: The force is $F = -AY\alpha\Delta T = -\pi r^2 Y\alpha\Delta T$. Using the given values for Y and α, $r = 5.00\times10^{-3}\ \text{m}$, and $\Delta T = 13.0°\text{C} - 25.0°\text{C} = -12°\text{C}$, we get $F = 1700\ \text{N}$.

EVALUATE: The bar tends to shrink when cooled, so the force prevent this. Therefore the forces are *tensile.*

VP17.4.4. **IDENTIFY:** The rods increase in length when their temperature is raised, so we are dealing with thermal expansion.

SET UP: The change in length of the combined rod is the sum of the changes of the two rods. So we know that $L = L_A + L_B$ and $\Delta L = \Delta L_A + \Delta L_B$, and we use $\Delta L = \alpha L_0 \Delta T$ for each rod. We want to solve for L_A in terms of the other quantities.

EXECUTE: $\Delta L = \Delta L_A + \Delta L_B = \alpha_A L_A \Delta T + \alpha_B (L - L_A)\Delta T$. Solve for L_A: $L_A = \dfrac{\alpha_B L - \dfrac{\Delta L}{\Delta T}}{\alpha_B - \alpha_A}$.

EVALUATE: The units may not look right. But realize that $\Delta L = \alpha L_0 \Delta T$ tells us that $\dfrac{\Delta L}{\Delta T} = \alpha L_0$ so the units in the numerator are those of αL, so the overall units are those of $\dfrac{\alpha L}{\alpha}$, which are units of length.

VP17.9.1. **IDENTIFY:** The heat lost by the aluminum is equal to the heat gained by the water, so the net heat transfer for the system is zero.

SET UP: The aluminum is hotter, so it loses heat and the water gains that heat. Use $Q = mc\Delta T$ for each substance. The target variable is the mass of the aluminum. From Table 17.3 we have $c_{\text{Al}} = 910\ \text{J/kg}\cdot\text{K}$ and $c_{\text{w}} = 4190\ \text{J/kg}\cdot\text{K}$.

EXECUTE: Use $Q_{\text{Al}} + Q_{\text{w}} = 0$: $m_{\text{Al}} c_{\text{Al}} \Delta T_{\text{Al}} + m_{\text{w}} c_{\text{w}} \Delta T_{\text{w}} = 0$. Using the numbers gives $m_{\text{Al}}(910\ \text{J/kg}\cdot\text{K})(-228.0\ \text{K}) + (5.00\ \text{kg})(4190\ \text{J/kg}\cdot\text{K})(2.0°\text{C}) = 0$, so $m_{\text{Al}} = 0.20$ kg.

EVALUATE: It is *not true* that $T_C = T_K$. But it *is true* that $\Delta T_C = \Delta T_K$ because the size of the Kelvin degree is the same as the size of the Celsius degree.

VP17.9.2. **IDENTIFY:** Heat is transferred to the copper cube to the ice cube, and this heat melts the ice. We are dealing with temperature changes and a change of phase for the ice from solid to liquid.

SET UP: The net heat transfer between the ice and copper is zero because the heat lost by the copper is gained by the ice cube. For temperature changes we use $Q = mc\Delta T$ and for the phase change we use $Q = mL_f$. The target variable is the initial temperature of the copper.

EXECUTE: Use $Q_{\text{ice}} + Q_{\text{Cu}} = 0$ and call T the initial temperature of the copper. This gives $m_{\text{Cu}} c_{\text{Cu}} \Delta T_{\text{Cu}} + m_{\text{i}} L_{\text{i}} = 0$. Using c_{Cu} from Table 17.3 and L_f from Table 17.4, we have $(0.460\ \text{kg})(390\ \text{J/kg}\cdot\text{K})(0.00°\text{C} - T) + (7.50\times10^{-3}\ \text{kg})(334\times10^{3}\ \text{J/kg}) = 0$, so $T = 14.0°$C.

EVALUATE: Just the melting a small ice cube can produce a large temperature change for the copper because c_{Cu} is small and L_f is large for water.

VP17.9.3. **IDENTIFY:** We mix ice and ethanol and wait until the mixture reaches an equilibrium temperature. The heat lost by the ethanol is equal to the heat gained by the ice, so the net heat transferred is zero.

SET UP: The target variable is the mass of the ice, m_i. For temperature changes we use $Q = mc\Delta T$ and for the phase change we use $Q = mL_f$. The heat transferred to the ice causes three changes: (1) increase in the ice temperature from –5.00°C to 0.00°C, (2) melt the ice at 0.00°C, and (3) increase the temperature of the melted ice from 0.00°C to 10.0°C.

EXECUTE: Use $Q_{\text{ice}} + Q_{\text{ethanol}} = 0$ and include the three changes for the ice listed above. This gives $m_{\text{i}} c_{\text{i}} \Delta T_{\text{i}} + m_{\text{i}} L_{\text{i}} + m_{\text{i}} c_{\text{w}} \Delta T_{\text{w}} + m_{\text{e}} c_{\text{e}} \Delta T_{\text{e}} = 0$. We know that $m_e = 1.60$ kg, and from Tables 17.3 and 17.4, we have $c_i = 2100\ \text{J/kg}\cdot\text{K}$, $c_w = 4190\ \text{J/kg}\cdot\text{K}$, $c_e = 2428\ \text{J/kg}\cdot\text{K}$, and $L_f = 334\times10^{3}\ \text{J/kg}$. The temperature changes are $\Delta T_{\text{i}} = 5.00°\text{C}$, $\Delta T_{\text{w}} = 10.0°\text{C}$, and $\Delta T_{\text{e}} = -18.0°\text{C}$. Putting in the numbers and solving for m_i gives $m_i = 0.181$ kg.

EVALUATE: We must treat the ice in three stages. In addition to melting at 0°C, the ice and liquid water have different specific heats so we cannot treat the ice change from –5.00°C to 10.0°C in a single step.

VP17.9.4. **IDENTIFY:** The ice cools a silver ingot. Several possible outcomes are possible depending on the relative masses of the ice and silver and their initial temperatures: the ice could remain ice but at a higher temperature, the ice could partially melt and remain at 0.00°C, the ice could all melt and remain at 0.00°C , or the ice could all melt and increase its temperature above 0.00°C.

SET UP: For temperature changes use $Q = mc\Delta T$ and for the phase change use $Q = mL_f$. First see if there is enough heat in the silver to bring the ice up to its melting point temperature of 0.00°C and to melt it at 0.00°C. Use quantities from Tables 17.3 and 17.4 for water, ice, and silver. The target variable is the final equilibrium temperature T of the system.

EXECUTE: The heat to cool the silver down to 0.00°C is $Q = mc\Delta T$, which gives $Q = (1.25\text{ kg})(234\ \text{J/kg}\cdot\text{K})(315°\text{C}) = 9.214\times10^4\ \text{J}$. The heat needed to melt all the ice is $Q = mc\Delta T$ + $mL_f = (0.250\text{ kg})(2100\ \text{J/kg}\cdot\text{K})(8.00°\text{C}) + (0.250\text{ kg})(334\times10^3\ \text{J/kg}) = 8.77\times10^4\ \text{J}$. As we see, there is enough heat in the silver ingot to melt all the ice. Now we use the same procedure as in the previous problem except we have silver instead of ethanol. This gives $m_i c_i \Delta T_i + m_i L_i + m_i c_w \Delta T_w + m_s c_s \Delta T_s = 0$. The temperature changes are $\Delta T_i = 8.00°\text{C}$, $\Delta T_w = T - 00.0°\text{C}$, and $\Delta T_s = T - 315°\text{C}$, $m_i = 0.250$ kg, and $m_s = 1.25$ kg. The result is $T = 3.31°\text{C}$, and all the ice melts.

EVALUATE: We must treat the ice in three stages. In addition to melting at 0°C, the ice and liquid water have different specific heats so we cannot treat the ice change from –8.00°C to 3.31°C in a single step.

VP17.15.1. **IDENTIFY:** The heat flows through the pane of glass, so we are dealing with heat conduction.

SET UP: The rate of heat flow is $H = kA\dfrac{T_H - T_C}{L}$.

EXECUTE: **(a)** We want the thermal conductivity k of the glass. Solve $H = kA\dfrac{T_H - T_C}{L}$ for k, which gives $k = \dfrac{LH}{A(T_H - T_C)} = \dfrac{(0.00600\text{ m})(1100\text{ W})}{(0.500\text{ m})^2(35.0\text{ C°})} = 0.754\ \text{W/m}\cdot\text{K}$.

(b) $H \propto 1/L$, so $\dfrac{H_9}{H_6} = \dfrac{1/9}{1/6} = \dfrac{2}{3}$, which gives $H_9 = \dfrac{2}{3}(1100\text{ W}) = 733\text{ W}$.

EVALUATE: Other ways to decrease the heat current would be to decrease the area of the pane or to use a double-pane window which traps a layer of air between two panes of glass. The air has a *much* lower thermal conductivity than glass.

VP17.15.2. **IDENTIFY:** Heat current flows through the two end-to-end rods (brass and lead), so we are dealing with heat conduction.

SET UP: Use $H = kA\dfrac{T_H - T_C}{L}$. Table 17.5 gives $k_{\text{brass}} = 109.0\ \text{W/m}\cdot\text{K}$ and $k_{\text{lead}} = 34.7\ \text{W/m}\cdot\text{K}$. The heat current is the same (6.00 W) in both rods. The target variables are the temperatures of the free ends of the two-rod system.

EXECUTE: **(a)** Brass: Using $H = kA\dfrac{T_H - T_C}{L}$ and putting in the numbers gives

$$6.00\text{ W} = (109.0\text{ W/m}\cdot\text{K})(2.00\times10^{-4}\text{ m})\left(\frac{T_{\text{brass}} - 185°\text{C}}{0.250\text{ m}}\right)$$, so $T_{\text{brass}} = 254°\text{C}$.

(b) Lead: We follow the same procedure as for brass, giving

$$6.00\text{ W} = (34.7\text{ W/m}\cdot\text{K})(2.00\times10^{-4}\text{ m})\left(\frac{185°\text{C} - T_{\text{lead}}}{0.250\text{ m}}\right)$$, so $T_{\text{lead}} = –31°\text{C}$.

EVALUATE: From $H = kA\frac{T_H - T_C}{L}$ we see that $\Delta T \propto \frac{1}{k}$. So, if all else is the same, an object with a small k should have a large temperature difference compared to one with a large k. Our results agree with this since $\Delta T_{lead} > \Delta T_{brass}$ and $k_{lead} < k_{brass}$.

VP17.15.3. IDENTIFY: We are dealing the radiation from a star.

SET UP: $H = Ae\sigma T^4$, where T must be in K, $e = 1$ for the star, and $A = 4\pi R^2$.

EXECUTE: $H = Ae\sigma T^4 = 4\pi R^2\sigma T^4$, so solve for R, giving $R = \sqrt{\frac{H}{4\pi\sigma T^4}} = \frac{1}{T^2}\sqrt{\frac{H}{4\pi\sigma}}$. Putting in the numbers gives $R = \frac{1}{(9940\text{ K})^2}\sqrt{\frac{9.7\times10^{27}\text{ W}}{4\pi\left(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4\right)}} = 1.2\times10^9\text{ m}$.

$\frac{R_{Sirius}}{R_{sun}} = \frac{1.2\times10^9\text{ m}}{6.96\times10^8\text{ m}} = 1.7$.

EVALUATE: The surface area of Sirius is $(1.7)^2 = 2.9$ times as great as our sun, so Sirius is a luminous star.

VP17.15.4. IDENTIFY: The building radiates heat into the air, but the hot air also radiates heat back into the building. So we are looking for the *net* radiation, which will be *into* the building because its surface is less hot than the outside air.

SET UP: $H_{net} = Ae\sigma\left(T^4 - T_s^4\right)$, where temperatures must be in K and $e = 0.91$.

EXECUTE: $H_{net} = (525\text{ m}^2)(0.91)(5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4)\left[(293\text{ K})^4 - (308\text{ K})^4\right] = -4.4\times10^4\text{ W}$. The minus sign tells us that net heat flows *into* the building from the hot desert air at a rate of 4.4×10^4 W = 44 kW.

EVALUATE: The heat flow into the building would be even greater during the day when the outside temperature could be 40°C or even higher.

17.1. IDENTIFY and SET UP: $T_F = \frac{9}{5}T_C + 32°$.

EXECUTE: **(a)** $T_F = (9/5)(-62.8) + 32 = -81.0°\text{F}$.

(b) $T_F = (9/5)(56.7) + 32 = 134.1°\text{F}$.

(c) $T_F = (9/5)(31.1) + 32 = 88.0°\text{F}$.

EVALUATE: Fahrenheit degrees are smaller than Celsius degrees, so it takes more F° than C° to express the difference of a temperature from the ice point.

17.2. IDENTIFY and SET UP: To convert a temperature between °C and K use $T_C = T_K - 273.15$. To convert from °F to °C, subtract 32° and multiply by 5/9. To convert from °C to °F, multiply by 9/5 and add 32°. To convert a temperature difference, use that Celsius and Kelvin degrees are the same size and that $9\text{ F}° = 5\text{ C}°$.

EXECUTE: **(a)** $T_C = T_K - 273.15 = 310 - 273.15 = 36.9°\text{C}$; $T_F = \frac{9}{5}T_C + 32° = \frac{9}{5}(36.9°) + 32° = 98.4°\text{F}$.

(b) $T_K = T_C + 273.15 = 40 + 273.15 = 313\text{ K}$; $T_F = \frac{9}{5}T_C + 32° = \frac{9}{5}(40°) + 32° = 104°\text{F}$.

(c) 7 C° = 7 K; 7 C° = (7 C°)(9 F°/5 C°) = 13 F°.

(d) 4.0°C: $T_F = \frac{9}{5}T_C + 32° = \frac{9}{5}(4.0°) + 32° = 39.2°\text{F}$; $T_K = T_C + 273.15 = 4.0 + 273.15 = 277\text{ K}$.

$-160°\text{C}$: $T_F = \frac{9}{5}T_C + 32° = \frac{9}{5}(-160°) + 32° = -256°\text{F}$; $T_K = T_C + 273.15 = -160 + 273.15 = 113\text{ K}$.

(e) $T_C = \frac{5}{9}(T_F - 32°) = \frac{5}{9}(105° - 32°) = 41°\text{C}$; $T_K = T_C + 273.15 = 41 + 273.15 = 314\text{ K}$.

EVALUATE: Celsius-Fahrenheit conversions do not involve simple proportions due to the additive constant of 32°, but Celsius-Kelvin conversions require only simple addition/subtraction of 273.15.

17.3. **IDENTIFY:** Convert ΔT between different scales.

SET UP: ΔT is the same on the Celsius and Kelvin scales. $180\ \text{F}° = 100\ \text{C}°$, so $1\ \text{C}° = \frac{9}{5}\text{F}°$.

EXECUTE: **(a)** $\Delta T = 49.0\ \text{F}°$. $\Delta T = (49.0\ \text{F}°)\left(\dfrac{1\ \text{C}°}{\frac{9}{5}\ \text{F}°}\right) = 27.2\ \text{C}°$.

(b) $\Delta T = -100\ \text{F}°$. $\Delta T = (-100.0\ \text{F}°)\left(\dfrac{1\ \text{C}°}{\frac{9}{5}\ \text{F}°}\right) = -55.6\ \text{C}°$

EVALUATE: The magnitude of the temperature change is larger in F° than in C°.

17.4. **IDENTIFY:** This problem requires conversion of temperature scales. We want T_K as a function of T_F and T_F as a function of T_K.

SET UP and EXECUTE: We know that $T_K = T_C + 273.15$ and $T_C = \dfrac{5}{9}(T_F - 32°)$. Using these gives

$T_K = T_C + 273.15 = \dfrac{5}{9}(T_F - 32°) + 273.15$. This reduces to $T_K = \dfrac{5}{9}T_F + 255.37$.

Solve this result for T_F, giving $T_F = \dfrac{9}{5}T_K - 459.67$.

EVALUATE: The fractions 5/9 and 5/9 occur because the Kelvin degree is not the same size as the Fahrenheit degree; the Kelvin degree is larger.

17.5. **IDENTIFY:** Convert ΔT in kelvins to C° and to F°.

SET UP: $1\ \text{K} = 1\ \text{C}° = \frac{9}{5}\text{F}°$

EXECUTE: **(a)** $\Delta T_F = \frac{9}{5}\Delta T_C = \frac{9}{5}(-10.0\ \text{C}°) = -18.0\ \text{F}°$

(b) $\Delta T_C = \Delta T_K = -10.0\ \text{C}°$

EVALUATE: Kelvin and Celsius degrees are the same size. Fahrenheit degrees are smaller, so it takes more of them to express a given ΔT value.

17.6. **IDENTIFY:** Set $T_C = T_F$ and $T_F = T_K$.

SET UP: $T_F = \frac{9}{5}T_C + 32°\text{C}$ and $T_K = T_C + 273.15 = \frac{5}{9}(T_F - 32°) + 273.15$

EXECUTE: **(a)** $T_F = T_C = T$ gives $T = \frac{9}{5}T + 32°$ and $T = -40°$; $-40°\text{C} = -40°\text{F}$.

(b) $T_F = T_K = T$ gives $T = \frac{5}{9}(T - 32°) + 273.15$ and $T = \frac{9}{4}(-(\frac{5}{9})(32°) + 273.15) = 575°$; $575°\text{F} = 575\ \text{K}$.

EVALUATE: Since $T_K = T_C + 273.15$ there is no temperature at which Celsius and Kelvin thermometers agree.

17.7. **IDENTIFY:** When the volume is constant, $\dfrac{T_2}{T_1} = \dfrac{p_2}{p_1}$, for T in kelvins.

SET UP: $T_{\text{triple}} = 273.16\ \text{K}$. Figure 17.7 in the textbook gives that the temperature at which CO_2 solidifies is $T_{CO_2} = 195\ \text{K}$.

EXECUTE: $p_2 = p_1\left(\dfrac{T_2}{T_1}\right) = (1.35\ \text{atm})\left(\dfrac{195\ \text{K}}{273.16\ \text{K}}\right) = 0.964\ \text{atm}$

EVALUATE: The pressure decreases when T decreases.

17.8. **IDENTIFY:** Convert T_K to T_C and then convert T_C to T_F.

SET UP: $T_K = T_C + 273.15$ and $T_F = \frac{9}{5}T_C + 32°$.

EXECUTE: **(a)** $T_C = 400 - 273.15 = 127°\text{C}$, $T_F = (9/5)(126.85) + 32 = 260°\text{F}$

(b) $T_C = 95 - 273.15 = -178°\text{C}$, $T_F = (9/5)(-178.15) + 32 = -289°\text{F}$

(c) $T_C = 1.55 \times 10^7 - 273.15 = 1.55 \times 10^7 °\text{C}$, $T_F = (9/5)(1.55 \times 10^7) + 32 = 2.79 \times 10^7 °\text{F}$

EVALUATE: All temperatures on the Kelvin scale are positive. T_C is negative if the temperature is below the freezing point of water.

17.9. **IDENTIFY** and **SET UP:** Fit the data to a straight line for $p(T)$ and use this equation to find T when $p=0$.

EXECUTE: **(a)** If the pressure varies linearly with temperature, then $p_2 = p_1 + \gamma(T_2 - T_1)$.

$$\gamma = \frac{p_2 - p_1}{T_2 - T_1} = \frac{6.50\times10^4\ \text{Pa} - 4.80\times10^4\ \text{Pa}}{100°\text{C} - 0.01°\text{C}} = 170.0\ \text{Pa/C°}$$

Apply $p = p_1 + \gamma(T - T_1)$ with $T_1 = 0.01°\text{C}$ and $p = 0$ to solve for T.

$$0 = p_1 + \gamma(T - T_1)$$

$$T = T_1 - \frac{p_1}{\gamma} = 0.01°\text{C} - \frac{4.80\times10^4\ \text{Pa}}{170\ \text{Pa/C°}} = -282°\text{C}.$$

(b) Let $T_1 = 100°\text{C}$ and $T_2 = 0.01°\text{C}$; use $T_2/T_1 = p_2/p_1$ to calculate p_2, where T is in kelvins.

$$p_2 = p_1\left(\frac{T_2}{T_1}\right) = 6.50\times10^4\ \text{Pa}\left(\frac{0.01+273.15}{100+273.15}\right) = 4.76\times10^4\ \text{Pa};$$ this differs from the 4.80×10^4 Pa that was measured so $T_2/T_1 = p_2/p_1$ is not precisely obeyed.

EVALUATE: The answer to part (a) is in reasonable agreement with the accepted value of $-273°\text{C}$.

17.10. **IDENTIFY:** Apply $T = T_{\text{triple}}\dfrac{p}{p_{\text{triple}}} = (273.16\ \text{K})\dfrac{p}{p_{\text{triple}}}$ and solve for p.

SET UP: $p_{\text{triple}} = 325$ mm of mercury

EXECUTE: $p = (325.0\ \text{mm of mercury})\left(\dfrac{373.15\ \text{K}}{273.16\ \text{K}}\right) = 444$ mm of mercury

EVALUATE: mm of mercury is a unit of pressure. Since $T = T_{\text{triple}}\dfrac{p}{p_{\text{triple}}} = (273.16\ \text{K})\dfrac{p}{p_{\text{triple}}}$ involves a ratio of pressures, it is not necessary to convert the pressure to units of Pa.

17.11. **IDENTIFY:** $\Delta L = L_0\alpha\Delta T$

SET UP: For steel, $\alpha = 1.2\times10^{-5}\ (\text{C°})^{-1}$

EXECUTE: $\Delta L = (1.2\times10^{-5}(\text{C°})^{-1})(1410\ \text{m})(18.0°\text{C} - (-5.0°\text{C})) = +0.39\ \text{m}$

EVALUATE: The length increases when the temperature increases. The fractional increase is very small, since $\alpha\Delta T$ is small.

17.12. **IDENTIFY:** Apply $\Delta L = \alpha L_0 \Delta T$ and calculate ΔT. Then $T_2 = T_1 + \Delta T$, with $T_1 = 15.5°\text{C}$.

SET UP: Table 17.1 gives $\alpha = 1.2\times10^{-5}\ (\text{C°})^{-1}$ for steel.

EXECUTE: $\Delta T = \dfrac{\Delta L}{\alpha L_0} = \dfrac{0.471\ \text{ft}}{[1.2\times10^{-5}\ (\text{C°})^{-1}][1671\ \text{ft}]} = 23.5\ \text{C°}$. $T_2 = 15.5°\text{C} + 23.5\ \text{C°} = 39.0°\text{C}$.

EVALUATE: Since then the lengths enter in the ratio $\Delta L/L_0$, we can leave the lengths in ft.

17.13. **IDENTIFY:** Apply $L = L_0(1+\alpha\Delta T)$ to the diameter D of the penny.

SET UP: $1\ \text{K} = 1\ \text{C°}$, so we can use temperatures in °C.

EXECUTE: Death Valley: $\alpha D_0\Delta T = [2.6\times10^{-5}\ (\text{C°})^{-1}](1.90\ \text{cm})(28.0\ \text{C°}) = 1.4\times10^{-3}$ cm, so the diameter is 1.9014 cm. Greenland: $\alpha D_0 \Delta T = -3.6\times10^{-3}$ cm, so the diameter is 1.8964 cm.

EVALUATE: When T increases the diameter increases and when T decreases the diameter decreases.

17.14. IDENTIFY: Apply $L = L_0(1+\alpha\Delta T)$ to the diameter d of the rivet.

SET UP: For aluminum, $\alpha = 2.4\times10^{-5}\ (\text{C}°)^{-1}$. Let d_0 be the diameter at –78.0°C and d be the diameter at 23.0°C.

EXECUTE: $d = d_0 + \Delta d = d_0(1+\alpha\Delta T) = (0.4500\ \text{cm})(1+(2.4\times10^{-5}(\text{C}°)^{-1}[23.0°\text{C} - (-78.0°\text{C})])$.
$d = 0.4511\ \text{cm} = 4.511\ \text{mm}$.

EVALUATE: We could have let d_0 be the diameter at 23.0°C and d be the diameter at −78.0°C. Then $\Delta T = -78.0°\text{C} - 23.0°\text{C}$.

17.15. IDENTIFY: Apply $\Delta V = V_0\beta\Delta T$.

SET UP: For copper, $\beta = 5.1\times10^{-5}\ (\text{C}°)^{-1}$. $\Delta V/V_0 = 0.150\times10^{-2}$.

EXECUTE: $\Delta T = \dfrac{\Delta V/V_0}{\beta} = \dfrac{0.150\times10^{-2}}{5.1\times10^{-5}\ (\text{C}°)^{-1}} = 29.4\ \text{C}°$. $T_\text{f} = T_\text{i} + \Delta T = 49.4°\text{C}$.

EVALUATE: The volume increases when the temperature increases.

17.16. IDENTIFY: $\Delta V = \beta V_0\Delta T$. Use the diameter at −15°C to calculate the value of V_0 at that temperature.

SET UP: For a hemisphere of radius R, the volume is $V = \frac{2}{3}\pi R^3$. Table 17.2 gives $\beta = 7.2\times10^{-5}\ (\text{C}°)^{-1}$ for aluminum.

EXECUTE: $V_0 = \frac{2}{3}\pi R^3 = \frac{2}{3}\pi(27.5\ \text{m})^3 = 4.356\times10^4\ \text{m}^3$.
$\Delta V = (7.2\times10^{-5}\ (\text{C}°)^{-1})(4.356\times10^4\ \text{m}^3)[35°\text{C} - (-15°\text{C})] = 160\ \text{m}^3$.

EVALUATE: We could also calculate $R = R_0(1+\alpha\Delta T)$ and calculate the new V from R. The increase in volume is $V - V_0$, but we would have to be careful to avoid round-off errors when two large volumes of nearly the same size are subtracted.

17.17. IDENTIFY: Apply $\Delta V = V_0\beta\Delta T$ to the volume of the flask and to the mercury. When heated, both the volume of the flask and the volume of the mercury increase.

SET UP: For mercury, $\beta_\text{Hg} = 18\times10^{-5}\ (\text{C}°)^{-1}$.

8.95 cm^3 of mercury overflows, so $\Delta V_\text{Hg} - \Delta V_\text{glass} = 8.95\ \text{cm}^3$.

EXECUTE: $\Delta V_\text{Hg} = V_0\beta_\text{Hg}\Delta T = (1000.00\ \text{cm}^3)(18\times10^{-5}\ (\text{C}°)^{-1})(55.0\ \text{C}°) = 9.9\ \text{cm}^3$.

$\Delta V_\text{glass} = \Delta V_\text{Hg} - 8.95\ \text{cm}^3 = 0.95\ \text{cm}^3$. $\beta_\text{glass} = \dfrac{\Delta V_\text{glass}}{V_0\Delta T} = \dfrac{0.95\ \text{cm}^3}{(1000.00\ \text{cm}^3)(55.0\ \text{C}°)} = 1.7\times10^{-5}\ (\text{C}°)^{-1}$.

EVALUATE: The coefficient of volume expansion for the mercury is larger than for glass. When they are heated, both the volume of the mercury and the inside volume of the flask increase. But the increase for the mercury is greater and it no longer all fits inside the flask.

17.18. IDENTIFY: Apply $\Delta V = V_0\beta\Delta T$ to the tank and to the ethanol.

SET UP: For ethanol, $\beta_\text{e} = 75\times10^{-5}\ (\text{C}°)^{-1}$. For steel, $\beta_\text{s} = 3.6\times10^{-5}\ (\text{C}°)^{-1}$.

EXECUTE: The volume change for the tank is
$\Delta V_\text{s} = V_0\beta_\text{s}\Delta T = (1.90\ \text{m}^3)(3.6\times10^{-5}(\text{C}°)^{-1})(-14.0\ \text{C}°) = -9.576\times10^{-4}\ \text{m}^3 = -0.9576\ \text{L}$.
The volume change for the ethanol is
$\Delta V_\text{e} = V_0\beta_\text{e}\Delta T = (1.90\ \text{m}^3)(75\times10^{-5}\ (\text{C}°)^{-1})(-14.0\ \text{C}°) = -1.995\times10^{-2}\ \text{m}^3 = -19.95\ \text{L}$.
The empty volume in the tank is $\Delta V_\text{e} - \Delta V_\text{s} = -19.95\ \text{L} - (-0.9576\ \text{L}) = -19.0\ \text{L}$. So 19.0 L of ethanol can be added to the tank.

EVALUATE: Both volumes decrease. But $\beta_e > \beta_s$, so the magnitude of the volume decrease for the ethanol is greater than it is for the tank.

17.19. IDENTIFY and SET UP: Use $\Delta A = 2\alpha A_0 \Delta T$ to calculate ΔA for the plate, and then $A = A_0 + \Delta A$.

EXECUTE: **(a)** $A_0 = \pi r_0^2 = \pi\left(\dfrac{1.350\text{ cm}}{2}\right)^2 = 1.431\text{ cm}^2$.

(b) Using $\Delta A = 2\alpha A_0 \Delta T$, we have

$\Delta A = 2(1.2\times10^{-5}\text{ C}^{\circ -1})(1.431\text{ cm}^2)(175°\text{C} - 25°\text{C}) = 5.15\times10^{-3}\text{ cm}^2$ $A = A_0 + \Delta A = 1.436\text{ cm}^2$.

EVALUATE: A hole in a flat metal plate expands when the metal is heated just as a piece of metal the same size as the hole would expand.

17.20. IDENTIFY: We are looking at the thermal expansion of the area of a metal plate.

SET UP: For length and width, we use $\Delta L = \alpha L_0 \Delta T$. We want to find a comparable formula for the change in the area of the plate. Fig. 17.20 shows the changes in the plate.

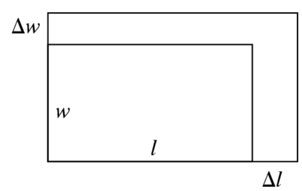

Figure 17.20

EXECUTE: The original area is $A_0 = \ell w$. The length expands by an amount $\Delta\ell = \alpha\ell\Delta T$ and width expands by $\Delta w = \alpha w \Delta T$. The expanded area is $A_2 = (\ell + \Delta\ell)(w + \Delta w) = \ell w + \ell\Delta w + w\Delta\ell + \Delta\ell\Delta w$. The change in area is $\Delta A = A_2 - A_0 = (\ell w + \ell\Delta w + w\Delta\ell + \Delta\ell\Delta w) - \ell w = \ell\Delta w + w\Delta\ell + \Delta\ell\Delta w$. Using $A_0 = \ell w$, $\Delta\ell = \alpha\ell\Delta T$, and $\Delta w = \alpha w\Delta T$, we get $\Delta A = \ell w\alpha\Delta T + w\ell\alpha\Delta T + \ell\alpha\Delta T w\alpha\Delta T = 2\alpha A_0\Delta T + \ell\alpha\Delta T w\alpha\Delta T$. The last term contains α^2, which is much smaller than α because α is typically very small. So we can drop the last term, leaving $\Delta A = 2\alpha A_0 \Delta T$.

EVALUATE: This result has the same form as linear and volume expansion. For volume expansion the coefficient of volume expansion is $\beta = 3\alpha$, and for area expansion the coefficient of area expansion is 2α.

17.21. IDENTIFY: Apply $\Delta L = L_0\alpha\Delta T$ and $\text{stress} = F/A = -Y\alpha\Delta T$.

SET UP: For steel, $\alpha = 1.2\times10^{-5}\ (\text{C}^\circ)^{-1}$ and $Y = 2.0\times10^{11}$ Pa.

EXECUTE: **(a)** $\Delta L = L_0\alpha\Delta T = (12.0\text{ m})(1.2\times10^{-5}\ (\text{C}^\circ)^{-1})(42.0\text{ C}^\circ) = 0.0060\text{ m} = 6.0\text{ mm}$.

(b) $\text{stress} = -Y\alpha\Delta T = -(2.0\times10^{11}\text{ Pa})(1.2\times10^{-5}\ (\text{C}^\circ)^{-1})(42.0\text{ C}^\circ) = -1.0\times10^{8}\text{ Pa}$. The minus sign means the stress is compressive.

EVALUATE: Commonly occurring temperature changes result in very small fractional changes in length but very large stresses if the length change is prevented from occurring.

17.22. IDENTIFY: Apply $\text{stress} = F/A = -Y\alpha\Delta T$ and solve for F.

SET UP: For brass, $Y = 0.9\times10^{11}$ Pa and $\alpha = 2.0\times10^{-5}\ (\text{C}^\circ)^{-1}$.

EXECUTE: $F = -Y\alpha\Delta T A = -(0.9\times10^{11}\text{ Pa})(2.0\times10^{-5}(\text{C}^\circ)^{-1})(-110\text{ C}^\circ)(2.01\times10^{-4}\text{ m}^2) = 4.0\times10^{4}\text{ N}$

EVALUATE: A large force is required. ΔT is negative and a positive tensile force is required.

17.23. **IDENTIFY:** We are dealing with the thermal expansion of two rods.

SET UP: Use $\Delta L = \alpha L_0 \Delta T$. From Table 17.1 we get the coefficients of linear expansion for aluminum and Invar. We know that $\Delta L_{\text{Al}} = 2\Delta L_{\text{Invar}}$ and $\Delta T_{\text{Al}} = \frac{1}{3}\Delta T_{\text{Invar}}$. We want $L_{\text{Al}}/L_{\text{Invar}}$.

EXECUTE: Apply $\Delta L = \alpha L_0 \Delta T$ to each bar and take the ratio of the length changes, giving $\frac{\Delta L_{\text{Al}}}{\Delta L_{\text{Invar}}} = \frac{\alpha_{\text{Al}} L_{\text{Al}} \Delta T_{\text{Al}}}{\alpha_{\text{Invar}} L_{\text{Invar}} \Delta T_{\text{Invar}}}$. Solving for the length ratio gives $\frac{L_{\text{Al}}}{L_{\text{Invar}}} = \frac{\alpha_{\text{Invar}} \Delta L_{\text{Al}} \Delta T_{\text{Invar}}}{\alpha_{\text{Al}} \Delta L_{\text{Invar}} \Delta T_{\text{Al}}} = \left(\frac{0.09}{2.4}\right)\left(\frac{\Delta L_{\text{Al}}}{\Delta L_{\text{Invar}}}\right)\left(\frac{3\Delta T_{\text{Al}}}{\Delta T_{\text{Al}}}\right) = 0.225$, which we round to 0.2. This also gives $\frac{L_{\text{Invar}}}{L_{\text{Al}}} = \frac{1}{0.225} = 4.$

EVALUATE: The coefficient of linear expansion for Invar is much less than that of aluminum, so the Invar rod needs to be much longer than the aluminum rod to expand half as much with only 1/3 the temperature change.

17.24. **IDENTIFY:** The heat required is $Q = mc\Delta T$. $P = 200\text{ W} = 200\text{ J/s}$, which is energy divided by time.

SET UP: For water, $c = 4.19\times10^3\text{ J/kg}\cdot\text{K}$.

EXECUTE: **(a)** $Q = mc\Delta T = (0.320\text{ kg})(4.19\times10^3\text{ J/kg}\cdot\text{K})(60.0\text{ C}°) = 8.04\times10^4\text{ J}$

(b) $t = \dfrac{8.04\times10^4\text{ J}}{200.0\text{ J/s}} = 402\text{ s} = 6.7\text{ min}$

EVALUATE: 0.320 kg of water has volume 0.320 L. The time we calculated in part (b) is consistent with our everyday experience.

17.25. **IDENTIFY** and **SET UP:** Apply $Q = mc\,\Delta T$ to the kettle and water.

EXECUTE: <u>kettle</u>

$Q = mc\Delta T$, $c = 910\text{ J/kg}\cdot\text{K}$ (from Table 17.3)

$Q = (1.10\text{ kg})(910\text{ J/kg}\cdot\text{K})(85.0°\text{C} - 20.0°\text{C}) = 6.5065\times10^4\text{ J}$

<u>water</u>

$Q = mc\Delta T$, $c = 4190\text{ J/kg}\cdot\text{K}$ (from Table 17.3)

$Q = (1.80\text{ kg})(4190\text{ J/kg}\cdot\text{K})(85.0°\text{C} - 20.0°\text{C}) = 4.902\times10^5\text{ J}$

Total $Q = 6.5065\times10^4\text{ J} + 4.902\times10^5\text{ J} = 5.55\times10^5\text{ J}.$

EVALUATE: Water has a much larger specific heat capacity than aluminum, so most of the heat goes into raising the temperature of the water.

17.26. **IDENTIFY** and **SET UP:** Use $Q = mc\,\Delta T$.

EXECUTE: **(a)** $Q = mc\Delta T$

$m = \frac{1}{2}(1.3\times10^{-3}\text{ kg}) = 0.65\times10^{-3}\text{ kg}$

$Q = (0.65\times10^{-3}\text{ kg})(1020\text{ J/kg}\cdot\text{K})\big(37°\text{C} - (-20°\text{C})\big) = 38\text{ J}.$

(b) 20 breaths/min $(60\text{ min/1 h}) = 1200$ breaths/h

So $Q = (1200)(38\text{ J}) = 4.6\times10^4\text{ J}.$

EVALUATE: The heat loss rate is $Q/t = 13\text{ W}$.

17.27. **IDENTIFY:** Apply $Q = mc\Delta T$ to find the heat that would raise the temperature of the student's body 7 C°.

SET UP: $1\text{ W} = 1\text{ J/s}$

EXECUTE: Find Q to raise the body temperature from 37°C to 44°C.

$Q = mc\Delta T = (70\text{ kg})(3480\text{ J/kg}\cdot\text{K})(7\text{ C}°) = 1.7\times10^6\text{ J}.$

$$t = \frac{1.7\times 10^6 \text{ J}}{1200 \text{ J/s}} = 1400 \text{ s} = 23 \text{ min.}$$

EVALUATE: Heat removal mechanisms are essential to the well-being of a person.

17.28. **IDENTIFY:** The heat input increases the temperature of 2.5 gal/min of water from 10°C to 49°C.
SET UP: 1.00 L of water has a mass of 1.00 kg, so
$9.46 \text{ L/min} = (9.46 \text{ L/min})(1.00 \text{ kg/L})(1 \text{ min}/60 \text{ s}) = 0.158 \text{ kg/s}$. For water, $c = 4190 \text{ J/kg}\cdot\text{C°}$.
EXECUTE: $Q = mc\Delta T$ so $H = (Q/t) = (m/t)c\,\Delta T$. Putting in the numbers gives

$H = (0.158 \text{ kg/s})(4190 \text{ J/kg}\cdot\text{C°})(49\text{°C} - 10\text{°C}) = 2.6\times 10^4 \text{ W} = 26 \text{ kW}$.

EVALUATE: The power requirement is large, the equivalent of 260 100-watt light bulbs, but this large power is needed only for short periods of time. The rest of the time, the unit uses no energy, unlike a conventional water heater, which continues to replace lost heat even when hot water is not needed.

17.29. **IDENTIFY:** Apply $Q = mc\Delta T$. $m = w/g$.
SET UP: The temperature change is $\Delta T = 18.0$ K.

EXECUTE: $c = \dfrac{Q}{m\Delta T} = \dfrac{gQ}{w\Delta T} = \dfrac{(9.80 \text{ m/s}^2)(1.25\times 10^4 \text{ J})}{(28.4 \text{ N})(18.0 \text{ K})} = 240 \text{ J/kg}\cdot\text{K}$.

EVALUATE: The value for c is similar to that for silver in Table 17.3, so it is a reasonable result.

17.30. **IDENTIFY:** The work done by the brakes equals the initial kinetic energy of the train. Use the volume of the air to calculate its mass. Use $Q = mc\Delta T$ applied to the air to calculate ΔT for the air.

SET UP: $K = \frac{1}{2}mv^2$. $m = \rho V$.

EXECUTE: The initial kinetic energy of the train is $K = \frac{1}{2}(25{,}000 \text{ kg})(15.5 \text{ m/s})^2 = 3.00\times 10^6$ J.

Therefore, Q for the air is 3.00×10^6 J.
$m = \rho V = (1.20 \text{ kg/m}^3)(65.0 \text{ m})(20.0 \text{ m})(12.0 \text{ m}) = 1.87\times 10^4$ kg. $Q = mc\Delta T$ gives

$$\Delta T = \frac{Q}{mc} = \frac{3.00\times 10^6 \text{ J}}{(1.87\times 10^4 \text{ kg})(1020 \text{ J/kg}\cdot\text{K})} = 0.157 \text{ C°}.$$

EVALUATE: The mass of air in the station is comparable to the mass of the train and the temperature rise is small.

17.31. **IDENTIFY** and **SET UP:** Set the change in gravitational potential energy equal to the quantity of heat added to the water.
EXECUTE: The change in mechanical energy equals the decrease in gravitational potential energy, $\Delta U = -mgh$; $|\Delta U| = mgh$. $Q = |\Delta U| = mgh$ implies $mc\Delta T = mgh$

$\Delta T = gh/c = (9.80 \text{ m/s}^2)(225 \text{ m})/(4190 \text{ J/kg}\cdot\text{K}) = 0.526 \text{ K} = 0.526 \text{ C°}$

EVALUATE: Note that the answer is independent of the mass of the object. Note also the small change in temperature that corresponds to this large change in height!

17.32. **IDENTIFY:** Set the energy delivered to the nail equal to $Q = mc\Delta T$ for the nail and solve for ΔT.

SET UP: For aluminum, $c = 0.91\times 10^3 \text{ J/kg}\cdot\text{K}$. $K = \frac{1}{2}mv^2$.

EXECUTE: The kinetic energy of the hammer before it strikes the nail is
$K = \frac{1}{2}mv^2 = \frac{1}{2}(1.80 \text{ kg})(7.80 \text{ m/s})^2 = 54.8$ J. Each strike of the hammer transfers $0.60(54.8 \text{ J}) = 32.9$ J, and with 10 strikes $Q = 329$ J. $Q = mc\Delta T$ and

$$\Delta T = \frac{Q}{mc} = \frac{329 \text{ J}}{(8.00\times 10^{-3} \text{ kg})(0.91\times 10^3 \text{ J/kg}\cdot\text{K})} = 45.2 \text{ C°}.$$

EVALUATE: This agrees with our experience that hammered nails get noticeably warmer.

17.33. IDENTIFY: Some of the kinetic energy of the bullet is transformed through friction into heat, which raises the temperature of the water in the tank.

SET UP: Set the loss of kinetic energy of the bullet equal to the heat energy Q transferred to the water. $Q = mc\Delta T$. From Table 17.3, the specific heat of water is 4.19×10^3 J/kg·C°.

EXECUTE: The kinetic energy lost by the bullet is

$K_i - K_f = \frac{1}{2}m(v_i^2 - v_f^2) = \frac{1}{2}(15.0\times10^{-3}\text{ kg})[(865\text{ m/s})^2 - (534\text{ m/s})^2] = 3.47\times10^3\text{ J}$, so for the water

$Q = 3.47\times10^3$ J. $Q = mc\Delta T$ gives $\Delta T = \dfrac{Q}{mc} = \dfrac{3.47\times10^3\text{ J}}{(13.5\text{ kg})(4.19\times10^3\text{ J/kg}\cdot\text{C°})} = 0.0613\text{ C°}$.

EVALUATE: The heat energy required to change the temperature of ordinary-size objects is very large compared to the typical kinetic energies of moving objects.

17.34. IDENTIFY: The amount of heat lost by the boiling water is equal to the amount of heat gained by the water in the beaker.

SET UP: Calculate Q for each mass of water and set their algebraic sum equal to zero. Let the water you add have mass m. The 750 g of cold water has a temperature change of $+65$ C° and a heat flow Q_c. The mass m of water has a temperature change of -25 C° and a heat flow Q_h. $Q = mc\,\Delta T$.

EXECUTE: $Q_c = mc\,\Delta T = (0.750\text{ kg})(4190\text{ J/kg}\cdot\text{C°})(65\text{ C°}) = 2.043\times10^5\text{ J}$

$Q_h = mc\,\Delta T = m(4190\text{ J/kg}\cdot\text{C°})(-25\text{ C°}) = -(1.048\times10^5\text{ J/kg})m$

$Q_h + Q_c = 0$ so $2.043\times10^5\text{ J} + (-1.048\times10^5\text{ J/kg})m = 0$ and $m = 1.95\text{ kg} = 1950\text{ g}$.

EVALUATE: The amount of water we need to add (1950 g) is considerably greater than the water already in the beaker (750 g). This is reasonable because we want the final temperature to be closer to the 100°C temperature of the boiling water than to the original 10.0°C temperature of the original water.

17.35. IDENTIFY and SET UP: Heat comes out of the metal and into the water. The final temperature is in the range $0 < T < 100°\text{C}$, so there are no phase changes. $Q_{\text{system}} = 0$.

(a) EXECUTE: $Q_{\text{water}} + Q_{\text{metal}} = 0$

$m_{\text{water}}c_{\text{water}}\Delta T_{\text{water}} + m_{\text{metal}}c_{\text{metal}}\Delta T_{\text{metal}} = 0$

$(1.00\text{ kg})(4190\text{ J/kg}\cdot\text{K})(2.0\text{ C°}) + (0.500\text{ kg})(c_{\text{metal}})(-78.0\text{ C°}) = 0$

$c_{\text{metal}} = 215\text{ J/kg}\cdot\text{K}$

(b) EVALUATE: Water has a larger specific heat capacity so stores more heat per degree of temperature change.

(c) If some heat went into the styrofoam then Q_{metal} should actually be larger than in part (a), so the true c_{metal} is larger than we calculated; the value we calculated would be smaller than the true value.

17.36. IDENTIFY: The heat that comes out of the person goes into the ice-water bath and causes some of the ice to melt.

SET UP: Normal body temperature is 98.6°F = 37.0°C, so for the person $\Delta T = -5$ C°. The ice-water bath stays at 0°C. A mass m of ice melts and $Q_{\text{ice}} = mL_f$. From Table 17.4, for water $L_f = 334\times10^3$ J/kg.

EXECUTE: $Q_{\text{person}} = mc\Delta T = (70.0\text{ kg})(3480\text{ J/kg}\cdot\text{C°})(-5.0\text{ C°}) = -1.22\times10^6$ J. Therefore, the amount of heat that goes into the ice is 1.22×10^6 J. $m_{\text{ice}}L_f = 1.22\times10^6$ J and $m_{\text{ice}} = \dfrac{1.22\times10^6\text{ J}}{334\times10^3\text{ J/kg}} = 3.7\text{ kg}$.

EVALUATE: If less ice than this is used, all the ice melts and the temperature of the water in the bath rises above 0°C.

17.37. **IDENTIFY:** The amount of heat lost by the iron is equal to the amount of heat gained by the water. The water must first be heated to 100°C and then vaporized.

SET UP: The relevant equations are $Q = mc\Delta T$ and $Q = L_v m.$ The specific heat of iron is $c_{\text{iron}} = 0.47\times10^3\ \text{J/(kg}\cdot\text{K)},$ the specific heat of water is $c_{\text{water}} = 4.19\times10^3\ \text{J/(kg}\cdot\text{K)},$ and the heat of vaporization of water is $L_v = 2256\times10^3\ \text{J/kg}.$

EXECUTE: The iron cools: $Q_{\text{iron}} = m_i c_i \Delta T_i.$

The water warms and vaporizes: $Q_{\text{water}} = c_w m_w \Delta T_w + m_w L_{v_w} = m_w(c_w \Delta T_w + L_{v_w}).$

Assume that all of the heat lost by the iron is gained by the water so that $Q_{\text{water}} = -Q_{\text{iron}}.$ Equating the respective expressions for each Q and solving for m_w we obtain

$$m_w = \frac{-m_i c_i \Delta T_i}{c_w \Delta T_w + L_{v_w}} = \frac{-(1.20\ \text{kg})(0.47\times10^3\ \text{J/kg}\cdot\text{K})(120.0^\circ\text{C} - 650.0^\circ\text{C})}{(4.19\times10^3\ \text{J/kg}\cdot\text{K})(100.0^\circ\text{C} - 15.0^\circ\text{C}) + 2256\times10^3\ \text{J/kg}} = 0.114\ \text{kg}.$$

EVALUATE: Note that only a relatively small amount of water is required to cause a very large temperature change in the iron. This is due to the high heat of vaporization and specific heat of water, and the relatively low specific heat capacity of iron.

17.38. **IDENTIFY:** The initial temperature of the ice and water mixture is $0.0°\text{C}.$ Assume all the ice melts. We will know that assumption is incorrect if the final temperature we calculate is less than $0.0°\text{C}.$ The net Q for the system (can, water, ice and lead) is zero.

SET UP: For copper, $c_c = 390\ \text{J/kg}\cdot\text{K}.$ For lead, $c_l = 130\ \text{J/kg}\cdot\text{K}.$ For water, $c_w = 4.19\times10^3\ \text{J/kg}\cdot\text{K}$ and $L_f = 3.34\times10^5\ \text{J/kg}.$

EXECUTE: For the copper can, $Q_c = m_c c_c \Delta T_c = (0.100\ \text{kg})(390\ \text{J/kg}\cdot\text{K})(T - 0.0°\text{C}) = (39.0\ \text{J/K})T.$

For the water, $Q_w = m_w c_w \Delta T_w = (0.160\ \text{kg})(4.19\times10^3\ \text{J/kg}\cdot\text{K})(T - 0.0°\text{C}) = (670.4\ \text{J/K})T.$

For the ice, $Q_i = m_i L_f + m_i c_w \Delta T_w$

$Q_i = (0.018\ \text{kg})(3.34\times10^5\ \text{J/kg}) + (0.018\ \text{kg})(4.19\times10^3\ \text{J/kg}\cdot\text{K})(T - 0.0°\text{C}) = 6012\ \text{J} + (75.4\ \text{J/K})T$

For the lead, $Q_l = m_l c_l \Delta T_l = (0.750\ \text{kg})(130\ \text{J/kg}\cdot\text{K})(T - 255°\text{C}) = (97.5\ \text{J/K})T - 2.486\times10^4\ \text{J}$

$\Sigma Q = 0$ gives $(39.0\ \text{J/K})T + (670.4\ \text{J/K})T + 6012\ \text{J} + (75.4\ \text{J/K})T + (97.5\ \text{J/K})T - 2.486\times10^4\ \text{J} = 0.$

$$T = \frac{1.885\times10^4\ \text{J}}{882.3\ \text{J/K}} = 21.4°\text{C}.$$

EVALUATE: $T > 0.0°\text{C},$ which confirms that all the ice melts.

17.39. **IDENTIFY:** The heat lost by the cooling copper is absorbed by the water and the pot, which increases their temperatures.

SET UP: For copper, $c_c = 390\ \text{J/kg}\cdot\text{K}.$ For iron, $c_i = 470\ \text{J/kg}\cdot\text{K}.$ For water, $c_w = 4.19\times10^3\ \text{J/kg}\cdot\text{K}.$

EXECUTE: For the copper pot,

$Q_c = m_c c_c\, \Delta T_c = (0.500\ \text{kg})(390\ \text{J/kg}\cdot\text{K})(T - 20.0°\text{C}) = (195\ \text{J/K})T - 3900\ \text{J}.$ For the block of iron,

$Q_i = m_i c_i\, \Delta T_i = (0.250\ \text{kg})(470\ \text{J/kg}\cdot\text{K})(T - 85.0°\text{C}) = (117.5\ \text{J/K})T - 9988\ \text{J}.$ For the water,

$Q_w = m_w c_w\, \Delta T_w = (0.170\ \text{kg})(4190\ \text{J/kg}\cdot\text{K})(T - 20.0°\text{C}) = (712.3\ \text{J/K})T - 1.425\times10^4\ \text{J}.$ $\Sigma Q = 0$ gives

$(195\ \text{J/K})T - 3900\ \text{J} + (117.5\ \text{J/K})T - 9988\ \text{J} + (712.3\ \text{J/K})T - 1.425\times10^4\ \text{J}.$

$$T = \frac{2.814\times10^4\ \text{J}}{1025\ \text{J/K}} = 27.5°\text{C}.$$

EVALUATE: The basic principle behind this problem is conservation of energy: no energy is lost; it is only transferred.

17.40. IDENTIFY: By energy conservation, the heat lost by the water is gained by the ice. This heat must first increase the temperature of the ice from −40.0°C to the melting point of 0.00°C, then melt the ice, and finally increase its temperature to 28.0°C. The target variable is the mass of the water m.

SET UP: $Q_{\text{ice}} = m_{\text{ice}}c_{\text{ice}}\Delta T_{\text{ice}} + m_{\text{ice}}L_{\text{f}} + m_{\text{ice}}c_{\text{w}}\Delta T_{\text{melted ice}}$ and $Q_{\text{water}} = mc_{\text{w}}\Delta T_{\text{w}}$.

EXECUTE: Using $Q_{\text{ice}} = m_{\text{ice}}c_{\text{ice}}\Delta T_{\text{ice}} + m_{\text{ice}}L_{\text{f}} + m_{\text{ice}}c_{\text{w}}\Delta T_{\text{melted ice}}$, with the values given in the table in the text, we have $Q_{\text{ice}} = (0.200\text{ kg})[2100\text{ J/(kg}\cdot\text{C°)}](40.0\text{C°}) + (0.200\text{ kg})(3.34\times10^5\text{ J/kg})$ $+(0.200\text{ kg})[4190\text{ J/(kg}\cdot\text{C°)}](28.0\text{C°}) = 1.071\times10^5\text{ J}$.

$Q_{\text{water}} = mc_{\text{w}}\Delta T_{\text{w}} = m[4190\text{ J/(kg}\cdot\text{C°)}](28.0\text{°C} - 80.0\text{°C}) = -(217{,}880\text{ J/kg})m$. $Q_{\text{ice}} + Q_{\text{water}} = 0$ gives $1.071\times10^5\text{ J} = (217{,}880\text{ J/kg})m$. $m = 0.491\text{ kg}$.

EVALUATE: There is about twice as much water as ice because the water must provide the heat not only to melt the ice but also to increase its temperature.

17.41. IDENTIFY: By energy conservation, the heat lost by the copper is gained by the ice. This heat must first increase the temperature of the ice from –20.0°C to the melting point of 0.00°C, then melt some of the ice. At the final thermal equilibrium state, there is ice and water, so the temperature must be 0.00°C. The target variable is the initial temperature of the copper.

SET UP: For temperature changes, $Q = mc\Delta T$ and for a phase change from solid to liquid $Q = mL_{\text{F}}$.

EXECUTE: For the ice,

$Q_{\text{ice}} = (2.00\text{ kg})[2100\text{ J/(kg}\cdot\text{C°)}](20.0\text{C°}) + (0.80\text{ kg})(3.34\times10^5\text{ J/kg}) = 3.512\times10^5\text{ J}$. For the copper, using the specific heat from the table in the text gives

$Q_{\text{copper}} = (6.00\text{ kg})[390\text{ J/(kg}\cdot\text{C°)}](0\text{°C} - T) = -(2.34\times10^3\text{ J/C°})T$. Setting the sum of the two heats equal to zero gives $3.512\times10^5\text{ J} = (2.34\times10^3\text{ J/C°})T$, which gives $T = 150\text{°C}$.

EVALUATE: Since the copper has a smaller specific heat than that of ice, it must have been quite hot initially to provide the amount of heat needed.

17.42. IDENTIFY: For a temperature change $Q = mc\Delta T$ and for the liquid to solid phase change $Q = -mL_{\text{f}}$.

SET UP: For water, $c = 4.19\times10^3\text{ J/kg}\cdot\text{K}$ and $L_{\text{f}} = 3.34\times10^5\text{ J/kg}$.

EXECUTE:

$Q = mc\Delta T - mL_{\text{f}} = (0.290\text{ kg})[(4.19\times10^3\text{ J/kg}\cdot\text{K})(-18.0\text{ C°}) - 3.34\times10^5\text{ J/kg}] = -1.187\times10^5\text{ J}$, which rounds to -1.19×10^5 J.

The minus sign says 1.19×10^5 J must be removed from the water.

$$(1.187\times10^5\text{ J})\left(\frac{1\text{ cal}}{4.186\text{ J}}\right) = 2.84\times10^4\text{ cal} = 28.4\text{ kcal}.$$

$$(1.187\times10^5\text{ J})\left(\frac{1\text{ Btu}}{1055\text{ J}}\right) = 113\text{ Btu}.$$

EVALUATE: $Q < 0$ when heat comes out of an object. The equation $Q = mc\Delta T$ puts in the correct sign automatically, from the sign of $\Delta T = T_{\text{f}} - T_{\text{i}}$. But in $Q = \pm mL$ we must select the correct sign.

17.43. IDENTIFY and SET UP: Use $Q = mc\,\Delta T$ for the temperature changes and $Q = mL$ for the phase changes.

EXECUTE: Heat must be added to do the following:

ice at $-10.0\text{°C} \rightarrow$ ice at 0°C

$Q_{\text{ice}} = mc_{\text{ice}}\Delta T = (18.0\times10^{-3}\text{ kg})(2100\text{ J/kg}\cdot\text{K})(0\text{°C} - (-10.0\text{°C})) = 378\text{ J}$

phase transition ice (0°C) $\rightarrow$ liquid water (0°C)(melting)

$Q_{\text{melt}} = +mL_{\text{f}} = (18.0\times10^{-3}\text{ kg})(334\times10^3\text{ J/kg}) = 6.012\times10^3\text{ J}$

water at 0°C (from melted ice) $\rightarrow$ water at 100°C

$Q_{\text{water}} = mc_{\text{water}}\Delta T = (18.0\times10^{-3}\text{ kg})(4190\text{ J/kg}\cdot\text{K})(100°\text{C} - 0°\text{C}) = 7.542\times10^{3}\text{ J}$

phase transition water $(100°\text{C}) \rightarrow$ steam $(100°\text{C})$(boiling)

$Q_{\text{boil}} = +mL_{\text{v}} = (18.0\times10^{-3}\text{ kg})(2256\times10^{3}\text{ J/kg}) = 4.0608\times10^{4}\text{ J}$

The total Q is $Q = 378\text{ J} + 6.012\times10^{3}\text{ J} + 7.542\times10^{3}\text{ J} + 4.068\times10^{4}\text{ J} = 5.45\times10^{4}\text{ J}$

$(5.45\times10^{4}\text{ J})(1\text{ cal}/4.186\text{ J}) = 1.30\times10^{4}\text{ cal}$

$(5.45\times10^{4}\text{ J})(1\text{ Btu}/1055\text{ J}) = 51.7\text{ Btu}.$

EVALUATE: Q is positive and heat must be added to the material. Note that more heat is needed for the liquid to gas phase change than for the temperature changes.

17.44. **IDENTIFY:** $Q = mc\Delta T$ for a temperature change and $Q = +mL_{\text{f}}$ for the solid to liquid phase transition. The ice starts to melt when its temperature reaches $0.0°\text{C}$. The system stays at $0.00°\text{C}$ until all the ice has melted.

SET UP: For ice, $c = 2.10\times10^{3}\text{ J/kg}\cdot\text{K}$. For water, $L_{\text{f}} = 3.34\times10^{5}\text{ J/kg}$.

EXECUTE: **(a)** Q to raise the temperature of ice to $0.00°\text{C}$:

$Q = mc\Delta T = (0.550\text{ kg})(2.10\times10^{3}\text{ J/kg}\cdot\text{K})(15.0\text{ C}°) = 1.73\times10^{4}\text{ J}.$ $t = \dfrac{1.73\times10^{4}\text{ J}}{800.0\text{ J/min}} = 21.7\text{ min}.$

(b) To melt all the ice requires $Q = mL_{\text{f}} = (0.550\text{ kg})(3.34\times10^{5}\text{ J/kg}) = 1.84\times10^{5}\text{ J}.$

$t = \dfrac{1.84\times10^{5}\text{ J}}{800.0\text{ J/min}} = 230\text{ min}.$ The total time after the start of the heating is 252 min.

(c) A graph of T versus t is sketched in Figure 17.44.

EVALUATE: It takes much longer for the ice to melt than it takes the ice to reach the melting point.

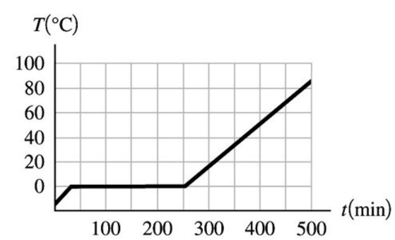

Figure 17.44

17.45. **IDENTIFY** and **SET UP:** The heat that must be added to a lead bullet of mass m to melt it is $Q = mc\Delta T + mL_{\text{f}}$ ($mc\Delta T$ is the heat required to raise the temperature from 25°C to the melting point of 327.3°C; mL_{f} is the heat required to make the solid $\rightarrow$ liquid phase change.) The kinetic energy of the bullet if its speed is v is $K = \frac{1}{2}mv^{2}$.

EXECUTE: $K = Q$ says $\frac{1}{2}mv^{2} = mc\Delta T + mL_{\text{f}}$

$v = \sqrt{2(c\Delta T + L_{\text{f}})}$

$v = \sqrt{2[(130\text{ J/kg}\cdot\text{K})(327.3°\text{C} - 25°\text{C}) + 24.5\times10^{3}\text{ J/kg}]} = 357\text{ m/s}$

EVALUATE: This is a typical speed for a rifle bullet. A bullet fired into a block of wood does partially melt, but in practice not all of the initial kinetic energy is converted to heat that remains in the bullet.

17.46. **IDENTIFY:** For a temperature change, $Q = mc\Delta T$. For the vapor $\rightarrow$ liquid phase transition, $Q = -mL_{\text{v}}$.

SET UP: For water, $L_{\text{v}} = 2.256\times10^{6}\text{ J/kg}$ and $c = 4.19\times10^{3}\text{ J/kg}\cdot\text{K}$.

EXECUTE: **(a)** $Q = +m(-L_\text{v} + c\Delta T)$

$Q = +(25.0\times10^{-3}\ \text{kg})(-2.256\times10^{6}\ \text{J/kg} + [4.19\times10^{3}\ \text{J/kg}\cdot\text{K}][-66.0\ \text{C}°]) = -6.33\times10^{4}\ \text{J}$

(b) $Q = mc\Delta T = (25.0\times10^{-3}\ \text{kg})(4.19\times10^{3}\ \text{J/kg}\cdot\text{K})(-66.0\ \text{C}°) = -6.91\times10^{3}\ \text{J}.$

(c) The total heat released by the water that starts as steam is nearly a factor of ten larger than the heat released by water that starts at $100°\text{C}$. Steam burns are much more severe than hot-water burns.

EVALUATE: For a given amount of material, the heat for a phase change is typically much more than the heat for a temperature change.

17.47. **IDENTIFY:** Use $Q = Mc\Delta T$ to find Q for a temperature rise from $34.0°\text{C}$ to $40.0°\text{C}$. Set this equal to $Q = mL_\text{v}$ and solve for m, where m is the mass of water the camel would have to drink.

SET UP: $c = 3480\ \text{J/kg}\cdot\text{K}$ and $L_\text{v} = 2.42\times10^{6}\ \text{J/kg}$. For water, 1.00 kg has a volume 1.00 L. $M = 400$ kg is the mass of the camel.

EXECUTE: The mass of water that the camel saves is

$$m = \frac{Mc\Delta T}{L_\text{v}} = \frac{(400\ \text{kg})(3480\ \text{J/kg}\cdot\text{K})(6.0\ \text{K})}{(2.42\times10^{6}\ \text{J/kg})} = 3.45\ \text{kg}$$ which is a volume of 3.45 L.

EVALUATE: This is nearly a gallon of water, so it is an appreciable savings.

17.48. **IDENTIFY:** For a temperature change, $Q = mc\Delta T$. For the liquid $\to$ vapor phase change, $Q = +mL_\text{v}$.

SET UP: The density of water is $1000\ \text{kg/m}^3$.

EXECUTE: **(a)** The heat that goes into mass m of water to evaporate it is $Q = +mL_\text{v}$. The heat flow for the man is $Q = m_\text{man}c\Delta T$, where $\Delta T = -1.00\ \text{C}°$. $\Sigma Q = 0$ so $mL_\text{v} + m_\text{man}c\Delta T = 0$ and

$$m = -\frac{m_\text{man}c\Delta T}{L_\text{v}} = -\frac{(70.0\ \text{kg})(3480\ \text{J/kg}\cdot\text{K})(-1.00\ \text{C}°)}{2.42\times10^{6}\ \text{J/kg}} = 0.101\ \text{kg} = 101\ \text{g}.$$

(b) $V = \dfrac{m}{\rho} = \dfrac{0.101\ \text{kg}}{1000\ \text{kg/m}^3} = 1.01\times10^{-4}\ \text{m}^3 = 101\ \text{cm}^3$. This is about 35% of the volume of a soft-drink can.

EVALUATE: Fluid loss by evaporation from the skin can be significant.

17.49. **IDENTIFY:** The asteroid's kinetic energy is $K = \frac{1}{2}mv^2$. To boil the water, its temperature must be raised to $100.0°\text{C}$ and the heat needed for the phase change must be added to the water.

SET UP: For water, $c = 4190\ \text{J/kg}\cdot\text{K}$ and $L_\text{v} = 2256\times10^{3}\ \text{J/kg}$.

EXECUTE: $K = \frac{1}{2}(2.60\times10^{15}\ \text{kg})(32.0\times10^{3}\ \text{m/s})^2 = 1.33\times10^{24}\ \text{J}$. $Q = mc\Delta T + mL_\text{v}$.

$$m = \frac{Q}{c\Delta T + L_\text{v}} = \frac{1.33\times10^{22}\ \text{J}}{(4190\ \text{J/kg}\cdot\text{K})(90.0\ \text{K}) + 2256\times10^{3}\ \text{J/kg}} = 5.05\times10^{15}\ \text{kg}.$$

EVALUATE: The mass of water boiled is 2.5 times the mass of water in Lake Superior.

17.50. **IDENTIFY:** $Q = mc\Delta T$ for a temperature change. The net Q for the system (sample, can and water) is zero.

SET UP: For water, $c_\text{w} = 4.19\times10^{3}\ \text{J/kg}\cdot\text{K}$. For copper, $c_\text{c} = 390\ \text{J/kg}\cdot\text{K}$.

EXECUTE: For the water, $Q_\text{w} = m_\text{w}c_\text{w}\Delta T_\text{w} = (0.200\ \text{kg})(4.19\times10^{3}\ \text{J/kg}\cdot\text{K})(7.1\ \text{C}°) = 5.95\times10^{3}\ \text{J}$.

For the copper can, $Q_\text{c} = m_\text{c}c_\text{c}\Delta T_\text{c} = (0.150\ \text{kg})(390\ \text{J/kg}\cdot\text{K})(7.1\ \text{C}°) = 415\ \text{J}$.

For the sample, $Q_\text{s} = m_\text{s}c_\text{s}\Delta T_\text{s} = (0.085\ \text{kg})c_\text{s}(-73.9\ \text{C}°)$.

$\Sigma Q = 0$ gives $(0.085\ \text{kg})(-73.9\ \text{C}°)c_\text{s} + 415\ \text{J} + 5.95\times10^{3}\ \text{J} = 0$. $c_\text{s} = 1.01\times10^{3}\ \text{J/kg}\cdot\text{K}$.

EVALUATE: Heat comes out of the sample and goes into the water and the can. The value of c_s we calculated is consistent with the values in Table 17.3.

17.51. **IDENTIFY** and **SET UP:** Heat flows out of the water and into the ice. The net heat flow for the system is zero. The ice warms to 0°C, melts, and then the water from the melted ice warms from 0°C to the final temperature.

EXECUTE: $Q_{\text{system}} = 0$; calculate Q for each component of the system: (Beaker has small mass says that $Q = mc\Delta T$ for beaker can be neglected.)

0.250 kg of water: cools from 75.0°C to 40.0°C

$Q_{\text{water}} = mc\Delta T = (0.250\text{ kg})(4190\text{ J/kg}\cdot\text{K})(40.0°\text{C} - 75.0°\text{C}) = -3.666\times10^4\text{ J}.$

ice: warms to 0°C; melts; water from melted ice warms to 40.0°C

$Q_{\text{ice}} = mc_{\text{ice}}\Delta T + mL_{\text{f}} + mc_{\text{water}}\Delta T.$

$Q_{\text{ice}} = m[(2100\text{ J/kg}\cdot\text{K})(0°\text{C} - (-20.0°\text{C})) + 334\times10^3\text{ J/kg} + (4190\text{ J/kg}\cdot\text{K})(40.0°\text{C} - 0°\text{C})].$

$Q_{\text{ice}} = (5.436\times10^5\text{ J/kg})m.$ $Q_{\text{system}} = 0$ says $Q_{\text{water}} + Q_{\text{ice}} = 0.$ $-3.666\times10^4\text{ J} + (5.436\times10^5\text{ J/kg})m = 0.$

$$m = \frac{3.666\times10^4\text{ J}}{5.436\times10^5\text{ J/kg}} = 0.0674\text{ kg}.$$

EVALUATE: Since the final temperature is 40.0°C we know that all the ice melts and the final system is all liquid water. The mass of ice added is much less than the mass of the 75°C water; the ice requires a large heat input for the phase change.

17.52. **IDENTIFY** and **SET UP:** Large block of ice implies that ice is left, so $T_2 = 0°\text{C}$ (final temperature). Heat comes out of the ingot and into the ice. The net heat flow is zero. The ingot has a temperature change and the ice has a phase change.

EXECUTE: $Q_{\text{system}} = 0$; calculate Q for each component of the system:

ingot

$Q_{\text{ingot}} = mc\Delta T = (4.00\text{ kg})(234\text{ J/kg}\cdot\text{K})(0°\text{C} - 750°\text{C}) = -7.02\times10^5\text{ J}$

ice

$Q_{\text{ice}} = +mL_{\text{f}}$, where m is the mass of the ice that changes phase (melts)

$Q_{\text{system}} = 0$ says $Q_{\text{ingot}} + Q_{\text{ice}} = 0$

$-7.02\times10^5\text{ J} + m(334\times10^3\text{ J/kg}) = 0$

$$m = \frac{7.02\times10^5\text{ J}}{334\times10^3\text{ J/kg}} = 2.10\text{ kg}$$

EVALUATE: The liquid produced by the phase change remains at 0°C since it is in contact with ice.

17.53. **IDENTIFY:** We mix liquids at different temperatures, so this is a problem in calorimetry.

SET UP: The unknown liquid cools down from 30.0°C to 14.0°C. The ice all melts and the resulting water increases from 0.0°C to 14.0°C. The heat gained by the ice all comes from the unknown liquid, so the net heat change for the mixture is zero. The ice goes through two changes: melting at 0.0°C followed by a temperature increase to 14.0°C. We use $Q = mc\Delta T$ and want to find the specific heat c of the unknown liquid.

EXECUTE: $Q_{\text{ice}} = Q_{\text{melt}} + Q_{\text{increase temp}} = m_{\text{ice}}L_{\text{f}} + m_{\text{ice}}c_{\text{water}}\Delta T_{\text{water}}$ and $Q_{\text{unknown}} = mc\Delta T_{\text{unknown}}$. Using $Q_{\text{ice}} + Q_{\text{unknown}} = 0$ gives $m_{\text{ice}}L_{\text{f}} + m_{\text{ice}}c_{\text{water}}\Delta T_{\text{water}} + mc\Delta T_{\text{unknown}} = 0$. Using the given masses and temperatures as well as $L_{\text{f}} = 334\times10^3$ J/kg and $c_{\text{water}} = 4190\text{ J/kg}\cdot\text{K}$, we get $c = 2370\text{ J/kg}\cdot\text{K}$.

EVALUATE: From Table 17.3 we see that this value is close to the specific heats of ethylene and glycol, so it is a reasonable result.

17.54. IDENTIFY: At steady state, the rate of heat flow is the same throughout both rods, as well as out of the boiling water and into the ice-water mixture. The heat that flows into the ice-water mixture goes only into melting ice since the temperature remains at 0.00°C.

SET UP: For steady state heat flow, $\frac{Q}{t}=\frac{kA\Delta T}{L}$. The heat to melt ice is $Q=mL_{\text{f}}$.

EXECUTE: **(a)** $\frac{Q}{t}=\frac{kA\Delta T}{L}$ is the same for both of the rods. Using the physical properties of brass and copper from the tables in the text, we have

$$\frac{[109.0\text{ W/(m}\cdot\text{K)}](100.0°\text{C}-T)}{0.300\text{ m}}=\frac{[385.0\text{ W/(m}\cdot\text{K)}](T-0.0°\text{C})}{0.800\text{ m}}.$$

Solving for T gives $T=43.0°\text{C}$.

(b) The heat entering the ice-water mixture is

$$Q=\frac{kAt\Delta T}{L}=\frac{[109.0\text{ W/(m}\cdot\text{K)}](0.00500\text{ m}^2)(300.0\text{ s})(100.0°\text{C}-43.0°\text{C})}{0.300\text{ m}}.\ Q=3.1065\times10^4\text{ J. Then}$$

$$Q=mL_{\text{f}}\text{ so } m=\frac{3.1065\times10^4\text{ J}}{3.34\times10^5\text{ J/kg}}=0.0930\text{ kg}=93.0\text{ g}.$$

EVALUATE: The temperature of the interface between the two rods is between the two extremes (0°C and 100°C), but not midway between them.

17.55. IDENTIFY: A heat current flows through the two bars, so we are dealing with thermal conduction.

SET UP: Both bars have the same length and cross-sectional area, and we want to find the thermal conductivity of the unknown metal. The graph plots T versus T_{H}, so we need to relate these quantities to interpret the graph. For this we use $H=kA\frac{T_{\text{H}}-T_{\text{C}}}{L}$. At steady state, H is the same in both bars.

EXECUTE: For the copper bar $H=k_{\text{Cu}}A\frac{T_{\text{H}}-T}{L}$, and for the unknown bar $H=kA\frac{T-0.0°\text{C}}{L}$.

Equating the heat currents and simplifying gives $k_{\text{Cu}}(T_{\text{H}}-T)=kT$. Solving for T gives $T=\frac{k_{\text{Cu}}}{k+k_{\text{Cu}}}T_{\text{H}}$,

so a graph of T versus T_{H} should be a straight line having slope $\frac{k_{\text{Cu}}}{k+k_{\text{Cu}}}$. Solving for k gives

$k=k_{\text{Cu}}\left(\frac{1}{\text{slope}}-1\right)$. From Table 17.5, we have $k_{\text{Cu}}=385\text{ W/mol}\cdot\text{K}$, so

$$k=(385\text{ W/m}\cdot\text{K})\left(\frac{1}{0.710}-1\right)=157\text{ W/m}\cdot\text{K}.$$

EVALUATE: From Table 17.5, $k=157\text{ W/m}\cdot\text{K}$ is between that of brass and aluminum, so our result is reasonable.

17.56. IDENTIFY: For a melting phase transition, $Q=mL_{\text{f}}$. The rate of heat conduction is $\frac{Q}{t}=\frac{kA(T_{\text{H}}-T_{\text{C}})}{L}$.

SET UP: For water, $L_{\text{f}}=3.34\times10^5\text{ J/kg}$.

EXECUTE: The heat conducted by the rod in 10.0 min is

$$Q=mL_{\text{f}}=(8.50\times10^{-3}\text{ kg})(3.34\times10^5\text{ J/kg})=2.84\times10^3\text{ J. }\frac{Q}{t}=\frac{2.84\times10^3\text{ J}}{600\text{ s}}=4.73\text{ W}.$$

$$k=\frac{(Q/t)L}{A(T_{\text{H}}-T_{\text{C}})}=\frac{(4.73\text{ W})(0.600\text{ m})}{(1.25\times10^{-4}\text{ m}^2)(100\text{ C}°)}=227\text{ W/m}\cdot\text{K}.$$

EVALUATE: The heat conducted by the rod is the heat that enters the ice and produces the phase change.
